Aim/Introduction: The development of FAPI-based radiopharmaceuticals has gained significant interest due to the potential to target multiple tumor types. ^{177}Lu-labeled FAPI agents are under active investigation, while ^{161}Tb offers potential advantages through the emission of conversion and Auger electrons. This study provides the first comparative in vivo evaluation of two ^{177}Lu-labeled FAPI dimers, DOTAGA.Glu.(FAPI)$_2$ and DO3A.Glu.(FAPI)$_2$, with human dosimetry extrapolation supporting future application of both ^{177}Lu and ^{161}Tb in targeted radionuclide therapy. ***Materials and Methods:*** DOTAGA.Glu(FAPi)$_2$ and DO3A.Glu(FAPi)$_2$ were labeled with lutetium-177. They were evaluated in vivo (biodistribution, metabolic stability in blood , SPECT/CT imaging and dosimetry) on PC3-mice. Furthermore, extrapolation of the murine dosimetry data to adult human estimates was performed for [^{177}Lu]Lu-DOTAGA.Glu.(FAPI)$_2$, [^{177}Lu]Lu-DO3A.Glu.(FAPI)$_2$, [^{161}Tb]Tb-DOTAGA.Glu.(FAPI)$_2$ and [^{161}Tb]Tb-DO3A.Glu.(FAPI)$_2$, using the OLINDA/EXM v.2.1 software. ***Results:*** [^{177}Lu]Lu-DOTAGA.Glu(FAPi)$_2$ and [^{177}Lu]Lu-DO3A.Glu(FAPi)$_2$ were prepared with molar activities of 30 MBq/nmol for the animal studies. Metabolic studies performed after 30 min p.i., revealed that both radiopharmaceuticals are stable in vivo. Biodistribution studies of [^{177}Lu]Lu-DOTAGA.Glu(FAPi)$_2$ and [^{177}Lu]Lu-DO3A.Glu(FAPi)$_2$ showed that the tumor uptake was 16.2±2.5 and 15±1.2% IA/g at 4h p.i., respectively. Tumor uptake slowly decreased over time, reaching 5.1±0.1 and 2.8 0.4 %IA/g at 48 h, respectively. Both radiopharmaceuticals exhibited low blood retention levels, decreasing from around 2.0±0.1% IA/g at 4 h p.i to 0.2±0.1 and 0.03±0.01 %IA/g at 48 and 96h p.i. Additionally, they both demonstrated favorable tumor-to-normal organ ratios at all tested time points. These findings are well illustrated by SPECT/CT imaging. In mice, tumor effective and biological half-lives for both radiopharmaceuticals were in the same range (~45h). However, [^{177}Lu]Lu-DOTAGA.Glu.(FAPI)$_2$ showed prolonged effective half-lives in non-tumor organs compared to [^{177}Lu]Lu-DO3A.Glu.(FAPI)$_2$. The extrapolated human (adult male/female) absorbed dose estimates (Gy/GBq) for [^{177}Lu]Lu-DOTAGA.Glu.(FAPI)$_2$ were generally higher across most organs compared to [^{177}Lu]Lu-DO3A.Glu.(FAPI)$_2$, particularly in the liver (0.16/0.20 vs. 0.060/0.073), kidneys (0.04/0.05 vs. 0.021/0.025), and salivary glands (0.103/0.126 vs. 0.073/0.088). Human extrapolation of ^{161}Tb-labeled radiotracers delivered ~38% higher absorbed doses in tissues as compared to their ^{177}Lu-labeled counterparts. Based on our dosimetric analysis, the red bone marrow was identified as the potential dose-limiting organ for both radiopharmaceuticals in the context of possible clinical translation. ***Conclusion:*** Our study provide evidence for the potential use of [^{177}Lu]Lu-DOTAGA.Glu.(FAPI)$_2$ and [^{177}Lu]Lu-DO3A.Glu.(FAPI)$_2$ as therapeutic radiotracers for targeting FAP-expressing tumors. Human dosimetry projections for both ^{177}Lu and ^{161}Tb offer valuable insights into the clinical translation of those FAP-targeted radiopharmaceuticals.

EPS-194

Development of ^{206}Bi as a SPECT Imaging Radiotracer to Annotate the in vivo Biodistribution of Bismuth Daughters

L. Wehner*, E. Aluicio-Sarduy, A. O. Adeniyi, L. Batley, B. Bednarz, J. W. Engle, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Alpha-emitting radionuclides have shown encouraging results in the treatment of advanced-stage cancers. However, the renal redistribution of Bismuth daughters ($^{213/212}$Bi) during targeted alpha therapy (TAT) decay leads to dose-limiting nephrotoxicity. To better understand the in vivo fate of radioactive Bismuth and reduce its renal deposition, we developed ^{206}Bi as a SPECT imaging radiotracer to investigate the mechanism of bismuth distribution to the kidney. ***Materials and Methods:*** ^{206}Bi ($T_{1/2}$ = 6.24 d) was produced via irradiation of an isotopically enriched ^{206}PbO target on a 16 MeV GE PETtrace cyclotron. In vitro, renal proximal tubule epithelial cells, RPTEC/TERT1, were seeded in 12-well plates and incubated with 0.074 MBq of ^{206}Bi alone or in combination with 1 mM $Bi(NO_3)_3$, 1 mM $FeCl_3$, or 15 µM apo-transferrin for 0.5h, 3h, 6h, and 12h (3-6 wells per condition). Membrane-bound and internalized cellular fractions were collected and quantified via gamma counting. In vivo, 1.3 MBq ^{206}Bi-citrate was intravenously injected into 4-week-old ICR mice (n = 12 total) for serial biodistribution at 4h, 26h, 48h, and 73h post-injection. Major tissues were quantified via gamma counting and the contralateral kidney cryosectioned for digital autoradiography. Longitudinal SPECT/CT imaging and serial biodistribution at 0.5h, 7h, 24h, 52h, 72h, 96h, and 144h post-injection were acquired in an ICR mice intravenously administered 2.7 MBq of ^{206}Bi-citrate. ***Results:*** Significant ($P < 0.0001$) internalization of ^{206}Bi was observed in RPTEC/TERT1 cells at all timepoints when treated with 1 mM $Bi(NO_3)_3$. After 12h, 46.3% ± 7.9 of the total activity was internalized when treated with 1 mM $Bi(NO_3)_3$ compared to 6.1% ± 2.4 in the ^{206}Bi control and 6.6 ± 1.3% in the 1 mM $FeCl_3$ group. When co-incubated with 1 mM $Bi(NO_3)_3$ and 15 µM apo-transferrin, ^{206}Bi internalization was further increased to 58.6% ± 2.5. In vivo, pronounced kidney uptake at 4h was quantified at

132.5 %IA/g ± 23.5 via gamma counting, gradually decreasing to 2.2 %IA/g ± 2.3 at 72 h. In vivo, SPECT/CT imaging similarly showed rapid, selective, and elevated accumulation to the kidneys and a protracted clearance with a $T_{1/2}$ of approximately 15.5 hr. Ex vivo autoradiography corroborated primarily ^{206}Bi distribution to the renal cortex. ***Conclusion:*** This work represents the first account of ^{206}Bi as a SPECT imaging radiotracer to characterize the in vivo distribution of radiobismuth and serves as an essential tool for devising interventions that can reduce the accumulation of these nephrotoxic radionuclides during TAT.

EPS-195

Exploiting PARP Trapping to Enhance the DNA-Targeting Efficiency of [^{123}I]CC1

L. Hernandez Cano[1], *N. Delgado Mayenco*[1], *H. Kramer*[1], *E. Diekstra*[1], *F. Amoroso*[1], *G. Alachouzos*[2], *W. Szymanski*[2,3,4], *M. van Vugt*[5], *B. Cornelissen*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging Department, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS,* [2]*Stratingh Institute for Chemistry, Faculty for Science and Engineering, University of Groningen, Groningen, NETHERLANDS,* [3]*Department of Radiology, Medical Imaging Centre, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,* [4]*Department of Medical Chemistry, Photopharmacology and Imaging, University of Groningen, Groningen, NETHERLANDS,* [5]*Department of Medical Oncology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands, Groningen, NETHERLANDS.*

Aim/Introduction: [^{123}I]CC1, an olaparib-based PARP inhibitor radiolabeled with an Auger electron emitter, has demonstrated a potent cytotoxic effect, both in vitro and in vivo, reducing tumor cell survival, and inhibiting tumor growth. We hypothesize that the cytotoxic effect of [^{123}I]CC1 is primarily driven by its ability to increase PARP levels associated with chromatin, prolonging the time during which ^{123}I can induce DNA damage. In this study, we analyzed if modulating the PARylation cycle affects radionuclide delivered to DNA. For this, we selected different drugs that impact PARP trapping. PARG inhibitor JA2131 decreases PARP trapping, while MMS (methyl methanesulfonate) increase DNA-associated PARP levels. ***Materials and Methods:*** A 500 µL suspension of 10 million PSN1 and U87 human cancer cells line was treated with 100 kBq [^{123}I]CC1 for 30 min at 37°C, either alone or after pretreatment with 0.01% MMS or 10 µM PARGi, followed by fractionation. PARP levels in the chromatin (PARP bound to DNA) and in the nuclear soluble fraction (free PARP) were analyzed by western blot. Additionally, a γ-counter was used to quantify the percentage of ^{123}I in the different cellular fractions. Total PARP and γH2AX were assessed by western blot to confirm that variations in PARP trapping levels are due to changes in DNA-associated PARP, rather than alterations in the PARP cycle or ^{123}I-induced DNA damage. ***Results:*** Exposure to 100 kBq (equivalent to 50 nM) [^{123}I]CC1 increases DNA-associated PARP, bringing it closer to DNA and thereby enhancing its ability to induce DNA damage. This result aligns with the cytotoxic activity of [^{123}I]CC1 previously reported by Chan et al 2023. Pretreatment with MMS leads to an increase in PARP trapping, which furthermore correlates with an increase in ^{123}I signal in the chromatin. Conversely, pretreating with PARGi reduces PARP trapping and decreases the radioactivity delivered to the nucleus. ***Conclusion:*** [^{123}I]CC1, at low concentrations and activities, prevents PARP dissociation from DNA, thereby enhancing the ability to produce substantial DNA damage. Moreover, modulating the PARylation cycle with MMS or PARGi alters DNA-associated PARP levels and the percentage of ^{123}I in the chromatin. These results confirm that [^{123}I]CC1 effectively tracks PARP and highlights the potential of combining it with other agents to enhance therapeutic efficacy. ***References:*** Chan, C. Y. et al. Exploring combinatory treatments to enhance targeted α- and β-radionuclide therapy in prostate cancer

M. Sabatella*, P. Engbers, T. Heredia-Genestar, A. Gebara Garcia de Lima, E. Hooijman, E. de Blois, J. Nonnekens;
Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: Prostate cancer (PCa) is the most common cancer in men in Europe, with about 318.800 cases and 37.600 deaths annually[1]. While localized PCa is therapeutically well managed with surgery or external beam radiotherapy (EBRT), metastatic PCa remains a major clinical challenge with limited curative options. Targeting radionuclide therapy (TRT) using prostate specific membrane antigen (PSMA)-targeting radiopharmaceuticals labelled with alpha or beta emitters has emerged as powerful treatment option. However, despite promising results in some patients, TRT outcomes remain inconsistent and off-targeted toxicity remains a concern. In this study, we explored novel combinatory treatment strategies to enhance the efficacy of TRT in PCa. ***Materials and Methods:*** We investigated combinatory treatments targeting the DNA damage response and cell cycle pathways, both critical in the response to radiation. PC3-PIP cells (PCa cells overexpressing PSMA) were treated with PSMA-I&T radiolabelled with either lutetium-177 or actinium-225, alone or in combination with a 700-compound drug library. EBRT was included as control. Cell viability was assessed using the CellTiter-Glo assay, comparing the ratio of luminescence signal from combinatory treatment versus monotherapy. Selected hits are currently being validated using viability and clonogenic assays. ***Results:*** We identified 171 possible radiosensitizers for [^{177}Lu]Lu-PSMA-I&T, 154 for [^{225}Ac]Ac-PSMA-I&T and 130 for EBRT. Among these, drugs targeting the DNA damage response factors ATM/ATR (1), DNA-PKcs (4) and PARP (5) or cell cycle regulation factors (13) have been identified as potential radiosensitizers in combination with TRT but not EBRT. Interestingly, 2 drugs interfering with cell division and the inflammatory response have been identified as potential radiosensitizer specifically for [^{225}Ac]Ac-PSMA-I&T. ***Conclusion:*** Quality control of our screening approach demonstrated high reproducibility. Further validation is ongoing to determine optimal concentrations, dosing and timing of these combinations for maximizing therapeutic efficacy. ***References:*** 1. EPS-197

Relative Biological Effectiveness (RBE) of ^{225}Ac-PSMA-I&T in-vitro treatment and its dependence on cellular incubation time

P. Hawarihewa[1], *M. Rumiantcev*[1], *H. Scherthan*[2], *R. Oos*[1], *M. Zacherl*[1], *F. Lindheimer*[1], *G. Böning*[1], *R. A. Werner*[1,3], *S. Ziegler*[4], *M. Brendel*[1,5,6], *A. Delker*[1];
[1]*LMU University Hospital, Munich, GERMANY,* [2]*Bundeswehr Institute of Radiobiology affiliated to the Univ. of Ulm, Munich, GERMANY,* [3]*Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Sciences, Division of Nuclear Medicine and Molecular Imaging, Baltimore, MD, UNITED STATES OF AMERICA,* [4]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY,* [5]*SyNergy, University of Munich, Munich, GERMANY,* [6]*DZNE - German Center for Neurodegenerative Diseases, Munich, GERMANY.*

Aim/Introduction: The relative biological effectiveness (RBE) is a critical, yet underexplored parameter in targeted radionuclide therapy due to the complex radiobiological behaviour of alpha, beta, and Auger emitters, time-dependent absorbed dose rates, as well as the heterogeneous radionuclide distribution at the cellular

level. Despite the clinical benefits of ^{225}Ac-PSMA and ^{177}Lu-PSMA treatment, investigations on the associated microdosimetric characteristics and cellular RBE are rare and especially missing following prolonged treatment. This study aims to address this important gap. ***Materials and Methods:*** LNCaP prostate cancer cells were treated with [^{177}Lu]Lu-PSMA-I&T and [^{225}Ac]Ac-PSMA-I&T to evaluate cellular time-activity-curves and S-values for cellular dosimetry, as well as clonogenic survival. The uptake assays were used (percentage of added activity per 100,000 cells (%AA/100,000 cells)) to quantify the total, membrane-bound, and internalized amount of radioactivity after different time points of incubation (3, 6, 18, and 24 hours) with 0.3 MBq/mL of [^{177}Lu]Lu-PSMA-I&T or 0.3 kBq/mL [^{225}Ac]Ac-PSMA-I&T. Membrane-bound and internalized fractions of cellular activity were further used to determine cellular S values using MIRDcell. The RBE of [^{225}Ac]Ac-PSMA-I&T was calculated based on the cell survival curves derived from clonogenic survival assays, the cellular dosimetry, and using ^{177}Lu as reference radiation. Therefore, cells were treated with varying activity concentrations of [^{177}Lu]Lu-PSMA-I&T (0.01 MBq/mL - 1 MBq/mL) and [^{225}Ac]Ac-PSMA-I&T (0.001 kBq/mL - 1 kBq/mL) for 3 and 24 hours, to assess both, short-term and long-term survival. ***Results:*** Both radiopharmaceuticals showed variable uptake patterns over 24 hours, with no significant difference between the membrane-bound and internalized fractions. For [^{177}Lu]Lu-PSMA-I&T, both the internalized fraction and overall uptake increased over time, peaking at 18 hours (internalized: 4.0 ±1.6 %AA/100,000 cells; total activity: 6.5±1.8 %AA/100,000 cells). Similarly, [^{225}Ac]Ac-PSMA-I&T showed the highest overall uptake at 18 hours (total activity: 4.0±1.7 %AA/100,000 cells). The absorbed doses after 24 hours of treatment were 36 Gy for ^{177}Lu-PSMA-I&T (0.3 MBq/mL) and 13 Gy for ^{225}Ac-PSMA-I&T (0.3 kBq/mL). For both radiopharmaceuticals clonogenic survival decreased linearly with the absorbed dose to the cell. The cellular RBE of [^{225}Ac]Ac-PSMA-I&T after 24 hours of treatment was 11.9 relative to [^{177}Lu]Lu-PSMA-I&T. However, for short-term exposure (3 hours of treatment), the RBE was lower, with a value of 3.6. ***Conclusion:*** This study disclosed similar cellular uptake of [^{177}Lu]Lu-PSMA-I&T and [^{225}Ac]Ac-PSMA-I&T and highlights the significantly higher RBE of the alpha emitter [^{225}Ac]Ac-PSMA-I&T during long-term compared to short-term incubation. In subsequent in vitro studies, DNA damage shall be used as the second RBE endpoint.

EPS-198

Development of a simulated preclinical database for 3D AI-based dosimetry prediction based on 2D nuclear imaging

G. Savvidis[1], *V. Paneta*[1], *V. Eleftheriadis*[1], *V. Lagaki*[1], *D. Anestis*[1], *S. Sarpaki*[1], *T. Karampelas*[1], *L. Fysikopoulos*[1], *G. Loudos*[1], *P. Papadimitroulas*[1,2];
[1]*BIOEMTECH, Athens, GREECE,* [2]*Medical Informatics Laboratory, School of Medicine, University of Thessaly, Larissa, GREECE.*

Aim/Introduction: We present a methodology for creating a simulated dosimetry database, utilizing Monte Carlo (MC) simulations driven by CT and SPECT preclinical imaging data. The complete database comprises numerous triplets, each consisting of a 3D simulated dose map, a 3D SPECT image, and a corresponding 2D planar image. The aim is to exploit the dosimetry simulation outputs as ground truth to train an AI model to directly estimate 3D dose distributions from 2D planar images. ***Materials and Methods:*** The input dataset comprises paired ^{111}In SPECT/CT scans, representing respective activity and attenuation maps. These pairs serve as inputs for MC simulations to generate corresponding three-dimensional dosimetry distributions. Simulations were conducted using GATE10, an extensively validated, open-source simulation platform based on the Geant4 framework[1]. Each simulation utilized 10^8 primary particles and was executed on the Leonardo high performance computing (HPC) center. Prior to simulation, all image pairs were resampled to an isotropic voxel size of 0.5×0.5×0.5 mm^3 and spatially co-registered to ensure precise alignment between SPECT and CT components. A preprocessing step involving noise removal was applied to enhance the quality of the activity maps and improve dosimetric accuracy. The generated 3D dose maps were subsequently paired with their corresponding 2D planar projections to form the training dataset for a GenAI model. A conditional Generative Adversarial Network (cGAN), specifically a Vox2Vox architecture[2] optimized for voxel-wise image translation tasks, was used. ***Results:*** MC simulations were completed for 300 image pairs, with the final dataset expected to include ~1,000 pairs. The resulting dose distributions preserve the high spatial resolution of 0.5×0.5×0.5 mm^3. The use of 10^8 primary particles per simulation yielded low dose statistical uncertainty below 2.5% in regions of interest. A preliminary GenAI model was trained on the initial dataset of 300 planar-volumetric image pairs to learn direct mapping from 2D input images to 3D dosimetric predictions. ***Conclusion:*** As Monte Carlo-based dosimetry remains the gold standard for internal dose estimation, the dataset generated through this approach offers a robust foundation for developing AI-driven predictive dosimetry models. Future efforts will focus on extending this framework to additional therapeutic radionuclides, such as ^{177}Lu, enabling accurate internal dose estimations directly from imaging data. ***References:*** 1. [1]The University of Wisconsin – Madison, Department of Medical Physics, Madison, WI, UNITED STATES OF AMERICA, [2]Hevesy Laboratory, Technical University of Denmark, Roskilde, DENMARK, [3]The University of Wisconsin – Madison, Department of Radiology, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: ^{103}Pd is a promising radionuclide for radiopharmaceutical therapy needing improved production methods to make it available for research for radiobiological studies and targeted pharmaceuticals' development. ***Materials and Methods:*** K_d measurements: Branched DGA (Triskem) and TK200 (Triskem) resins and AG1-X8 anion exchange resin (Bio-Rad) (all 50.1 ± 0.3mg) were equilibrated with HCl (0.03 - 8.0M) and contacted by ^{nat}Pd and ^{nat}Rh (186 ± 5ppm). Supernatant metal concentrations were quantified by ICP-OES. Electrodeposition: Rh was electrodeposited onto graphite discs chosen for their chemical resistance and electrical and thermal conductivity. Electrodeposition proceeded under two conditions: a) constant current (10-20mA), 6.0M HCl electrolyte, 4g·L^{-1} of $RhCl_3$ at 70ºC, and b) constant current (5-10mA), 0.2M HCl with 1% w/v sodium sulfamate, 41g·L^{-1} $RhCl_3$ at 60ºC. Deposition rates of 0.6-1.0mg·mA^{-1} h^{-1} and thicknesses of 66-123mg·cm^{-2} were achieved. Irradiation: Optimal Rh target thicknesses of 0.301mm degrade $E_{0,p+}$ from 13MeV to ~5MeV.[1,2] Electroplated and foil targets

(for radiochemical development) were irradiated for up to 80µAh at 13 or 10MeV. Electrochemical Dissolution: Rh was dissolved by applying 10V AC in 6.0M HCl using a graphite electrode[3]. The Rh foil dissolves at a rate of 24.1±3.1mg·h^{-1}. Dynamic separation: Two separation procedures were tested. First, equilibrated columns containing 2.0g of AG1-X8 resin were loaded with $RhCl_3$ in 6M HCl and washed with 6M HCl and 0.03M HCl. [^{103}Pd]Pd$(NH_3)_2Cl_2$ was eluted in 1:1 1M NH_4OH:1M NH_4Cl. Alternatively, 1.0g branched DGA resin was loaded with dissolved Rh (18mg) in 3M HCl and washed with 3M HCl, eluting Rh. $^{103}PdCl_2$ was eluted in c.HCl. Titrimetric Binding: Evaporated eluate from the DGA column mixed with TETA in 0.1M ammonium acetate and heated to 80°C for 20 min. Conversion to the [^{103}Pd]Pd-TETA complex was tracked by radio-TLC. ***Results:*** Results from collaborating institutions are summarized in the table below. ***Conclusion:*** We report the fabrication of Rh targets, irradiation, dissolution, and separation of n.c.a. ^{103}Pd from a small cyclotron. This work was supported by the European Union's Horizon 2020 research and innovation program under grant agreement No 101008571 (PRISMAP). ***References:*** [1] doi.org/10.1016/S0168-583X(00)00190-7 [2] doi.org/10.1016/0092-640X(82)90004-3 [3] doi.org/10.1016/0020-708X(84)90080-2.

Production of alpha emitters Ac-225, Bi-213, Pb-212, and Th-227 from Th-232 spallation at TRIUMF

H. Yang[1,2,3], *Q. Miao*[1], *B. McNeil*[1,2], *L. Wharton*[1], *S. W. McNeil*[1,3], *H. Meeres*[1,3], *C. Ramogida*[1,2], *P. Schaffer*[1,2,3], *C. Hoehr*[1];
[1]TRIUMF, Vancouver, BC, CANADA, [2]Simon Fraser University, Burnaby, BC, CANADA, [3]The University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: Targeted Alpha Therapy (TAT) has garnered tremendous attention in recent years due to its promising clinical efficacy. There is a surge of preclinical and clinical work underway to explore TAT for various cancer treatments. One of the major hurdles for this fast-growing field is the limited availability of alpha-emitting radionuclides. To address this shortage, at TRIUMF, we have been using the Th-232 spallation reaction to produce and purify medically relevant alpha-emitters. ***Materials and Methods:*** A target cassette composed of a 10 g Th-232 foil is welded into a target frame and irradiated at up to 12,000 µAh with ~480 MeV protons . Targets are transferred to a hotcell and subsequently processed. After dissolution, bulk thorium is precipitated and removed by filtration. The solution is further processed using two columns to extract Ac-225 (containing Ac-227), which is also used as a generator for Bi-213. After allowing the Ac-225 decay, Ac-227 is then used as a generator for Th-227. Separately, the fraction containing Ra-225 is used to extract Ac-225 without Ac-227. Further to the above, the thorium precipitate is redissolved and used to extract Th-228 as a generator for Pb-212. ***Results:*** In our recent productions, six targets yielded 2.2 GBq Ac-225 containing Ac-227, and ~350 MBq of pure Ac-225 (from Ra-225). Previous work has also demonstrated that up to 6 MBq of Ac-227, and up to 120 MBq of Th-228 can be extracted from each target processing. From radiolabeling tests, gamma spectroscopy analysis, and ICP-MS analysis, good radionuclidic and chemical purity of Ac-225 was demonstrated. Ac-225, Bi-213, Pb-212, and Th-227 produced from this process have been used for radiochemistry testing and various preclinical studies. ***Conclusion:*** High-energy, proton-based spallation of Th-232 is an efficient method for producing several alpha-emitting isotopes of clinical interest. At TRIUMF, we have generated Ac-225, Bi-213, Pb-212, and Th-227 in quantities and purity suitable for radiochemistry and preclinical work. Further research is underway to explore other alpha-emitters that can potentially be extracted from this process.

OP-581

Optimal energy interval for the cyclotron production of ^{68}Ga using solid targets

M. Avila-Rodriguez, *A. Zarate-Morales, A. Flores-Moreno;
Facultad De Medicina, Universidad Nacional Autónoma De México, Ciudad De México, MEXICO.*

Aim/Introduction: Gallium-68 can be efficiently produced with compact cyclotrons via the ^{68}Zn(p,n)^{68}Ga nuclear reaction using solid targets. Natural Zinc possess five isotopes (^{64,66,67,68,70}Zn) and each of them leads to the production of Ga radioisotopes, so a high isotopic enrichment of ^{68}Zn is crucial to obtain ^{68}Ga with high radionuclidic purity, to be suitable for human use. But even in the event of using highly enrich ^{68}Zn (>99%) the radionuclidic purity of ^{68}Ga will be constrained to the proton energy because the competing (p,2n) reaction at E >12 MeV. ***Materials and Methods:*** To investigate the impact of isotopic enrichment and proton energy on the radionuclidic purity (RNP) of ^{68}Ga produced via the ^{68}Zn(p,n) reaction, a series of theoretical calculations were conducted taking into account the co-production of ^{66}Ga via the ^{66}Zn(p,n) reaction, and ^{67}Ga via the ^{67}Zn(p,n) and ^{68}Zn(p,2n) reactions. Calculations were made using the saturations yields from the NDS-IAEA home page [1] considering thick solid targets of ^{68}Zn with different isotopic enrichment (98.2, 99.0, and 99.5%), for different proton energies (11-15 MeV) and irradiation times of 1 and 2 half-lives of ^{68}Ga. ***Results:*** The optimal energy interval to produce ^{68}Ga by proton irradiation of ^{68}Zn targets is 13 → 9 MeV (Ein → Eout). This energy interval produces ^{68}Ga with a high RNP and optimizes the use of target material as it gives the best yield per unit mass. The target thickness for this energy interval, as determined from the analysis of the CSYR-plot [2] of this nuclear reaction, would be around 158 mg/cm^2, with a corresponding production yield at saturation of approximately 7.4 GBq/µA. The production yield of such a target would be 148 GBq of ^{68}Ga (68 min of bombardment at 40 µA) with a RNP of 99.95% at EOB. No surprisingly isotopic enrichment of ^{68}Zn improves RNP while longer irradiation times favors the production of impurities, as both ^{66}Ga and ^{67}Ga have longer half-life compared to ^{68}Ga. The maximum recommended proton energy for the cyclotron production of ^{68}Ga using solid targets is 14 MeV. ***Conclusion:*** Multi-curie levels of ^{68}Ga with RNP>99.9%, suitable for the radiolabeling of Ga-based radiopharmaceuticals for clinical applications, can be efficiently produced using solid targets by wisely selecting the isotopic enrichment of ^{68}Zn and proton energy to balance the yield and RNP. ***References:*** [1] NDS-IAEA, Charged-particle cross section database for medical radioisotope production. Available from: https://www-nds.iaea.org/medical/index.html, [2] Current Radiopharmaceuticals, 2021, 14, 340-353.

OP-582

Production of high-purity ^{212}Pb from natural ^{232}Th for alpha radionuclide therapy

R. Wang, *Z. Liu;
Changping Laboratory, Beijing, CHINA.*

Aim/Introduction: The ^{212}Pb/^{212}Bi in vivo generator is a promising candidate for alpha radionuclide therapy, as has been proved in multiple pre-clinical and clinical studies. However, the availability of ^{212}Pb is still rather limited, impeding the development of ^{212}Pb-based radiopharmaceuticals. At this moment, ^{212}Pb is usually supplied by the ^{224}Ra/^{212}Pb generators. As ^{212}Pb is a part from the decay chain of ^{232}Th, it is possible to establish a ^{212}Pb production route by directly separating ^{212}Pb from aged ^{232}Th as previously reported[1]. However, it remains challenging to obtain ^{212}Pb with low level of metallic impurities (e.g. Th) using the reported set-up. ***Materials and Methods:*** An optimized method for the extraction of ^{212}Pb with high purity from aged $^{232}Th(NO_3)_4$ solution is reported in this work. Initial separation of ^{212}Pb from ^{232}Th was achieved

by the PB resin. After being stripped from the PB resin by 8 M HCl or 0.2 M $(NH_4)_2HCit$, ^{212}Pb was further purified by either the AG50W X8-AG1 X8 route or the TK101-AG1 X8 route. The final ^{212}Pb product was dispersed in 0.01 M HCl, which can be directly used for radiolabeling. The chemical and radionuclide purity of the ^{212}Pb product were assessed by ICP-MS and HPGe detector measurements, respectively. Subsequently, the radiolabeling of purified ^{212}Pb on various peptides was systematically studied to achieve clinically relevant specific activity. ***Results:*** With the optimized method, more than 1.85 MBq of ^{212}Pb can be routinely obtained. The whole purification process can be completed within 2 h. Radionuclide purity of the purified ^{212}Pb was found to be as high as 99.9% while the main metallic impurities were at ppb level. The radiochemical yield of ^{212}Pb radiolabeling was found to be more than 85% for all tested peptides with a specific activity of ~185 kBq/nmol. ***Conclusion:*** In conclusion, a simple but efficient method for ^{212}Pb extraction from natural ^{232}Th is described. The ^{212}Pb product was found to be both chemical and radionuclide pure and can be used for radiolabeling with high radiochemical yield and specific activity. This work gave a good example for producing ^{212}Pb without the use of complex nuclear facilities, providing a possible solution to the shortage of ^{212}Pb in pre-clinical studies. ***References:*** 1. Chen, J.; Xu, M.; Liu, Y.; Duan, D.; Han, Y.; Liu, Z., Isolation of ^{212}Pb from natural thorium for targeted alpha-therapy. Chinese Chemical Letters 2022, 33 (7), 3474-3477.

OP-583

Cyclotron Production of ^{135}La from enriched $^{135}BaCO_3$ targets.

E. Aluicio-Sarduy*, A. P. Olson, J. C. Mixdorf, T. E. Barnhart, J. W. Engle;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: ^{135}La ($t_{1/2}$ =19.93h, 98.1% EC) is an attractive radionuclide for targeted Auger therapy due to its unique decay characteristics and chemical properties resembling those of commonly used therapeutic radiometals [1,2]. However, high production yields and radionuclidic purity are essential for its potential use in preclinical and clinical settings. Our goal is to develop a scalable, automatable, and cost-efficient production method of ^{135}La from isotopically enriched ^{135}Ba targets. ***Materials and Methods:*** Enriched $^{135}BaCO_3$ (94.9%) was irradiated with 13MeV protons using a GE PETtrace cyclotron at 10μA. Lanthanum-135 was isolated by single column extraction chromatography using N,N,N',N'-tetrakis-2-ethylhexyldiglycolamide functionalized (branched-DGA) resin. Final product radionuclidic and elemental purity were verified by HPGe gamma spectrometry and microwave plasma-atomic emission spectroscopy (MP-AES), respectively. Apparent molar activity (AMA) was quantified by complexation of the purified ^{135}La with DOTA and macropa. The target material was recycled by precipitation/decantation using a saturated $(NH_4)_2CO_3$ solution. ***Results:*** Lanthanum-135 was produced with a physical yield of 50 ± 5 MBq/μAh (EoB-corrected) from ~150 mg/cm^2 $^{135}BaCO_3$ targets. After target dissolution, the resin's differential affinity for Ba^{2+} and La^{3+} ions at different nitric acid concentrations was leveraged to selectively load La^{3+} from the 3M HNO_3 (25 mL) target dissolution. Subsequent rinsing with decreasing HNO_3 concentrations (15 mL 3M HNO_3 and 3 mL 0.5M HNO_3) eluted trace metal impurities. Lanthanum(3+) was eluted in a small volume of 0.1M HCl (0.3 - 0.5 mL) with a radiochemical yield of 96.7 ± 0.5%. MP-AES analysis (n=4) established 0.65 ± 0.51 ppm (Ba), 0.16 ± 0.11 ppm (Zn), and 0.03 ± 0.03 ppm (Cu) of the only detectable impurities in the purified ^{135}La solution. AMA was 11 ± 4 GBq/μmol DOTA and 35 ± 7 Gbq/μmol macropa (n=4). The enriched target material was recovered with a run-to-run efficiency of 98.1 ± 1.4 % (n=4). ***Conclusion:*** We developed and characterized a method for cost-effective production of radiopharmaceutical-quality ^{135}La, facilitating its potential preclinical/clinical use. A similar strategy can also be followed to produce the positron-emitting radioisotope ^{132}La. ***References:*** 1- Aluicio-Sarduy E, et al., 2019, doi:10.1038/s41598-019-47137-0 2- Aluicio-Sarduy E, et al., 2020, doi: 10.1002/chem.201905202.

Multi Copper and Gallium Radioisotopes Production by Irradiation of ZnO Target via Medical Cyclotron

F. Porto*[1], G. Speltri[1], S. Cisternino[2], C. Favaretto[3], N. Bergamaschi[3], D. Peruzzi[3], J. Amico[3], P. Bovone[3], G. Gorgoni[3], A. Boschi[1], R. Tassinari[1], L. Marvelli[1], R. Napolitano[1], A. Niorettini[1], L. Uccelli[1], L. Mou[2], G. Piteo[4], A. Kotliarenko[2], L. De Dominicis[2], G. Pupillo[2], J. Esposito[2], E. Cazzola[3], P. Martini[1];*
[1]University of Ferrara, Ferrara, ITALY, [2]National Institute for Nuclear Physics, Legnaro, ITALY, [3]IRCCS Sacro Cuore Don Calabria Hospital, Negrar di Valpolicella, ITALY, [4]University of Padova, Padova, ITALY.

Aim/Introduction: Copper radioisotopes, such as copper-61, copper-64, and copper-67, are gaining increasing relevance in nuclear medicine due to their versatile decay properties, suitable for both diagnostic and therapeutic applications. Our study investigated their production via proton irradiation of enriched zinc oxide (ZnO) targets. Specifically, ^{61}Cu can be produced via the (p,α) reaction on a ^{64}Zn target in the energy range of 10-20 MeV, ^{64}Cu through the ^{68}Zn(p,nα) reaction in the range of 20-40 MeV, and ^{67}Cu through the ^{70}Zn(p,α) reaction in the range of 10-70 MeV. Interestingly, gallium radioisotopes, also of medical relevance, emerged as significant by-products during the irradiation process. From these observations arises the idea of developing a multi-radioisotope production method through ZnO irradiation. Based on this, a Zn/Cu separation method was developed to enable the recovery of both gallium and copper radioisotopes. In addition, a protocol was developed and applied to recover ZnO from waste, enabling target recycling. ***Materials and Methods:*** Sintered ^{nat}ZnO pellets (~260 mg) were produced via Spark Plasma Sintering and attached to Au/Nb backing support. Irradiations were carried out using a TR19 cyclotron. Copper radioisotopes were separated via an automated protocol using CU and TK201 resins. The copper-rich eluate was collected from TK201, while the zinc/gallium-containing waste from the CU resin was further purified using ZR and DGA resins. Purity and recovery efficiencies were assessed by ICP-MS and γ-spectrometry. Both copper and gallium fractions were tested for radiolabelling with DOTA and NODAGA-RGD. ZnO was recovered from waste via NaOH precipitation followed by calcination. ***Results:*** ^{nat}ZnO targets were successfully irradiated at 19 MeV, 30 μA, for 30 minutes. The automated copper purification yielded ~95% recovery with high radionuclidic purity; γ-spectra confirmed the presence of copper-61 as the main isotope, while impurities of zinc, gallium, and cobalt in the waste were below instrumental detection limits. Additionally, gallium was effectively separated from zinc and eluted in water. Radiolabelling of DOTA and NODAGA-RGD with both purified copper and gallium yielded >95% radiochemical purity. ZnO was recovered from the acidic waste solution with ~85% yield and reused for new pellet production. ***Conclusion:*** This work presents a sustainable radiochemical approach for the dual production of copper and gallium radioisotopes from a single irradiation of ZnO targets. The developed method combines efficient radionuclide separation with recovery of valuable by-products and target material. This strategy aligns with green chemistry principles, optimizing resource use while minimizing radioactive and chemical waste.

Production of ^{225}Ac for Targeted Alpha Therapy Using an Electron Linear Accelerator: Improving Radiolabeling Quality Comparable to ^{229}Th Generator-Produced ^{225}Ac

M. Maeda*[1], Y. Ueno[1], K. Nishida[1], Y. Kani[1], M. Yoshimoto[2], H. Fujii[2], A. Inaki[2], H. Kikunaga[3], T. Yokokita[3], S. Kashiwagi[3], K. Shirasaki[4,5];*
[1]Hitachi Ltd., Research & Development Group, Hitachi, JAPAN, [2]National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Kashiwa, JAPAN, [3]Research Center for Accelerator and Radioisotope Science, Tohoku University, Sendai, JAPAN, [4]Institute for Materials Research, Tohoku University, Sendai, JAPAN, [5]Radioisotope Research Center, Institute for Radiation Sciences, Osaka University, Toyonaka, JAPAN.

Aim/Introduction: ^{225}Ac is recognized as one of the most promised radionuclides for targeted alpha therapy (TAT). However, its current supply from a ^{229}Th / ^{225}Ac generator is limited, so another mass production method needs to be established. We have reported on the experimental production of ^{225}Ac using an electron linear accelerator in which no long-lived actinium isotopes are co-produced. In this production method, ^{225}Ac is produced via the ^{226}Ra (γ, n)^{225}Ra photonuclear reaction, followed by the beta decay of ^{225}Ra to ^{225}Ac. In our previous study, we produced megabecquerel quantities of ^{225}Ac but improvements in production amount and radiolabeling quality were necessary to use ^{225}Ac for preclinical research purposes [1]. In this study, we aimed to produce ^{225}Ac with a radiolabeling quality comparable to that of ^{225}Ac produced by a ^{229}Th generator by further increasing the production amount. ***Materials and Methods:*** To increase the ^{225}Ac production, ^{226}Ra target amount was increased to about 200 MBq and its size was reduced to 3 mm in diameter. Other improvements in target structure were made. Also, current value and time of the irradiation was increased. Irradiation was performed using the electron linear accelerator at the Research Center for Accelerator and Radioisotope Science, Tohoku University. To evaluate the quality of ^{225}Ac, a DOTA-conjugated peptide was radiolabeled. The result of the radiolabeling was compared with that using ^{225}Ac produced by a ^{229}Th generator purchased from the U.S. National Isotope Development Center. ***Results:*** ^{225}Ac was separated from Ra isotopes 26 days after the irradiation. The activity of ^{225}Ac at this point was 63 MBq. Based on the ^{225}Ac accumulation curve calculated from the decay of ^{225}Ra, the maximum activity of ^{225}Ac at 17 days after irradiation was estimated to be 69 MBq. After 5 days of manual separation, 39 MBq of purified ^{225}Ac was obtained. The chemical yield was 88%. The radiolabeling yield and specific activity of the DOTA-conjugated peptide were >98% and 0.34 MBq/nmol, respectively, which were comparable to those using ^{225}Ac produced by a ^{229}Th generator. ***Conclusion:*** ^{225}Ac with radiolabeling quality comparable to that of ^{229}Th generator-produced ^{225}Ac was obtained by ^{226}Ra irradiation using an electron linear accelerator. The radioisotope produced has started to be utilized for preclinical research. The production is planned to further increase through the automation currently under consideration for the separation process. ***References:*** [1] M. Maeda et al.; J. Nucl. Med. (2023) 64 P24.

OP-586

Resin Based Extraction of $^{45}Ti^{4+}$ for Radiopharmaceutical Applications

M. DeLuca[1], *E. Aluicio-Sarduy*[1], *T. E. Barnhart*[1], *J. C. Mixdorf*[1], *P. N. Tran*[2], *A. Marlin*[3], *E. Boros*[2], *J. W. Engle*[1];
[1]*University of Wisconsin - Department of Medical Physics, Madison, WI, UNITED STATES OF AMERICA,* [2]*University of Wisconsin - Department of Chemistry, Madison, WI, UNITED STATES OF AMERICA,* [3]*PSL University - Chimie ParisTech, Paris, FRANCE.*

Aim/Introduction: ^{45}Ti ($t_{1/2}$=3.08 h) is attractive for positron emission tomography (PET) imaging (84.8% β^+, $E_{<\beta+>}$ = 439 keV). It can be produced by cyclotron irradiation of ^{nat}Sc via the (p,n) reaction (σ_{max} = 350-400 mb, 10-14 MeV). Incorporating ^{45}Ti into radiopharmaceuticals requires isolation from ^{nat}Sc target material and recovery in labile chemical form. We and others have studied isolation of ^{45}Ti using Zr resin [1]. ^{45}Ti has high affinity (D_w ~10^4) for Zr resin in HCl and HNO_3, requiring organic eluate that compete with chelators and compromise apparent molar activity. TEVA (Tetravalent Actinide) resin (Eichrom) has previously been used to separate Ti/Sc in the context of a ^{44}Ti/^{44}Sc generator [2]. We report exploration of TEVA resin for isolation of $^{45}Ti^{4+}$ from ^{nat}Sc. ***Materials and Methods:*** ^{45}Ti and ^{nat}Sc distribution volumes (K_d) were measured by contacting known mass of TEVA resin with HCl/$H_2C_2O_4$ solutions (.2-4M HCl/0-.1M $H_2C_2O_4$) spiked with dissolved ^{nat}Sc foil irradiated with 13 MeV protons on a GE PETtrace at the University of Wisconsin - Madison. The K_d of ^{45}Ti was determined by comparing activity in a 50 µL aliquot of the supernatant with 50 µL of an unreacted solution, and that of ^{nat}Sc was determined by ICP OES of analogous fractions. Results were used to design column separations of ^{45}Ti from irradiated ^{nat}Sc targets. ***Results:*** Measured values suggest loading in .2M HCl/.05-.1M $H_2C_2O_4$ due to a high affinity for ^{45}Ti (K_d >3000) and low affinity for ^{nat}Sc (K_d <20). At lower concentrations of $H_2C_2O_4$ and higher concentrations of HCl, ^{45}Ti affinity decreases. Measured ^{45}Ti K_d values reflect a low affinity (K_d <10) for the resin in all HCl concentrations, indicating this eluent is suitable for recovering ^{45}Ti. However, measured ^{45}Ti elution profiles broaden with decreasing HCl concentration. Additionally, as ^{nat}Sc mass was increased, we observed insoluble ScC_2O_2, which suggests the potential to reduce the initial target mass via selective precipitation. ***Conclusion:*** Measured K_d values indicate TEVA resin can separate $^{45}Ti^{4+}$ from Sc target material by extracting in HCl/$H_2C_2O_4$ solutions and eluting in HCl. These results motivate ongoing work testing resin performance with larger ^{nat}Sc target masses and higher ^{45}Ti activity, comparing ^{45}Ti radiochemical yields and apparent molar activity with TREN-CAM to results obtained with Zr resin. ***References:*** [1] doi.org/10.1007/s10967-023-09270-z. [2] doi.org/10.3390/molecules26216371.

OP-587

Purifying radionuclides using microfluidic chips: towards the automated liquid-liquid extraction of Ac-225

R. de Kruijff*, S. Trapp, A. Santoso, E. Paulssen;*
Delft University of Technology, Delft, NETHERLANDS.

Aim/Introduction: In recent years, extremely promising results have been obtained in clinical trials using targeted alpha therapy (TAT), in particular using Ac-225. However, its limited availability greatly hampers further translation and new innovations. Increasing the global supply of requires a production and separation system that is not only fast and efficient, but also continuous and automatable. We therefore propose an innovative two-step liquid-liquid extraction (LLE) procedure that enables very fast radionuclide extraction and allows for direct target solution recycling. We have adapted microfluidic chips, which offer precise control over two-phase flows and their interfaces, for establishing an automated purification system for medical radionuclides, and show a proof-of-principle with the separation of Ac-225 from radium, using di-2-ethylhexylphosphoric acid (D2EHPA) as the chelator. ***Materials and Methods:*** Ac-225 was supplied in 0.05 M HCl, and Ra-223 was supplied as $^{223}RaCl_2$. The aqueous target solutions contained 0.1 M $Ba(NO_3)_2$ with trace Ac-225 and Ra-223, and the organic extracting solutions consisted of $CHCl_3$ with 10 %v/v D2EHPA. Batch extraction experiments were carried out in Eppendorf vials with a 1:1 ratio of aqueous and organic solutions. Microfluidic extraction experiments were performed in SiO_2-coated PDMS microfluidic chips, the solutions were loaded on two separate syringe pumps and connected to the chips using PTFE tubing for different contact times. Back-extraction was performed by contacting the organic extraction liquid with HCl solutions. ***Results:*** Batch extraction experiments demonstrated very fast complexation of Ac-225 with the D2EHPA chelator (< 1 minute), and high extraction efficiencies (> 98 %) from Ra-223 solutions. Co-extraction of the Ra-223 target material into the organic phase remained below 0.3 %. Ac-225 back-extraction efficiencies were over 98 % when using 0.1 M HCl as back-extracting agent. In the microfluidic chips, perfect phase separation was obtained between the aqueous and organic phase. A comparable Ac-225 extraction efficiency of 97.2 % ± 1.5 % was obtained for extremely short contact times (1.7 seconds), although the back-extraction efficiency of Ac-225 was somewhat lower (80.2 % ± 0.8 % and 39.9 % ± 6.2 % for 4 M and 0.1 M HCl solutions, respectively). ***Conclusion:*** A microfluidic PDMS-based chip coated with SiO_2

was developed for the LLE of Ac-225. Overall, excellent extraction and back-extraction efficiencies were achieved for Ac-225 with the developed microfluidic extraction method Ac-225 (97.2 % ± 1.5 % and 80.2 % ± 0.8 %, respectively), presenting a promising alternative to conventional separation methods. ***References:*** DOI:10.1038/s41598-024-81177-5.

Comparison between semi-automated vertebral segmentation and manual bone marrow sampling for quantitative SPECT/CT-based bone marrow dosimetry in 177Lu radiopharmaceutical therapy

V. Forget[1], *S. Hammouda*[1], *F. A. Buteau*[2], *G. April*[2], *F. Arsenault*[2], *A. Beaulieu*[2], *J. M. Beauregard*[1];
[1]*Department of Radiology and Nuclear Medicine, Université Laval, Quebec City, QC, CANADA,* [2]*Department of Medical Imaging, CHU de Québec - Université Laval, Quebec City, QC, CANADA.*

Aim/Introduction: For bone marrow dosimetry, activity sampling dosimetry using small vertebral volumes of interest (VOIs) has been proposed but is subject to inter-observer variability (1). We aimed to compare this manual approach to a semi-automated vertebral CT segmentation technique. ***Materials and Methods:*** 71 patients enrolled in the personalized PRRT clinical trial (NCT02754297) underwent quantitative SPECT/CT at approximately 24h and 72h after each of 4 induction cycles of ^{177}Lu-DOTATATE (1.6-33.7 GBq). For the small volume manual segmentation method (SV), two 2-cm spherical VOIs were placed over L4 and L5 vertebrae, or over other vertebrae to avoid metastases, to obtain the mean activity concentration (Bq/mL). For the semi-automated method, the lumbar spine was segmented using a 125HU threshold from L1 to L4 on CT, from which the mean ($AUTO_{mean}$) and median ($AUTO_{med}$) activity concentrations were extracted. Absorbed doses were computed by multiplying the area under monoexponential time-activity concentration curves by 87 mGy·g/MBq·h. $AUTO_{mean}$ and $AUTO_{med}$ were correlated with SV bone marrow absorbed dose estimates. Dosimetric estimates were also correlated with haematological toxicity in terms of relative blood count variations. Subacute toxicity was defined as a variation occurring during each individual cycle, whereas late toxicity was defined as variations occurring from 8 weeks after the last cycle up to 52 weeks after therapy initiation. ***Results:*** Median bone marrow absorbed doses of all induction cycles (IQR) for the SV, $AUTO_{mean}$ and $AUTO_{med}$ techniques were 0.28 (0.18-0.45), 0.22 (0.14-0.43), and 0.17 (0.12-0.24) Gy, respectively. $AUTO_{mean}$ and SV absorbed doses during the first cycle showed a moderate correlation (r=0.68; P<0.001) which improved when $AUTO_{med}$ was correlated with SV (r=0.77; P<0.001). This was expected as bone metastasis has a weaker influence on median than mean activity concentration from lumbar spine VOIs. On average, $AUTO_{med}$ absorbed doses were 34% lower than those from SV. Individual cycles and cumulative doses yielded similar results. $AUTO_{med}$ absorbed doses showed weak but significant correlations with subacute thrombocytopenia, late thrombocytopenia and late anaemia (r=-0.27, -0.31 and -0.26, respectively; P<0.05) which were comparable to those obtained with SV (r=-0.30, -0.35 and -0.34, respectively; P<0.05). ***Conclusion:*** $AUTO_{med}$ bone marrow dose estimates were comparable to those obtained with SV and correlations with clinical outcomes were similar for both methods. This simple, accessible and implicitly observer-independent semi-automated technique could enable a standardised approach to bone marrow dosimetry in ^{177}Lu radiopharmaceutical therapy. ***References:*** (1) JNuclMed2018;60:1406-13, DelPrete,EJNMMIPhys2018;5:25.

OP-589

A semi-automatic model for correcting adjacent-organ cross-talk in bone marrow dosimetry after [^{177}Lu]Lu-DOTATATE treatment

K. Smits[1], *J. Hemmingsson*[1], *T. Rydén*[2], *A. Theisen*[3], *M. van Essen*[4], *J. Svensson*[5], *A. Hallqvist*[5], *J. Tran-Gia*[3], *P. Bernhardt*[2];
[1]*Institute of Clinical Sciences, Gothenburg, SWEDEN,* [2]*Department of Medicial Physics and Biomedical Engineering, Gothenburg, SWEDEN,* [3]*Department of Nuclear Medicine, Wurzburg, GERMANY,* [4]*Institute of Medicine, Gothenburg, SWEDEN,* [5]*Department of Oncology, Gothenburg, SWEDEN.*

Aim/Introduction: Previous studies on bone marrow dosimetry have shown a significant decrease in activity concentration in vertebrae adjacent to high-uptake regions. In this work, we developed a segmentation model that semi-automatically generates patient-specific activity maps. These activity maps are used for patient-specific correction of adjacent-organ cross-talk in the bone marrow, with the aim to compensate for signal loss in vertebrae close to high-uptake organs. ***Materials and Methods:*** A semi-automatic segmentation model was developed using multiple AI networks trained to delineate anatomic structures (e.g. kidney, spleen, liver) on patient low-dose CT images. Mean activity concentrations in the segmented organs are automatically extracted from the reconstructed SPECT images (OSEM, 8 iterations, 10 subsets), while those for the background (subcutaneous adipose tissue near the hip bone) and lumbar vertebrae are manually defined. The model then generates an activity map with patient-specific activity ratios between organs and background. Monte Carlo simulations are used to generate new SPECT images from the activity maps, allowing for the determination of patient-specific corrections for adjacent-organ cross-talk in the bone marrow (one correction factor for each lumbar vertebral body). To evaluate the segmentation model, we used a digital XCAT phantom by creating an activity map mimicking a [^{177}Lu]Lu-DOTATATE SPECT scan 24 hours post injection. A SPECT projection dataset of this phantom was simulated using in-house Monte Carlo simulation code. Thirty noise realizations were created and reconstructed, and the segmentation model was applied to each of the resulting SPECT images to derive a set of correction factors. Subsequently, the mean recovery in the lumbar vertebrae was evaluated for each noise realization both with and without spill-over correction. ***Results:*** By applying correction factors generated by the segmentation model, the mean recovery in the XCAT phantom's bone marrow increased from 0.23 to 0.80 (L1), 0.37 to 0.81 (L2), 0.58 to 0.95 (L3), 0.66 to 0.93 (L4), and 0.62 to 0.87 (L5) before and after spill-over correction, respectively. ***Conclusion:*** The segmentation model presented here significantly improved the recovery in all lumbar vertebrae of an XCAT phantom for 30 different noise realizations. Applying this model seems of particular use for vertebrae closely located to high-uptake organs (e.g., L1-L2), to overcome the problem of signal loss in these vertebrae due to adjacent-organ cross-talk.

OP-590

Main sources of uncertainty affecting vertebral activity quantification in SPECT/CT imaging after [^{177}Lu]Lu-DOTATATE therapy using a physical phantom and patient simulations

A. Theisen[1], *J. Leube*[1], *L. Pieper*[1], *M. Laßmann*[1], *K. Smits*[2], *J. Hemmingsson*[2], *P. Bernhardt*[2], *M. Salas-Ramirez*[1], *J. Tran-Gia*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Sahlgrenska Academy, Gothenburg, SWEDEN.*

Aim/Introduction: Accurate quantification of bone marrow activity is essential in radiopharmaceutical therapy, particularly for [^{177}Lu]Lu-DOTATATE, where the red marrow is a dose-limiting organ. SPECT/CT-based dosimetry is challenging due to low uptake, partial volume effects, and spill-in from high-activity organs like the kidneys. This study evaluates errors in bone marrow activity quantification using patient-specific phantom experiments and Monte Carlo simulations. Specifically, we used a 3D-printed lumbar vertebrae phantom based on ICRP 145 [1] and 30 patient-specific geometries to evaluate quantification accuracy. ***Materials and Methods:*** Phantom measurements were performed with a 3D-printed lumbar spine (L1-L5) and kidney phantom designed based on the ICRP 145 male mesh model [1]. Attenuation in the cortical bone was achieved using high-density printing material, while the spongiosa was modeled with a K_2HPO_4 solution containing 33 kBq/ml [^{177}Lu]$LuCl_3$ in DTPA. Standard-resin kidney phantoms were filled with 310 kBq/ml [^{177}Lu]$LuCl_3$ in HCl(aq). SPECT/CT imaging was performed in a water-filled IEC NEMA phantom under varying acquisition parameters (MELP collimation, 120 projections of 10/20/30 s, 10/20/10% around 208 keV peak, 128/256 matrix). To assess the impact of background, acquisition parameters, and scatter correction (SC), projection images were generated using SIMIND [2] (120 vs. 60 projections with the same total acquisition time; air/cold/hot background). Anatomical variability was analyzed on SIMIND-generated projection data of 30 vertebra+kidney activity masks segmented on [^{177}Lu]Lu-DOTATATE patient scans. Poisson noise (100 realizations per patient) was added. Reconstructions were performed with PyTomography (OSEM, AC, TEW-SC, resolution modeling) [3]. Four volume-of-interest (VOI) drawing techniques were evaluated by comparing SPECT-derived and true activity: 0.7/4.0-ml spherical VOI, CT-based VOI, and enlarged CT-based VOI. ***Results:*** Main quantification uncertainties were driven by reconstruction biases associated with high kidney activity, scatter conditions, VOI definition, and the noise behavior of OSEM reconstructions. Among VOI definition strategies, 4-mL spherical VOIs resulted in the highest accuracy but lower precision (e.g., 20s/projection, L1-L5: 94% ± 7%), while enlarged CT-based VOIs showed the highest precision but systematically underestimated activity (e.g., 20s/projection, L1-L5: 79% ± 1%). ***Conclusion:*** This study identifies key factors influencing SPECT/CT-based bone marrow dosimetry of lumbar vertebrae, particularly in those adjacent to the kidneys. While high precision is achieved, further optimization regarding image reconstruction and patient-specific VOI selection is essential to enhance accuracy, ultimately improving the reliability of dosimetry in clinical practice. ***References:*** [1] Kim C et al., ICRP 49(3);2020:13-201 [2] Ljungberg M, Strand SE. OP-591

Proof of concept for in vivo organ dosimetry with a tissue-equivalent 3D-printed heart

R. Ringler[1], *A. Poellmann*[1], *N. Zeiss-Carstens*[1], *D. Hellwig*[2], *D. Schmidt*[2];
[1]*Technical University of applied sciences Amberg-Weiden, Weiden, GERMANY,* [2]*University Hospital Regensburg, Department of Nuclear Medicine, Regensburg, GERMANY.*

Aim/Introduction: The use of 3D-printed, tissue-equivalent organ models enables the assessment of radiation exposure and organ-specific dose in both nuclear medicine and radiological procedures. By integrating thermoluminescent dosimeters (TLDs) with quantitative SPECT imaging, it is possible to verify radiation exposure associated with various radiopharmaceuticals in nuclear medicine, as well as with different dose protocols in computed tomography (CT). ***Materials and Methods:*** A 3D heart model printed at the university (FDM 3D printing) was used. The heart muscle was simulated with agar agar and CuSO4 (0-250 mg/ml) and the HU values were checked in CT (Somatom Emotion 6, 110 kV, 140 mAs). The proof of concept of the 3D heart was performed on a SPECT/CT (Siemens Symbia Intevo Bold) with an activity of A(Tc-99m) = 29.8 MBq. 2x20 MCP N TLD discs - calibrated with Tc99m in a PMMA phantom (dose reference: Black Piranha external measuring probe) - are packaged in a watertight vacuum container. 18 TLDs are attached to the 3D heart for 20 minutes and record the dose. The second batch of 18 TLDs remains on the 3D heart for 1 hour, which is placed in a modified, water-filled body phantom with 3D lungs, 3D spine and 3D ribs. This is used to perform a standard SPECT/CT examination. 2x2 TLDs are used to determine the background. ***Results:*** Quantification of Hounsfield Unit (HU) values using the $CuSO_4$ calibration series yielded concentrations of 6.2 mg/ml and 25 mg/ml for myocardial tissue without and with contrast enhancement, respectively. These values are consistent with those reported in the literature The proof-of-concept study demonstrated a heterogeneous dose distribution, attributable to the inhomogeneous uptake of Tc-99m within the simulated myocardial tissue. This observation was qualitatively confirmed through analysis of the acquired SPECT imaging data. ***Conclusion:*** Based on available datasets and literature, myocardial tissue is characterized by Hounsfield Unit (HU) values of 40 ± 9 without contrast enhancement and 114 ± 7 with contrast enhancement. These HU values can be accurately reproduced using appropriate concentrations of $CuSO_4$. Dose distribution within the phantom can be effectively assessed using thermoluminescent dosimeters (TLDs) in conjunction with Tc-99m. The subsequent phase of the study will involve a quantitative evaluation and comparison with SPECT imaging, as well as the simulation of relevant pathophysiological myocardial conditions within the 3D heart model.

OP-592

Nephron-Level Dosimetry of ^{161}Tb- and ^{177}Lu-DOTA-TATE Reveals Greater Absorbed Dose Heterogeneity from ^{161}Tb in Murine Renal Substructures

M. Andersson[1,2], *T. Opsomer*[3], *N. Reynaert*[2], *H. Levillain*[2], *C. Saldarriaga Vargas*[1];
[1]*Dosimetry Research for Targeted Radionuclide Therapy – Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM,* [2]*Medical Physics Department, Institut Jules Bordet – Université Libre de Bruxelles, Brussels, BELGIUM,* [3]*Nuclear Medical Applications – Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM.*

Aim/Introduction: Non-uniform radiopharmaceutical retention in kidney tissues results in nephron-scale absorbed dose heterogeneity, confounding radiation-induced nephrotoxicity investigations in radiopharmaceutical therapy (RPT). The radionuclide ^{161}Tb is of interest as it emits more low-energy electrons than ^{177}Lu, irradiating tumours more locally, but its impact on absorbed dose-dependent effects in normal tissues remains unclear. This study combined quantitative biodistribution data with a novel computational multi-nephron model to investigate and compare nephron substructure-specific absorbed dose distributions from [^{161}Tb]Tb- and [^{177}Lu]Lu-DOTA-TATE in murine kidneys. ***Materials and Methods:*** A realistic murine multi-nephron model was developed from 3D multiphoton microscopy data (1), representing kidney tissue sections including superficial,

midcortical, and juxtamedullary nephrons and their main substructures (glomeruli, proximal tubules (PT) and distal tubules). Nephron substructure- and type-specific S values for ^{161}Tb and ^{177}Lu were calculated (GATE v9.2). In-vivo biodistribution data were obtained from female C57BL6/Jjr mice injected with either [^{161}Tb]Tb- or [^{177}Lu]Lu-DOTA-TATE. Whole-organ activity was measured at five time points (15 minutes, 1,4,24 and 72 hours), and tissue-level activity distribution was quantified using digital autoradiography data and histological segmentation. Nephron-level activity distribution was estimated by mapping tissue-level activity data to nephron substructures using occupancy-based weighting. Time-integrated absorbed dose coefficients (ADCs) were calculated by fitting bi-exponential curves to absorbed dose rate data. ***Results:*** Renal uptake was primarily localized in the cortex and outer stripe of outer medulla (≥90% from 1h onward). Absorbed dose distributions were highly heterogeneous across nephron types and substructures for both radionuclides. Despite similar macroscopic biodistribution, ^{161}Tb led to significantly higher absorbed dose heterogeneity due to its higher emission of low-energy electrons. The ADCs to the PT were 71% higher than to glomeruli for ^{161}Tb compared to 28% higher for ^{177}Lu. Juxtamedullary nephrons had the highest ADCs across substructures. ADCs to juxtamedullary PT and glomeruli were 18-21% higher for ^{161}Tb and 14-17% higher for ^{177}Lu compared to superficial PT and glomeruli, respectively. ***Conclusion:*** The integration of high-resolution biodistribution data with a computational multi-nephron model enabled detailed renal dosimetry. ^{161}Tb showed greater nephron-level absorbed dose heterogeneity than ^{177}Lu across nephron substructures and types, with highest ADCs to juxtamedullary PT. Nephron-level absorbed dose heterogeneity highlight the importance of substructure-specific dosimetry in evaluating nephrotoxicity risk. These findings support the refinement of dosimetry models used in RPT development and provide a framework for identifying critical substructures, supporting the development of absorbed dose effect-relationships and nephroprotective strategies for clinical translation. ***References:*** (1) Blanc T et al. Kidney int. 2021;99(3):632-45.

OP-593

Time-dependent biodistribution and dosimetry of radiolabelled FAP-targeting single-domain antibody 4AH29 in Göttingen minipigs

N. Dumauthioz[1], *L. Navarro*[1], *M. Berdal*[1], *S. Nagachinta*[1], *J. Eersels*[1], *V. Gaspariunaite*[1], *A. R. Pombo Antunes*[1], *T. Jørgensen*[2], *L. Kellemann Kristensen*[2], *T. Starostka*[2], *D. Mantzilas*[1], *T. Lahoutte*[1], *M. D'Huyvetter*[1];
[1]*Precirix, Brussels, BELGIUM,* [2]*Minerva Imaging, Oelstykke, DENMARK.*

Aim/Introduction: Fibroblast activation protein alpha (FAP) is a pan-tumor target highly expressed on cancer-associated fibroblasts. We developed 4AH29, a single-domain antibody (sdAb) to bind FAP, which showed promising results in mice [1]. In tumor-bearing mice, 4AH29 radiolabelled with therapeutic radioisotopes exhibited prolonged tumor retention, leading to dose-dependent efficacy. Here we investigated the biodistribution of radiolabelled 4AH29 in Göttingen minipigs and extrapolated the dosimetry to human. ***Materials and Methods:*** [^{131}I]I-GMIB-4AH29 and [^{111}In]In-DOTA-4AH29 were administered to 3 male and 3 female Göttingen minipigs. The blood activity profile was determined over time by gamma-counter and biodistribution kinetic was performed by SPECT/CT imaging. The data obtained with [^{111}In]In-DOTA-4AH29 was used as a surrogate for the ^{225}Ac- and ^{177}Lu-labelled variants. Extrapolation to human absorbed dose was calculated with OLINDA. ***Results:*** Radiolabelled 4AH29 showed good tolerability in female and male minipigs, indicated by absent compound-related adverse effects. It displayed fast blood clearance driven by renal excretion. Kidney clearance dynamic of [^{131}I]I-GMIB-4AH29 and [^{111}In]In-DOTA-4AH29 seemed visually distinct, likely due to the different radiolabelling processes, linking chemistry and radionuclide pharmacokinetics of a halogen or metal respectively. However, the contrasting pharmacokinetics of a halogen and metal did not translate into differences in mean residence time (MRT), which displayed no variation in kidneys, bone marrow or liver when comparing ^{131}I with ^{177}Lu-labelled 4AH29. Extrapolation to human absorbed dose with [^{131}I]I-GMIB-4AH29 in kidneys showed 8.23E-01 mGy/MBq, whereas [^{177}Lu]Lu-DOTA-4AH29 led to 5.86E-01 mGy/MBq. Consequently, the maximum administered activity for [^{131}I]I-GMIB-4AH29 and [^{177}Lu]Lu-DOTA-4AH29 calculated 28 and 39 GBq respectively to reach the renal dose limit of 23 Gy as determined by EBRT. In red marrow, another commonly dose-limiting organ, equivalent dose for [^{131}I]I-GMIB-4AH29 and [^{177}Lu]Lu-DOTA-4AH29 were 3.8E-02 mGy/MBq and 1.36E-02 mGy/MBq respectively. Thus, 52 GBq with [^{131}I]I-GMIB-4AH29 and 147 GBq with [^{177}Lu]Lu-DOTA-4AH29 can be administered to reach the EBRT set dose limit of 2 Gy. Extrapolation to human absorbed dose for [^{225}Ac]Ac-DOTA-4AH29 exhibited 7.26E+02 mGy/MBq in kidneys and 2.66E+01 mGy/MBq in bone marrow, which resulted in a maximum activity administered of 32 MBq for kidneys and 75 MBq for bone marrow. ***Conclusion:*** Radiolabelled 4AH29 is well tolerated in Göttingen minipigs. Dosimetry of ^{225}Ac, ^{131}I, and ^{177}Lu-labelled 4AH29 indicates that repeated administrations within the clinically tested range have the potential to treat future patients without reaching kidney toxicity limits. ***References:*** 1.Dekempeneer, Y. et al. Preclinical evaluation of a radiotheranostic single-domain antibody against fibroblast activation protein α. Journal of Nuclear Medicine 64, 1941-1948 (2023).

Feasibility study of ^{225}Ac-PSMA-CY313 dosimetry in mCRPC patients using SPECT

S. Li[1], *Y. Shi*[1], *Z. Li*[2], *Y. Xu*[3], *Y. Zhou*[3], *J. Liu*[2], *Y. Wu*[2];
[1]*Department of Nuclear Medicine, Affiliated Hospital of North Sichuan Medical College, Nanchong, CHINA,* [2]*C-Ray Pharmaceuticals (Chengdu) Co. Ltd., Chengdu, CHINA,* [3]*United Imaging Healthcare Technology Group Co., Ltd, Shanghai, CHINA.*

Aim/Introduction: Several prostate-specific membrane antigen (PSMA) radiopharmaceuticals have been used for the treatment of metastatic castration-resistant prostate cancer (mCRPC). ^{225}Ac-PSMA targeted alpha therapy (TAT) demonstrates efficacy/safety in mCRPC via high LET and short particle range, yet faces dosimetry challenges due to undetectable α-emission externally, complex decay chains, and high SPECT noise from low gamma yield. ^{225}Ac-PSMA-CY313 is a novel TAT enabling tumor-specific α-particle delivery. In this study, SPECT imaging protocols and dosimetry calculations were optimized via multi-timepoint acquisitions with advanced reconstruction algorithms. ***Materials and Methods:*** This is a dosimetry sub-study with 4 mCRPC patients out of a prospective open-label and single-arm study of ^{225}Ac-PSMA-CY313 therapy (200 μCi ± 10%, q8w×4 cycles). Dynamic 1-bed SPECT/CT (GE Discovery NM/CT 670 Pro) non-circular orbit acquisition (120 projections, 60s/view) followed by whole-body planar imaging were acquired at 6, 24, 48, and 96 h post-injection. Uniform phantom scans were performed for calibration of SPECT tomographic and planar imaging, respectively. SPECT tomography images were reconstructed useing OS-EM algorithm with compensation for the attenuation, resolution blur, scatter, as well as the crosstalk and down-scatter contamination between different energy peaks. The volumes of interest including tumor and organ volumes were manually defined on CT images with reference on ^{18}F-PSMA-CY313 whole-body PET. Finally, the organ uptakes were volume-adjusted to the standard ICRP 103 adult male phantom to generate time activity curves (TACs) for Fr-221 and Bi-213, respectively. Rapid 3D-RD-S software was used for dose calculation. ***Results:*** The tumor absorbed dose was 2.40±3.33 Gy

(soft tissue lesions: 5.03±5.51 versus bone metastases: 1.65±2.19 Gy). Organ absorbed doses ranked kidneys (1.56±0.38 Gy) > liver (1.07±0.19 Gy) > spleen (0.54±0.29 Gy). Absorbed dose coefficients (ADC) showed a consistent ranking: tumors 0.36±0.50 Gy/MBq (soft lesions 0.75±0.82 vs bone 0.25±0.33), kidneys (0.23±0.07), liver (0.16±0.03). Tumor-to-organ ADC ratios were 1.56 (kidneys), 14.59 (red marrow), and 4.94 (salivary glands). Treatment was well-tolerated with no SAEs or grade 3 AEs observed. ***Conclusion:*** Quantitative 1-bed SPECT with whole-body planar imaging is a feasible method for 225Ac-based dosimetry in TAT therapy. ^{225}Ac-PSMA-CY313 delivers high absorbed doses to tumors.

OP-595

Radiation Dosimetry of ^{15}O-water Based on Dynamic Large Axial Field of View PET

M. Lubberink[1], *A. Åhlström*[1], *T. Maaniitty*[2], *T. Tolvanen*[2], *J. Knuuti*[2]; [1]*Uppsala University, Uppsala, SWEDEN,* [2]*Turku PET Centre, Turku University and Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: Previously published effective dose coefficient estimates for ^{15}O-water are in the range of 0.9 µSv/MBq to 1.2 µSv/MBq[1-3], resulting in an effective dose of around 0.45 mSv for a typically injected amount of 400 MBq in clinical cardiac scans. These values were based on limited PET information combined with pharmacokinetic models. Large axial field of view (LAFOV) PET allows for dynamic scanning of all relevant organs in a single scan, and hence should result in more accurate dosimetry estimates. The aim of the present work was to estimate radiation dosimetry of ^{15}O-water based on dynamic LAFOV PET. ***Materials and Methods:*** 10 subjects (mean age 59, range 44-73; mean body mass index 28.5, range 22.5-36.1; 4 females) underwent 4.5 min dynamic PET scans after automated bolus injection of 350±27 MBq (mean ± SD) 15O-water on a Quadra LAFOV PET scanner (Siemens Healthineers) at Turku PET Centre. All organs with visual uptake over background (brain, thyroid, lungs, heart wall, gall bladder, liver, spleen, small intestine, stomach, pancreas, kidneys, adrenal glands, red marrow, urinary bladder) were segmented using TotalSegmentator[4] and time-activity curves were calculated and uncorrected for decay. Time-integrated activity coefficients (TIAC) were calculated by trapezoidal integration followed by exponential extrapolation. The remainder of the body TIAC was calculated as the theoretical maximum TIAC minus the sum of all source organs. Organ absorbed doses and effective dose according to ICRP 103 were calculated using IDAC-DOSE 2.1[5]. ***Results:*** The highest TIACs were found in the lungs (0.15±0.03 min), liver (0.15±0.04 min) and brain (0.14±0.03 min). The fraction of the TIACs due to extrapolation beyond the last measured data point ranged from 10±1% in lungs to 35±6% in urinary bladder contents. The fraction of the maximum residence time included in the PET FOV was 71±9%, which was comparable to the fraction of the patient weight within the FOV (70±6%). The effective dose coefficient was 0.57 ± 0.04 (mean ± SD) µSv/MBq. The highest absorbed dose was found in kidneys, lungs and spleen (1.0 and 1.2 µGy/MBq for males and females, respectively). ***Conclusion:*** The effective dose of 15O-water is roughly half of the previously published values, amounting to an effective dose of approximately 0.2 mSv for a typical cardiac scan. ***References:*** [1]Smith et al, Eur J Nucl Med 1994; [2]Brihaye et al, J Nucl Med 1995; [3]ICRP 1998; [4]Wasserthal et al, Radiology:AI 2023; [5]Andersson et al, EJNMMI Research 2017.

OP-596

Biodistribution and dosimetry for a ^{11}C labelled PARP1 inhibitor

A. Törnblom[1], *C. He*[1], *M. Bolin*[1], *A. Tzortzakakis*[1], *J. Fernebro*[1], *C. Li*[1], *S. Fridsten*[2], *R. Altena*[1], *R. Axelsson*[1], *J. Siikanen*[1], *C. Hindorf*[1]; [1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Karolinska University Hospital, Stockholm, SWEDEN.*

Aim/Introduction: Polyadenosine 5'diphosphoribose polymerase inhibitors (PARP1i) treat metastasised ovarian, breast, and prostate cancer with either germline or somatic BRCA-mutations. However, not all patients respond to these drugs. A ^{11}C-radiolabelled PARP1i tracer [^{11}C]AZ14193391 might be used with a PET/CT to identify eligible patients. Prediction of PARP1i-response could reduce unnecessary exposure to side effects and reduce healthcare costs. The aim of this study (EU CT 2022-502918-87-00) was to determine biodistribution, dosimetry and safety for [^{11}C]AZ14193391. ***Materials and Methods:*** Six patients (two ovarian, one prostate, three breast cancer) qualified for PARP1i-treatment were injected with a median activity of 5.8 MBq/kg range [3.7-6.0]. PET/CT-scans started simultaneously with the injection. All patients were scanned eyes-to-thighs at five time points (0, 5, 12, 21, 33 min post-injection). Scan time was increased with sequential scans to achieve equivalent count statistics in all images. Reconstruction was performed with BSREM (β=350). Segmentation was performed on a localisation-CT with an automatic segmentation tool and the segments were reviewed and corrected by a radiologist based on the PET-images. Time-Integrated Activity Coefficients (TIACs) and effective doses were calculated. Total blood activity was estimated from aortic activity concentration in the image and a factor 65 (women) or 75 (men) ml blood per kg body weight. Organs included in effective dose calculations were blood, kidneys, liver, pancreas, red marrow, spleen, thyroid, and urinary bladder. ***Results:*** No acute adverse effects were reported. High visual uptake was observed in liver, pancreas, kidneys, salivary glands, small intestine, urine bladder, and red marrow. Median TIACs for the three normal tissues with predominant uptake were liver, red marrow, and kidneys with 0.100 h, 0.025 h, and 0.012 h respectively. Median effective dose was 4.4 µSv/MBq [4.1-4.8]. The organs receiving the highest median absorbed dose per injected activity were liver=0.017 mGy/MBq [0.013-0.023], spleen=0.012 mGy/MBq [0.006-0.023], and kidneys=0.011 mGy/MBq [0.011-0.016]. The effective dose was lower compared to the result of the non-human primate study that showed 5.2 µSv/MBq. The short time frame (1 h) for imaging was a limitation for measurements of the biological half-life of AZ14193391. Uptake curves of pancreas, red marrow, and spleen showed a continuation of accumulation during all 5 scans. A review from 2012 (PMID: 22160195) on ^{11}C-dosimetry showed comparable effective doses. ***Conclusion:*** Imaging with [^{11}C]AZ14193391 is feasible and safe. Our results suggest that the radiation induced risk associated of imaging with [^{11}C]AZ14193391 is low compared to the potential benefits.

PROQURE-I: Results of the phase I dose- escalation study combining [^{177}Lu]Lu-PSMA-617 and EBRT in curative intent treatment of N1 prostate cancer

D. Hoogenkamp[1], *L. G. Zuur*[1], *E. C. A. van der Sar*[2], *M. G. E. H. Lam*[2], *J. R. N. van der Voort-van Zyp*[2], *P. J. van Leeuwen*[1], *B. J. de Wit - van der Veen*[1], *D. M. V. de Vries-Huizing*[1], *J. J. M. A. Hendrikx*[1], *A. J. A. T. Braat*[1,2], *W. V. Vogel*[1]; [1]*Netherlands Cancer Institute, Amsterdam, NETHERLANDS,* [2]*University Medical Centre Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: For patients with treatment-naïve prostate cancer (PCa) presenting with locoregional lymph node disease (N1M0), the standard treatment typically includes external beam radiotherapy (EBRT) combined with prolonged androgen deprivation therapy (ADT). Although this extensive regimen has improved overall survival rates, it is linked to considerable toxicity

and a five-year recurrence rate of up to 47%. [^{177}Lu]Lu-PSMA-617 has demonstrated promising outcomes in metastatic disease. For patients with regional PSMA-positive lesions identified via PSMA-PET/CT, incorporating [^{177}Lu]Lu-PSMA-617 into the EBRT and ADT regimen may offer better control of both macroscopic and microscopic disease, enhancing the likelihood of curation and potentially reducing the dependency on long-term ADT. ***Materials and Methods:*** The PROQURE-I study was a multi-center dose-escalation study in PSMA-PET/CT based iTxN1M0 treatment-naïve prostate cancer patients, eligible for standard first-line radiation treatment (seven weeks EBRT and three years ADT). Standard treatment was combined with escalating doses of [^{177}Lu]Lu-PSMA-617. A Bayesian Optimal Interval (BOIN) dose escalation model was followed to determine the maximum tolerated dose of administered radioactivity (MTD) using one (3, 6 or 9 GBq in the second week of EBRT) or two cycles (2x 7.4 GBq, in week 2 and 4 of EBRT) of [^{177}Lu]Lu-PSMA-617. Any treatment related grade 3 toxicity according to CTCAE v5.0 was considered as dose limiting toxicity. SPECT/CT and planar imaging for dosimetry analysis was performed at 4, 24 and 168 hours after [^{177}Lu]Lu-PSMA-617 injection. Tumor and organ dosimetry were performed using MIM Sureplan MRT. ***Results:*** Fourteen patients were included. No grade 3 toxicity or higher was observed and MTD was not reached. All reported grade 1 and 2 toxicities were considered related to EBRT. The first patient received 3 GBq, the second 6 GBq, six patients received 9 GBq and subsequently six patients received two cycles of 7.4 GBq [^{177}Lu]Lu-PSMA-617. EBRT dose was 70-77 Gy to the prostate, 60 Gy to visible lymph node metastases and 52 Gy to elective nodal fields. [^{177}Lu]Lu-PSMA-617 provided an additional dose to the tumor of 10.27 Gy (range 1.1-38.7 Gy) in the first cycle and 3.4 Gy (range 1.38-5.84 Gy) in the second cycle. ***Conclusion:*** Curative intent combination treatment with EBRT, [^{177}Lu]Lu-PSMA-617 and ADT is safe and well tolerated in treatment naïve men with iN1M0 prostate cancer. The addition of [^{177}Lu]Lu-PSMA-617 increased the total dose to the primary tumor. The suggested clinical benefit will be evaluated in an upcoming phase 2 study.

Aim/Introduction: [^{177}Lu]Lu-PSMA-617 radioligand therapy is a novel treatment for patients with metastatic castration resistant prostate cancer. Previously, we showed that [^{177}Lu]Lu-PSMA-617 could be safely applied to patients with PSMA-expressing oligometastatic hormone-sensitive prostate cancer (mHSPC) with encouraging outcomes (Privé et al, CCR 2021). Now we report the results of the following randomised phase II trial. ***Materials and Methods:*** BULLSEYE was an international, multicentre, open-label, randomised phase II trial (NCT04443062), with crossover design. Fifty-eight patients were randomised in a 1:1 ratio to [^{177}Lu]Lu-PSMA-617 vs. standard of care (SoC) of deferred androgen deprivation therapy (ADT). Eligibility consisted of fast-progressing mHSPC (PSA doubling time ≤6 months) following local treatment, with ≤5 metastases on PSMA-PET/CT. Patients received 2 (+2) cycles of 7.4 GBq [^{177}Lu]Lu-PSMA-617. Patients in the SoC arm were allowed to cross over to receive [^{177}Lu]Lu-PSMA-617 upon disease progression. The primary outcome was progression-free survival (i.e., time without ADT). Progressive disease (PD) was defined as the initiation of ADT, a 100% increase in PSA since randomisation, and radiographic or clinical progression. Secondary outcomes were PSA response, adverse events, quality of life, and outcomes observed in the crossover arm. ***Results:*** Between April 2020 and July 2024, 78 men were screened, of whom 58 were eligible. Data cutoff was set on March 31st, 2025. Patients received a median number of 4 (IQR 4-4) cycles of 7.4 GBq of [^{177}Lu]Lu-PSMA-617. During the present median follow-up of 27 months (IQR 18-32), one SoC arm patient (3%) remained without disease progression as compared to 14 (48%) patients in the [^{177}Lu]Lu-PSMA-617 group. The median per protocol progression-free survival was 5 (IQR 3-7) and 18 (IQR 10-28) months for the SoC arm and [^{177}Lu]Lu-PSMA-617, respectively (HR 0.07, 95%CI 0.03-0.17; P<0.001). In total, 31/56 of patients treated with [^{177}Lu]Lu-PSMA-617 had a ≥90% PSA decline. Fourteen had a complete biochemical response. The most common treatment-related adverse events were: grade 1 xerostomia (59%), fatigue (46%), nausea (41%), and bone marrow toxicity (25%). Clinically relevant grade ≥2 adverse events were observed in less than 10% of patients. Quality of life remained stable during the study. ***Conclusion:*** [^{177}Lu]Lu-PSMA-617 showed promising efficacy in patients with oligometastatic prostate cancer to defer from androgen deprivation therapy. It had mild side effects and patients retained a good quality of life. Long-lasting remissions are seen in approximately 25% of patients. After surgery and external beam radiotherapy, [^{177}Lu]Lu-PSMA-617 could become a third metastases-directed treatment for this oligometastatic patient group.

OP-599

PEACE 6 Poor-responders: A randomized phase III trial evaluating the efficacy and safety of 177Lu-PSMA-617 in addition to Standard of Care (SoC) versus SoC alone in de novo metastatic hormone-sensitive prostate cancer (mHSPC)

D. Deandreis[1], *G. Gravis*[2], *S. Foulon*[3], *F. Tantot*[4], *C. Leger*[4], *F. Courbon*[5], *L. Turpin*[6], *A. Giraudet*[7], *K. Fizazi*[1]; [1]*Gustave Roussy, 114 Rue Edouard Vaillant, Villejuif, FRANCE,* [2]*Institut Paoli Calmette, Marseille, FRANCE,* [3]*Gustave Roussy, Villejuif, FRANCE,* [4]*Unicancer, Kremlin Bicetre, FRANCE,* [5]*IUCT Oncopole, Toulouse, FRANCE,* [6]*Hopital Foche, Suresnes, FRANCE,* [7]*CLCC Leon Berard, Lyon, FRANCE.*

Aim/Introduction: The management of patients with metastatic prostate cancer is still a challenge and the optimal therapeutic sequence needs to be still defined in some settings. The PEACE-6 umbrella program aims to assess, in randomized comparative trials, the efficacy and safety of combination therapy vs SOC according to patient and disease characteristics in metastatic prostate cancer patients. ***Materials and Methods:*** PEACE-6 PR is a phase III, international, multicenter, randomized, open-label, controlled trial sponsored by UNICANCER/GETUG [CL1] (EU CT n°: 2022-502408-57-00). It aims to evaluate the efficacy and safety of ^{177}Lu-PSMA-617 combined with SOC compared to SOC alone in patients with de novo mHSPC who do not present with a satisfactory response characterized by a serum PSA level ≥ 0.2 ng/ml, 6 to 8 months after initiation of systemic treatment for mHSPC in the absence of evidence of disease progression (including a rising PSA increase). Patients will be randomized in a 1:1 ratio to receive either ^{177}Lu-PSMA-617 + SOC or SOC alone. SOC include either ADT + ARSI ± RT or ADT + Docetaxel + ARSI ± RT. The co-primary endpoints are overall survival (OS) and radiographic progression-free survival (rPFS). OS is defined as the time from the date of randomization to the date of death due to any cause. rPFS is defined as the time from randomization to the date of radiographic progression according to PCWG3 criteria by investigator assessment, or death, whichever occurs first. All patients will undergo a pre randomization ^{68}Ga-PSMA PET and will be treated regardless of the ***results:*** patients with PSMA-positive or PSMA-negative disease according to PROMISE 2.0 criteria are eligible. For the experimental arm, the radioligand ^{177}Lu-PSMA-617 is scheduled to be intravenously injected at a single dose of 7 400

MBq once every 6 weeks (± 1 week) to a total of 4 cycles. A total of 500 patients is expected (250 for each arm) to be recruited in 100 centers in Europe (23 in France) in 63 months (5.25 years). ***Results:*** PEACE-6 PR is open to inclusion since October 2024. As of April 2025, a total of 11 patients have been already randomized, 5 in the SOC arm and 6 in the ^{177}Lu-PSMA-617 + SOC arm respectively. ***Conclusion:*** PEACE-6 PR trial will be essential to define the best therapeutic strategy in the setting of de novo metastatic hormonosensitive prostate cancer patients.

Prognostic Impact of Homologous Recombination Repair and Mismatch Repair Gene Alterations in Patients with Metastatic Castration-Resistant Prostate Cancer Treated with Prostate-Specific Membrane Antigen-directed Radioligand Therapy

A. Antic Nikolic[1], *S. Xue*[2], *S. Wen*[2], *J. Baessler*[1], *M. Hacker*[2], *X. Li*[2], *C. Lapa*[1];
[1]*Nuclear Medicine, Faculty of Medicine, University of Ausgburg, Augsburg, GERMANY,* [2]*Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Vienna, AUSTRIA.*

Aim/Introduction: Prostate-specific membrane antigen-targeted radioligand therapy (PSMA-RLT) has emerged as an effective treatment for metastatic castration-resistant prostate cancer (mCRPC). However, therapeutic responses remain heterogeneous, potentially due to mutations in DNA repair-related genes that may contribute to treatment resistance. This study aimed to evaluate the prognostic significance of mutations in genes involved in homologous recombination repair (HRR) and mismatch repair (MMR) pathways in mCRPC patients undergoing PSMA-RLT. ***Materials and Methods:*** We retrospectively analyzed 35 patients with metastatic castration-resistant prostate cancer (mCRPC) who received at least two cycles of prostate-specific membrane antigen-targeted radioligand therapy (PSMA-RLT). All included patients had available next-generation sequencing data covering genes involved in homologous recombination repair (ATM, BARD1, BRCA1, BRCA2, BRIP1, CDK12, CHEK1, CHEK2, FANCA, FANCC, FANCD2, FANCG, FANCL, NBN, PALB2, RAD51B, RAD51C, RAD51D, RAD54L, TP53) and mismatch repair (MSH2, MSH6, MLH1, PMS2, EPCAM) pathways. Patients were stratified into HRR/MMR-mutant (n = 12) and HRR/MMR wild-type (n = 23) groups. Therapeutic response was evaluated by the percentage change in PSA levels (ΔPSA%) after two treatment cycles. Group differences in PSA response were assessed using non-parametric statistical tests. Progression-free survival (PFS) was estimated using Kaplan-Meier analysis and compared using the log-rank test. Additionally, the mean tumor-absorbed dose during the first treatment cycle was compared between groups using a t-test. ***Results:*** The median PSA decline after two treatment cycles was significantly lower in the HRR/MMR-mutant group (ΔPSA% = -90.4%) compared to the wild-type group (ΔPSA% = -167.4%) ($P < 0.05$). The HRR/MMR-mutant group showed a trend toward shorter progression-free survival (PFS), with a hazard ratio of 2.146 ($P = 0.07$), indicating more than a two-fold increased risk of disease progression compared to the wild-type group. No statistically significant difference in mean absorbed dose after the first treatment cycle was observed between the HRR/MMR-mutant and wild-type groups ($P = 0.28$). ***Conclusion:*** HRR/MMR gene mutations in mCRPC patients were associated with reduced PSA response and a trend toward shorter progression-free survival following PSMA-RLT. The observed lack of difference in absorbed dose between HRR/MMR-mutant and wild-type groups is based on preliminary data from a single treatment cycle and warrants further investigation. HRR/MMR mutation status may serve as a prognostic biomarker to guide personalized therapeutic strategies in advanced prostate cancer.

Safety and efficacy of ^{177}Lu-PSMA-I&T for RLT in mCRPC - a prospective multicenter Swiss Registry study

A. Chirindel[1], *G. Nicolas*[1], *M. Tissier*[2], *M. del Sol Pérez Lago*[3], *F. Forrer*[4], *A. Afshar-Oromieh*[5], *S. Beintner-Skawran*[6], *A. Bauman*[7], *F. Melpomeni*[7], *E. Nitzsche*[8], *N. Schaefer*[2], *D. Wild*[1];
[1]*University Hospital of Basel, Department of Theranostics, Nuclear Medicine, Basel, SWITZERLAND,* [2]*CHUV, Department of Nuclear Medicine, Lausanne, SWITZERLAND,* [3]*Luzerner Kantonsspital, Department of Nuclear Medicine, Lucerne, SWITZERLAND,* [4]*Kantonsspital St. Gallen, Department of Nuclear Medicine, St. Gallen, SWITZERLAND,* [5]*Inselspital, Department of Nuclear Medicine, Bern, SWITZERLAND,* [6]*University Hospital Zurich, Department of Nuclear Medicine, University of Zurich, Zurich, SWITZERLAND,* [7]*University Hospital of Basel, Department of Theranostics, Radiopharmaceutical Chemistry, Basel, SWITZERLAND,* [8]*Kantonsspital Aarau, Department of Nuclear Medicine, Aarau, SWITZERLAND.*

Aim/Introduction: Several prior prospective studies[1,2] have established [^{177}Lu]Lu-PSMA-617 for radioligand therapy(RLT) in patients with metastatic castration-resistant prostate cancer(mCRPC), demonstrating improved overall survival (OS) compared to the standard of care and a more favorable toxicity profile than chemotherapy. [^{177}Lu]Lu-PSMA-I&T has been used as an alternative radioligand with assumed bioequivalence for RLT in mCRPC. However, no prospective data on its safety and efficacy are currently available. ***Materials and Methods:*** This prospective, multicenter Swiss Registry study(NCT06830408) enrolled mCRPC patients identified with progression of disease and referred for RLT with [^{177}Lu]Lu-PSMA-I&T. Treatment-emerged adverse events (AEs) were recorded per CTCAE v5.0 before each therapy cycle and at 12 weeks post-therapy. Xerostomia was evaluated using a standardized questionnaire. Efficacy was assessed through PSA response (PCWG3) and imaging after each cycle (SPECT/CT) and at 8-12 weeks post-RLT (CT, MRI, or PSMA PET-CT). Follow-ups were performed every 6 months or as clinically indicated. Descriptive statistics were used to summarize patient and treatment characteristics. Time-to-event outcomes—including PSA progression-free survival (PSA-PFS), imaging-based progression-free survival (rPFS), and overall survival (OS) were analyzed using Kaplan-Meier methodology. ***Results:*** A total of 333 consecutive mCRPC patients received a median of 4 cycles (range: 1-6) of [^{177}Lu]Lu-PSMA-I&T over 5.6 months (0.7-11.3 months), with a median cumulative activity of 24 GBq(7-48 GBq). Baseline characteristics included Gleason score ≥8 (72%), metastases in lymph nodes (71%), bones (94%) and visceral organs (26%). Most patients received prior treatment with second generation antiandrogen drugs (90%) and taxane-based chemotherapy (81%). The median follow-up was 12 months (1-54 months). Hematologic toxicity (all grades) was recorded with anemia (30%), thrombocytopenia (26%), leukopenia (18%) and neutropenia (13%). Of these, grade 3-4 events were observed in 8%, 3%, 1.7%, and 0%, respectively. Increased creatinine occurred in 16% of patients (only grade 1-2). Xerostomia grade 1 and 2 was noticed in 25% and <5% of patients, respectively. Best PSA response during RLT demonstrated partial response in 43% and stable disease in 28% of patients. A 90% PSA reduction was achieved in 25% patients. Median OS was 13.2 months (95% CI: 11.8-14.7), PSA-PFS was 4.4 months (3.4-5.4), and rPFS was 6.8 months (6.1-7.5). ***Conclusion:*** Real world data of the first multicenter prospective study demonstrate that [^{177}Lu]Lu-PSMA-I&T is safe and effective for RLT in mCRPC. When comparing these data to previously reported phase II/III studies, the toxicity profile and treatment efficacy appears similar to that of the established [^{177}Lu]Lu-PSMA-617. ***References:*** 1.Sartor et al. N.Engl.J.Med.2021;385:1091-1103.2.Hofman et al. Lancet.2021;397:797-804.

OP-602

Retreatment with [177Lu]Lu-PSMA-617 in mCRPC patients treated under the French Early access program

D. Taieb[1], *P. Robin*[2], *P. Barthelemy*[3], *C. Peltier*[4], *S. Chêne*[5], *A. Douillet*[5], *F. Somme*[3];
[1]*APHM-AMU, Marseille, FRANCE,* [2]*Université de Brest, Inserm, UMR 1304, GETBO, CHU Brest, Brest, FRANCE,* [3]*Institut de cancérologie Strasbourg Europe, Strasbourg, FRANCE,* [4]*ICTA PM, Dijon, FRANCE,* [5]*Novartis, Rueil-Malmaison, FRANCE.*

Aim/Introduction: [177Lu]Lu-PSMA-617 is an approved targeted therapy for PSMA-expressing metastatic castration-resistant prostate cancer available in France since December 2021 through an early access program. This exploratory retrospective analysis focuses on patients retreated beyond 6 cycles with [177Lu]Lu-PSMA-617. ***Materials and Methods:*** Patients with mCRPC who had previously received at least one line of chemotherapy and one androgen receptor pathway inhibitor (ARPI), and who were positive on [68Ga]Ga-PSMA-11 PET, were eligible for treatment with [177Lu]Lu-PSMA-617, similar criteria applied for retreatment. The treatment schedule consisted of 6 injections maximum of 7.4 GBq every 6 weeks during initial treatment and during retreatment. Patients' characteristics, efficacy and safety data were systematically collected during follow-up visits. ***Results:*** At the end of January 2025, a total of 3198 patients were included in the early access program, with 96.9% receiving a standard schedule without retreatment, and 3.1% (n=98) underwent RLT retreatment including 55 patients still under retreatment at data cut-off (DCO). Baseline characteristics only differed for non-retreated and retreated patients in terms of line of taxanes >1: 43.7% vs 61.2% (p=0.0023), and opioids used for pain control: 26.3% vs 16.3% (p=0.026). The median time between the last dose of the standard dosing schedule and the first dose of the retreatment was 8.94 months. During this interval, 9 patients received 1 ARPI and 5 patients received 1 line of chemotherapy. 84.7 % of the retreated patients received 6 injections during the initial schedule and amongst those who completed the retreatment (n=43) a median of 3 cycles [1-6] has been reached. 4 patients initiated a 3rd treatment schedule and 1 reached 15 cycles at DCO. During the initial schedule, median imaging-based PFS was statistically different between non-retreated and retreated patients : 7.00 months [6.18-7.52] vs 10.35 months [8.80-NR] (p<0.0001). During retreatment, symptom control was maintained for 94.9% of patients, 70.7% showed disease control based on imaging, and 80.3% had controlled PSA levels. 10.2% of retreated patients had dose reductions, compared to 23.3% of non-retreated patients. 10 patients (10.2%) reported at least one treatment-related adverse event (including 5 cases of thrombocytopenia) during the initial schedule, and 3 (3.1%) during the retreatment. ***Conclusion:*** Analysis of patients retreated and not retreated with [177Lu]Lu-PSMA-617 for mCRPC shows few differences in baseline characteristics. Upon disease progression, retreatment with [177Lu]Lu-PSMA617 demonstrated sustained clinical activity and appears to be well-tolerated in selected patient population. Updated efficacy and safety results will be presented at EANM congress.

OP-603

Final analysis of patients treated with [177Lu]Lu-PSMA-617 in early access program in metastatic castration-resistant prostate cancer (mCRPC) in France

C. Bailly[1], *P. Olivier*[2], *L. Vija*[3], *A. Giraudet*[4], *V. Massard*[5], *G. Roubaud*[6], *S. Girault*[7], *S. Abadie-Lacourtoisie*[7], *C. Viala*[1], *A. Flechon*[4], *S. Chêne*[8], *Y. Godbert*[6];
[1]*Centre Hospitalier Universitaire, Nantes, FRANCE,* [2]*Centre hospitalier régional et universitaire, Vandoeuvre-lès-Nancy, FRANCE,* [3]*Institut Universitaire du Cancer de Toulouse, Toulouse, FRANCE,* [4]*Centre Léon Bérard, Lyon, FRANCE,* [5]*Institut de Cancérologie de Lorraine, Vandoeuvre-lès-Nancy, FRANCE,* [6]*Institut Bergonié, Bordeaux, FRANCE,* [7]*Institut de cancérologie de l'Ouest Paul Papin, Angers, FRANCE,* [8]*Novartis, Rueil-Malmaison, FRANCE.*

Aim/Introduction: VISION study showed that [177Lu]Lu-PSMA-617 added to BSoC prolonged imaging-based progression-free survival and overall survival in patients with PSMA-positive mCRPC. French Health Authorities has granted a "cohort" early access for [177Lu]Lu-PSMA-617 in this indication since Dec 2021. ***Materials and Methods:*** PSMA positive mCRPC patients pretreated with at least 1 taxane-based chemotherapy regimen and ≥1 androgen receptor pathway inhibitor (ARPI) were included. [177Lu]Lu-PSMA-617 (7.4 GBq) was administered up to 6 cycles every 6 weeks. Patients' characteristics and safety data are described for the entire population. 3198 patients were included (data cut-off (DCO) 1 : 1/31/2025) and 2119 patients were analyzed for efficacy (DCO 2 : 5/31/2024), respectively. Adverse events (AE) grading was not evaluated. ***Results:*** At DCO 1, characteristics of patients at baseline were : median age 73.8 (37-100) years; ECOG 0-1: 87.2%; median PSA level 44.0 (0-6972) ng/ml; metastatic sites: bone 92.5%, lymph node 60.0%, liver 8.6%; previous taxane regimen: 98.9% of which 44.2% have received 2; prior ARPI treatment: 100% and 53.1% received 2 or more (median: 2). The incidence of 2 prior taxane regimen has reduced over time. Patients received a median of 3 anterior treatments. Concomitant treatment with ARPI was observed in 21.4%. At DCO 2, with a median follow-up of 6.7 months, median imaging-based PFS was 7.5 months. Imaging follow-up consisted of CT scan and scintigraphy, with PET in some instances. Median time to clinical progression was 8.1 months. A PSA decrease was observed in 69.6% of patients at any time. The median time to PSA decrease was 1.28 months (range, 0.0-15.7). Patients received an average of 4.2 [177Lu]Lu-PSMA-617 cycles, and 40.7% completed 6 cycles. 12.8% (n=410) of patients experienced >1 treatment-related (TR) AE, including 302 patients with ≥1 serious AE. The most reported TRAEs were thrombocytopenia (4.5% of patients) and anemia (3.8% of patients). 12 deaths related to treatment have been reported. ***Conclusion:*** In this largest ever reported real-life cohort of mCRPC patients treated with [177Lu]Lu-PSMA-617 during more than 3 years profile has evolved to less heavily pretreated patients. In the cohort, patients received less concomitant ARPI treatment compared to VISION study. Safety profile of [177Lu]Lu-PSMA-617 remains favorable. Final results of this early access cohort will be presented at EANM congress, including longer follow-up period and higher number of patients who completed treatment. Meanwhile, analyses on specific sub-populations of interest are currently underway.

[1]*Hospital del Mar, Barcelona, SPAIN,* [2]*Cliniques universitaires Saint Luc, Brussels, BELGIUM,* [3]*The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM,* [4]*Centre hospitalier de l'Université de Montréal, Montréal, QC, CANADA,* [5]*Parc Taulí Hospital Universitari, Sabadell, SPAIN,* [6]*Hospital Israelita Albert Einstein, Sao Paulo, BRAZIL,* [7]*Institut Gustave Roussy, Paris, FRANCE,* [8]*Tallaght University Hospital, Dublin, Dublin, IRELAND,* [9]*European Organisation of Research and Treatment of Cancer, Brussels, BELGIUM,* [10]*Oncology Institute of Southern Switzerland, EOC, Bellinzona, SWITZERLAND.*

Aim/Introduction: PEACE-3 showed that adding radium-223 (RAD) to enzalutamide (ENZ) significantly improves progression-free survival (PFS) and overall survival (OS) in metastatic castration-resistant prostate cancer (mCRPC) with bone metastases. We report an update on the fracture events and treatment received at progression. ***Materials and Methods:*** From 11/2015 to 03/2023, 446 men progressing to mCRPC were randomized 1:1 to ENZ alone or combined with 6 cycles of RAD (ENZ-RAD). As of March 2018, the co-administration of bone protective agents (BPA) was mandatory. We report the fracture rate for the study here. ***Results:*** Fractures (symptomatic or pathologic) occurred in 30 (13.4%)

patients (pts)in ENZ and 53 (24.3%) in ENZ-RAD. In ENZ-RAD, fractures occurred in 53.6% of pts enrolled before the mandatory BPA co-administration and in 14.2% of pts enrolled afterward. In ENZ, fracture incidence dropped from 20.3% before the mandatory BPA co-administration to 10.9% afterward. The hazard ratio (HR) for time to first fracture was 2.00 (95%CI 1.27-3.14). 12- and 24-month estimates of cumulative incidence of fracture (95% CI) were 7.6% (4.6%-11.6%) and 11.3% (7.5%-16.0%) in ENZ and 12.9% (8.8%-17.7%) and 17.1% (12.4%-22.6%) in ENZ-RAD.Adding RAD to ENZ significantly increased time to the subsequent treatment (TTNT). HR for TTNT is 0.57 (95%CI 0.44-0.75; p=<0.0001). At the time of rPFS analysis, 133 (59.4%) pts in ENZ and 94 (42.3%) in ENZ-RAD received a subsequent anti-neoplastic agent. In ENZ vs ENZA-RAD, the first subsequent treatment was chemotherapy in 103 (71.5%) pts vs 79 (74.5%), hormone therapy in 20 (13.9%) vs 18 (17.0%), PARP inhibitor in 8 (5.6%) vs 5 (4.7%) and other in 13 (9.0%) vs in 2 (1.9%). ***Conclusion:*** This final analysis confirms the positive impact of concomitant BPA use in lowering fracture risk in mCPRC pts receiving ENZ or ENZ-RAD. Chemotherapy was the most common subsequent treatment in both arms. ***References:*** PEACE III: ClinicalTrials.gov ID NCT02194842.

Efficacy of Lutetium-177 [177Lu]Lu-PSMA radioligand therapy re-treatment beyond six cycles in patients with metastatic castration-resistant prostate cancer.

J. Weindler[1], *E. Medhurst*[1], *N. Papa*[1], *L. Kostos*[2], *B. Emmerson*[1], *A. A. Azad*[2], *M. S. Hofman*[1], *J. P. Buteau*[1];
[1]*Prostate Cancer Theranostics and Imaging Centre of Excellence (ProsTIC), Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [2]*Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.*

Aim/Introduction: Lutetium-177 [177Lu]Lu-PSMA radioligand therapy is a life-prolonging treatment for patients with metastatic castration-resistant prostate cancer (mCRPC). Landmark studies reported outcomes using up to 6 cycles of [177Lu]Lu-PSMA. We aimed to evaluate the efficacy of re-treatment with [177Lu]Lu-PSMA in patients who received more than 6 cycles in total. ***Materials and Methods:*** We conducted a retrospective, single-centre analysis of patients with mCRPC who completed at least one re-treatment course of [177Lu]Lu-PSMA upon disease progression and received more than 6 cycles in total by data cut-off (February 11, 2025). Patients were initially treated on clinical trials or registry with [177Lu]Lu-PSMA-617 or [177Lu]Lu-PSMA-I&T. Re-treatment was defined as an interval of at least 12 weeks between [177Lu]Lu-PSMA cycles. The primary endpoint was PSA response, defined by a reduction of at least 50% (PSA50-RR) and 90% (PSA90-RR) following first re-treatment. The secondary endpoint of overall survival (OS) was calculated using Kaplan-Meier method from time of screening PSMA PET/CT prior to commencement of [177Lu]Lu-PSMA and also from first re-treatment to death or last follow-up. ***Results:*** Between August 26, 2015 and January 31, 2024, 54 patients met the inclusion criteria and started treatment with [177Lu]Lu-PSMA. They had a median age at re-treatment of 75 years (IQR 70-80). Prior treatments included androgen-receptor pathway inhibitors in 53 (98%) patients, docetaxel in 48 (89%) and cabazitaxel in 16 (30%). A median of 9 total cycles of [177Lu]Lu-PSMA (IQR 8-10) were administered with a cumulative median radioactivity of 60.0 GBq (IQR 55.7-67.9). PSA50-RR and PSA90-RR were achieved by 98% and 78% of patients during their initial [177Lu]Lu-PSMA course. Median time from the last cycle of the initial [177Lu]Lu-PSMA treatment course to the first cycle of re-treatment was 36 weeks (IQR 25-51), with PSA50-RR and PSA90-RR occurring in 40%, and 11% of patients, respectively. 22 patients received a second re-treatment block, with PSA50-RR and PSA90-RR observed in 41% and 14%, respectively. Median OS was 36 months (95%CI: 33-41) from screening PSMA PET/CT and 16 months (95%CI: 12-19) from the first re-treatment. ***Conclusion:*** Re-treatment with [177Lu]Lu-PSMA is effective for a select group of patients with mCRPC who initially responded to treatment and had received more than 6 cycles in total.

Aim/Introduction: Positron emission tomography (PET) with amino acid tracers plays an important role in distinguishing progressive or recurrent brain metastases (PRBMs) from treatment-induced changes. Despite the expanding clinical use of checkpoint inhibitors (CPIs) for metastatic cancers, their influence on the diagnostic accuracy of amino acid PET remains unclear. ***Materials and Methods:*** This retrospective study evaluated 32 patients with MRI-suspected PRBMs following radiotherapy, all of whom underwent 18F-fluorethyltyrosine (18F-FET) PET imaging within four weeks prior to resection or biopsy. The cohort comprised nine currently or previously CPI-treated patients (CPI+ group) and 23 controls managed with chemotherapy, targeted therapies, or no systemic treatment (CPI- group). ***Results:*** Demographic variables, including age, baseline metastasis burden, and interval between radiotherapy and PET imaging, showed no significant intergroup differences. Pathological PET findings were observed in 8 CPI+ patients vs. 22 CPI- patients. False-positive rates significantly differed between the subgroups, with 75% (6/8) in the CPI+ vs. 14% (3/22) in the CPI- group. Histopathological examination of CPI+ specimens revealed inflammatory reactions characterized by lymphocytic infiltrates. ***Conclusion:*** These results indicate that the history of CPI therapy is strongly associated with an elevated risk of false-positive amino acid PET findings in PRBM assessment. It may stem from CPI-induced immunological hyperactivity, which has been documented to provoke inflammatory responses across multiple organ systems. Clinicians should exercise heightened caution when interpreting amino acid PET results in CPI-treated patients with suspected PRBMs.

Diagnostic Accuracy and Optimal Thresholding of [^{18}F] fluoroethyl-L-tyrosine PET to Detect Tumor Tissue in Patients with Glioblastoma

E. Van de Giessen, *J. L. Ebenau, T. Koopman, F. Barkhof, P. Wesseling, J. C. Reijneveld, W. P. Vandertop, P. C. de Witt Hamer, P. J. Pouwels, R. Boellaard, M. M. Yaqub, N. Verburg;*
Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: O-(2-[^{18}F]fluoroethyl)-L-tyrosine (FET) positron emission tomography (PET) is increasingly used in neuro-oncology. A tumor-to-brain ratio (TBR) threshold of 1.6 is the current standard to distinguish tumor tissue from surrounding (non-tumor) brain (1). The study on which this threshold was based had a heterogeneous population though, including patients with a wide range of WHO tumor grades, and only 2 out of 28 patients with glioblastoma (2). We investigated the optimal threshold for the detection of tumor tissue in glioblastoma for [^{18}F]FET PET and compared this to the current standard, i.e. a tumor-to-brain ratio (TBR) threshold of 1.6. ***Materials and Methods:*** We included 10 patients (63±7y, 3 females) with glioblastoma, IDH-wildtype. All participants underwent MRI and [18F]FET PET within 14 days before surgery. Biopsy samples were obtained from regions inside and outside of imaging abnormalities and assessed for tumor presence by two experienced neuropathologists. Mean TBR was calculated in the region of interest (ROI) corresponding with the biopsy site (1 cm^3). We used Receiver Operation Characteristics analysis to calculate the sensitivity and specificity and determined the optimal TBR threshold using the Youden index. We compared the diagnostic accuracy of this optimal threshold with the current standard 1.6 threshold using McNemar's chi^2 test. ***Results:*** A total of 98 samples was obtained (median nine samples per patient) with tumor present in 72 (73%) samples. The optimal threshold to distinguish tissue with tumor from non-tumor tissue was 1.39. Sensitivity of this optimal threshold was higher than that of the 1.60 threshold (72% versus 57%, p<0.01), while specificity was similar (both 81%). ***Conclusion:*** In patients with glioblastoma, a [^{18}F] FET PET TBR of 1.39 better distinguished tumor from non-tumor tissue than the current standard TBR threshold of 1.6. These results contribute to more accurate tumor delineation and may benefit planning of surgical resection and radiotherapy. ***References:*** 1. N. L. Albert, N. Galldiks, B. M. Ellingson, M. Aim/Introduction: Adult high-grade gliomas (HGGs) are aggressive with high recurrence rates and poor prognosis. Accurate preoperative delineation of tumor boundaries is crucial to maximize safe resection while preserving healthy brain tissue. This study aimed to evaluate the capability of integrated ^{18}F-fluoroethyltyrosine (FET) PET/MR in defining tumor boundaries in adult HGG patients, and to explore the additional diagnostic value of MRI parameters in enhancing PET indices. ***Materials and Methods:*** Seventeen patients with HGG underwent integrated ^{18}F-FET PET/MR imaging, followed by image-guided stereotactic biopsy. A total of 70 samples (51 tumor and 19 non-tumor) were collected. For each biopsy location, a 5 mm volume of interest (VOI) was used to extract quantitative values from PET, including maximum and mean tumor-to-background ratio (TBRmax and TBRmean), and from MRI, including apparent diffusion coefficient (ADC), contrast-enhanced T1-weighted imaging (T1CE), and T2-weighted fluid-attenuated inversion recovery imaging (T2-FLAIR). Diagnostic performance was assessed using receiver operating characteristic (ROC) analysis, with histopathology as the reference. ***Results:*** PET parameters showed excellent performance for tumor boundary delineation, with TBRmax achieving an area under the curve (AUC) of 0.914 (accuracy = 84.6%, sensitivity = 74.5%, specificity = 94.3%) and TBRmean achieving an AUC of 0.909 (accuracy = 83.7%, sensitivity = 72.6%, specificity = 94.3%). MRI parameters, such as T1CE and T2-FLAIR, were moderately diagnostic (AUC = 0.785 and 0. 825, respectively), while ADC alone showed limited value (AUC = 0.667). Combining PET with MRI did not significantly improve diagnostic accuracy compared to PET alone. However, combining T2-FLAIR modestly improved sensitivity (90.2%), though without a substantial gain in overall AUC. TBRmax remained the most reliable single parameter for preoperative tumor boundary definition. ***Conclusion:*** Integrated ^{18}F-FET PET/MR demonstrates accurate preoperative delineation of tumor boundaries in adult HGGs. The PET parameter TBRmax outperformed all other imaging parameters. Although MRI parameters such as T2-FLAIR may enhance sensitivity when combined with PET, their added value remains limited. These findings support the use of ^{18}F-FET PET as a valuable assistance to MRI for guiding surgical planning for HGGs.

Aim/Introduction: Amino acid PET is increasingly used in the clinical management of gliomas. While improved prognostic stratification is urgently needed given ongoing changes in the treatment landscape of IDH-mutant glioma, the prognostic significance of quantitative PET parameters in molecular subgroups remains unclear. ***Materials and Methods:*** In this retrospective, bicentric cohort study, patients diagnosed with IDH-mutant glioma who underwent amino acid PET within one year before/after histological diagnosis have been included. Maximum/mean tumor-to-background ratios (TBR_{max}, TBR_{mean}) and PET-positive volume (PET volume) were evaluated. Tumor extent in MRI was evaluated according to RANO 2.0 criteria based on the product of maximum perpendicular diameters in T2/FLAIR and contrast-enhanced T1 (T1CE). As endpoints, time to next intervention (TTNI) and overall survival (OS) were used. ***Results:*** Overall, 457 patients were included (54.9% astrocytoma, 45.1% oligodendroglioma; median age at diagnosis: 40 years [range: 18-81]). In univariate analysis of patients with astrocytoma who underwent PET before resection, TTNI was associated with TBR_{max} (Hazard ratio [HR] 1.44 [95%CI: 1.23-1.68], p<0.001), TBR_{mean} (HR 1.91 [95%CI: 1.35-2.72], p<0.001) and PET volume (HR 1.17 [95%CI: 1.07-1.26], p<0.001) as well as tumor extent in T2/FLAIR (HR 1.03 [95%CI: 1.02-1.05], p<0.001) and T1CE (HR 1.12 [95%CI: 1.04-1.21], p = 0.002). In patients with oligodendroglioma, TTNI was associated with PET volume (HR 1.11 [95%CI: 1.05-1.19], p<0.001). Multivariate TTNI analysis in astrocytoma showed an independent prognostic value of TBR_{max} (HR 1.48 [1.09-2.01], p = 0.012) and tumor extent in T2/FLAIR (HR 1.03 [95%CI: 1.02-1.05], p<0.001) also including established prognostic factors such as age, WHO grade, MGMT promoter methylation, extent of resection, and postoperative treatment. In multivariate analysis of patients with oligodendroglioma, PET volume remained a significant prognostic factor (HR 1.18 [95%CI: 1.03-1.36], p = 0.017) for TTNI. Univariate OS analysis in astrocytoma showed a prognostic impact of TBR_{max} (HR 1.40 [95%CI: 1.13-1.74], p = 0.002), TBR_{mean} (HR 1.97 [95%CI: 1.21-3.22], p = 0.006). and PET volume (HR 1.23 [95%CI: 1.10-1.37], p<0.001). Further analysis in distinct subgroups according to timepoints and type of surgical intervention (resection vs. biopsy) showed similar results. ***Conclusion:*** In this retrospective study, uptake (TBR_{max}/TBR_{mean}) and PET volume were strongly associated with outcome in IDH-mutant glioma, demonstrating independent prognostic value beyond established clinical factors such as WHO grade. While amino acid PET may therefore support clinical decision-making, independent validation is needed to corroborate these findings.

Aim/Introduction: In clinical trials for patients with IDH-mutant gliomas, "measurable disease" on MRI is a key inclusion criterion for MRI-based response assessment. Recently, amino acid PET-based criteria have been proposed for response assessment in clinical trials (PET RANO 1.0 criteria). We aimed at comparing "measurable disease" using MRI-based RANO 2.0 and PET RANO 1.0 criteria in patients with IDH-mutant gliomas. ***Materials and Methods:*** In this retrospective single-center study, patients with newly diagnosed IDH-mutant gliomas with available [^{18}F]FET PET and MRI either preoperatively prior to biopsy or resection, or postoperatively within a maximum of 12 months after resection, were identified. Analysis was performed by two independent investigators to assess "measurable disease" according to MRI-based RANO 2.0 and PET-based PET RANO 1.0 criteria, and lesion size, uptake intensity (maximal and mean target-to-background ratio: TBR_{max}, TBR_{mean}) and PET volume were assessed. ***Results:*** A total of 212 patients (median age 47 years, range 24-90; 44.8% female) were analyzed, including 148 preoperative (median time between PET and surgery: 0.3 months, range 0.0 - 6.8) and 64 postoperative cases (median time between surgery and PET: 2.1 months, range 0.2 - 11.7). Overall, patients had significantly more often measurable disease on PET compared to MRI (61.3% vs. 49.1%, p=0.015). Preoperatively, MRI and PET identified similar rates of measurable disease (60.8% vs. 59.5%, p > 0.5), while PET identified a significantly higher number of postoperative cases with measurable disease than MRI (65.6% vs. 21.9%, p < 0.001). While MRI showed a similar rate of measurable disease in oligodendroglioma and astrocytoma (50% vs. 48.2%; p>0.05), PET revealed a significantly higher rate in oligodendroglioma compared to astrocytoma (79% vs. 45.5%; p<0.01). ***Conclusion:*** Amino acid PET detects measurable disease more frequently than MRI, particularly in oligodendrogliomas and postoperative cases. These findings support the use of PET-based evaluation of disease burden in IDH-mutant glioma.

Aim/Introduction: Automatic segmentation of gliomas on amino-acid PET is essential for quantitative tumor assessment, and enables the integration of radiomics into clinical routine. While deep learning segmentation models have been developed for ^{18}F-FET PET, such tools are lacking for ^{18}F-FDOPA, which presents a different physiological uptake. This study aimed to develop a deep learning segmentation model of gliomas for ^{18}F-FDOPA PET with an external validation. ***Materials and Methods:*** Patients who underwent static ^{18}F-FDOPA PET scans in 3 European centers for suspected glial lesions characterization, progression or treatment response assessment were retrospectively included. Data from 530 patients at Nancy Hospital (2 PET/CT systems) were used for training, 66 patients from Pitié-Salpêtrière Hospital (1 PET/CT and 1 PET/MR system) and 30 patients from Turin Hospital (1 PET/CT system) for testing. Ground truth segmentations were performed by experienced nuclear physicians following international guidelines: healthy brain regions defined by crescent-shaped ROIs encompassing white and grey matter across six axial slices, and tumor VOIs semi-automatically segmented using a threshold of 1.6 times the mean healthy brain uptake. For our model, brain were first skullstripped and centered in the image. Images were then resampled to 256x256x164 voxels of 1x1x1mm. A 3D UNet model was trained to segment both tumor and healthy brain VOIs using nnUNet framework (using Ranger21 optimizer and

250 epochs to achieve faster convergence). Performance was evaluated using the median [Q1; Q3] Dice score with ground truth lesion segmentation and was considered as failed if Dice was inferior to 0.5. Absolute differences for PET RANO criteria TBRmax, TBRmean and MTV parameters were quantified. Open source JuST_BrainPET ^{18}F-FET model was also tested on our dataset. ***Results:*** For tumor segmentation, the model achieved a Dice score of 0.906 [0.831;0.942] in training (cross-validation), with 6.79% failed cases. Test set performances were 0.820 [0.717;0.888] (10.42% failures). Absolute differences in TBRmax, TBRmean and MTV were 0.03 [-0.00;0.05], 0.01 [-0.03;0.04], 0.00 [-0.35;0.59] mL and 0.02 [-0.02;0.10], -0.09 [-0.13;-0.03] and 1.01 [0.34;4.85] mL in training and test sets, respectively. Dice scores using JuST_BrainPET ^{18}F-FET model were 0.667 [0.033;0.856] (40.3% failure) and 0.634 [0.023;0.826] (45.8% failure) in training and test sets, respectively. ***Conclusion:*** Despite the heterogeneity in image quality across centers, our deep learning model for segmenting gliomas in ^{18}F-FDOPA PET imaging demonstrated robust performance and generalizability, unlike existing ^{18}F-FET models. This paves the way for fully automated quantitative analysis in clinical routine through extraction of brain amino acid PET parameters.

OP-612

Metabolic tumor volume (MTV) reflects the presence of seizure better than target-to-background-ratio (TBR) in patients with gliomas: a [18F]Fluorodopa (F-DOPA) PET study

G. Garelli[1,2], *M. Zotta*[2], *F. Bruno*[3], *E. Pronello*[3], *A. Pellerino*[3], *A. Lesca*[2], *G. Rovera*[1,2], *R. Rudà*[3], *S. Morbelli*[1,2];
[1]*Department of Medical Sciences, University of Turin, Turin, ITALY,* [2]*Nuclear Medicine Unit, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [3]*Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", AOU Città della Salute e della Scienza di Torino and University of Turin, Turin, ITALY.*

Aim/Introduction: Tumor-associated epilepsy, a condition termed as multiple seizures observed in a patient secondary to their lesion, is seen in up to thirty percent of gliomas. There's a lack of data specifically assessing the capability of PET-derived parameters to correlate with the presence of seizure at baseline and after treatment. We aimed to evaluate F-DOPA-PET correlates of seizure in patients with gliomas at baseline and after therapy. ***Materials and Methods:*** We included patients with gliomas presenting with seizure and with a positive [18F]Fluorodopa PET studied in our center (January-2021 and December-2024). Presence/persistence of seizures was defined as ≥1 unprovoked seizure within 30 days from PET. To investigate the relationship between PET-based-parameters and response to treatment in a homogeneous population, we focused on a prospective-cohort of grade-2 IDH-mutant-glioma patients treated with Vorasidenib. MRI and F-DOPA-PET were performed at baseline and every 3-cycles. We computed SUVmax, TBRmax and MTV (threshold 1.6XSUVmean of healthy-brain). ***Results:*** 32/110 patients with a positive FDOPA-PET had seizure (13 low- and 19 high-grade). TBRmax was slightly but significantly higher in patients with high-grade gliomas and seizure with respect to patients without seizure (2.7±1.2 versus 2.3±1.0;p<0.03), while no significant differences were highlighted in TBRmax and SUVmax in patients with low-grade gliomas subgroups. In these subgroups, MTV was directly associated with the presence of seizure at baseline and after therapy. 10 patients (6 astrocytomas and 4 oligodendrogliomas) treated with Vorasidenib had persistent seizures before treatment. 7 patients had measurable F-DOPA-uptake at baseline (mean SUVmax, TBRmax and MTV: 3.2, 2.8, and 6.5 cm3). After 6 months, 9/10 experienced seizure reduction without changes in antiseizure medication; 8/10 achieved early seizure freedom within 2 cycles, whereas one had gradual, sustained improvement over time. 6 patients who experienced seizure reduction also showed a trend toward metabolic response by cycle 3 (mean changes: SUVmax: -6.3%; TBRmax: -7.5%; MTV: -4.7 cm3) and 6 (SUVmax: -20.9%; TBRmax: -10.9%; MTV: -35.9 cm3), which translated into 3 partial-responses and 3 stable-diseases (RANOcriteria 1.0). All patients had stable disease on MRI at cycles 3 and 6 (including one patient who experienced seizure-worsening). ***Conclusion:*** FDOPA-PET correlates of seizure are different in high- and low-grade gliomas. MTV best captured seizure activity in low-grade glioma. In the subgroup of patients treated with Vorasidenib, seizure improvement correlated with decreased F-DOPA-PET uptake despite stable disease on conventional MRI, supporting the value of F-DOPA-PET as a more sensitive tool for assessing treatment efficacy.

OP-613

Role of 68Ga-DOTATOC PET/CT in Assessing Treatment Response in Re-Irradiated Recurrent Meningiomas: A Volumetric and Molecular Perspective

L. Picori[1], *D. Donner*[1], *S. Agostini*[1], *D. Scartoni*[1], *D. Amelio*[1], *F. Chierichetti*[1], *P. Feraco*[2];
[1]*Ospedale Santa Chiara, Trento, ITALY,* [2]*University of Trento, Trento, ITALY.*

Aim/Introduction: Recurrent meningiomas remain a clinical challenge, particularly after prior surgery and radiation. Proton therapy re-irradiation represents an increasingly used strategy due to its dosimetric advantages. However, robust biomarkers for assessing treatment response remain under investigation. 68Ga-DOTATOC PET/CT, which targets somatostatin receptor subtype 2, offers high sensitivity for meningioma detection, but the utility of SUVmax and volumetric measures as reliable indicators of response remains unclear. The purpose of this study was to assess the value of SUVmax and tumor metabolic volume derived from 68Ga-DOTATOC PET/CT in evaluating treatment response following proton therapy re-irradiation in patients with recurrent meningioma. ***Materials and Methods:*** A retrospective study was conducted on 22 patients with histologically confirmed recurrent meningiomas (5 Grade I, 14 Grade II, 3 Grade III) treated with proton therapy re-irradiation between 2018 and 2022. All patients underwent PET/CT scans before and after treatment. Tumor regions were manually segmented to extract SUVmax standardized uptake volume ratio differences and (SRD) somatostatin receptor density values and volumes. Non-parametric statistical analyses were applied to evaluate differences across timepoints and tumor grades. ***Results:*** No statistically significant difference was observed between pre- and post-treatment, SUVmax values (mean: 17.01 vs. 18.29; p = 0.548). Similarly, no significant variation in SUVmax was noted across tumor grades. Conversely, a volumetric reduction of approximately 20% was observed post-treatment, with a 22% decrease in the Grade II subgroup. ***Conclusion:*** While SUVmax did not change significantly following re-irradiation, metabolic tumor volume demonstrated a consistent reduction. This discrepancy between metabolic activity and volume suggests potential biological and technical factors influencing tracer uptake, such as prior treatments, intratumoral fibrosis, or tumor dedifferentiation. These findings underscore the importance of volumetric PET metrics and support a multiparametric imaging approach combining PET and MRI for optimal evaluation of treatment response in recurrent meningiomas. ***References:*** Improved Detection of Postoperative Residual Meningioma with [68Ga] Ga-DOTA-TOC PET Imaging Using a High-resolution Research Tomograph PET doi: 10.1158/1078-0432.CCR-20-3362. [^{177}Lu]Lu-DOTATATE for refractory meningiomas: factors associated with the therapeutic response and initial tumor dosimetric data

C. Boursier, *T. Zaragori, N. Garabedian, M. Blonski, T. Obara, L. Taillandier, L. Imbert, A. Verger;*
CHRU Nancy, Vandoeuvre-les-Nancy, FRANCE.

Aim/Introduction: This study aimed to reveal the factors affecting the therapeutic response of refractory meningiomas treated with [^{177}Lu]Lu-DOTATATE and to collect initial tumor absorbed doses. ***Materials and Methods:*** Patients with refractory meningiomas treated with [^{177}Lu]Lu-DOTATATE from 2021 to 2024 were retrospectively included. Association analyses of clinical factors, WHO grade, prior therapy (surgery, radiation, systemic therapy: bevacizumab or a combination of octreotide/everolimus), 3D-MRI volume and pretreatment PET parameters with posttreatment progression-free survival (PFS), as defined by the 3D-RANO criteria, were performed. Growth rates obtained via MRI and tumor absorbed doses (TAD) were also calculated. ***Results:*** Sixteen patients (60 [55;68] years old) underwent 4 [2;4] cycles of [^{177}Lu]Lu-DOTATATE, with a TAD/cycle of 0.45 [0.30;0.83] Gy/GBq/cycle. Only prior systemic therapy was found as a risk factor for posttreatment PFS ($p \leq 0.05$), with an impact on tumor growth rate (TGR) (4 vs. 12 patients, +125% vs. -107%, $p<0.01$). For the 12 well-selected candidates the PFS was 67% (8/12 patients) whereas it was 0% in the other group, those with prior systemic therapy. No associations between the TAD and difference in the TGR before/after SSTR-RT were observed in the overall population ($p=0.10$) or in the population of well-selected candidates ($p=0.72$). ***Conclusion:*** [^{177}Lu]Lu-DOTATATE is effective in refractory meningiomas with no prior systemic therapy, even if the TADs are relatively low. Somatostatin-receptor radionuclide therapy should be proposed as early as possible in the treatment course of refractory meningiomas. Efforts should be made to increase the tumor absorbed dose.

Evaluating Concordance in SIOPEN Scoring 123I MIBG scintigraphy among Nuclear Medicine Physicians

H. Noamen*, M. Borsali, L. Agrigoroaie, Y. Cras, K. Trabelsi, A. Daverio, D. Deandreis, C. Garcia;*
Gustave Roussy Cancer Campus, Villejuif, FRANCE.

Aim/Introduction: The SIOPEN score is a semi-quantitative tool in neuroblastoma, playing a critical role in disease staging, treatment response evaluation, and prognostic stratification. This study aimed to evaluate the inter-observer concordance between junior and senior Nuclear Medicine physicians in interpreting the SIOPEN score on 123I-MIBG scintigraphy in pediatric neuroblastoma. ***Materials and Methods:*** Twenty pediatric MIBG scans were performed on a double head Anger gamma camera. Five observers (three senior, two junior nuclear medicine physicians) independently and blindly assessed the SIOPEN score based on planar images. Valid data across all observer pairs ranged from 85% to 100%. Mean scores varied, with Senior 1 reporting the highest average (6.11) and Senior 2 the lowest (5.56); score variability was high across observers (standard deviations: 7-10). Inter-observer agreement was calculated using the intraclass correlation coefficient (ICC; model 2,1). ***Results:*** Agreement between junior and senior observers was good, with ICC values of 0.77 (Junior 1 vs seniors) and 0.84 (Junior 2 vs seniors), both statistically significant ($p < 0.01$). Concordance among senior observers was excellent (ICC = 0.953, $p < 0.01$), indicating strong reliability in experienced readers. ***Conclusion:*** Despite overall good concordance, discrepancies observed between junior and senior physicians highlight the need for targeted training in SIOPEN scoring. Focused education and standardized interpretation protocols are essential to improve scoring consistency and accuracy, particularly among junior physicians. Enhancing reliability in SIOPEN assessment is crucial for accurate disease staging, effective treatment planning, and robust prognostic evaluation in neuroblastoma management.

EPS-200

Artificial Intelligence-assisted Fast Silent PET/MRI for Diagnostic and Therapeutic Assessment in Pediatric Diseases

T. Cai[1], *H. Jun*[1], *C. Zhou*[2], *Y. Bai*[1], *Y. Zhang*[1], *L. Jiang*[3], *Y. Hu*[2], *Z. Lin*[4], *Y. Yang*[5], *Y. Wei*[4], *Z. Zhang*[4], *W. Fan*[2], *W. Lu*[3], *J. Hu*[1], *B. Li*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Sun Yat-sen University Cancer Center, Guangzhou, CHINA,* [3]*Department of Pediatrics, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, CHINA,* [4]*United Imaging Healthcare Co., Ltd., Shanghai, CHINA,* [5]*Beijing United Imaging Healthcare Co., Ltd., Beijing, CHINA.*

Aim/Introduction: While PET/MRI achieves reduced radiation dose over PET/CT in pediatric imaging, clinical adoption remains constrained by prolonged acquisition times (typically 30-45 minutes), excessive acoustic noise (85-95 dB), and frequent sedation requirements. This study presents an integrated technological solution combining four innovations: 1) Flexible coil arrays; 2) Silent MRI sequences; 3) AI-accelerated compressed sensing (ACS) reconstruction for MRI; 4) Deep progressive reconstruction (DPR) for PET. We hypothesize this multimodal optimization enables

diagnostic-quality imaging with reduced acquisition time, noise levels, and radiopharmaceutical dose. ***Materials and Methods:*** Prospective cohort (N=25) of pediatric patients underwent next-generation PET/MRI (uPMR890, United Imaging Healthcare, Shanghai, China) with: 1.85 MBq/kg, flexible 24-channel coil for chest and abdomen coverage, silent MRI sequences, ACS-based MRI reconstruction, and DPR-based PET reconstruction. For comparison, 15 retrospective pediatric cases using conventional protocols (injection dose: 3.7 MBq/kg) were enrolled. Two experienced nuclear medicine physicians independently evaluated the image quality of both the next-generation protocol and the conventional protocol. A Likert 5-point scale was applied to assess the overall image quality, artifacts, lesion conspicuity, and noise of PET and MRI. A score higher than 3 is considered to meet the clinical diagnostic requirements. The quantitative assessment was performed by evaluating the hepatic signal-to-noise ratio (SNR). ***Results:*** In the fast silent pediatric PET/MRI workflow, the total acquisition time was reduced to approximately 12 minutes. Children aged over 5 years successfully completed the entire scan without sedation. The conventional protocols produced an average sound intensity of 86.94±8.53 dB, while the proposed new protocols significantly reduced to 78.59 ±10.29 dB ($p < 0.0001$). The new protocols demonstrated marginally lower subjective quality scores than the conventional workflow in PET image noise, overall MRI image quality, and MRI artifacts (all >3 points, meeting clinical diagnostic requirements). No statistically significant differences were observed in other evaluated metrics. The new workflow demonstrated a statistically significant increase in PET SNR compared to the conventional protocol (25.56±6.41 vs 21.43±5.73, $p<0.05$). ***Conclusion:*** The AI-assisted fast silent pediatric PET/MRI protocol demonstrates significant reductions in acquisition time, radiation dose, acoustic noise, and sedation requirements, while substantially improves patient comfort. Moreover, the obtained image quality is sufficient to meet diagnostic standards, highlighting its clinical utility.

EPS-201

^{99m}Tc labelled heat denatured red cell scintigraphy in suspected right isomerism

K. Chan, *T. Tong, L. Cheung, Y. Hui, W. Ho;*
Queen Mary Hospital, Hong Kong, HONG KONG.

Aim/Introduction: ^{99m}Tc labelled heat denatured red cell scintigraphy is a nuclear medicine technique used to detect functional spleen, with indications including intrapancreatic accessory spleen, assessment of residual spleen in patients after splenectomy. One of the indications is to detect the presence of spleen in patient with suspected heterotaxy or right isomerism. This study presents a retrospective case series of patients with congenital heart abnormalities and suspected right isomerism, assessing the diagnostic value of this imaging modality. ***Materials and Methods:*** A retrospective review was conducted of all patients referred for ^{99m}Tc labelled heat denatured red cell scintigraphy at our institution between 2008 and 2020. A total of 22 cases were identified, all with congenital heart abnormalities and suspected right isomerism. The median age was 123.5 days, with four adult patients included. SPECT imaging was available in 19 cases. Imaging findings were analysed to determine splenic status. ***Results:*** Of the 22 cases, 14 (63.6%) demonstrated absent splenic uptake, confirming asplenia. The remaining cases showed evidence of splenic function, with most demonstrating uptake consistent with a nearly normal functioning spleen, although not all had SPECT imaging for further characterisation. ***Conclusion:*** ^{99m}Tc labelled heat denatured red cell scintigraphy remains a valuable tool for assessing splenic function in patients with congenital heart abnormalities and suspected right isomerism. In this cohort, the majority of cases were confirmed as asplenia. The availability of SPECT imaging enhanced diagnostic confidence. These findings support the continued use of scintigraphy in the evaluation of congenital splenic anomalies.

EPS-202

Validation of a Pediatric Dose Calculator, L_PDC v2025.04.1, for SPECT and PET Radiopharmaceuticals

M. Buaki Sogo[1], *L. Nunes-Lemos*[2], *L. Rubio Álvarez*[2], *A. Palomar-Muñoz*[2], *Ó. Hernández-Cristancho*[2], *J. Suils-Ramón*[2], *F. Dellepiane-Clarke*[2], *A. García-Burillo*[2], *C. Gámez-Cenzano*[2];
[1]*Unidad de Radiofarmacia, Hospital Universitario Vall D'Hebrón, Barcelona, SPAIN,* [2]*Servicio de Medicina Nuclear, Hospital Universitario de Vall D'Hebrón, Barcelona, SPAIN.*

Aim/Introduction: Products available for pediatric dose calculation have its limitations with intermediate and odd weights, so we generate a spreadsheet based on the recommendations of the Committees of the European Association of Nuclear Medicine (EANM) to facilitate as well as to validate a pediatric dose calculator for SPECT and PET radiopharmaceuticals; to improve the accuracy of dose calculation in pediatric patients based on the most recent recommendations. ***Materials and Methods:*** A Microsoft Excel-based calculator named L_PDC was designed and programmed to determine pediatric doses for SPECT and PET radiopharmaceuticals. The design followed the current recommendations, using data derived from the official EANM Dosage Card[1]. Since the card provides standard values for discrete weights, additional intermediate values were calculated using interpolation formulas to cover odd and intermediate body weights. The spreadsheet was developed with built-in features to enhance usability and accuracy. These included: automatic dose calculation based on input weight, visual alerts when calculated doses fell below the minimum recommended activity, and thresholds that triggered color-coded indicators for both suboptimal and optimal dose ranges. To validate the tool, retrospective data from 51 pediatric patients were collected. For each patient, these parameters were recorded: body weight (kg), dose administered according to the hospital's radiopharmaceutical software (Dadm, in MBq), dose calculated using the official EANM online dosage calculator (DEANM, in MBq), and dose obtained with L_PDC (DL_PDC, in MBq). Both absolute and relative errors were calculated for DL_PDC and Dadm, using DEANM as the reference standard. Statistical analysis was performed to assess agreement and accuracy. This included Student's t-test to compare means, and linear regression analysis to determine the correlation between DL_PDC and DEANM, as well as between Dadm and DEANM. The validation aims to ensure that DL_PDC provided results statistically equivalent to DEANM and more consistent than manually prescribed doses. ***Results:*** The mean values of DEANM, DL_PDC, and Dadm were 73,49 ± 103,62 MBq, 72,69 ± 104.92 MBq, and 82,95 ± 137,07 MBq, respectively. There were no statistically significant differences between the calculated doses. Regression analysis revealed an R^2 of 0.998 for DL_PDC versus DEANM, indicating high correlation and accuracy. The absolute error for DL_PDC was 1.1%, compared to -12,8% for Dadm. ***Conclusion:*** L_PDC is a reliable and validated tool for calculating pediatric doses of radiopharmaceuticals, compared with the online calculator DEANM. It offers precision, usability, and time efficiency, managing doses for odd and intermediate weights. ***References:*** 1. 1. EANM Dosage Card.

EPS-203

The impact of F-18 FDG PET/CT on the management of complicated Tuberculosis in children

C. Burger, *D. Smith-Tsibolane, C. le Roux, A. Doruyter, P. Goussard;*
Stellenbosch University, Cape Town, SOUTH AFRICA.

Aim/Introduction: Children are at higher risk for severe forms of Tuberculosis (TB). Early diagnosis and treatment limit morbidity, mortality and transmission. Diagnosis is challenging due to diverse presentation, paucibacillary burden, and difficulty

obtaining samples. Imaging is essential, particularly when microbiological tests remain negative. Chest X-ray has limitations. CT can evaluate mediastinal lymph nodes and complicated TB, but its utility in detecting active disease is frequently limited. ^{18}F-fluorodeoxyglucose positron emission tomography combined with computed tomography (FDG PET/CT) detects active inflammation, assists in diagnosis, determines disease extent, and guides biopsies. This study focused on evaluating the potential of FDG PET/CT to improve the diagnosis and management of complicated paediatric TB. ***Materials and Methods:*** A retrospective review of imaging, bronchoscopy and microbiology results of children aged 3 months to 16 years who presented at Tygerberg Hospital between January 2013 and October 2024 with at least one FDG PET/CT. The PET/CT findings (reviewed by a nuclear physician) were compared to the diagnostic CT (reviewed by a radiologist) or the low dose CT of the PET/CT (depending on availability). Representative volumes of interest were drawn for target lesions on the PET/CT. Bronchoscopy and microbiological results, clinical outcome, and impact of PET/CT on patient management were reviewed by a paediatric pulmonologist. ***Results:*** Scans of thirty-four (n=34) patients (16 male), with median age of 7.1 years (range: 0.5-11.9 years) of which 4 HIV positive were reviewed. Most patients (19/34, 56%) underwent a diagnostic CT prior to the PET/CT (median interval: 42 days, IQR: 30.5-67.5). PET/CT detected a total of 142 intrathoracic nodal sites, while CT detected 99 (p=0.001144). Extrapulmonary disease was detected in 17 patients (50%) on PET/CT, compared to 6 patients (18%) on CT (p=0.009823). The mean SUVmax was 3.6 (SD 2.3) for mediastinal nodal sites, 2.6 (SD 3.1) for pulmonary lesions, and 2.0 (SD 3.0) for extrapulmonary sites. PET/CT confirmed persistent disease in 17 patients (50%), detected biopsy sites (that were diagnostic) in 9 patients (26%), and excluded TB in 4 patients (12%). It guided surgical intervention in 2 patients (6%), identified non-responding patients (2 patients, 6%), and confirmed recurrence in 1 patient (3%). ***Conclusion:*** FDG PET/CT impacted management in most patients, mostly by confirming persistent disease and identifying biopsy sites. PET/CT detected more intrathoracic nodal disease and extrapulmonary disease. This study adds to the limited literature and shows the potential value of FDG PET/CT in complicated paediatric TB.

EPS-204

The Role Of Tc-99m Sestamibi Myocardial Perfusion Scintigraphy On Patient Management In Pediatric Kawasaki Patients With Giant Coronary Aneurysm

H. Kapucu, *B. Esen Akkas, M. Kaya, K. Toplutas;*
University of Health Sciences Cam Sakura City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: This retrospective study evaluated the impact of myocardial perfusion scintigraphy (MPS) on the management of pediatric Kawasaki Disease (KD) patients with giant coronary aneurysms before undergoing surgery. ***Materials and Methods:*** The study included five pediatric patients diagnosed with giant coronary aneurysm among 20 patients who followed up with KD between 2018 and 2024. For stress MPS imaging, 7.4 MBq/kg (minimum two mCi/74 MBq) [99mTc]Tc-sestamibi injection was performed in the 3rd minute of a 6-minute adenosine infusion at a rate of 140 mcg/kg/min (1). Single photon emission computed tomography (SPECT) imaging was performed 30-45 minutes after injection in the supine position under anaesthesia. Patients with hypoperfused areas on stress images underwent rest imaging the following day under anaesthesia. Since prone imaging was not possible for technical reasons, low-dose computed tomography (CT) was used for attenuation correction in patients imaged without anaesthesia. GATED images synchronised with electrocardiography (ECG) were obtained in stress images. ***Results:*** One of the patients was female, and four were male. The mean age at diagnosis was 28.8 months. The mean CRP, leukocyte, and neutrophil values were 174.9 mg/L, 24.8 10^9/L, and 19.9 10^9/L, respectively. According to MPS results, the hypoperfused area in the apex, anterior wall apical-mid segments in stress of one patient (Case 1) was reperfused in the rest images. The patient's ejection fraction (EF) value was 51%, end-diastolic volume (EDV) was 25 ml, end-systolic volume (ESV) was 12 ml, and summed stress score was 5. Rest imaging was not performed in the other four patients because left ventricular perfusion was within normal limits on stress images. In case 1 with ischaemic findings, the coronary bypass was performed by opening just distal to the aneurysmatic tissue in the LIMA-LAD artery. In the control ECHO performed after the surgical procedure, blood flow was normal. EF was calculated as 67%. The complaint of dyspnea, which reduced the quality of life before the surgery, almost completely improved after the surgery. The other four patients were offered follow-up with medical therapy and did not develop any new cardiac symptoms or events. ***Conclusion:*** In this case series, MPS findings prevented unnecessary surgical interventions in four pediatric cases and provided accurate surgical planning in one case, thereby alleviating the patient's symptoms. MPS is an easy-to-use and reliable noninvasive imaging method for surgical planning and patient management in KD. ***References:*** 1.Fukazawa R, et al. doi: 10.1253/circj.CJ-19-1094.

EPS-205

Persistent FDG-PET Uptake After First-Line Therapy in Paediatric Lymphoma and Risk of Progression: a Monocentric Retrospective Analysis

F. Serani[1], *E. Carraro*[2], *D. Cecchin*[1], *C. Giraudo*[3], *M. Pillon*[2], *P. Zucchetta*[1];
[1]*Nuclear Medicine Unit, Department of Medicine DIMED, University-Hospital of Padova, Padua, ITALY,* [2]*Oncohematology Unit, Department of Woman and Child Health, University of Padova School of Medicine, Padua, ITALY,* [3]*Unit of Advanced Clinical and Translational Imaging, Department of Cardiac, Thoracic, Vascular Sciences and Public Health-DCTV, University of Padova, Padua, ITALY.*

Aim/Introduction: Persistent focal uptake on post-therapy FDG-PET in paediatric lymphoma may represent residual disease or benign sequelae, creating ambiguity in clinical management. This study investigates whether quantitative PET parameters of pre-therapy lesions and post-therapy persistent lesions can predict relapse in children who lack clear evidence of recurrence. ***Materials and Methods:*** In this single-centre retrospective analysis, we identified 18 children (median age 14.2 years, IQR = 3 years) with Hodgkin and Non-Hodgkin lymphoma subtypes who performed a pretherapy PET/MR and End-of-Therapy (EoT) PET/MR between 2015 and 2024 and had a clinical follow-up of at least eight months. For each patient, the initial disease volume was semi-automatically contoured on staging PET parameters, and any persistent lesion was contoured at (EoT) PET. Semiquantitative measurements including the SUVmax of the persistent lesion (PERS), SUVmean of PERS, the maximum hepatic SUV (SUVmax liver). Metabolic tumour volume (MTV), and total lesion glycolysis (TLG) were considered for both initial disease and PERS. Statistical analyses were performed using Fisher's exact test for categorical comparisons and the Mann-Whitney U test for continuous variables. ***Results:*** Four of the 18 patients (22%) experienced histologically or radiologically confirmed relapse during follow-up. Of all the PET parameters both on staging and on EoT PET only the SUVmean greater than SUVmax liver showed a statistically significant correlation with the follow-up data (p<0,05). Of these 18 patients, three had persistent lesion SUVmean PERS exceeding the SUVmax liver, whereas none of the 14 non-relapsing patients exhibited this finding. None of the other PET semiquantitative measurements taken into consideration take, neither MTV nor TLG—whether of the residual lesion or the initial tumour—

showed a statistically significant correlation with relapse risk. ***Conclusion:*** Persistent post-therapy lesion SUVmean greater than SUVmax liver appears to correlate with paediatric lymphoma patients at higher risk of relapse, whereas volumetric metrics (MTV, TLG) both on staging and EoT therapy lack clear predictive value in this cohort. Given the retrospective nature of this analysis and the small population, these findings require validation in larger cohort, preferably in prospective multicentre trials.

EPS-206

Use of semiquantitative parameters on baseline Tc99m mebrofenin hepatobiliary scintigraphy for predicting post Kasai outcome in ExtraHepatic Biliary Atresia- a retrospective analysis

N. Kundu, *V. Singh, A. Mahalik, A. Roy, K. Jain, J. Choudhary, J. Krishna, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: The HIDA scan is a key imaging tool for distinguishing extrahepatic biliary atresia (EHBA) from neonatal hepatitis in infants with congenital hyperbilirubinemia. EHBA, a surgically correctable condition, is treated using the Kasai portoenterostomy, whose success significantly depends on the infant's age at surgery—outcomes worsen if performed after 60 days. Visual indicators on HIDA scans, such as hepatic radiotracer uptake and bowel visualization, help identify EHBA. However, there is currently no research exploring semiquantitative HIDA scan parameters that might predict post-surgical outcomes following the Kasai procedure, highlighting a gap in the existing diagnostic and prognostic framework. ***Materials and Methods:*** A retrospective review of 15 EHBA patients (9 males, 6 females) imaged between 20202025 in our department was performed. All children underwent preoperative HIDA within two weeks before Kasai and had ≥ 6month clinical/imaging followup. Regionsofinterest were placed on 15min static frames over (i) whole liver and (ii) cardiac bloodpool to derive: Liver counts @ 15 min (LC15), Cardiac counts @ 15 min (CC15), Livertocardiac ratio (LCR = LC15 / CC15). Delayed 24h static images yielded: Liver counts @ 24 h (LC24) and fractional hepatic retention (FHR= LC24 / LC15). PostKasai status (success=bile flow demonstrated & cholestasis resolved, failure=None of the above) served as the target variable. Mann-Whitney U compared indices between groups; pointbiserial correlation (r) assessed associations with outcome (α = 0.05). ***Results:*** Mean age of chiLdren at the time of diagnosis was 76 +/-45 days. Eight children (53 %) achieved Kasai success, seven (47 %) failed. Median earlyliver counts were lower in the success group (168 000, IQR 122 000-248 000) than in failures (260 000, IQR 179 000-324 000; p = 0.12, r = 0.39), and a similar trend was observed for cardiac counts (34 000 vs 50 000; p = 0.19, r = 0.34). The livertocardiac ratio showed minimal separation between successes and failures (medians 3.52 vs 4.61; p = 0.69), whereas the fractional hepatic retention at 24 hourswas higher in successful cases (median 0.155, IQR 0.129-0.198) compared with failures (0.114, IQR 0.105-0.128), yielding the strongest correlation with outcome (r = +0.44).Sex did not correlate with any scintigraphic variable (r= 0.25). ***Conclusion:*** In this pilot series, children who eventually cleared jaundice after Kasai exhibited lower early liver counts and higher 24h tracer retention, underscoring that brisk washout on baseline HIDA may herald an unfavourable outcome. Although pvalues were limited by small sample size, the moderate correlations (|r| ≈ 0.4-0.45) suggest that simple semiquantitative parameters—readily available on routine HIDA—could enrich preoperative counselling and prioritise candidates for early livertransplant evaluation. Larger prospective cohorts are warranted to establish definitive cutoff values and integrate these metrics into multidisciplinary decision algorithms.

EPS-207

Meckel's Diverticulum in Paediatric Patients. Diagnostic Performance of [^{99m}Tc]Tc- pertechnetate Scintigraphy. A Retrospective Study.

A. Guerra, *C. Salomon, E. Durand, M. Vivar, A. Puig, M. Gimenez, C. Peña;*
Servicio de Medicina Nuclear, Hospital Universitari Son Espases, Palma, SPAIN.

Aim/Introduction: Meckel's diverticulum is the most common congenital gastrointestinal anomaly, often presenting in paediatric patients with an incidence of 1-3%, with painless rectal bleeding or abdominal pain. Early detection is essential to avoid complications such as anemia, bowel obstruction, or perforation. [^{99m}Tc]Tc-pertechnetate scintigraphy is the imaging modality of choice for detecting ectopic gastric mucosa within Meckel's diverticulum. The aim of this study is to evaluate the utility of [^{99m}Tc]Tc-pertechnetate scintigraphy in the diagnosis of Meckel's diverticulum in paediatric population. ***Materials and Methods:*** Retrospective study of 78 paediatric patients (under 18 years old) with suspected Meckel's diverticulum, which underwent [^{99m}Tc]Tc-pertechnetate scintigraphy over a 13 year period (2011-2024). Examination was performed after [^{99m}Tc]Tc-pertechnetate was endovenously administration 1-3.5 MBq/Kg, and an anterior planar image of abdomen and pelvis was obtained at 1, 7, 15, 30 and 45 minutes. A final image was taken 60 minutes after injection following bladder emptying in a standing position. Scan parameters included 500K counts for each image, a 256x256 matrix, with age appropriate zoom using low-energy general purpose collimator. Imaging results were classified as positive when a well-defined focus of radiopharmaceutical uptake in abdomen or pelvis, and as negative when no tracer accumulation was visualized. To verify the veracity of the scintigraphy was determined through surgical and/or histopathological findings. ***Results:*** Out of 78 examinations (52 boys, 26 girls, mean of age 5 years), 11 (14%) patients had positive scintigraphy image and 67 (85%) were negative. The 11 positive scans underwent surgical resection and the diagnosis of Meckel's diverticulum was confirmed, 2 intraoperatively and the rest by histopathological analysis. Among the 67 patients with negative scintigraphy, 2 were finally diagnosed with Meckel's diverticulum by histopathological study. In our study the [^{99m}Tc] Tc-pertechnetate scintigraphy reported a sensitivity of 85%, a specificity of 100%, positive predictive value 100% and negative positive predictive value 97% in the diagnosis of bleeding Meckel's diverticulum in paediatric population. ***Conclusion:*** [^{99m}Tc]Tc-pertechnetate scintigraphy is a valuable and sensitive diagnostic tool for detecting Meckel's diverticulum in paediatric patients. False negatives remain a limitation, underscoring the need for clinical correlation and, in selected cases, adjunct imaging or surgical exploration.

EPS-208

Role of SSTR PET-CT in paediatric neuroblastoma patients-A promising one stop shop modality.

D. Halanaik, *S. Kumar, H. Goyal, P. Srinivasan, S. Keerthivasagam; Jawaharlal Institute of postgraduate medical education and Research, Puducherry, INDIA.*

Aim/Introduction: Neuroblastoma is a common pediatric malignancy with diverse clinical presentations and metastatic patterns. Imaging is essential for diagnosis, staging, and monitoring the treatment response. Somatostatin receptor (SSTR) PET/CT using Ga-68 DOTATATE/DOTANOC has emerged as a valuable tool for detecting SSTR expression in neuroblastoma and sites of distant metastases, thereby facilitating comprehensive disease evaluation. ***Materials and Methods:*** This retrospective study included 11 pediatric patients diagnosed with neuroblastoma, who underwent SSTR PET/CT for baseline staging and response assessment between January 2024 and April 2025 at a tertiary care hospital.

Clinical history, imaging findings, histopathological records and follow-up data were reviewed. Imaging reports focused on lesion location, its size, SSTR expression (SUVmax), and sites of metastatic involvement. Relevant clinical and radiological data were extracted and summarized. ***Results:*** Patients were predominantly infants and toddlers, with 50% under 1.5 years. Majority of the patients presented primarily with abdominal distension, pain, and palpable masses. Primary tumors were predominantly located in the suprarenal and retroperitoneal regions. Variable SSTR expression ranging from low to moderate levels was observed, with median SUVmax value 5.01 (±2.29). 100% of patients exhibited distant metastases with metastatic disease identified in lymph nodes (47.6%), and liver (47.6%) in several cases, predominantly. Only 4 patients underwent response evaluation PET/CT post-treatment. Treatment responses varied: some patients exhibited partial response (2/11, 9.5%) with significant lesion size reduction post-chemotherapy, while others showed stable or residual disease. ***Conclusion:*** SSTR PET/CT imaging effectively delineates primary and metastatic neuroblastoma lesions, thereby providing critical information for staging and evaluating treatment response. The imaging findings correlate with clinical outcomes and can guide therapeutic decision-making in pediatric neuroblastoma management.

EPS-209

Comparative diagnostic performance of 68GaDOTANOC PET/CT versus 131ImIBG SPECT/CT in newly diagnosed pediatric neuroblastoma- a prospective single centre study.

N. Kundu, *D. Khan, S. Sagar, S. Bakhshi, R. Seth, S. Agarwala, A. K. Pandey, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: To quantify and compare the diagnostic yield of wholebody 68GaDOTANOC PET/CT and 131ImIBG SPECT/CT for primary tumour detection and metastatic mapping in treatmentnaïve paediatric neuroblastoma. ***Materials and Methods:*** Forty treatment naïve children (median age = 36 months) with biopsy proven/biochemically proven or radiologically diagnosed neuroblastoma underwent paired 68GaDOTANOC PET/CT and 131ImIBG planar ± focal SPECT/CT imaging after obtaining informed written consent and institute ethics committee clearance. 68GaDOTANOC (1.5 MBq kg^{1}, 45 min uptake) PET/CT covering vertextotoes; 131ImIBG (0.14 mCi kg^{1}) planar ± focal SPECT/CT were acquired 48-72 h postinjection. Both studies were evaluated by 2 experienced nuclear medicine physicians who performed patientbased and lesionbased analyses blinded to diagnoses. On visual analysis of 68Ga-DOTANOC PET/CT, a lesion was considered positive when focal uptake was present at non-physiologic site, having intensity greater than the mediastinal blood pool with corresponding lesion on CT. Discrepant foci were adjudicated by correlative MRI/CT, histology or 12month clinical followup. McNemar and Wilcoxon tests were used to assess paired proportions and lesion counts. ***Results:*** DOTANOC localised the primary in 35/39 cases (90 %) versus 29/39 (74 %) for mIBG (P = 0.07). Metastatic disease was demonstrated in 30/40 studies with DOTANOC and 25/40 with mIBG (P = 0.03). Altogether, DOTANOC uncovered 1,083 lesions, of which 880 were osseous or marrow; mIBG revealed 235 lesions (163 skeletal) (P < 0.001). Incremental detection was greatest for occult marrow deposits (DOTANOC +81 %). No DOTANOCavid/mIBGpositive discordance occurred, but seven primaries and six metastatic sets were DOTANOCpositive/mIBGnegative, altering stage in 12.5 % of patients. ***Conclusion:*** Wholebody 68GaDOTANOC PET/CT significantly outperforms 131ImIBG SPECT/CT for lesion enumeration and metastatic staging—including cryptic marrow disease—without sacrificing primarytumour sensitivity. These findings support use of DOTANOC as a firstline functional tracer where generatorbased gallium is available, and reserve mIBG chiefly for theranostic stratification.

EPS-210

Meckel's Scan Revisited

J. Lanctôt-Bédard, *R. Lambert, S. Turpin;*
CHU Sainte-Justine, Montréal, QC, CANADA.

Aim/Introduction: ^{99m}Tc-Pertechnetate Scintigraphy (^{99m}Tc-PS) or Meckel`s scan, has been a mainstay of nuclear medicine for many years for the detection of ectopic gastric mucosa. With time, modifications have been made in the patient`s preparation. The purpose of our retrospective study was to identify the best pharmacological preparation (PP). ***Materials and Methods:*** Medical file, ^{99m}Tc-PS images and radiological report of patients imaged between 2014 and 2024 were reviewed. The use of pharmacological preparation (PP) with intravenous (iv) or per os (po) Ranitidine (R) and Famotidine (F), po proton pump inhibitors (PPI) was compiled. ^{99m}Tc-PS images were reviewed for the detection and time from injection of duodenal visualisation (elution) and influence on diagnostic. Comparison between the presence or absence of elution between no-PP, PP+ and PP categories was made using Chi Square and for the elution times using unpaired student t-test. Significance level was established at p<0.05. ***Results:*** 231 studies were performed in 99 girls and 132 boys, 6.4 +/-5.4 years old. ^{99m}Tc-PS consisted of a 30-minutes dynamic study followed by static images +/- SPECT +/-CT. ^{99m}Tc-PS demonstrated 15 Meckel+ proven by surgery and 2 dubious Meckel + with final diagnosis of bleeding Meckel and inflammed small bowel lymphoid hyperplasia.PP was performed in 141 studies (R po = 40; R iv = 27 ; F po=17 ; F iv = 49; PPI po =8).Elution was more frequent with no-PP than with PP+ : 69.5% versus 46.5%, p=0.04. Elution was found in 37.5% of studies for R po, 37% for R iv, 58.8% for F po, 53% for F iv and 71% for IPP po. Frequency differences in PP+ were not significant (p=0.21) as a whole or in paired analysis, with the exception of bordeline significance for PPI po versus R po (p=0.09). However, times to elution were similar between no-PP and PP + : 18.6+/-10.5 min vs 18.6+/-7.8 min, p=ns. Time to elution were also similar inbetween PP categories, with the exception of R po versus F iv : 13.9+/-7.1 min versus 21.3 +/- 8.5 min, p=0.008. Despite elution, all studies were deemed diagnostic. ***Conclusion:*** The use of PP decreased the frequence of elution where compared to non-PP but elution remained present. All studies were diagnostic. Elution occured later during the acquistion with F iv. In conclusion, recommendation is made to perform ^{99m}Tc-PS with F iv preparation.

EPS-211

Scintigraphic Localization of Intestinal Bleeding in a Pediatric Patient with High-Grade B-cell Lymphoma: A Life-Saving Intervention

L. Nunes Lemos, *L. Rubio-Álvarez, A. Cardozo-Saavedra, O. Hernández-Cristancho, A. Palomar-Muñoz, I. Navales-Mateu, M. de Bonilla Candau, A. García-Burillo, C. Gámez-Cenzano;*
Nuclear Medicine Department, Vall d'Hebron Hospital Universitari, Vall d'Hebron Barcelona Hospital Campus, Barcelona, SPAIN.

Aim/Introduction: We present the case of an 8-year-old girl with high-grade B-cell lymphoma, undergoing chemotherapy and suffering from extensive abdominal mucositis as an adverse effect. The patient developed life-threatening gastrointestinal bleeding, unlocalized by conventional angiographic and endoscopic studies. This case highlights the pivotal role of [99mTc]Tc-RBC (red blood cell) scintigraphy in detecting the bleeding sites and guiding therapeutic interventions. ***Materials and Methods:*** Due to hemodynamic instability and inconclusive results from contrast-enhanced CT and angiography, gastrointestinal bleeding

scintigraphy (GIBS) was performed. A dose of 9 mCi of [99mTc]Tc-labelled RBCs (in vivo-vitro technique) was administered, adjusted using the EANM Pediatric Dosage Card. The protocol included dynamic flow acquisition and abdominal SPECT/CT. Imaging was interpreted according to the 2019 EANM guidelines for GI bleeding scintigraphy. ***Results:*** Dynamic imaging revealed two foci of extravascular tracer accumulation: one at the gastroduodenal region and another in the proximal jejunum. The gastroduodenal site appeared first and demonstrated active bleeding with rapid intraluminal progression. The addition of SPECT/CT significantly contributed to the precise localization of both bleeding sites, particularly the jejunal focus, which was less evident on planar imaging. This confirmed and allowed prompting urgent endoscopy treatment of the bleeding duodenal ulcer via clip placement, as well as targeted embolization by interventional radiology of the jejunal haemorrhage focus. Both interventions stabilized the patient's condition, significantly reduced transfusion needs, and allowed discontinuation of vasoactive support. ***Conclusion:*** [99mTc]Tc-RBC scintigraphy enabled accurate localization of multiple occult gastrointestinal bleeding sources in a critically ill pediatric patient, directly influencing life-saving clinical management. In this case, where conventional modalities failed, nuclear medicine not only provided diagnostic clarity but also offered a minimally invasive, rapid, and patient-tailored approach that avoided blind surgical interventions. The addition of SPECT/CT was crucial for anatomical precision, enabling prompt and targeted treatment. This case exemplifies how nuclear medicine can decisively shift the diagnostic and therapeutic pathway, offering real-time insights that translate into meaningful clinical outcomes. In vulnerable populations, such as pediatric oncology patients, our specialty has the power to detect, guide, and help heal—making the difference between uncertainty and action, between risk and resolution. We must continue to advocate for broader access to these techniques and their integration into emergency diagnostic algorithms. ***References:*** Giammarile F, et al. EPS-212

Contribution of FDG PET-CT to Risk Stratification and Treatment Response in Pediatric Hodgkin Lymphoma

A. Khelifa*, F. Koudri, A. Talbi, M. Lamali, L. Chelghoum, L. Belabas, S. Benzerdjeb, D. Tahmi, S. Brahmi, S. Rahabi, D. Mouas, A. Taibi, S. E. Bouyoucef, A. Amimour;*
Bab El Oued Hospital, Algiers, ALGERIA.

Aim/Introduction: In Algeria, Hodgkin lymphoma (HL) ranks as the third most common pediatric cancer, accounting for 10.7% of cases. It is generally associated with a favorable prognosis. FDG-PET/CT has significantly enhanced staging accuracy, risk-adapted treatment planning, and response evaluation, enabling therapy de-escalation and reduction of long-term toxicity. However, real-world constraints can affect adherence to standard imaging protocols.The aim of the study is to assess the contribution of FDG PET-CT to risk stratification and therapeutic response evaluation in pediatric Hodgkin lymphoma in real-world clinical practice. ***Materials and Methods:*** We conducted a retrospective study of 116 pediatric patients diagnosed with HL between 2021 and 2024. The cohort included 67 boys and 49 girls, with a mean age of 12.75 years ± 3.91. FDG PET-CT scans were performed at baseline, during treatment (interim), and post-treatment (final), and interpreted using the Deauville score. Baseline PET-CT was not consistently performed due to the frequent initiation of treatment immediately upon diagnosis, reflecting real-world constraints in urgent clinical settings. Treatment decisions, including radiotherapy indications, were reviewed in relation to PET findings. ***Results:*** Of the 116 patients, 68 underwent baseline PET, 75 interim PET, and 58 final PET; only 25 completed all three scans. Mean SUVmax values were 14.12 (baseline), 7.88 (interim), and 4.10 (final). Deauville scores at baseline showed a predominance of high metabolic activity (Score 5: 31 patients, Score 4: 30 patients). At interim PET, 30 out of 75 patients (40%) showed a good metabolic response (Deauville scores 1 to 3), while 45 patients (60%) exhibited a poor metabolic response (Score 4: 30 [40%], Score 5: 15 [20%]). These findings underline the value of interim PET in identifying non-responders and adapting treatment intensity. Radiotherapy was administered in 17 patients (14.7%), often guided by persistent metabolic activity observed on PET. ***Conclusion:*** FDG PET-CT is a pivotal tool in the management of pediatric Hodgkin lymphoma. In real-world practice, interim PET emerges as the most feasible and informative scan, effectively guiding therapeutic decisions when baseline or final imaging is unavailable. These findings reinforce the value of interim PET in treatment adaptation and long-term outcome optimization.

EPS-213

AI based automatic measurement of split renal function in [^{18}F]PSMA-1007 PET/CT

K. Valind*[1,2], J. Ulén[3], A. Gålne[1,2], J. Jögi[1,2], D. Minarik[1,4], E. Trägårdh[1,2];*
[1]Department of Translational Medicine, Wallenberg Centre for Molecular Medicine, Lund University, Malmö, SWEDEN, [2]Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund and Malmö, SWEDEN, [3]Eigenvision AB, Lund, SWEDEN, [4]Department of Radiation Physics, Skåne University Hospital, Lund and Malmö, SWEDEN.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) targeted positron emission tomography (PET) with computed tomography (CT) has become an important diagnostic modality in prostate cancer. In addition to overexpression in cancer cells, PSMA is physiologically expressed in the proximal tubules of the kidneys. Because of this, PSMA PET is being explored for functional imaging of the kidneys. Uptake of PSMA targeted radiopharmaceuticals in the left and right kidneys have shown strong correlations to split renal function (SRF) as measured with other modalities [1]. Manual kidney segmentation in PET images is time consuming, which limits the practicality of this method of determining SRF. In this study, we designed, trained and validated an artificial intelligence (AI) model for automatic segmentation and measurement of SRF in [^{18}F]PSMA-1007 PET images. ***Materials and Methods:*** One nuclear medicine physician segmented kidneys in a training set of 135 [^{18}F]PSMA-1007 PET/CT studies. These data were then used to train an AI model based on the 3D UNET architecture [2]. The model was evaluated in 40 test studies, segmented by 3 nuclear medicine physicians. All segmentations (human and AI) were compared against each other regarding left renal function percentage (LRF%) and volume. ***Results:*** LRF% measurements ranged from 40% to 67%. Spearman correlation coefficients for LRF% measurements ranged between 0.98 and 0.99 when comparing segmentations. The largest LRF% difference between measurements in a single exam was 3 percentage points. The AI model performed similarly to human readers. ***Conclusion:*** Automatic measurement of SRF in PSMA PET is possible. It could be used to provide additional data in investigation of renal functional impairment, potentially saving patients time and radiation exposure. ***References:*** 1. Valind K, Minarik D, Garpered S, Persson E, Jogi J, Tragardh E. [(18)F]PSMA-1007 PET is comparable to [(99m)Tc]Tc-DMSA SPECT for renal cortical imaging. Eur J Hybrid Imaging. 2023;7:25. 2. EPS-214

Relationship Between Prostatic FDG Uptake, Prostatic Calcifications, and Symptom Scores of NIH-CPSI and IPSS in male patients undergoing health checkups

J. Lee, *G. Lee, J. Choi, H. Son;*
Dankook University Hospital, Cheonan, KOREA, REPUBLIC OF.

Aim/Introduction: Since FDG PET/CT has been introduced in oncology, it has also proven clinically valuable in the evaluation of infections, connective tissue disorders, and neurodegenerative diseases. However, its potential role about genitourinary symptom assessment of the Chronic Prostatitis Symptom Index of the National Institutes of Health (NIH-CPSI), the International Prostate Symptom Score (IPSS) and Quality of life (QoL) has not been well defined. This study aims to explore the relationship between incidental prostate FDG uptake, prostatic calcifications, and symptom scores of NIH-CPSI, IPSS and QoL in men undergoing health screening. ***Materials and Methods:*** A total of 368 men (age <75) who underwent health checkups with FDG PET/CT and completed NIH-CPSI and IPSS questionnaires were included. Visual analysis of FDG uptake in the prostate and identification of prostatic calcifications on CT were performed. Additionally, PSA, Rapid plasma reagin (RPR), C-reative Protein (CRP), and Erythrocyte sedimentation rate (ESR) tests were performed and applied as adjustment variables. Univariate analysis was performed according to the presence or absence of FDG uptake and calcification. Associations with symptom scores were analyzed using multiple logistic regression analysis and spearman correlation analyses. ***Results:*** Among the study population, 31 patients exhibited positive FDG uptake, 84 patients had prostatic calcification and 104 patients showed both. Spearman correlation revealed strong associations between total NIH CPSI or IPSS scores and QoL (correlation coefficient: 0.58 and 0.78, $p < 0.001$, both). Univariate analysis showed that patients with either prostatic FDG uptake or calcification had higher scores on NIH-CPSI, IPSS and QoL scores, and were significantly associated with increasing age (Table 1). In multivariate regression logistic analysis, the presence of prostatic FDG uptake [odds ratio (OR): 6.5, 95% confidence intervals (CI): 2.86-14.95, $P < 0.001$ and OR:4.54, 95% CI:1.86-11.06, $P < 0.001$] and calcification [OR:4.36, 95% CI: 2.29-8.30, $P < 0.001$ and OR:4.86 95% CI:2.41-9.86 $P < 0.001$] were associated with the risk factors of IPSS and QoL high risk scores (8 and 3, each) (Table 2 and Table 3). ***Conclusion:*** Although FDG PET/CT was performed for screening purposes, prostatic FDG uptake and calcifications were significantly associated with systemic scoring systems such as NIH-CPSI and IPSS used to assess patients with lower urinary tract symptoms and measure treatment effectiveness in prostate diseases, especially chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) and benign prostatic hyperplasia. These findings suggest that PET/CT may provide adjunctive value in assessing latent urinary tract symptoms and contribute to the evaluation of CP/CPPS.

Assessment of Tumor Response to Neoadjuvant Hormone Therapy in Prostate Cancer Using F-18 PSMA-1007 PET: A Feasibility Study

S. Cho[1], *H. Han*[2], *S. Lee*[3], *M. Jung*[4], *Y. Oh*[5], *M. Yun*[3];
[1]*Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Artificial Intelligence, Yonsei University, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Nuclear Medicine, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [4]*Department of Pathology, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [5]*Department of Radiology, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: The role of prostate-specific membrane antigen (PSMA)-targeted positron emission tomography (PET) in assessing response to neoadjuvant androgen deprivation therapy (nADT) remains underexplored [1]. This study investigated the potential utility of ^{18}F PSMA-1007 PET for evaluating residual tumor burden following nADT, compared to multiparametric MRI (mpMRI). ***Materials and Methods:*** This retrospective study included 14 patients with localized prostate cancer who received nADT followed by radical prostatectomy. All patients underwent baseline mpMRI, post-nADT ^{18}F PSMA-1007 PET, and post-nADT mpMRI before surgery. Tumor volumes on PET were segmented using three methods: semi-automated thresholding based on a percentage of the max SUV (SUVmax), segmentation using the mean SUV (SUVmean) of benign prostatic tissue, and manual. Correlation between PET-derived and pathological tumor volumes was assessed using Spearman's rank correlation coefficient. MRI parameters, including apparent diffusion coefficient (ADC) and transfer constant (Ktrans), were extracted from tumor regions, and compared between pre- and post-treatment using Wilcoxon signed-rank tests. Mann-Whitney U tests were used to compare imaging parameters between tumor regions and benign prostatic hyperplasia (BPH) regions. ***Results:*** Among the 14 patients, one showed complete pathological response. ^{18}F PSMA-1007 PET detected residual tumor in 12 patients, whereas mpMRI detected residual lesions in 3. Tumor volume estimates obtained using SUVmean-based semi-automated segmentation correlated strongly with pathological tumor volumes (Spearman's $\rho = 0.877$, $p < 0.001$). Threshold-based methods using 40% and 50% of SUVmax also showed statistically significant correlations ($\rho = 0.778$ and $\rho = 0.723$, respectively; both $p < 0.001$). Median ADC increased significantly after nADT, from 0.865 to 1.101×10^{-3} mm^2/s ($p = 0.005$), while median Ktrans decreased from 0.224 to 0.075 min^{-1} ($p = 0.007$). Pre-nADT median ADC was significantly lower in tumor regions compared to BPH regions, with values of 0.865 and 1.250×10^{-3} mm^2/s, respectively ($p = 0.002$). No significant differences were observed between malignant and benign regions in pre-nADT Ktrans, post-nADT ADC, post-nADT Ktrans, or SUVmax. ***Conclusion:*** ^{18}F PSMA-1007 PET appeared more sensitive than mpMRI in identifying residual disease. PET-based tumor volume estimates correlated strongly with pathological volumes and may be useful for evaluating residual tumor following nADT in prostate cancer. These preliminary findings support the feasibility of ^{18}F PSMA-1007 PET in post-treatment assessment and warrant prospective validation. ***References:*** 1. Vaz S, Hadaschik B, Gabriel M, Herrmann K, Eiber M, Costa D. Influence of androgen deprivation therapy on PSMA expression and PSMA-ligand PET imaging of prostate cancer patients. EPS-216

^{18}F-FDG PET/CT in diagnosis, staging and management of pediatric patients with Langerhans histiocytosis

P. Grecu-Bodnariuc[1], *M. Gutu*[1,2];
[1]*"Sfântul Ioan cel Nou" County Hospital of Emergency, Suceava, ROMANIA,* [2]*"Ştefan cel Mare" University, Faculty of Medicine, Suceava, ROMANIA.*

Aim/Introduction: Langerhans cell histiocytosis (LCH) is a rare disease, most common in childhood, occurring only in up to 8.9 per million children under the age of 15[1], and is consisting in abnormal clonal proliferation of Langerhans cells that can involve multiple organs. Positron emission tomography/computed tomography (PET/CT) has been widely used in tumor staging and therapeutic efficacy evaluation. However, in case of LCH there are few ^{18}F-fluorodeoxyglucose (FDG) PET/CT studies, especially for pediatric patients. This paper aimed to present our experience with the role of ^{18}F-FDG PET/CT in diagnosis, staging and management of pediatric patients with LCH. ***Materials and Methods:*** A 9 months (June 2024-March 2025) retrospective study of 9 examinations (age range, 18 months-16 years; mean age 2 y 10 m) with histologically proven LCH who underwent ^{18}F-FDG PET/

CT whole body scans, 8 of them under sedation. We compared PET/CT examinations with other complementary investigations such as CT (computed tomography), ultrasonography or X ray film in order to evaluate the usefulness, specificity and sensitivity of PET/CT. ***Results:*** For 2 cases PET/CT changed the classification from single system (SS) disease to multisystem (MS) disease, one directly from SS-single site to MS. FDG PET/CT was rated superior identifying lesions 56/25 (224%) compared with patient's complementary investigations. The most common localizations were bone (78%), lung (56%) and skin (11%). PET scans confirmed active LCH in 22/56 (39.28%). In 3 cases (33.33%) PET evaluation was decisive for therapeutic management because the lesions described on complementary imaging had no metabolic activity. ***Conclusion:*** According to our small data, whole body ^{18}F-FDG PET/CT can detect LCH activity and early response to therapy with greater accuracy than other imaging modalities in patients with LCH, particularly in the bones. In some cases, FDG PET/CT had changed the initial classification performed on complementary imaging, thus having a higher sensitivity even for staging. ***References:*** 1. Rodriguez-Galindo C, Allen CE. Langerhans cell histiocytosis. Blood. 2020 Apr 16;135(16):1319-1331.

EPS-217

SIOPEN Semiquantitative Score Adapted to 68GaDOTANOC PET/CT: A Superior DiseaseBurden Biomarker

N. Kundu, *D. Khan, S. Sagar, R. Kumar, A. K. Pandey, S. Bakhshi, R. Seth, S. Agarwala;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: mIBG scoring system was developed in 1995 for semi-quantification of the extent of MIBG uptake and prognostication outcome. The role of two commonly used semiquantitative MIBG scoring systems, i.e, the Curie score (CS) and the SIOPEN score as a prognostic indicator for high-risk neuroblastoma has been reported in both institutional and cooperative group trials, including trials within the COG and the SIOPEN Research Network. Both the CS and SIOPEN scoring systems are based on planar imaging findings. In our study, we aim to validate the SIOPEN skeletal score on 68GaDOTANOC PET maximumintensity projections (MIPs) and compare its burdenstratification capability with the conventional score derived from 131ImIBG planar imaging. ***Materials and Methods:*** Baseline DOTANOCPET MIPs and paired mIBG planar scans of 40 children were independently scored (0-60) across 12 skeletal segments by two experienced nuclear medicine physicians. Scores were correlated with risk factors such as age (< 18 months vs ≥ 18 months), bonemarrow biopsy (positive or negative) and urine catecholamine levels (elevated or normal). Wilcoxon and MannWhitney U tests explored intermodality and interriskgroup differences. ***Results:*** Median DOTANOC SIOPEN score was 19 (IQR 0-42) vs 6 (IQR 0-21) on mIBG ($P < 0.01$). Patients ≥ 18 months showed higher DOTANOC SIOPEN scores than infants (24 ± 22 vs 10 ± 16; $P = 0.046$), mirroring outcome risk. Positive marrow biopsies corresponded to markedly higher DOTANOC scores (41 ± 13) than negative biopsies (8 ± 14; $P < 0.001$). However, there was no significant difference in SIOPEN scores between the patients with elevated and normal urine catecholamine levels ($p=0.808$). mIBG scores followed the same trend but with weaker separation. Interobserver agreement was excellent ($\kappa = 0.92$). ***Conclusion:*** Applying the SIOPEN scoring to highresolution DOTANOC MIPs amplifies diseaseburden discrimination across established risk strata and correlates robustly with marrow involvement. DOTANOCSIOPEN scoring could refine upfront risk allocation and response quantification in future multicentre trials.

EPS-218

Correlation of [^{18}F]FDG PET/CT Metabolic Activity with Clinical Presentations and Outcomes in Children Diagnosed with Langerhans Cell Histiocytosis

E. Aslan, *N. Gülaldi;*
University of Health Sciences, Department of Nuclear Medicine, Ankara Bilkent City Hospital, Ankara, TÜRKIYE.

Aim/Introduction: [^{18}F]FDG PET/CT in paediatric Langerhans Cell Histiocytosis (LCH) plays an important role in detecting bone and non-bone lesions, evaluating treatment response, and identifying potential sites of disease recurrence. The clinical presentation of the disease is usually characterized by either bone lesions or lymph node involvement. This study aims to reveal the relation of metabolic parameters obtained by PET/CT with prognosis and treatment response and also blood ALP, LDH values in both groups. ***Materials and Methods:*** Eighteen patients were included in this study (10 months- 17 y.o. median age: 8.1). SUVMax, SUVmean, MTV, and TLG values calculated from the lesions with the highest metabolic activity uptake were extracted from 36 [^{18}F] FDG PET/CT images including the treatment follow-up of these patients. ALP and LDH values were analyzed within 4 days after PET/CT. Patients were divided into 2 groups; bone involvement and lymph node involvement. In addition, those with lung, thymus, high-risk organs (liver, spleen, bone marrow), and central nervous system involvement were identified. ***Results:*** Ten patients presented with lytic lesions in bones, 5 patients had lymph node involvement and 2 patients had both lymph and bone lesions. 2 patients had thymus involvement, 1 patient had CNS involvement and 2 patients had high-risk organ involvement. Patients with bone lesions and those without bone lesions were compared with the Wilcoxon Signed Rank test due to their non-homogeneous distribution and MTV values calculated from all positive bone lesions were significantly different from MTV values calculated from lymph nodes ($p<0.05$). 3 patients showed progression of their diseases within 1 year of diagnosis. Two of them had lytic bone lesions, and 1 had lymph node involvement. However, ALP, LDH SUVMax, SUVmean, and TLG values did not differ between the groups. The rate of complete response to treatment was higher in patients with lymph node involvement than in patients with bone involvement, and progression was more common in patients with lytic bone involvement. ***Conclusion:*** Metabolic activity values of bone lesions were higher than those of patients with lymph node involvement. Thus, patients with bone lesions showed a more aggressive pattern and showed an earlier treatment response than patients with lymph node involvement. The tendency of patients with bone involvement to show a more aggressive pattern during LHH staging with PET/CT suggests that the option of increasing treatment protocols and especially the addition of radiotherapy should be considered for this group.

EPS-219

Mean Parenchymal Transit Time measurement on Tc-99m EC Diuretic renography can help differentiate obstructed from non-obstructed kidneys and help monitor response post-pyeloplasty.

N. Gupta, *M. Ponnusamy, K. G, P. Mathiyazhagan;*
JIPMER, Pondicherry, INDIA.

Aim/Introduction: Diuretic renography is used to rule out pelviureteric junction obstruction (PUJO) in hydronephrotic kidneys. In addition to Normalised Residual Activity (NORA20) and Output Efficiency at 20 minutes (OE20), Mean parenchymal transit time (MPTT) measured through deconvolution analysis is a continuous quantitative parameter that can be used for follow up. The objectives of the study were to compare MPTT values obtained with Tc-99m EC diuretic renography in obstructed and non-obstructed hydronephrotic kidneys in children with suspected PUJO and to find the association with other transit time

parameters. ***Materials and Methods:*** In a cross-sectional analytical design, this study analysed data of Tc-99m EC diuretic renography performed in children suspected to have PUJO under the age of 18 years. The renography data was transferred to MATLAB and values of NORA20, OE20, and MPTT were obtained using separate algorithms. The contralateral non-hydronephrotic kidney was considered normal. Obstructed kidneys were identified based on the diuretic renography images and curve pattern by an experienced nuclear medicine physician. The MPTT values were compared between normal, hydronephrotic non-obstructed, and obstructed kidneys; and post pyeloplasty in affected kidneys. In addition, association between values NORA20, OE20 and MPTT was studied. ***Results:*** Analyzing data from 201 patients (396 renal units), the median MPTT in non-hydronephrotic (n=178), hydronephrotic non-obstructed kidneys (n=144), and obstructed kidneys (n=74) were 3.30 minutes (IQR: 2.91, 3.93), 5.69 (IQR: 4.10, 8.27), and 12.84 (IQR: 10.47, 14.88), respectively. A significant difference existed between the groups (p <0.01). Median NORA20 for hydronephrotic non-obstructed and obstructed kidneys were 0.47 (IQR: 0.02, 0.86) and 2.52 (IQR: 2.05, 3.06), while OE20 values were 77.34 (IQR: 64.41, 87.36) and 41.52 (IQR: 33.78, 50.60). There was a strong positive correlation between MPTT and NORA20 in hydronephrotic non-obstructed and obstructed kidneys (correlation coefficient: 0.84, p <0.01 and -0.87, p <0.01, respectively), and there was a strong negative correlation between MPTT and OE20 in obstructed kidneys (correlation coefficient: -0.81, p<0.01) but weak in the other two subgroups. The mean MPTT values pre and post pyeloplasty in obstructed kidneys (n=32) were 12.49 and 8.22 (p <0.01). ***Conclusion:*** MPTT values obtained on Tc-99m EC diuretic renography showed a significant difference between the hydronephrotic non-obstructed and hydronephrotic obstructed kidneys, implying that MPTT is significantly prolonged in obstructed kidneys. The MPTT values in obstructed kidneys showed considerable improvement after pyeloplasty, implying improvement in kidney function after an effective intervention. The MPTT values correlated with NORA20 and OE20 values.

Technologists' Track Oral Presentations 3 - Technologists Committee: Interdisciplinary Nuclear Medicine Workforce Sustainability and Training

OP-619

Technologist perspective in practice change and mitigations during the installation of two Total Body PET scanners in a busy department

S. Pereira[1,2], *G. Testanera*[1,2], *G. Cook*[1,2], *J. John*[1,2], *S. Chicklore*[1,2], *G. Krokos*[1,2], *S. Giles*[1,2];
[1]*King's College London, London, UNITED KINGDOM,* [2]*Guy's and St Thomas' Hospital NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: Kings College London (KCL)/Guys and St Thomas (GSTT) PET Centre has recently installed two Long axial field of view (LAFOV) PET/CT scanners, Biograph Vision Quadra, Siemens Healthineers. LAFOV PET scanners are highly sensitive and offer high-resolution, low-noise imaging with extended coverage. To fully leverage these advantages, a multidisciplinary team was formed to implement an efficient and reliable service. This transition posed several challenges including departmental redesign, staff training, and continuous adjustment of operational practices. Despite ongoing construction, scanning services continued uninterrupted throughout the installation. ***Materials and Methods:*** Before the installation, the mitigations included maximizing the patients' list by redirecting approximately 30 patients daily to our residual functioning scanners and outsourcing services, as well as extended hours of work during the week and weekend lists. During the installation, the layout of the department allowed for patient redirection to avoid unnecessary radiation doses to the building workers whilst parallel working. Following the installation of the first total-body PET scanner, imaging protocols were redesigned to increase the number of slots allocated for clinical studies. This optimization included decreasing the injected activity for patients and overall scanning time while rearranging the daily schedule to accommodate more complex studies, such as dynamic scans, paediatric scanning under general anaesthetic, and different traces. The staff were trained by the manufacturer on operating and performing quality controls. In-house training was provided to identify any knowledge gaps or protocol issues. ***Results:*** The mitigation strategies put in place prior to the installation ensured that patient throughput was maintained with minimal delays. After the first scanner went live, staff went through an adjustment period of a faster working pace whilst getting used to a new system, mainly due to the extended FOV. The redesign of the department allowed for an increase of 20% in the uptake bays and more spacious areas. The optimization of the imaging protocol, with a weight-based protocol and a reduction of the scanner time to 50%, permitted an increase in slots from two to three patients per hour. The department capacity has increased without compromising the comfort and experience of the patient. ***Conclusion:*** After a year of structural changes and process redesign, the PET Centre now operates two Quadra LAFOV scanners, providing a service that offers faster, more comfortable scans with lower radiation exposure and improved image quality. This advancement significantly boosts our capacity for clinical studies and supports complex and unique research opportunities.

OP-620

Exploring curriculum considerations to prepare future radiographers for an AI-assisted healthcare environment: a scoping review

C. Kammies[1], *E. Archer*[2], *P. Engel-Hills*[3], *M. Volschenk*[2];
[1]*University of Johannesburg, Johannesburg, SOUTH AFRICA,* [2]*Stellenbosch University, Cape Town, SOUTH AFRICA,* [3]*Cape Peninsula University of Technology, Cape Town, SOUTH AFRICA.*

Aim/Introduction: The integration of AI in various aspects of clinical radiography has sparked intense discussions about appropriate education and training, both for the existing and future workforce. Evaluating and integrating AI-related competencies into existing curricula requires an informed, considerate approach. Therefore, the scoping review maps the available evidence on the adjustments needed in the radiography curriculum to prepare radiography students for the demands of AI-assisted healthcare environments. ***Materials and Methods:*** A scoping review was conducted following the six-step Joanna Briggs Institute (JBI) methodology. Articles that focused on radiography education and technologies that incorporate AI were searched across four databases: EBSCOhost, PubMed, Scopus, and Web of Science for studies that were published from inception until October 2024. ***Results:*** Electronic database searches have retrieved 2 127 results. Title and abstract screening of 1 930 articles were completed. Data charting and the remaining steps of the scoping review, including dissemination, will be available by August 2025. Preliminary screening results show that radiographers are already adopting AI technologies into clinical practice, however, education and training of current and future radiographers are lacking. Educators need to be knowledgeable about AI to equip students for a workforce where AI will function as their "colleague." The incorporation of this technology may influence the relationship between patients and radiographers. Moreover, advancements

in AI-driven technologies hold significant potential to enhance patient-centred care. ***Conclusion:*** Despite the recognition that AI is being adopted in clinical practice, curriculum development is still in its early stages. However, the successful incorporation of AI tools into radiography education necessitates a balance between technological proficiency and a commitment to patient-centered care. As with the recognition that AI should form an essential part of the curriculum, the advocacy for radiographers to maintain the core value of patient-centred care has been strongly supported. Patient-centred care is fundamental in the radiography profession and the successful incorporation of AI education in the curriculum necessitates a balance between technological proficiency and a commitment to patient-centered care.

OP-621

A national collaborative initiative for knowledge sharing among nuclear medicine staff

C. Holm[1], *M. Hylle*[2], *T. Kirk Lehnskov*[3];
[1]*Odense University Hospital, Odense C, DENMARK,* [2]*Aalborg University Hospital, Aalborg, DENMARK,* [3]*Copenhagen University Hospital, Copenhagen, DENMARK.*

Aim/Introduction: In Denmark, there are 16 nuclear medicine departments across five regions. While various forums exist to facilitate knowledge sharing among specialists and leadership, there has been no dedicated platform for frontline staff—those who interact directly with patients and play a crucial role in daily routine. Recognizing this gap, we established a structured online forum to enhance collaboration, promote professional development, and share best practices for nuclear medicine departments in Denmark. The purpose of this initiative is to provide a space where nuclear medicine staff can discuss operational challenges, innovative techniques, and potential areas for collaboration in research and clinical practice. ***Materials and Methods:*** The first national online meeting was conducted on April 3, 2024, with participation from all nuclear medicine departments in Denmark. The session lasted two hours and was designed as an interactive knowledge sharing platform. A pre-meeting questionnaire was distributed to department representatives before each session. The questionnaire aimed to identify key topics of interest, challenges faced by staff, and areas where shared experiences could improve clinical practice. Participation is flexible on a department level, i.e. different representatives from individual departments may attend different meetings based on their expertise and relevance. Following each session, all attendees receive a contact list to encourage ongoing communication, networking, and potential collaborative efforts in research and clinical improvements. The online meetings are scheduled to take place 3 times a year, while there will be a physical meeting. ***Results:*** Over the course of four meetings, participants reported increased commitment to cross-departmental discussions, leading to a broader exchange of best practices in patient care, workflow optimization, and quality assurance in nuclear medicine. The forum also served as a catalyst for interdepartmental collaborations, enabling staff to explore opportunities for research partnerships and innovation within the field. Feedback from participants highlighted the benefits of structured knowledge sharing, including improved standardization of procedures and enhanced professional support across departments. ***Conclusion:*** After four successful online meetings with nationwide representation, our findings suggest that this initiative to facilitate knowledge sharing has considerable improved communication and collaboration among nuclear medicine staff on a national scale. Minor adjustments to the meeting structure after the initial sessions have optimized the format, making discussions more efficient and relevant. Moving forward, this initiative has the potential to expand into a structured, long-term professional network, supporting continued education, innovation, and research across Denmark's nuclear medicine departments.

OP-622

Developing Interdisciplinary VR-Education on Scanxiety: A Technologists Perspective

C. Van Den Haak[1], *A. J. Nijkerk*[2], *J. J. Pool*[2], *E. W. Elings*[2], *J. C. Houting*[2], *J. A. Adam*[2];
[1]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC and University of Amsterdam, Amsterdam, NETHERLANDS.*

Aim/Introduction: One of the advantages of working in an academic hospital as a technologist is direct involvement in educational activities. Scanxiety, the anxiety before, during and after medical imaging has hardly been highlighted in medical education up to now. However, education on this aspect is necessary, not only for the patient but also for the healthcare professionals, such as technologists. Current education of technologists focuses on execution and quality of the scans, but education on patient perspective is missing. Training empathy as a competence is seen as an essential part of making healthcare professionals 'future-proof'. Virtual reality offers an easily applicable unique insight into the scan procedure from the patient perspective, without the students having to undergo a sham scan themselves. Our aim was to develop a novel interdisciplinary educational material to create awareness for the patient perspective and scanxiety. ***Materials and Methods:*** An interdisciplinary team was gathered to develop the educational material, consisting of a nuclear medicine physician, technologist, medical educators and audiovisual crew. All members were asked to participate from their own perspective. In the case of the technologists, the different roles of the technologist are shown, such as informative, operational and supportive. The Scanxiety Educational Module consists of an introduction, an 8-minute VR film and a debriefing. VR, as an educational design, was chosen to convey the patient perspective in an immersive way. To create the script for the VR film, the experiences of actual patients and the technologist have been gathered. The film shows a patient journey, from the waiting room to the preparation, getting the IV and the actual scan. During the film, the patient's thoughts become audible, based on testimonials from healthcare professionals who have undergone medical imaging themselves. ***Results:*** The introduction informs the students on the background of patient perspective and scanxiety. The VR film evokes emotions, and a change in perspective is initiated, and the student's empathy is called upon. During the debriefing, the students' experience is discussed from different angles with an emphasis on empathy and shared vulnerability. Students are also given the assignment to provide concrete suggestions for improvement with regard to patient experience. ***Conclusion:*** Developing educational material in an interdisciplinary team provides several benefits. Emphasizing the technologists' perspective provides additional value to the education on patient experience and scanxiety. Participating in educational projects as a technologist is inspiring and a welcome addition to the technologists' professional activities.

OP-623

From Doctors to Technologists: Operational Efficiency following role reassignment in sentinel node procedures

A. Moura, *C. Rodrigues;*
Imperial College NHS Healthcare Trust, London, UNITED KINGDOM.

Aim/Introduction: Sentinel lymph node imaging for melanoma is a time-sensitive diagnostic procedure. Until 2023, this involved a sequence of activities starting with application of numbing cream (5% lidocaine/prilocaine) and concluding with the completion of SPECT/CT imaging. Historically, nuclear medicine doctors had performed intradermal administration of radiopharmaceuticals. To

optimise workflow and resource utilisation, the responsibility of injection was moved to clinical technologists. This study evaluates the impact of this role change on the overall procedural time, with a specific focus on the total time patients spent on the scanner and in the department. ***Materials and Methods:*** A retrospective analysis was conducted on twenty-two sentinel node melanoma cases performed between January and September 2023. The cases were divided into two cohorts: injections performed by doctors (n=12) and injections performed by technologists (n=10). Key timepoints were recorded, including numbing cream application, radiotracer draw-up and injection, CT acquisition, and final scan completion. The primary metric was the total elapsed time from numbing cream application to scan completion on RIS (radiology information system). Comparative trends were visualised using a line plot, and descriptive statistics were used to compare efficiency between the two roles. ***Results:*** The scans led by the technologist group demonstrated a consistent and significantly reduced procedural time, with an average duration of approximately 101 minutes (+/- 23 minutes), compared to the doctor cohort's average of around 132 minutes (+/- 33 minutes). Moreover, the technologist-led cases exhibited lower variability, suggesting improved standardization. In contrast, doctor-led cases showed greater time fluctuations. The data suggests that delegating injection responsibilities to technologists not only reduces the overall scan timeline but also enhances operational predictability. ***Conclusion:*** The transition from doctor-led to technologist-led intradermal injections in sentinel node melanoma imaging is associated with measurable improvements in workflow efficiency. The observed time savings can enhance patient throughput, reduce resource strain, and support better scheduling flexibility. Importantly, this change also aligns with broader trends in healthcare, promoting role optimisation and inter-professional collaboration. Further prospective studies are recommended to evaluate patient satisfaction, diagnostic outcomes, and scalability of this model to other nuclear medicine procedures.

OP-624

More Than Just Teaching: The Hidden Impact of the London Nuclear Medicine Practice Educators

H. Chandler[1,2], *C. Rodrigues*[1,3];
[1]*London Imaging Academy/University College Hospitals London, London, UNITED KINGDOM,* [2]*London Northwest University Healthcare NHS Trust, London, UNITED KINGDOM,* [3]*Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.*

Aim/Introduction: The introduction of Nuclear Medicine Practice Educators (PE) in London marked a pioneering initiative aimed at addressing the gap in educational support for learners in the Nuclear Medicine field. This role, typically filled by a registered healthcare professional, facilitates training and mentorship alongside clinical and academic teams [1]. Following the implementation of two PEs in London, this work now evaluates the impact, challenges, and opportunities that have arisen from this role, as well as future directions. ***Materials and Methods:*** Building on the initial engagement with 22 hospital sites across London, with 16 expressing a need for PE support, a comprehensive follow-up survey and ongoing hospital site visits were conducted. Feedback from clinical staff, trainees, and managers was gathered to assess the effectiveness of the initiatives introduced, with particular focus on continued gaps, evolving needs, and the role of PEs in addressing these. ***Results:*** The impact of the PE role has been substantial, with notable improvements in key areas such as the competency of mentors and assessors, standardisation of training materials, and increased exposure to diverse clinical scenarios. Notably, the PEs' efforts in bridging international knowledge gaps and supporting the development of soft skills in learners have been particularly impactful. Regional collaboration through workforce meetings, the launch of online resources via the London Imaging Academy, and face-to-face teaching sessions have further strengthened educational delivery. Additionally, educational and well-being newsletters, interactive study days, and university collaborations have created stronger engagement with prospective Nuclear Medicine professionals. Sites also found that the PE's strengthened inclusive networking across sites and built effective partnerships for cross-departmental collaboration. Several responses emphasised the need for the role to be full-time and extended, to be able to fully support departments long-term. ***Conclusion:*** The establishment of the Nuclear Medicine Practice Educator role has made a significant, positive impact on training and development in the field within London. By addressing critical gaps in training, mentorship, and departmental needs, this initiative has been well-received across the region. The feedback from stakeholders demonstrates the growing importance of this role, and future evaluations will continue to assess its long-term impact and viability, shaping the future of Nuclear Medicine practice and education across London. ***References:*** [1] Health Education England (n.d.). Practice Educators: Imaging. Available from: https://www.hee.nhs.uk/our-work/cancer-diagnostics/imaging/practice-educators.

OP-625

The Role of Technologists in the TOTEM Study: Operational Challenges and Fostering a Research Culture in a 2 LAFOV PET Scanner Department

G. Testanera*, S. Lam, S. Pereira, J. Joemon, S. L. Giles, G. Cook, S. Gould, P. K. Marsden, L. Agoro;*
King College London, London, UNITED KINGDOM.

Aim/Introduction: Long Axial Field of View (LAFOV) PET scanners offer high-resolution, low-noise imaging with extended coverage, reduced radiation dose, and shorter scan times than standard PET/CT[1]. However, global experience and standardised protocols for LAFOV PET remain limited. At Guy's and St Thomas (GSTT)/King's College London (KCL) PET Centre, after two LAFOV PET scanners were installed, we launched the ethically approved "TOTEM - Total Body PET Exploring new iMaging" (IRAS: 339077) study. This study aims to optimise imaging protocols, explore data analysis methods, and improve scan efficiency while minimising radiation exposure. The expanded capacity creates an opportunity to embed research culture within a busy clinical setting, even among staff without prior research experience. ***Materials and Methods:*** TOTEM seeks to recruit 9999 participants over five years. All adult patients undergoing standard LAFOV PET scans are eligible to consent for use of anonymised data. Selected participants may also undergo additional research scans, including dynamic or delayed acquisitions, as part of TOTEM substudies. Nuclear Medicine Technologists (NMTs) and Radiographers are responsible for patient engagement, obtaining consent, and entering data into a secure REDCap database. Anticipated challenges included time constraints, training needs, and integrating research into routine clinical workflows. ***Results:*** All NMTs and Radiographers completed Good Clinical Practice (GCP), study protocol, consent, and REDCap data entry training. Over 30 participants were recruited within the first few weeks. Although these tasks are additional to routine responsibilities, shorter clinical scan times have created extra capacity for research-related activities. Data management challenges were mitigated through infrastructure improvements and streamlined data collection. An unforeseen challenge was the reduced interval between referral and appointment due to LAFOV efficiency, limiting time to send study information in advance. To address this, an ethics amendment will be submitted to allow same-day consent for data sharing. For additional research scans, the 24-hour information period remains mandatory. ***Conclusion:*** Close collaboration among technologists, radiographers, administrative staff, clinicians, and research teams has been vital for the successful implementation of TOTEM. Early identification

of operational challenges enabled timely solutions. The team has embraced an evolving research culture, which will support an expanding portfolio of commercial and non-commercial studies as part of the UK National PET Imaging Platform (NPIP)[2]

OP-626

Embedded Student Program - Delivering a sustainable workforce pipeline to address a critical Nuclear Medicine Scientist shortage across Queensland, Australia.

T. Pearson[1], *S. Daniel*[1], *L. McBride*[2], *E. Gacitua*[2];
[1]*Metro North Hospital & Health Service, Brisbane, AUSTRALIA,*
[2]*Office of the Chief Allied Health Officer, Brisbane, AUSTRALIA.*

Aim/Introduction: Continued growth of nuclear medicine services, combined with persistent critical workforce shortages has resulted in significant pressure on service delivery within a large public health organisation of 130,000 employees in Australia. These challenges are disproportionately experienced in regional areas, where positions are frequently advertised multiple times attracting a single qualified applicant. A required workforce pipeline to address Nuclear Medicine Scientist (NMS) workforce current and future demands across an area the approximate size of Western Europe. ***Materials and Methods:*** To understand the problem, targeted collection and analysis occurred together with a review of existing models available in Australia and overseas. Model development included broad collaboration across multiple stakeholders focussed through a Statewide forum. Participation included engagement with the public and private sectors, university partners, professional bodies, and unions. This forum outlined that the required solution must support local training models across Queensland (regional and metropolitan areas) and be accessible for three target groups: 1. mature-age students, 2. school leavers, and 3. First Nations people. The forum identified that any model must address student clinical 'placement poverty', a significant barrier to healthcare students in Australia completing their qualifications unpaid clinical placement requirements. ***Results:*** The Queensland NMS Embedded Student Program (ESP) launched in March 2025 in collaboration the Royal Melbourne Institute of Technology (RMIT). This unique and novel ESP for training was developed and implemented to meet public health needs in Queensland. The ESP supports the delivery of theoretical training through distance education in conjunction with student's meeting their required clinical placement objectives locally throughout the university semester. In its first year of delivery, the ESP attracted high quality recruits across each of the 8 public health sites, with offers in each of the 3 targeted groups. ***Conclusion:*** 8 ESP students commenced in March 2025 across Queensland Health, aligning with the NMS workforce pipeline needs. The ESP students can also support service needs as paid assistants during their university semester breaks. Formal evaluation of the program from a public health perspective is currently underway and will follow the first cohort through their studies. This presentation will showcase the journey to arrive at a model to deliver a workforce pipeline for NMS in Queensland, as well as the details of novel the ESP. It is anticipated this model can be used to support NMS workforce pipelines in other regional areas without access to a local university training provider.

OP-627

Enhancing Nuclear Medicine Services Through a Hybrid, Collaborative Workforce: Integrating Technologists and Radiographers

M. Casanova Martins*, N. Hopson;*
Swansea Bay University Health Board, Swansea, UNITED KINGDOM.

Aim/Introduction: As nuclear medicine continues to advance with hybrid imaging modalities such as PET-CT and SPECT-CT, the boundaries between traditional professional roles are becoming increasingly blurred. Diagnostic radiographers bring critical expertise in anatomical imaging, while nuclear medicine technologists contribute in-depth knowledge of radiopharmaceuticals and functional imaging. The integration of these complementary skills presents a unique opportunity to develop a hybrid, collaborative workforce model aimed at improving clinical outcomes and service efficiency. This study aims to explore the development and impact of a hybrid workforce model that fosters collaboration between nuclear medicine technologists and diagnostic radiographers and to evaluate how this approach can enhance patient care, workflow efficiency, and professional development within nuclear medicine departments. ***Materials and Methods:*** We performed a qualitative analysis of workforce integration strategies within multiple UK nuclear medicine departments. Data were gathered through structured staff interviews and workflow observations to assess the feasibility, implementation challenges, and impacts of creating hybrid roles. Outcomes evaluated included patient throughput, staff satisfaction, imaging service diversification, and overall operational effectiveness. ***Results:*** Departments employing collaborative models reported increased operational efficiency, particularly in high-throughput imaging environments. The shared expertise between radiographers and technologists enabled more streamlined workflows, reduced patient appointment times, and improved scanner utilisation. Staff expressed higher job satisfaction due to diversified responsibilities and interprofessional learning opportunities. Crucially, the hybrid workforce model facilitated the expansion of the imaging portfolio, including the introduction of calcium scoring integrated into myocardial perfusion (MPS) protocols, diagnostic-quality CT head imaging as part of dementia studies, and the use of low-dose, mA-modulated diagnostic CT acquisitions to complement hybrid imaging for bone and other isotope scans. These developments enhanced the diagnostic value of nuclear medicine examinations and improved the overall patient diagnostic pathway. Despite clear benefits, challenges persisted around regulatory scope clarity, consistent training standards, and the need for standardized competency frameworks. ***Conclusion:*** Integrating nuclear medicine technologists and diagnostic radiographers into a cohesive hybrid workforce provides substantial benefits, including improved patient care, expanded imaging capabilities, and increased departmental flexibility. To further support this model's widespread adoption, collaboration between national professional bodies and regulators is necessary to establish unified competencies, robust cross-training curricula, and clear governance structures. This hybrid approach will be critical to addressing future clinical and technological advancements in nuclear medicine.

TROP Session - Case Report Session 1: Case-based Learning in Theranostics

OP-628

Molecular Response Assessment of combined intravesical Radio-Ligand-Therapy (iRLT) and systemic chemotherapy of Muscle Invasive Bladder Cancer patients by liquid biopsy testing from urine - the RadioMolecularIncubator Experience within the Bladder BRIDGister

R. Wirtz[1], *E. Storz*[2], *M. von Brandenstein*[2], *F. Friedersdorff*[3], *D. Barski*[4], *T. Otto*[4], *J. Graff*[5], *M. Waldner*[5], *E. Veltrup*[1], *P. Gehle*[1], *R. Hake*[6], *S. Eidt*[6], *C. Rieger*[2], *T. Ecke*[7], *A. Heidenreich*[2], *L. Greifenstein*[8], *R. P. Baum*[8];
[1]*STRATIFYER Molecular Pathology GmbH, Köln, GERMANY,* [2]*Dpt. of Urology, University Clinic Cologne, Köln, GERMANY,* [3]*Dpt. of Urology, Charité - Universitätsmedizin Berlin, Berlin, GERMANY,* [4]*Dpt. of Urology, Rheinlandklinikum, Neuss, GERMANY,* [5]*Dpt. of Urology St. Elisabeth Hospital,, Köln, GERMANY,* [6]*Institute of Pathology at the St. Elisabeth Hospital, Köln, GERMANY,* [7]*Dpt. of Urology, HELIOS Klinik Bad Saarow, Berlin, GERMANY,* [8]*CURANOSTICUM Wiesbaden-Frankfurt, Wiesbaden, GERMANY.*

Aim/Introduction: Patients with Muscle Invasive Bladder Cancer (MIBC) achieving pathological complete response (pCR) upon neoadjuvant chemotherapy (NACT) have improved prognosis. Intravesical Radioligandtherapy (iRLT) is effective in NACT resistant tumors. While gene expression profiles from tumor tissues are predictive of response, no expression profiling of tumor cells in urine is established to monitor tumor response towards ongoing treatment. However, tumor specific gene expression in urine samples may enable non-invasive testing and distinguish responding from non-responding tumors for early treatment adoption. ***Materials and Methods:*** Tumor cells were isolated from 10 ml urine collected before TUR biopsy and before each cycle of treatment as well as before deep TURB or cystectomy. Similiarly whole urine was drawn before each cycle. FFPE tissues as well as matched urine samples from patients receiving systemic chemotherapy +/- intravesical Radioligandtherapy were prospectively collected, RNA was extracted, and relative gene expressionwas analyzed by RT-qPCR. Dynamics of expression profiles were compared to pathological outcome. ***Results:*** A 67-y-o male suffering a pT2a high grade bladder cancer with heterogenous cancer histology was selected based on high CXCR4 expression on mRNA and protein level. PET/CT Imaging by Ga^{68} CXCR4 confirmed substantial uptake in the tumor tissue. Subsequently, Lu^{177} CXCR4 was instilled one week before application of 3 cycles ddMVAC. Second PET/CT Imaging by Ga^{68} CXCR4 after 6 weeks revealed molecular complete response, which was validated histopathologically by analysis of additional deep TUR biopsy tissue. Molecular tissue analysis comfirmed tumor heterogeneity by detecting a high expression of luminal KRT20 and basal KRT5 at initial TUR biopsy. Molecular urine analysis similarly revealed high expression of both KRT5 and KRT20 mRNA. After intravesical RLT the KRT5 and KRT20 expression dropped 4 fold, indicating a significant tumor response within one week of treatment due to Lu^{177} CXCR4 treatment alone. Subsequent chemotherapy cycles further reduced the KRT5 and KRT20 mRNA levels from urine samples stepwise. Importantly, when looking at cells isolated from urine this effect was particularly striking with KRT20 mRNA becoming completely undetectable before the 3rd chemotherapy cycle. ***Conclusion:*** To the best of our knowledge this is the first-in-human clinical efficacy proof of intravesical radioligand therapy (iRLT) targeting CXCR4 combined with neaoadjuvant chemotherapy (NACT) in MIBC. Gene expression profiles from urine samples recapitulated clinical response in vitro. Molecular urine profiling is feasible and may help to adopt treatments early on, which will be analyzed in upcoming phase I/II iRLT umbrella trials of the Bladder BRIDGister.

OP-629

Role of Post-Therapy SPECT/CT in Detecting Pseudoprogression during Lu-177 PSMA Radioligand Therapy: A Case Report

K. Resuello*, W. Lim, P. Fernando;*
St. Luke's Medical Center - Global City, Taguig, PHILIPPINES.

Aim/Introduction: Lu-177 PSMA (LuPSMA) radioligand therapy has shown advancement in treating metastatic castration-resistant prostate cancer (mCRPC). However, early assessment of therapeutic response is complicated by the possibility of pseudoprogression and imaging flare, which can initially mimic disease progression and potentially lead to premature changes in treatment strategy. While pseudoprogression is known in the context of modalities such as immune checkpoint inhibitor therapy, current literature is scarce on its prevalence and implications during LuPSMA therapy. ***Materials and Methods:*** We report a case of a 76-year-old male with mCRPC who received three cycles of Lu-177 PSMA therapy (± 8.15 GBq every 5 to 6 weeks). Imaging treatment response was evaluated by reviewing the patient's baseline F-18 PSMA PET/CT, as well as the planar and SPECT/CT gamma camera images obtained 14-16 hours after each cycle of Lu-177 PSMA therapy. Concordance of biochemical response was verified through review of changes in PSA levels between cycles. ***Results:*** Baseline PET-CT showed metastatic PSMA-avid left abdominopelvic adenopathy, left proximal ureteral mass, and skeletal lesions. After cycle 1, there was interval increase in the number of skeletal lesions, which was concordant with an interval increase in PSA. The cycle 2 post-therapy scan revealed significant increase in extent of LuPSMA-avid bone lesions, now more diffuse, accompanied by a further rise in PSA. However, PSA decline was noted upon administration of cycle 3 of therapy, and there was concomitant regression in PSMA activity of the skeletal disease on post-therapy imaging, suggesting of an resolving imaging flare. ***Conclusion:*** This is the first instance of pseudoprogression encountered in our institution after several years of experience in performing Lu-177 PSMA radioligand therapy. It highlights the value of post-therapy SPECT/CT imaging after every therapy cycle. Such finding may support the administration of 3 cycles as a minimum standard before assessing overall treatment benefit. Further studies are suggested on the implications of such phenomenon on patient prognosis and overall survival. ***References:*** 1. OP-630

Non-Invasive Management of an Asymptomatic Lu-177-PSMA-617 Extravasation: A Case Report with Scintigraphic and Dosimetric Evaluation

Y. Cras, *M. Borsali, P. Lacassagne, L. Ferreol, D. Deandreis, C. Garcia;*
Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: Extravasation of therapeutic radiopharmaceuticals such as Lu-177-PSMA-617 is rare but may lead to local complications. We report a case of asymptomatic extravasation detected incidentally after injection, managed non-invasively with dosimetric and scintigraphic follow-up. ***Materials and Methods:*** A 77-year-old man with multimetastatic castration-resistant prostate cancer, previously treated with docetaxel and three lines of ARPI, received 6886 MBq of Lu-177-PSMA-617. Post-therapeutic whole-body scintigraphy performed 4 hours after injection revealed focal extravasation at the injection site. The patient reported no pain, erythema, or edema. Management consisted of limb elevation, massage, arm contraction-relaxation exercises, and warm sodium chloride compresses during a 24-hour hospital stay. Scintigraphic follow-up using a CZT-based SPECT/CT system was conducted at 4 hours (D0), 24 hours (D1), and 5 days (D5) post-injection. A volume of interest (VOI) was drawn on each scan with standardized thresholding. Residual activity was quantified at each time point. ***Results:*** The extravasated activity was estimated at 1288 MBq (19% of the injected activity) at D0. It decreased to 8 MBq (0.1%) at D1 and to 2 MBq (0.03%) at D5, corresponding to a >99% reduction within the first 24 hours. The absorbed dose at the site was estimated at 6 Gy. No clinical sequelae were observed at the 3-week follow-up. ***Conclusion:*** This case demonstrates that Lu-177-PSMA-617 extravasation may be asymptomatic and can be effectively managed with non-invasive strategies. Sequential imaging allows accurate monitoring of activity clearance and dosimetric impact. Routine post-injection assessment is recommended to detect and manage such events, ensuring patient safety in radioligand therapy.

OP-631

Validation of SPECT-based dosimetry in 177Lu-DOTATATE peptide receptor radionuclide therapy: ex-vivo confirmation after liver transplantation

C. Avigo[1], *F. Bonutti*[2], *L. Barresi*[1], *S. Peric*[1], *V. Cherchi*[2], *U. Baccarani*[2,3], *E. Scarpa*[2], *A. Mangogna*[2], *G. Fanetti*[1], *E. Borsatti*[1], *A. Drigo*[1];
[1]*Centro di Riferimento Oncologico di Aviano (CRO) IRCCS, Aviano, ITALY,* [2]*University Hospital, Udine, ITALY,* [3]*University of Udine, Udine, ITALY.*

Aim/Introduction: Peptide-receptor-radionuclide therapy (PRRT) with 177Lu-DOTATATE is an emerging treatment for patients with advanced gastro-entero-pancreatic neuroendocrine neoplasms (GEP-NENs). Accurate estimation of the radiation dose delivered to both tumours and healthy organs is essential for optimising this therapy. Radiopharmaceutical uptake can be quantified by measuring the gamma emissions from 177-Lu using serial SPECT imaging. This study aimed to validate the estimated activity in a liver metastasis by ex-vivo measurement of a transplanted liver specimen, in order to improve the accuracy of personalised dosimetry. ***Materials and Methods:*** A patient with progressive liver GEP-NEN and enlarged hepatic hilar lymph nodes underwent three cycles of PRRT. Six days after the third cycle, the patient received a liver transplantation [1]. A 68cc metastasis sample was excised from the liver and analysed using a solid-state detector (HPGe) to directly measure the tissue radioactivity. The main hepatic metastasis was segmented using MIM software on serial SPECT scans (since it appeared morphologically indistinguishable from normal liver on CT images), acquired at four time points following the first cycle of treatment (5h, 24h, 48h, 168h). Due to the lack of standardised guidelines for GEP-NEN lesion segmentation, two thresholds were used: 21% (87,25cc) and 10% (175,11cc). The personalised mono-exponential time-activity curve (TAC) was estimated and then rescaled with the lesion activity measured 24h after the third treatment cycle, allowing the prediction of the 177-Lu activity in the metastasis at the time of transplantation. ***Results:*** Spectroscopic analysis of the lesion sample (68cc) measured 12,6±0,9MBq of activity at the time of transplant. In-vivo SPECT-based estimates for the full lesion were 33±7 MBq (TAC for 21% threshold 87,25cc) and 35±8 MBq (TAC for 10% threshold 175,11cc). Assuming homogeneous activity distribution, and rescaling for the volume, activity within the 68cc metastasis sample was estimated at 25±5 MBq (21% threshold) and 14±3 MBq (10% threshold). ***Conclusion:*** Liver transplantation enabled direct validation of SPECT-based dosimetry. The ex-vivo measurements closely matched the predicted values, particularly for the lesion segmented with the 10% threshold. The discrepancy observed with the 21% threshold may be due to the peripheral sampling of the lesion. The ability to accurately assess the patient-specific radiation dose is crucial for improving the safety and efficacy of PRRT in GEP-NEN patients, thereby optimising treatment outcomes while minimising the risk of adverse effects. ***References:*** [1] Bonutti et al.,Surgical staff doses during liver transplantation on a patient undergoing Lu-177-DOTATATE radioligand therapy, Radiation Protection Dosimetry, 2025, https://doi.org/10.1093/rpd/ncaf026.

OP-632

From Diagnosis to Treatment: A Multimodal Journey in Metastatic PanNET: A Case Report

R. Marao, *D. Barbosa, D. Silva, N. Vasconcelos, I. Próspero, J. Ferro, L. Violante, S. Fontão de Castro, R. Ferreira, I. Lucena Sampaio;*
Instituto Português Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: Neuroendocrine neoplasms (NENs) are a heterogeneous group of tumours, that can display different degrees of differentiation between and within lesions. [68Ga]-DOTA-TOC-PET/CT plays a key role in staging, treatment planning (including patient selection for peptide receptor radionuclide therapy - PRRT), and follow-up of patients with well-differentiated NENs. [^{18}F]FDG PET/CT may offer complementary data in cases that exhibit or are more likely to exhibit aggressive behaviour. Therapeutic decision should be based on key features like proliferative activity, somatostatin receptor expression, tumour growth rate, disease extension and functionality. In patients with disease progression under somatostatin analogues (SSA), several therapeutic options are available, including PRRT or, in cases of liver-only disease, locoregional therapies, such as embolization or selective internal radiation therapy (SIRT). ***Materials and Methods:*** We present the case of a 54-year-old man with metastatic functional pancreatic NET (gastrinoma; G2; mitotic count: 4/2mm^2; Ki-67: 3-20%). Since diagnosis in 2020, the patient started SSA and underwent surgical resection of the primary tumour, lymph nodes, and three hepatic metastases, followed by two sessions of hepatic embolization (February and July 2021), with clinical and imaging stability for 2.5 years. In March 2024, the patient showed clinical progression, confirmed by elevated gastrin and chromogranin A levels and liver disease progression documented on [68Ga]-DOTA-TOC PET/CT. Due to rapid tumor progression, an additional [^{18}F]FDG PET/CT was performed, detecting intense uptake in the largest hepatic lesion, while the remaining lesions were FDG-negative. A multidisciplinary tumour board proposed a combined approach: SIRT targeting the FDG-avid lesion, followed by PRRT. The patient underwent SIRT with Holmium-166 microspheres, delivering 7.4 GBq and an absorbed tumour dose of 186 Gy. ***Results:*** Following SIRT, the patient reported significant clinical improvement, accompanied by a marked biochemical response,

with decreased gastrin (2824 to 348 pg/ml) and chromogranin A (597 to 155.4 ng/ml) levels. Additionally, the [^{18}F]FDG PET/CT revaluation showed no significant uptake in the previously FDG-avid hepatic lesion, suggesting effective local response. Shortly after, a new [68Ga]-DOTA-TOC PET/CT was performed, revealing increased extent and intensity of the remaining hepatic lesions, prompting consideration for PRRT. ***Conclusion:*** This case highlights the complementary role of dual imaging with [68Ga]-DOTA-TOC and [^{18}F]FDG PET/CT in characterizing tumour heterogeneity and guiding personalized, multimodal treatment strategies in patients with metastatic NETs. Moreover, this case indicates that radioembolization should be taken in consideration as an effective option, isolated or in combination with PRRT, in the management of liver-limited or predominant disease.

OP-633

Taming the Insulinoma: A Case of Glycaemic Recovery with [^{177}Lu]Lu-DOTATATE

D. Carvalho, *S. Barata, S. Paiva, I. Casimiro, J. Silva, L. Lemos, M. Monteiro, P. Lapa, G. Costa;*
ULS Coimbra - HUC, Coimbra, PORTUGAL.

Aim/Introduction: Insulinomas are rare pancreatic neuroendocrine tumours (NETs) characterized by autonomous insulin secretion, leading to recurrent hypoglycaemia, which can be fatal. Peptide receptor radionuclide therapy (PRRT) is indicated for metastatic or unresectable cases with adequate somatostatin receptor expression, as recommended by ENETS 2023 guidelines. ***Materials and Methods:*** We report the case of a 38-year-old male with history of HIV found unconscious due to a severe hypoglycaemia episode. Biochemical evaluation revealed hyperinsulinemia, imaging identified a pancreatic mass metastasis and histopathological confirmed a well-differentiated NET G2. The patient initiated diazoxide, continuous administration of hypertonic glucose and high-dose corticosteroids and was referred to our tertiary centre where he underwent multidisciplinary assessment. Given the extent of disease, and especially due to severe hypoglycaemia, he was proposed to initiate pasoreotide and PRRT was planned. ***Results:*** The hospital stay was marked by multiple, serious and life-threatening infections and complications attributed to immunosuppression and high-dose corticosteroids which required the transfer of the patient to a High-Dependency Care Unit. At this time the patient's clinical situation was very serious, he was not responding to antibiotic treatment, and there was a very high risk of death. The only way to save the patient was to reduce corticosteroid but, for that to be possible, a better control of hypoglycaemia episodes was needed. The pasireotide failed to control insulin secretion and the patient was in no condition for chemotherapy. Therefore, [^{177}Lu]Lu-DOTATATE was the only hope of controlling hormone secretion and to save the patient's life. In the 5 weeks following the 1st-cycle of PRRT, there was no improvement of hypoglycaemia. The team was already disappointed when, suddenly, glycaemic control began to improve. That allowed gradual withdrawal of hypertonic-glucose, progressive reduction in the corticosteroid and with this, the respiratory infection also began to improve. After clinical improvement and cessation of corticosteroids, the patient remained asymptomatic and normoglycemic without pharmacological support. The patient has already received three cycles of [^{177}Lu]Lu-DOTATATE and is scheduled to receive the fourth. Post-treatment whole-body-SPECT/CT scans demonstrated progressive reduction in radiotracer uptake in known lesions. This finding, along with clinical improvement, is consistent with good therapeutic response. ***Conclusion:*** This case highlights the therapeutic potential of PRRT in achieving glycaemic control in metastatic insulinoma unresponsive to conventional medical therapy that, particularly in this case, also saved the patient's life by allowing reduction of the corticosteroids dose.

OP-634

Ramsay-Hunt Syndrome and Encephalitis following [^{177}Lu]Lu-DOTA-TATE: a case report

F. Silva-Ribeiro, *B. Martins, F. P. Branco, V. C. Sousa;*
Unidade Local de Saúde de Loures / Odivelas, Lisbon, PORTUGAL.

Aim/Introduction: Ramsay-Hunt Syndrome (RHS) is caused by the reactivation of the varicella-zoster virus (VZV) within the geniculate ganglion of the facial nerve. It presents as a triad of ipsilateral facial paralysis, vesicular rash, and otalgia—the latter often being the initial presenting symptom. Although various triggering factors are recognized, no association has been established between RHS and [^{177}Lu]Lu-DOTA-TATE treatment. ***Materials and Methods:*** The patient's clinical records were collected and analyzed. A comprehensive literature search was conducted using the PubMed database and Cochrane Library to identify reported cases, along with prior pharmacovigilance reports to further contextualize the present finding. ***Results:*** A 79-year-old male with a neuroendocrine tumor of the small intestine (high-grade, Ki-67 index of 30%), and no other relevant medical history, was admitted to hospital with a 2-day history of nausea, vomiting and weight loss associated with fever, left otalgia and vertigo 16 days after the 2nd cycle of [^{177}Lu]Lu-DOTA-TATE (Lutathera®), which was completed without acute complications. No introduction of new medications occurred during this period. Diagnostic hypotheses included left otitis and hypovolemic hyponatremia. Although the tumor was classified as high-grade, the patient exhibited intense somatostatin receptor expression, minimal [^{18}F]FDG uptake, no bulky disease or symptoms. Given the patient's advanced age, first-line treatment with Lanreotide was initiated. Upon disease progression with metastatic involvement of the liver, bone, and peritoneum, with sustained high somatostatin receptor expression and no [^{18}F]FDG/[^{68}Ga]Ga-DOTANOC mismatch, treatment with [^{177}Lu]Lu-DOTA-TATE was commenced. On the second day of hospitalization, the patient developed grade IV peripheral facial paralysis, characterized by deviation of the labial commissure, loss of the nasolabial fold, and presence of lagophthalmos on the left side. Vesicular lesions in the left external auditory canal and the hard palate were observed. The diagnosis of RHS was established. Due to a decreased level of consciousness and hemodynamic instability, a lumbar puncture was performed with isolation of DNA for Epstein-Barr virus and VZV suggesting neurological involvement with encephalitis. Following 21 days of Acyclovir, the patient showed improved consciousness being discharged to a long-term care unit. He remained off targeted therapy until his death, 23 months after the second cycle of [^{177}Lu]Lu-DOTA-TATE. ***Conclusion:*** To the best of our knowledge, this is the first reported case of Ramsay-Hunt Syndrome occurring as a possible adverse event of [^{177}Lu]Lu-DOTA-TATE. It therefore becomes an important potential complication to consider, as early diagnosis and treatment improve recovery rates.

OP-635

TARE Application for Bridging Liver Transplantation in Unresectable Embryonal Rhabdomyosarcoma of Biliary Tract Origin in a Toddler

N. Gülaldi, *V. Çayhan;*
University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: In this case report, we would like to present a 3-year-old toddler with rhabdomyosarcoma of biliary origin that completely covered the portal hilus and extended to the upper abdomen. ***Materials and Methods:*** This child presented with a gross mass in the liver. A biopsy of the mass revealed rhabdomyosarcoma of biliary origin. The patient was decided to be unresectable in the multidisciplinary hepatic cancer board. We offered TARE (transarterial radioembolization) of the tumor with [^{90}Y]-Resin microspheres to shrink the mass and eventually control the disease progress. This procedure is used in hepatocellular

carcinoma in adults for transplantation to reduce tumor load and give a chance of liver transplantation. ***Results:*** After tumor blood supply mapping with Tc99m-MAA, the process of radioablation of the tumor was scheduled with 90Y-resin microspheres administered in the hepatic artery feeding the tumor with 3 separate doses of 259 MBq, 184 MBq and 148 MBq on the 3rd day of MAA scan. At the 6th month, abdominal MRI and [^{18}F] FDG PET/CT imaging showed that the mass showed significant shrinkage and the part extending to the upper abdomen was regressed. The lesion size on contrast CT was decreased from 72x55x60mm to 38x34x42 mm after 6 months.After this stage, the patient was sent to a specialized surgical clinic of a university hospital for cadaveric liver transplantation. The liver transplantation as well as removing whole liver with residual tumors were carried out successfully and the child regained his health after that. ***Conclusion:*** This case report is important to show that TARE can be used as a bridging procedure in toddlers for liver sarcomas to prepare for transplantation as in adults. To the best of our knowledge, there is no reported TARE application in early childhood in the literature for unresectable rhabdomyosarcoma of the biliary tract.

OP-636

When Fire Meets Fuel: Thyrotoxic Crisis Following Radioactive Iodine Therapy for an Autonomous Thyroid Nodule

S. Ramos Barata[1], *S. Paiva*[1], *J. Silva*[1], *D. Carvalho*[1], *I. Casimiro*[1], *A. Albuquerque*[1], *G. Costa*[1,2];
[1]*Hospitais da Universidade de Coimbra - ULS Coimbra, Coimbra, PORTUGAL,* [2]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Thyrotoxic crisis is a rare, life-threatening endocrine emergency. Most cases are triggered by precipitating events. Radioactive iodine (RAI) therapy is a potential, albeit uncommon, cause. The destruction of follicular cells following RAI administration can lead to a rapid release of stored thyroid hormones into circulation, potentially precipitating a thyrotoxic crisis. ***Materials and Methods:*** We present the case of an 85-year-old woman with poorly controlled subclinical hyperthyroidism due to an autonomous thyroid nodule, referred for RAI therapy. Prior to treatment, thyroid scintigraphy with Na[^{99m}Tc]TcO_4 revealed a "hot" nodule with complete suppression of the remaining thyroid parenchyma. The 24-hour iodine uptake was measured at 17%, and an estimated activity of Na[^{131}I]I was calculated based on a functional mass of 12 grams. Antithyroid drug was suspended five days before treatment, and on February 22, 2024, the patient underwent outpatient RAI therapy with 717MBq. On March 2, 2024, the patient presented to the emergency department with palpitations and chest discomfort that began one day prior. At that time, she was taking one tablet of thiamazole daily. Relevant past medical history included heart failure, a biological aortic valve prosthesis, and atrial fibrillation (AF) under anticoagulation. Chronic medication included bisoprolol. Laboratory results showed suppressed TSH (<0.004mU/L; N: 0.4-4), elevated free T3 (6.2pg/mL; N: 1.8-4.2), and free T4 (2.79ng/dL; 0.7-1.5). The patient was admitted to the intensive care unit with AF with rapid ventricular response (RVR) secondary to a thyrotoxic crisis induced by RAI therapy. The Burch-Wartofsky Point Scale score was 45, supporting the diagnosis of thyroid storm. ***Results:*** Following stabilization, the patient was transferred to the endocrinology ward, where she remained hemodynamically stable and was discharged with a tapering regimen of thiamazole and propranolol. Subsequently, she was re-admitted to the cardiology department for heart failure decompensation, during which thiamazole was discontinued due to a TSH of 9mU/L. In the following weeks, the patient had multiple emergency visits for episodes of AF with RVR, prompting the reintroduction of thiamazole and adjustment of beta-blocker therapy. She remained under close follow-up in the endocrinology department. Thiamazole was ultimately discontinued after a TSH increase to 12mU/L. The patient is currently euthyroid without antithyroid therapy. ***Conclusion:*** This case illustrates the need for rigorous pre-treatment evaluation, individualized risk stratification, and close post-RAI monitoring. Integrating patient education on early symptom recognition into pre-therapy discussions is essential to allow prompt intervention and improve outcomes.

Preclinical studies of structurally optimized ^{64}Cu- and ^{68}Ga-labeled bicyclic peptides for improved imaging of nectin-4-positive tumors
***T. Krönke**, J. Trommer, M. Ullrich, M. Laube, R. Löser, K. Kopka, S. Stadlbauer, J. Pietzsch, R. Wodtke;*
Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY.

Aim/Introduction: The cell adhesion protein nectin-4 has been proven a valid target for therapeutic approaches to urothelial carcinoma with enfortumab vedotin being the sole clinically approved treatment option. Furthermore, the nectin-4 targeting bicyclic toxin conjugate BT8009 is currently tested in clinical trials (NCT04561362). To support patient stratification for such targeted therapies, there is a clinical need for molecular imaging agents capable of quantifying nectin-4 levels in vivo. For this purpose, we developed ^{64}Cu- and ^{68}Ga-labeled nectin-4 ligands, which are structurally derived from BT8009, for non-invasive imaging with positron emission tomography. We modified the original bicyclic scaffold to increase the (radio)chemical stability and binding affinity toward nectin-4. Radiochemical and pharmacokinetic characteristics are presented in comparison to the previously reported radioligand ^{68}Ga-N188.[1] ***Materials and Methods:*** Bicyclic peptides were synthesized via solid-phase peptide synthesis, followed by cleavage from the resin, cyclization in solution and RP-HPLC purification. Binding affinities were determined with a fluorescence anisotropy-based competitive binding assay and with surface plasmon resonance spectroscopy using recombinant human nectin-4. Radiolabeling was performed under standard conditions ([^{64}Cu]$CuCl_2$: NH_4OAc pH=5.6, 20 min, 60°C; [^{68}Ga]$GaCl_3$: NaOAc pH=4.5, 10 min, 90°C). The metabolic stability of the radioligands in human plasma was assessed by RP-HPLC analysis. Specificity towards nectin-4 was evaluated by comparing cell binding to nectin-4 positive (HT-1376) and -negative (5637) urothelial carcinoma cells. PET/CT imaging was conducted in HT-1376 tumor-bearing mice. ***Results:*** A small library of modified bicyclic peptides was synthesized and characterized for their binding affinity towards nectin-4, revealing distinct structure-activity relationships. While the binding affinities varied only moderately (2-6 nM), large differences (up to a factor 30) were observed regarding the rate constants for association and dissociation. All ligands were radiolabeled with high radiochemical yield and purity (≥95%). The most promising radioligand, [64Cu]Cu-TKR2-24, showed no proteolytic degradation in human plasma in vitro over 24 h. Furthermore, this radioligand showed potent nectin-4-specific binding (Kd of 3.3 nM) to HT-1376 cells. PET imaging demonstrated a specific uptake of [^{64}Cu]Cu-TKR2-24 in subcutaneous HT-1376 tumor xenografts with improved tumor uptake and tumor-to-background ratio compared to the previously reported radioligand ^{68}Ga-N188. ***Conclusion:*** Due to its high binding affinity, good stability in human plasma, and high contrast visualization of tumors in mice, [^{64}Cu]Cu-TKR2-24 warrants further clinical evaluation as a diagnostic PET radiotracer for assessing the nectin-4 status in cancer patients. ***References:*** 1 Duan et. al., Clin Cancer Res (2023) 29 (17): 3395-3407.

OP-653
Development of a Novel ^{68}Ga-Labelled Lasso Peptide Radiotracer for EphA2: Advancements in Prostate Cancer Imaging and Beyond
***X. Cui**, Z. Liu;*
Changping Laboratory, Beijing, CHINA.

Aim/Introduction: This study aimed to develop a novel ^{68}Ga-labelled lasso peptide radiotracer targeting erythropoietin-producing hepatocellular A2 (EphA2)[1], a receptor tyrosine kinase overexpressed in multiple cancers, for precise positron emission tomography (PET) imaging. The primary objectives were to optimize peptide-ligand stability and binding affinity through structural modifications, reduce renal retention, and validate tumour-targeting efficacy in preclinical models to discover a lead compound for clinical translation. ***Materials and Methods:*** A cyclic peptide scaffold was engineered to enhance EphA2 affinity and metabolic stability. Key modifications included strategic cyclization, incorporation of non-natural amino acids, and optimization of linker chemistry to minimize off-target interactions. The lead candidate was conjugated with a chelator for ^{68}Ga radiolabelling. In vitro binding kinetics were assessed via surface plasmon resonance (SPR). In vivo biodistribution and tumour-targeting efficacy were evaluated in EphA2-positive xenograft models (stable transient HT-1080-EphA2 cell line; PC-3 prostate and HCT-116 colorectal cancer cell lines) using

PET/CT imaging. Comparative studies with existing EphA2-targeting agents were conducted to benchmark performance[2]. ***Results:*** The optimized lasso peptide with unnatural amino acids demonstrated high affinity for EphA2, with a SPR-derived K_D of 0.25 nM, representing a 4-fold improvement over the initial hit. The plasma and renal stability were improved by identifying enzyme metabolic weaknesses and corresponding rational modifications. In HT-1080-EphA2 tumour-bearing mice, PET imaging revealed rapid tumour uptake (SUV_{max} = 2.8 ± 0.3 at 30 min post-injection), significantly higher than a reference compound (SUV_{max} = 1.5 ± 0.2, $p < 0.01$). Notably, renal retention was reduced by 40% compared to initial hit compound, probably attributed to optimized hydrophilicity and stability. In PC-3 and HCT-116 models, both tumour uptake reached 5.0 ± 0.5% ID/g at 1 h (n = 4), with minimal non-specific uptake in normal tissues. Pharmacokinetic analysis showed rapid blood clearance ($t_{1/2}$ = 12 min) and sustained tumour retention (>4% ID/g at 2 h). ***Conclusion:*** The novel ^{68}Ga-labelled lasso-peptide-based radiotracer exhibits superior EphA2-targeting specificity, enhanced metabolic stability, and favourable pharmacokinetics, addressing limitations of prior agents. Its high tumour uptake, moderate renal accumulation, and robust imaging contrast underscore its potential as a clinical diagnostic tool for EphA2-positive malignancies. A clinical investigator initiate trial is undergoing to validate these preclinical findings and explore its utility in personalized oncology. ***References:*** (1)Watabe, T. et al. OP-654

Preclinical Evaluation of 3B010: A Novel GPC3-Targeting Peptide Radioligand with High Tumor Retention and Remarkable Tumor-to-Kidney Ratio

W. XU*, J. Zhang;*
PepLib, Metuchen, NJ, UNITED STATES OF AMERICA.

Aim/Introduction: Glypican-3 (GPC3) is a membrane-bound proteoglycan highly expressed in hepatocellular carcinoma (HCC) and other solid tumors, making it an attractive target for peptide-based radioligand development. We have developed a peptide discovery platform that integrates physical peptide screening including disulfide-rich peptide phage display with an AI-driven in silico peptide design platform. This peptide discovery platform enables rapid identification and optimization of high-affinity, tumor-specific peptide ligands with favorable pharmacokinetic properties. Using this approach, we developed and characterized 3B010, a novel GPC3-targeting peptide radioligand with improved tumor specificity and reduced renal accumulation. ***Materials and Methods:*** 3B010 was selected and optimized through peptide screening and computational modeling, then conjugated with DOTA for radiolabeling with Gallium-68. In vitro binding assays were performed using GPC3-positive and negative cell lines to assess affinity and specificity. For in vivo evaluation, BALB/c nude mice bearing subcutaneous GPC3-positive xenografts (HepG2) were injected intravenously with 68Ga-3B010. PET/CT imaging was performed at multiple time points post-injection, followed by ex vivo biodistribution analysis at 4 hours to quantify organ-level uptake. ***Results:*** 3B010 demonstrated high binding affinity to human GPC3, with a K_D of 2.2 nM, and showed cross-species binding to GPC3 from mouse and cynomolgus monkey. In vitro assays confirmed strong and specific binding to GPC3-expressing cells, with negligible interaction in GPC3-negative controls. In vivo PET/CT imaging in mice revealed rapid tumor targeting and sustained retention up to 4 hours post-injection, with efficient clearance from non-target tissues. Ex vivo biodistribution data confirmed high tumor uptake and significantly reduced kidney accumulation, resulting in a tumor-to-kidney uptake ratio of approximately 4. ***Conclusion:*** 3B010, developed through our peptide discovery platform, exhibits excellent preclinical performance as a GPC3-targeting radioligand. Its high tumor retention and low kidney uptake support its potential for clinical translation in diagnostic imaging and radiotherapeutic applications. Exploratory IIT in human subjects are currently in preparation. ***References:*** 1. Filmus J, Capurro M, Rast J. Glypican-3: A novel serum and histochemical marker for hepatocellular carcinoma. Dimerization and ^{177}Lu-labeling of HER2-receptor Targeting Peptide

S. GUPTA*[1,2], M. Kumar[2], K. Repaka[3], A. Kengar[1], D. Satpati[2,4];*
[1]KET's V. G. Vaze College, Mumbai University, Mumbai, INDIA, [2]Radiopharmaceuticals Division, Bhabha Atomic Research Centre, Mumbai, INDIA, [3]Board of Radiation and Isotope Technology, Mumbai, INDIA, [4]Homi Bhabha National Institute, Mumbai, INDIA.

Aim/Introduction: Multimeric peptides display improved binding affinity towards the target, higher concentration and retention in the tumor and enhanced in vivo stability over their corresponding monomeric forms. Overexpression of HER2 receptors in breast cancer is associated with metastatic aggression. Early and precise detection is vital for management of HER2-positive breast cancer patients. Hence, in our pursuit of designing HER2-receptor targeting radiolabeled tracers, previously established monomeric peptide, rL-A9 was dimerized. The dimeric peptide, DOTA-$(rL\text{-}A9)_2$ was radiolabeled with Lu-177 and its efficacy was investigated. ***Materials and Methods:*** The peptide dimer was synthesized on solid phase by initial anchoring of Fmoc-lys(alloc)-OH. Subsequently, bi-functional spacer N,N-bis[3-(Fmoc-amino) propyl]glycine was coupled with the α-amino group of Lys. Deprotection of Fmoc group was followed by simultaneous build-up of two units of rL-A9 peptide chains. Alloc group was then deprotected and chelator DOTA was conjugated at ε-amine group of lysine (Fig. 1). Dimeric peptide, DOTA-$(rL\text{-}A9)_2$ was purified and characterized. ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ {200 µg, pH 5, 90°C, 20 min) was analyzed by RP-HPLC. Cell binding studies were performed in HER2-expressing human breast carcinoma SKBR3 cells. Stability in human serum (48 h) and metabolic stability in mice urine and blood (2 h) was determined. ***Results:*** The peptide, DOTA-$(rL\text{-}A9)_2$ could be synthesized in >99% purity and 20% yield. The peptide was characterized by MALDI TOF MS: m/z 2672.55 observed (calcd. for $C_{118}H_{185}N_{33}O_{38}$: 2672.36). Radiolabeling yield of ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ was >95%. Partition coefficient (log $P_{o/w}$) value of ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ was observed to be -3.30 ± 0.01, indicating high hydrophilicity of the radiopeptide. ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ exhibited high binding affinity [K_d: 70.33±8.6 nM] towards HER2-expressing SKBR3 cells. ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ was observed to be stable in human serum (>95% intact) as well in mice blood and urine (>90% intact). ***Conclusion:*** Monomeric rL-A9 peptide could be successfully dimerized during solid phase synthesis and obtained in high purity. DOTA-$(rL\text{-}A9)_2$ could be radiolabeled with Lu-177 in high yields. ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ exhibited high binding affinity towards HER2-positive breast carcinoma cells. ^{177}Lu-DOTA-$(rL\text{-}A9)_2$ demonstrated high metabolic stability, pharmacokinetics and tumor uptake shall be further ascertained by performing in vivo biodistribution studies. ***References:*** Peptides Targeting HER2-Positive Breast Cancer Cells and Applications in Tumor Imaging and Delivery of Chemotherapeutic. Preclinical Evaluation of [^{161}Tb]Tb-DPI-4452 for CAIX-Targeted Radionuclide Therapy in Pancreatic Cancer

C. Van Laere[1,2], *C. Segers*[2], *A. Coolkens*[2], *M. Dewilde*[1], *F. Cleeren*[1], *M. Ooms*[2];
[1]*KU Leuven, Leuven, BELGIUM,* [2]*SCK CEN, Mol, BELGIUM.*

Aim/Introduction: Carbonic anhydrase IX (CAIX) is a transmembrane enzyme highly overexpressed in hypoxic tumours and those with mutations in the von Hippel-Lindau tumour suppressor gene, while its expression in normal tissues remains limited. This tumour-selective expression profile makes CAIX an attractive target for therapeutic strategies. DPI-4452, a novel CAIX-targeting cyclic peptide equipped with a DOTA chelator, has shown potential as a theranostic agent in the form of [^{68}Ga]Ga-DPI-4452/[^{177}Lu]Lu-DPI-4452 for patients with clear cell renal cell carcinoma (ccRCC)(Massière F, et al., 2024). However, further optimization could maximize its therapeutic efficacy. In this study, we explore the use of terbium-161 for radiolabelling DPI-4452 and evaluate its potential in models of pancreatic ductal adenocarcinoma (PDAC). ***Materials and Methods:*** CAIX expression was assessed in AsPC-1, PANC10.05 (PDAC), and SK-RC-52 (ccRCC) cells under normoxic (20% O_2) and hypoxic (1% O_2) conditions using Western blot as well as immunocytochemistry with an anti-CAIX antibody and a Cy5-labelled analogue of DPI-4452. Subcellular localization was confirmed by Western blot analysis of membrane and cytosolic fractions. Radiolabelling protocols were optimized and the stability of the radioconjugate was assessed using radio-HPLC. Saturation binding assays with [^{161}Tb]Tb-DPI-4452 (1-250 nM) were performed on AsPC-1 and SK-RC-52 cells to determine K_D and B_{max}. Non-specific binding was assessed in the presence of the CAIX inhibitor S4. Immunohistochemistry and ex vivo autoradiography were conducted on three PDAC patient-derived xenograft (PDX) models to evaluate CAIX-specific binding and tissue distribution of [^{161}Tb]Tb-DPI-4452. Non-specific binding was assessed in the presence of the CAIX inhibitor S4. ***Results:*** CAIX expression was oxygen-dependent in PDAC cell lines but constitutive in ccRCC cells. PANC10.05 cells expressed CAIX only under hypoxic conditions, while AsPC-1 cells exhibited low baseline expression in normoxia with more than a threefold increase under hypoxia. Western blot analysis of subcellular fractions confirmed CAIX was exclusively localized to the membrane in the PDAC cell lines. Preliminary saturation binding assays with [^{161}Tb]Tb-DPI-4452 showed specific binding to CAIX in both AsPC-1 (K_D = 12.95 nM, B_{max} = 0.155 fmol/10^5 cells) and SK-RC-52 (K_D = 14.72 nM, B_{max} = 0.977 fmol/10^5) cells.Ex vivo autoradiography of PDAC PDX cryosections showed specific accumulation of [^{161}Tb]Tb-DPI-4452, correlating with CAIX expression as confirmed by immunohistochemistry. ***Conclusion:*** Our results demonstrate the successful targeting of CAIX using [^{161}Tb]Tb-DPI-4452 in PDAC cell lines and tissue slices of PDX models. Currently, in vitro and in vivo studies are ongoing to further investigate the potential of [^{161}Tb]Tb-DPI-4452 for PDAC.

OP-657

Substantially Higher Treatment Efficacy of ^{161}Tb-Labelled GRPR Antagonists over ^{177}Lu-Labelled GRPR Antagonists in PC3 Tumour-Bearing mice

T. Günther[1], *A. S. Moses*[1], *E. H. Günther*[1], *M. R. Landry*[1], *S. Ramaekers*[2], *M. Van de Voorde*[2], *M. Ooms*[2], *B. Ponsard*[3], *C. Beinat*[1];
[1]*Molecular Imaging Program at Stanford (MIPS), Department of Radiology, School of Medicine, Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA,* [2]*Nuclear Medical Applications, Belgian Nuclear Research Centre, Mol, BELGIUM,* [3]*BR2 Reactor, Belgian Nuclear Research Centre, Mol, BELGIUM.*

Aim/Introduction: ^{161}Tb shows similar physical properties to ^{177}Lu, but additionally emits more Auger electrons per decay, which might lead to improved treatment efficacy when combined with high-affinity peptides, such as the gastrin-releasing peptide receptor (GRPR) antagonists RM2 (DOTA-Pip^5-D-Phe^6-Gln^7-Trp^8-Ala^9-Val^{10}-Gly^{11}-His^{12}-Sta^{13}-Leu^{14}-NH_2) and AMTG (DOTA-Pip^5-D-Phe^6-Gln^7-α-Me-Trp^8-Ala^9-Val^{10}-Gly^{11}-His^{12}-Sta^{13}-Leu^{14}-NH_2). In this study we evaluated differences in treatment efficacy of ^{161}Tb- and ^{177}Lu-labelled RM2 and AMTG, respectively, in PC3 tumour-bearing mice. ***Materials and Methods:*** Tumours were established via subcutaneous injection of 4.0×10^6 PC3 cells per Nu/J mouse (n=7 per group). Treatment studies were initiated once tumour volume was ~100 mm^3. ^{161}Tb- and ^{177}Lu-labelling was completed at 90°C within 10 min (1.0 M NaOAc buffer, pH = 5.5, molar activity of 50 MBq/nmol). Radiolabelled compounds were injected on day 0 and day 7 (~15 MBq each). Animals were sacrificed once tumour volume surpassed 1,500 mm^3. To estimate toxicity of each compound, a complete blood count and metabolic panel analysis was completed after euthanasation of healthy animals (n=3 per group) at 60 days after receiving the same activity as the treatment groups. ***Results:*** Animals were assigned to five groups at day 0 of the treatment study (control group: 139±36 mm^3, [^{177}Lu]Lu-RM2: 114±28 mm^3, [^{177}Lu]Lu-AMTG: 127±47 mm^3, [^{161}Tb]Tb-RM2: 120±57 mm^3, [^{161}Tb]Tb-AMTG: 128±26 mm^3). Each group received a total activity amount of 26-31 MBq of the respective radiolabelled compound (all labellings proceeded quantitatively) ([^{177}Lu]Lu-RM2: 31.0±1.2 MBq, [^{177}Lu]Lu-AMTG: 26.0±2.8 MBq, [^{161}Tb]Tb-RM2: 30.3±0.7 MBq, [^{161}Tb]Tb-AMTG: 29.0±1.2 MBq). Overall survival was best when treated with [^{161}Tb]Tb-AMTG (54.9±2.2 d after start of treatment), followed by [^{161}Tb]Tb-RM2 (44.9±3.8 d), [^{177}Lu]Lu-AMTG (39.5±2.6 d), and [^{177}Lu]Lu-RM2 (26.8±1.9 d), and worst for the non-treated group (22.8±1.2 d). Apart from a reduced number of lymphocytes observed in animals treated with ^{161}Tb- and ^{177}Lu-labelled GRPR ligands, no adverse effects or signs of toxicity were observed during this study. ***Conclusion:*** Combination of ^{161}Tb with the GRPR ligands RM2 and AMTG led to a substantially improved overall survival in PC3 tumour-bearing mice than their ^{177}Lu-labelled analogues, which confirmed the impact of the higher number of Auger electron emissions by ^{161}Tb. Due to its higher in vivo stability, the AMTG peptide enabled a superior tumour control and overall survival than the RM2 peptide when labelled with the same radionuclide. While first clinical data on [^{177}Lu]Lu-AMTG suggests an improvement over GRPR ligands currently used for the treatment of GRPR-expressing malignancies, [^{161}Tb]Tb-AMTG might surpass each of these compounds, thus warranting its future application in clinical trials.

OP-658

Improved Tumour Targeting and Efficacy with Comparable Daughter Redistribution of ^{225}Ac-SSO110 versus ^{225}Ac-DOTA-TATE in a Preclinical SCLC Model

P. Desai, *M. Huber, M. Ruediger, G. Gericke, A. Jaekel;*
Ariceum Therapeutics GmbH, Berlin, GERMANY.

Aim/Introduction: ^{225}Ac-SSO110 (^{225}Ac-DOTA-JR11) is a somatostatin receptor 2 (SSTR2) antagonist under clinical investigation in extensive-stage small cell lung cancer (ES-SCLC) and Merkel cell carcinoma. Actinium-225 is a potent alpha-emitter with high linear energy transfer and short path length. However, recoil-induced release of daughter radionuclides raises concerns about off-target toxicity. Internalizing agonists are speculated to retain daughters more effectively in tumour tissue than non-internalizing antagonists. To test this, we compared the biodistribution of ^{225}Ac and its daughter ^{213}Bi following administration of ^{225}Ac-labelled SSO110 and DOTA-TATE (SSTR2 agonist) in SCLC xenografts, while also evaluating efficacy and tolerability. ***Materials and Methods:*** In-vivo studies were performed in SSTR2-positive NCI-H69 xenografts. For biodistribution, mice received 90 kBq/0.6 nmol ^{225}Ac-labelled SSO110 or DOTA-TATE; tissues were collected at 30 min, 4 h, 24 h, 48 h, and 96 h. Organ radioactivity was measured every 13 min over 20 h, and ^{225}Ac/^{213}Bi were quantified via bi-exponential fitting. For efficacy, mice received up to 37 kBq/0.6 nmol (single dose), with tissues collected for histopathology at study end. ***Results:*** ^{225}Ac-

SSO110 demonstrated 2.3-fold higher tumour area under curve and 1.9-fold higher tumour-to-kidney ratios than ^{225}Ac-DOTA-TATE, attributed to higher tumour uptake and prolonged retention, indicating a favourable therapeutic index. Comparable patterns of daughter radionuclide redistribution were observed for ^{225}Ac-SSO110 and ^{225}Ac-DOTA-TATE. ^{213}Bi was largely retained in tumours for both compounds. Loss of ^{213}Bi ranged from -12% to -18% for ^{225}Ac-SSO110 and -8% to -12% for ^{225}Ac-DOTA-TATE, corresponding to a reduction of up to 10% in tumour-absorbed dose relative to the ideal scenario of complete local retention. Importantly, no excess ^{213}Bi was observed in kidneys beyond 30 minutes or in liver beyond 4 hours post-injection for either compound, indicating minimal daughter redistribution following early-phase uptake of circulating ^{221}Fr generated in blood or ^{213}Bi-DTPA. In an in-vivo efficacy study, a single dose of 30 kBq ^{225}Ac-SSO110 induced complete tumour remissions and long-term survival, whereas ^{225}Ac-DOTA-TATE failed to control tumour growth. Both treatments were well-tolerated without histopathological findings. ***Conclusion:*** ^{225}Ac-SSO110 demonstrated superior tumour uptake, retention, and therapeutic efficacy compared to ^{225}Ac-DOTA-TATE in a preclinical SCLC model, achieving complete tumour remissions after single-dose administration while being well tolerated. Despite not being internalized, ^{225}Ac-SSO110 exhibited similar retention of daughter radionuclide as the internalizing agonist, indicating that the plasma membrane does not present a significant barrier to the recoil effect. These findings support the potential of ^{225}Ac-SSO110 as a promising targeted alpha therapy for SSTR2-positive malignancies.

OP-659

Preclinical evaluation of GRPR-antagonist PK3 as a candidate for targeted alpha therapy with Ac-225

P. Kanellopoulos[1], *A. Lebedev*[2], *E. Papalanis*[3], *K. Obeid*[1], *E. A. Bezverkhniaia*[1], *C. Byrne*[2], *T. Pack*[2], *V. Tolmachev*[3], *A. Orlova*[1], *S. V. Selivanova*[2];
[1]*Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [2]*Canadian Nuclear Laboratories, Chalk River, ON, CANADA,* [3]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) is overexpressed in numerous malignancies including prostate (PC) and breast cancers (BC). Peptide-based GRPR-antagonists have proven their potency as radiopharmaceuticals for theranostic use in preclinical studies and several variants are currently in clinical trials. However, poor metabolic stability and/or pharmacokinetics remain major issues. We have recently developed a novel variant of the GRPR-antagonist RM2, PK3 (DOTA-PEG2-Pip-DPhe-Gln-αMT-Ala-Sar-His-Sta-Leu-NH_2; αMT: α-methyl-L-Trp). [^{177}Lu]Lu-PK3 demonstrated high affinity (K_{D1}= 58pM) and selectivity to GRPR, improved in vivo metabolic stability, and a promising biodistribution profile [1]. These encouraging data prompted us to investigate PK3 for targeted alpha delivery labelled with Ac-225. ***Materials and Methods:*** Ac-225 was eluted from generator. All radioactivity measurements were performed at secular equilibrium between Ac-225 and its progenies. PK3 was labelled with Ac-225 in 0.4M NaOAc at 85°C-45min. The radiochemical yield was determined using iTLC. The in vitro specificity and internalization of [^{225}Ac]Ac-PK3 was tested using PC-3 prostate cancer and BT474 breast cancer cells. Biodistribution of [^{225}Ac]Ac-PK3 was measured in nude mice bearing PC-3 xenografts at 0.5, 1, 4, 24, 48, and 165h post-injection (pi). In vivo specificity of [^{225}Ac]Ac-PK3 was tested by co-injection of a large excess of unlabelled counterpart NOTA-PEG2-RM26. Areas under decay-uncorrected time-activity curves for tumours and normal organs were compared to estimate dosimetry. ***Results:*** PK3 was labelled with Ac-225 with radiochemical yield >95% and molar activity 215MBq/µmol. [^{225}Ac]Ac-PK3 demonstrated high GRPR-specific binding in vitro. The internalization was relatively slow (internalized fraction 20-25% after 24h), which is typical for radioantagonists. In vivo, [^{225}Ac]Ac-PK3 cleared rapidly from normal tissues. The highest uptake at 0.5h was in pancreas (24±4%IA/g), kidneys (18±6%IA/g) and tumours (10±2%IA/g). The uptake in the pancreas decreased rapidly to 4-5%IA/g at 4h pi. The tumour uptake remained high over time, being 16±2, 11±3, 10±2 and 3.5±0.1%IA/g at 4, 24, 48 and 165h pi, respectively. The time-integrated radioactivity for tumours was 300-, 10-, 4-, and 54-fold greater than that for the blood, pancreas, kidneys, and bones, respectively. Co-administration of unlabelled NOTA-PEG2-RM26 led to >70% decrease in [^{225}Ac]Ac-PK3 uptake in pancreas and tumours, thus confirming the binding specificity in vivo. ***Conclusion:*** [^{225}Ac]Ac-PK3 can be synthesized with high radiochemical yield and sufficient molar activity. [^{225}Ac]Ac-PK3 binds specifically to the GRPR-expressing cancer cells in vitro and in vivo. [^{225}Ac]Ac-PK3 demonstrated excellent targeting properties and favourable biodistribution and pharmacokinetic profile. It is a promising candidate for targeted alpha-therapy of GRPR-expressing malignancies. ***References:*** 1. Kanellopoulos et al. ISRS2025, abstract-ID:353.

OP-660

ImmunoPET Imaging of TIM3 Expression in the Tumor Microenvironment Using [68Ga]-Labelled Cyclic Peptide Tracers: From Bench to Bedside

J. Hou, *S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: T cell immunoglobulin and mucin domain-containing protein 3 (TIM3) has emerged as the next-generation immune checkpoint and a highly promising prognostic biomarker for immunotherapy. Similar to inhibitors targeting programmed cell death protein 1/programmed death-ligand 1 (PD-1/PD-L1) and cytotoxic T-lymphocyte antigen 4 (CTLA-4), positron emission tomography (PET) imaging strategies hold significant potential to enhance clinical decision-making in TIM3-related therapeutic approaches [1,2]. In this comprehensive study, we developed and rigorously validated [68Ga]-labeled cyclic peptide tracers for PET imaging of TIM3 expression, spanning from preclinical research to early clinical evaluation. ***Materials and Methods:*** A cyclic peptide with specificity for TIM3 was modified and radiolabeled using gallium-68 trichloride ([68Ga]$GaCl_3$). The radiolabeled tracer's affinity, specificity, biodistribution, pharmacokinetic properties, and radiation dosimetry were systematically evaluated through in vitro and in vivo experiments. Additionally, hu-PBL-SCID (PBL) mouse models were established to assess the ability of [68Ga]Ga-CK-1 to visualize the infiltration of TIM3-positive lymphocytes via PET imaging. Finally, [68Ga]Ga-CK-1 advanced to a first-in-human study, where its safety profile, biodistribution characteristics, and potential for imaging TIM3 expression were carefully investigated. ***Results:*** We successfully engineered a TIM3-targeting cyclic peptide, which served as the lead compound for the design and development of the [68Ga]-labeled PET tracer. In vitro binding assays demonstrated that [68Ga]Ga-CK-1 exhibited high affinity and specificity towards Chinese hamster ovary-human TIM3 cells and peripheral blood mononuclear cells. In vivo PET imaging studies revealed that [68Ga]Ga-CK-1 had excellent imaging performance, with a tumor uptake of 1.42±0.32% injected dose per gram and a tumor-to-muscle ratio of 26.21±4.35 at 60 minutes post-injection. Moreover, [68Ga]Ga-CK-1 was able to detect TIM3-expressing cell infiltrates in the spleen, lung, and salivary gland of PBL mice. In patients with melanoma and non-small cell lung cancer, [68Ga]Ga-CK-1 PET imaging showed modest uptake in primary tumor lesions compared to [18F]FDG PET. Significantly, [68Ga]Ga-CK-1 was capable of delineating the heterogeneity of TIM3 expression within large tumors. ***Conclusion:*** The results of this study firmly establish [68Ga]Ga-CK-1 as a promising PET tracer for quantifying TIM3 expression in the tumor microenvironment. These findings highlight its potential as a companion diagnostic tool for patient stratification and monitoring therapeutic response in anti-TIM3 immunotherapy. ***References:*** [1]Wolf Y, Anderson AC, Kuchroo VK. Performance evaluation for a dual-collimator 3D CZT Camera

R. Zananiri, *A. Devir-Wolfman, M. Wilk, O. Ziv, J. Bouhnik; GE HeathCare, Haifa, ISRAEL.*

Aim/Introduction: Over recent years, CZT-based, multi-detector, 3D nuclear medicine (NM) camera configurations have emerged. These cameras, with a single fixed collimator - balancing between low-energy sensitivity and high energy coverage - lacked optimized collimators to address all energies of conventional NM practices. Here, we introduce a new system design based on GE Healthcare's StarGuide™ with a redesigned detector that features dual collimators encasing the CZT modules, creating a dual collimator StarGuide (DCS). With optimized CZT crystal design - smaller pixels and two collimators tuned for high sensitivity (HS) and low penetration (LP) - its performance is compared to dual-head NaI-based cameras for Tc99m (DCS-HS vs. 870DR-LEHRS) and I131 (DCS-LP vs. 870DR-HEGP). ***Materials and Methods:*** Camera Design: DCS detectors were installed on the StarGuide™ gantry. Both collimators were designed to obtain identical StarGuide™ resolution. The HS collimator was designed to obtain 1.9x higher sensitivity and the LP collimator optimized for reducing high energies penetration. Tc99m Phantom: Flangeless Deluxe Jaszczak, 28mCi Tc99m, was used to assess Tc99m SPECT sensitivity and SPECT Resolution. It was acquired on each camera for 15 minutes. System sensitivity was compared as the ratio of the obtained projection counts. The resolution was assessed visually by comparing the central sphere slice and the summed rods slices. DCS-HS was reconstructed using OSEM150x2. while 870DR 2x10. No post filters, and Chang AC-ed. I131 Phantom: A custom-made, feature-to-background of 1:8, 5.4mCi NEMA IEC filled with Ba133 and Cs137 (1:0.1) mimicking I131 was used to assess the performance with I131. The phantom was scanned on the DCS-LP and on 870DR-HEGP, both for 15 minutes. The assessment was done visually and quantitatively following NEMA(2). ***Results:*** For Tc99m, DCS possesses superior image quality compared to 870DR with the camera sensitivity (~2.6x) and resolution. The DCS image quality is comparable to Jaszczak reported by Le Rouzic and Zananiri(1) for StarGuide™, however DCS was measured to obtain 1.9x counts for the same acquisition duration. Using LP collimator results in a comparable I131 image quality to the NaI-HEGP camera. ***Conclusion:*** DCS possesses a superior performance to 870DR for Tc99m. Also, to the best of our knowledge, this is the first report of CZT-based camera capable of imaging I131 in presence of strong background activity with comparable image quality to NaI system. ***References:*** (1) Le Rouzic and Zananiri, First performance measurements of a new multi-detector CZT-Based SPECT/CT system: GE StarGuide, JNM, 2021. Performance Evaluations in ^{161}Tb SPECT Imaging: Sensitivity, Septal Penetration, and Dead-Time Effects

F. Westerbergh[1], *L. McDougall*[2], *P. Ritt*[3], *J. G. Fricke*[2], *N. P. van der Meulen*[4,5], *C. Müller*[6,5], *R. Schibli*[5,6], *D. Wild*[2], *P. Bernhardt*[1,7]; [1]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN,* [2]*Division of Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND,* [3]*Chair for Clinical Nuclear Medicine, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, GERMANY,* [4]*Laboratory of Radiochemistry, PSI Center for Nuclear Engineering and Sciences, Villigen-PSI, Villigen, SWITZERLAND,* [5]*Center for Radiopharmaceutical Sciences, PSI Center for Life Sciences, Villigen-PSI, Villigen, SWITZERLAND,* [6]*Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND,* [7]*Department of Medical Physics and Biomedical Engineering (MFT), Sahlgrenska University Hospital, Gothenburg, SWEDEN.*

Aim/Introduction: Terbium-161 (^{161}Tb) has a complex emission pattern consisting of many photons over a wide energy range, which may complicate quantification. This study aimed to evaluate the performance of a SPECT/CT system currently deployed in an ongoing clinical trial (BETA PLUS; NCT05359146), with a particular emphasis on system sensitivity, septal penetration, and dead-time behavior. ***Materials and Methods:*** Experiments were carried out on a Siemens Symbia Intevo system using two collimators, low-energy high-resolution (LEHR) and medium-energy low-penetration (MELP), and two energy windows: 75 keV ±10% and 48 keV ±20%. To evaluate sensitivity and penetration, planar measurements were performed using a ^{161}Tb solution in a Petri dish. Penetration was measured for each collimator-energy window combination according to NEMA standards. A set of ^{161}Tb point sources were used for intrinsic dead-time assessments. Additionally, SPECT acquisitions of a homogeneous cylindrical phantom were used to estimate the activity thresholds at which dead-time becomes significant. Clinical relevance was investigated by analyzing SPECT projection data from eight patients given 1 GBq of [^{161}Tb]Tb-DOTA-LM3. ***Results:*** Sensitivity was similar at 75 keV for both collimators (LEHR: 15.7 cps/MBq; MELP: 18.5 cps/MBq) but increased notably at 48 keV (LEHR: 44.4 cps/MBq; MELP: 67.9 cps/MBq). Significant septal penetration was observed at 75 keV with the LEHR collimator, reaching 22% at the minimal source-to-collimator distance. Analysis of acquired spectra showed that over 50% of detected counts with LEHR appeared above the 75 keV window, whereas only 12.2% were detected above this threshold with MELP. Dead-time analysis indicated nonlinear detector responses at wide-spectrum count rates exceeding 93 kcps, corresponding to a minimum activity of 1.4 GBq for LEHR and 1.7 GBq for MELP. Both detector heads exhibited the same dead-time constant (0.42 µs), however, the maximum measureable count rate differed substansially (384 kcps vs. 546 kcps). Patient data indicated a peak wide-spectrum count rate of approximately 40 kcps per GBq at 3 h p.i. with LEHR. ***Conclusion:*** Attention to dead-time effects is crucial in ^{161}Tb SPECT imaging. The broad photon emission spectrum, as compared to ^{177}Lu, results in an elevated wide-spectrum count rate, increasing the risk of dead time. Use of low-energy collimators leads to greater septal penetration and scatter, exacerbating this concern. At therapeutic activity levels (e.g., 7.4 GBq), dead-time effects should be monitored to guarantee accurate quantification.

OP-663

Final results of the first in human validation of a DROP-IN β-probe during robotic PSMA-guided Surgery: insights and perspectives

F. Collamati[1], *F. Ceci*[2], *G. Musi*[2], *R. Mirabelli*[3], *S. Morganti*[1], *F. Mattana*[4], *S. Luzzago*[4], *F. Nicolanti*[3], *F. W. B. van Leeuwen*[5], *M. N. van Oosterom*[6], *R. Faccini*[7]; [1]*INFN Rome, Rome, ITALY,* [2]*IEO Milan, Milan, ITALY,* [3]*Università Sapienza Roma, Rome, ITALY,* [4]*IEO Milan, Rome, ITALY,* [5]*Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS,* [6]*Interventional Molecular Imaging Laboratory, Leiden University Medical Center, Leiden, NETHERLANDS,* [7]*Università Sapienza Roma, Rome, ITALY.*

Aim/Introduction: Prostate cancer patients are routinely diagnosed using PSMA-PET. Identifying these lesions during surgery can however be challenging. Radio-Guided Surgery (RGS) provides an approach that helps (robotic) surgeons to identify target tissues intraoperatively in real time. An approach that is most directly aligned with preoperative PSMA-PET diagnostics

when the same β+ emitting radiopharmaceuticals are being used (^68Ga-based compounds). In addition, the beta emission of PET radiopharmaceuticals offers short-range tissue penetration (few millimeters), which should limit shine through of background signals generated by tracer uptake in non-tumor tissue.This study reports the final results of the first in-human validation of a DROP-IN β probe for PSMA-guided robotic prostate cancer surgery with ^68Ga-PSMA. ***Materials and Methods:*** The β detector consists of a mono-crystalline para-terphenyl scintillator (6 mm diameter, 3 mm height) coupled to a silicon photomultiplier. 15 primary prostate cancer patients with at least one PSMA-PET-positive lymph node were enrolled. These patients were scheduled to undergo prostatectomy and extended pelvic lymph node dissection surgery. Each patient received 1.1 MBq/kg of [^68Ga] Ga-PSMA prior to surgery to allow for the radio guidance. Beta+ detection was performed intraoperatively with a laparoscopic β probe in the first 3 cases. In the remaining 12 patients, a sterilizable DROP-IN β probe (11mm diameter, 45mm length, 6g weight) — compatible with the da Vinci robotic system —was employed. To support the surgeon in discriminating between probe signals coming from tumor and healthy tissue, a statistical software algorithm was developed and optimized on a subset of this dataset. Surgical samples were evaluated at pathology. ***Results:*** Full statistical analysis was performed in the last consecutive 11 patients. In these, the DROP-IN β probe enabled effective intraoperative identification of PSMA-avid lymph nodes during robotic surgery. The DROP-IN probe showed excellent maneuverability and signal discrimination in a minimally invasive setting. During intraoperative lymph node dissection, 98 lymph nodes were harvested and assessed, of which 51 (52%) were malignant at pathology. Using an optimized detection algorithm for the DROP-IN probe, trained on a subset of 8 patients, a 93% detection rate for PET-positive nodes was achieved (26/28), and a 80% sensitivity and 91% specificity ***Conclusion:*** Robotic use of an innovativeDROP-IN β probe demonstrated high specificity and reliable tumor RGS, also in anatomically complex areas. These findings pave the way for broader clinical exploration of β-RGS.

OP-664

An investigation of noise in standardised NEMA image quality phantoms used in multi-centre trials

S. Jin, *G. Krokos, A. Harman, D. M. L. Lilburn, S. Barrington, P. K. Marsden;*
King's College London, London, UNITED KINGDOM.

Aim/Introduction: Scanner harmonisation is essential to acquire images of comparable quality in multi-centre trials. Although rigorous processes have been established for assessing the accuracy of quantification using a NEMA Image Quality (IQ) phantom, current guidelines define an upper cutoff of 15% for the coefficient of variation (CoV) in the background region to assess image noise. The project aims to investigate if a more thorough method of assessing image noise could improve image standardisation. ***Materials and Methods:*** NEMA IQ phantoms scanned on 37 different scanners across the UK using instructions provided by the UK PET Core Lab were analysed. Six concentric circles of varying diameters (ranging from 10-37mm) were placed in the background on the slice corresponding to the centre of the field of view, twelve copies of those six regions of interest (ROIs) were also placed around the background on this slice. These ROIs were also placed in the same way on the neighbouring ±4 and ±8 axial slices (360 regions in total). To assess image noise, the image roughness (IR), which estimates the pixel-to-pixel variability, and the background variability (BV), which estimates the region-to-region variability, were measured. ***Results:*** IR increased with ROI size, exhibiting up to 5% increase, while BV showed a decrease of up to 7%. There was a positive correlation between increasing scanning duration and IR. A large variation in both noise metrics across all scans was noted, despite following defined procedures, scans of the same duration with IR varying between 6%-16% and BV between 4%-11%. For a small number of phantoms, this was attributed to inconsistent sphere-to-background ratios with activity concentrations of approximately 2kBq/ml compared to the instructed 5kBq/ml. However, all were compliant with the EARL criteria of a maximum of 15% in CoV for the background and were therefore accredited. ***Conclusion:*** Current methods assessing noise in NEMA phantoms for harmonisation, may not be thorough enough. Although the scans analysed are accredited by the UK PET Core Lab and are considered harmonised for multi-centre trials, there's still a large variation in noise between the scans that can affect image quality. The phantoms show a 10% and 7% variation in IR and BV respectively and noise should be assessed more thoroughly for the purposes of multi-centre trials. Other contributing factors: reconstruction methods and scanner generation are being investigated, as well as the impact of this large noise variation within the NEMA IQ on clinical scans.

OP-665

Optimising Diagnostic CT in PET/CT: Balancing Dose and Image Fidelity with a Catphan® 600 Phantom

V. Menezes[1,2], *C. Gomes*[3], *P. Bergamo*[3], *R. Machado*[2], *T. Chang*[2], *A. Duarte*[2];
[1]*Hospital das Clinicas da UFPE, Recife, BRAZIL,* [2]*Memorial Star Red D'or, Recife, BRAZIL,* [3]*RADTEC, RECIFE, BRAZIL.*

Aim/Introduction: Dose reduction in positron-emission tomography/computed-tomography (PET/CT) is desirable, but only if the images still "look right" to radiologists who rely on high-fidelity CT for lesion localisation. Quantitative metrics such as modulation-transfer function (MTF) and contrast-to-noise ratio (CNR) provide objective guidance, yet subjective preference strongly influences clinical acceptance. Using a Catphan 600 phantom, we sought CT settings that satisfy both measurable quality indices and clinician-driven expectations while lowering patient exposure. ***Materials and Methods:*** Fourteen helical scans of the phantom were acquired on a Discovery MI PET/CT system. Slice thickness (0.625-3.75 mm) and pitch (0.98-1.375) were varied; rotation time (1 s), noise index (10) and maximum tube current (350 mA) were fixed. Each dataset was reconstructed ten times with filtered back-projection or adaptive statistical iterative reconstruction using standard, noise-suppressing or high-frequency kernels, yielding 140 series. Image quality was assessed by MTF50, CNR, signal-to-noise ratio (SNR), mean noise-power spectrum and uniformity; radiation output was recorded as volume CT dose index (CTDI_vol). ***Results:*** CTDI_vol ranged from 4.4 to 10.1 mGy. The current reference protocol (3.75 mm, pitch 1.375, high-resolution "LU" kernel) produced the best objective scores—MTF50 0.964 lp mm^{-1}, CNR 0.399, SNR 5.33—but at 10.1 mGy and with an image texture many readers considered "over-processed." A candidate routine protocol (3.75 mm, pitch 0.98, iterative "Plus" kernel) preserved spatial resolution (MTF50 0.991 lp mm^{-1}) and kept CNR and SNR within 5 % of the reference while halving dose to 4.4 mGy; radiologists judged its texture indistinguishable from full-dose scans. For applications requiring finer detail, a thin-slice protocol (1.25 mm, pitch 1.375, "IQ Plus" kernel) delivered MTF50 0.981 lp mm^{-1} and acceptable noise at 8.2 mGy. High-frequency kernels sharpened edges but reduced CNR by up to 30 % and were subjectively noisy. ***Conclusion:*** Phantom data indicate that the proposed routine protocol achieves a 65 % dose reduction without perceptible loss of diagnostic quality, making it a strong default for PET/CT attenuation correction and reporting. The thin-slice option offers higher in-plane resolution when clinically warranted, whereas the high-dose reference should be reserved for exceptional cases. Crucially, incorporating radiologist feedback alongside quantitative metrics ensures dose optimization efforts remain clinically acceptable and sustainable.

OP-666

Advantages of Minimally Invasive MIBI-Radioguided Parathyroidectomy.

C. Villaprado, *I. Blanco, A. Barrera, K. Sanabria, E. Goñi, F. Lozada, P. Boya, M. Ribelles, L. Paruta, A. Rosero, M. Garcia, E. Anda, N. Cruz, P. Salvador;*
Hospital Universitario de Navarra, Pamplona, SPAIN.

Aim/Introduction: Minimally Invasive Radioguided Parathyroidectomy (MIRP) is a proven and effective surgical technique for treating primary hyperparathyroidism (PHPT), allowing immediate confirmation of the removal of the pathological gland. Its value is especially notable in complex cases, such as those with ectopic parathyroid lesions or a history of cervical surgery, where traditional approaches may be more challenging. ***Materials and Methods:*** An observational prospective unicentric study was conducted on 183 consecutive PHPT patients treated with MIRP over five years ((January 2020-(January 2025). All patients underwent preoperative imaging with ultrasound and dual-phase MIBI SPECT-CT; Choline PET-CT was used if prior studies were negative or inconclusive. The MIRP procedure involved intravenous administration of 99mTc-MIBI (185 MBq) one hour before surgery, followed by imediate imaging adquisition and intraoperative localization with a portable gamma camera and gamma probe. Early in the study, intraoperative biopsy confirmed surgical success, but later cases relied on imaging and count rates of the excised lesion. ***Results:*** Mean age was 61.87 ± 11.2; 137 (75.4%) women. Sensitivity of preoperative studies to locate the lesion was: US 69.4% (n=127), MIBI 90.1% (n=165), PET 91,4% (n=64/70). Successful surgical resection of the parathyroid lesion occurred in 179 patients (97.8%), achieved by minimally invasive access in 92%; only in two patients was it necessary during the surgical procedure to widen the initial incision to complete the resection. Two synchronous parathyroid lesions were removed in 6 patients, in 4 of whom the image acquired the day of the intervention allowed the localization of the second adenoma, which had not been previously identified in diagnostic studies. An ectopic adenoma was found in 35 patients (19.1%); Radioguided procedure allowed a minimally invasive surgery of 32 (91.4%). Previous cervical surgery was registered in 11 (6.1%); a successful PMIR achieved in 9 (81%). In 15 patients, despite negative/inconclusive MIBI diagnosis (PET diagnosis), radioguided surgery was successfully performed. Biochemical normalization in 97.6% of the 168 patients with follow-up longer than 6 months, including the 6 patients with synchronous adenoma removed. ***Conclusion:*** MIBI Radioguided procedure allows minimally invasive surgical excision of ectopic adenomas, lesions in previously operated patients, and occasionally second lesions, previously unknown. This selective surgical approach has been successfully applied even in patients with a previous non-diagnostic MIBI scan. Real-time evaluation of excised lesions avoids intraoperative biopsy.

OP-667

Quantifying the Contribution of Residual ^{68}Ga in ^{18}F Imaging - the First Step to a 'One Stop Shop'?

N. Davis[1], *H. Natarajan*[1,2], *B. F. Holman*[1];
[1]*Royal Free London NHS Foundation Trust, London, UNITED KINGDOM,* [2]*King's College London, London, UNITED KINGDOM.*

Aim/Introduction: As the importance of PETCT in oncology continues to increase, the number of patients that require scans with both [^{18}F]-FDG and [^{68}Ga]-Ga-DOTA-TATE increases with it. Many patients are required to attend the PET/CT centre on two separate days. Performing both scans on the same day would be advantageous, but the inability of the scanner to distinguish between annihilation photons produced by the two nuclides is problematic. Long Axial Field of View (LAFOV) PET/CT cameras show significant improvement in sensitivity allowing for reduced scan times and decreased injected activities making same day scanning with both nuclides a possibility. This work aims to determine the time delay required between an initial ^{68}Ga administration and the subsequent ^{18}F administration to ensure no significant contribution from the ^{68}Ga is present in the subsequent study images. ***Materials and Methods:*** Our current clinical protocol is to administer 0.75 MBq/kg [^{68}Ga]-Ga-DOTA-TATE and 1.5 MBq/kg [^{18}F]-FDG. To replicate this, sterilin tubes were filled with 15 ml of different concentrations of ^{68}Ga from 2.26 to 0.02 kBq/ml (covering the range we would expect in patients during the day following their scan). These were scanned on a Siemens Biograph Vision Quadra LAFOV PET/CT using the local clinical protocol for [^{18}F]-FDG oncology scans for 5 minutes and reconstructed using PSF and ToF corrections. Cylindrical VOIs were drawn in Hermes. The total number of kBq/cc in each was measured and plotted against activity of ^{68}Ga. Another tube containing 15 ml of 2 kBq/ml of ^{18}F (representing tissue background) was scanned using the same protocol. The percentage contribution to the image from ^{68}Ga at different concentrations, and the time taken to reach these from an assumed initial concentration of 10 kBq/ml, were calculated. ***Results:*** The concentration of ^{68}Ga that contributed the equivalent of 5% of the 'counts' from ^{18}F was reached after 4.3 hours, and 1% after 7.0 hours. It should therefore be possible to perform scans with this order of delay between injections. ***Conclusion:*** It is feasible to successfully perform an ^{18}F scan 4.3 to 7.0 hours after a ^{68}Ga scan with our current protocol. The interval could be further reduced by increasing the activity of ^{18}F administered to the patient. Performing same patient ^{68}Ga and ^{18}F scans on the same day, will improve patient experience, reduce waiting times and lead to faster diagnosis and treatment. Further work should be conducted to assess the impact in clinical images.

OP-668

Addressing brain PET harmonization challenges in clinical settings: joint estimation of true activity and effective image resolution using paired T1W MRI

L. Fu, *S. Yang, L. Yin;*
Department of Nuclear Medicine,China-Japan Friendship Hospital, Beijing, CHINA.

Aim/Introduction: Quantitative harmonization of brain PET acquired across different systems and sites is challenging due to variations in effective spatial resolution, leading to partial volume effects (PVE) that compromise quantitative accuracy. Achieving consistent quantitative recovery, even with Hoffman phantom, highlights the profound influence of system-specific resolution limitations. Accurate PVE correction and effective resolution characterization are crucial for reliable quantitative analysis. ***Materials and Methods:*** This work introduces a novel iterative method addressing these issues by simultaneously recovering a more accurate true underlying brain FDG-PET activity map and characterizing the system-specific effective image resolution (EIR). This is guided by paired T1W MRI scan of the same subject, which is typically feasible in clinical settings. This method operates directly on 3D image, treating the problem as joint deconvolution and kernel estimation. It leverages aligned T1-weighted MRI scans and their segmentations into major tissue types like CSF, WM, and GM as robust anatomical priors. The process initializes the true activity estimate as the observed blurred PET image and provides an initial guess for the blurring kernel (e.g., Gaussian FWHM). An iterative loop then refines these estimates. In each iteration, the true activity is updated using regularized deconvolution. This deblurring step is guided by the MRI segmentations, enforcing piecewise smoothness within CSF, WM, and GM regions while preserving sharp transitions at tissue boundaries. Simultaneously, the EIR kernel is estimated by comparing the blurred version of the current true activity estimate to the observed PET image. This estimation step is guided by the segmentation boundaries (or MRI edges), for instance, by analyzing blurring profiles across edges or

through optimization. ***Results:*** The method's performance was evaluated using a Hoffman 3D brain phantom and 3 patients data, demonstrating convergence. Estimated EIR values were consistent for a given system configuration (e.g., 4.0-5.0 mm FWHM for a Siemens Biograph Vision 600 with all-pass filter reconstruction). For the Hoffman phantom (4:1 GM:WM ground truth), the recovered true activity map yielded a ratio closely approximating this (estimated near 3.8:1), indicating significant PVE correction and improved activity recovery. ***Conclusion:*** By jointly estimating the PVE-corrected activity distribution and EIR from individual scans, this approach offers a promising pathway towards mitigating harmonization challenges, enabling more reliable quantitative comparisons in brain PET analyses.

Aim/Introduction: Technical heterogeneity in image acquisition and reconstruction hampers multicenter validation of nuclearmedicine biomarkers. Dopamine transporter (DaT)-SPECT — a recognised tool for quantifying nigrostriatal degeneration in Parkinson's disease (PD)[1] — is highly susceptible to such variability. We therefore coordinated a harmonisation study across 11 institutions within the National Virtual Institutes for Parkinson's and Dementia using a travelling DaT-SPECT phantom. The aim was to measure and minimise intersite variability and to lay the groundwork for creating harmonised, highfidelity synthetic DaT brain phantoms for research and dataaugmentation. ***Materials and Methods:*** The anthropomorphic phantom mimics DaT uptake in both striatum and background. It was sequentially filled with four predefined striataltobackground ratios (SBRs = 10:1, 7.5:1, 5:1, 2.5:1) of ^{123}Iioflupane SPECT (DaT-SPECT). Each centre (N = 11) acquired images and reconstructed them with filtered backprojection (FBP) and orderedsubsets expectationmaximisation (OSEM), yielding N × 4 datasets per reconstruction algorithm. Preprocessing comprised reconstructionspecific template generation, rigid coregistration, and manual segmentation of bilateral striatal and occipital reference regions. Harmonisation of voxel intensities was performed with NeuroComBat[2] with and without inclusion of dilution ratio as a biological covariate. Coefficient of variation (CV) served as the variability metric. Harmonised volumes were then fed into a validated latentdiffusion model [3] to reconstruct synthetic DaT phantoms whose fidelity was evaluated with structural similarity index (SSIM), meansquared error (MSE), rootMSE (RMSE) and the linear association (R^2) between original and synthetic SBRs. ***Results:*** NeuroComBat markedly reduced intercentre variability, lowering CV by 91.06 ± 0.67 % when no covariate was used and by 77.51 ± 2.13 % when the dilution ratio was included. The generative pipeline reproduced the harmonised images with high agreement (MSE = 0.002 ± 0.001; RMSE = 0.052 ± 0.013; SSIM = 0.976 ± 0.005) and preserved quantitative contrast, as confirmed by a strong correlation between synthetic and original SBRs (R^2 = 0.93). ***Conclusion:*** A coordinated travellingphantom experiment combined with NeuroComBat offers an effective, nationally scalable harmonisation pipeline for DaT-SPECT. When integrated with an advanced diffusionbased generative model, the pipeline yields realistic, quantitatively faithful synthetic datasets that mitigate intersite variability and lower datasharing barriers in PD imaging research. The same workflow will now be applied to clinical DaT-SPECT scans from network centres to enable largescale multicentre biomarker studies. ***References:*** [1] Armstrong,doi: 10.1001/jama.2019.22360; [2] Fortin,doi:https://doi.org/10.1016/j.neuroimage.2017.11.024; [3] Rombach, doi: 10.1109/CVPR52688.2022.01042.

A First-in-human, Phase 1 Dose Escalation and Expansion Study Evaluating the Safety, Tolerability, and Anti-tumor Activity of [^{225}Ac]Ac-FL-020, an Anti-PSMA Radioconjugate in Patients with Metastatic Castration-Resistant Prostate Cancer (mCRPC).

S. Ngai[1], *G. Cardaci*[2], *A. Singh*[2], *A. Iagaru*[3], *C. Artigas*[4], *K. Goffin*[5], *R. Villanueva Vázquez*[6], *K. Herrmann*[7], *C. S. Kramer*[8], *A. Robert*[8], *K. Schumacher*[8], *S. Heeger*[8], *D. Barton*[9], *A. Hansen*[1];
[1]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [2]*GenesisCare Australia. St John of God Hospital Murdoch, Murdoch, AUSTRALIA,* [3]*Stanford University, Stanford, CA, UNITED STATES OF AMERICA,* [4]*Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Brussels, BELGIUM,* [5]*Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM,* [6]*ICO Hospitalet, l'Hospitalet de Llobregat, Barcelona, SPAIN,* [7]*University Hospital Essen, Essen, GERMANY,* [8]*Full-Life Technologies GmbH, Heidelberg, GERMANY,* [9]*Full-Life Technologies U.S. Inc., Dover, DE, UNITED STATES OF AMERICA.*

Aim/Introduction: [^{225}Ac]Ac-FL-020 is a next-generation prostate-specific membrane antigen (PSMA) alpha radioconjugate developed using the proprietary Clear-X™ technology platform. It is intended for the treatment of patients with metastatic castration-resistant prostate cancer (mCRPC), aiming to enhance tumour uptake and therapeutic efficacy while minimizing off-target effects, particularly in radiosensitive organs such as salivary glands. This Phase 1 clinical trial investigates the safety, tolerability, and preliminary anti-tumour activity of [^{225}Ac]Ac-FL-020 in patients with advanced PSMA-positive mCRPC. ***Materials and Methods:*** This is a first-in-human, open-label, multicentre Phase 1 study consisting of two parts: a dose escalation phase (Part 1) and a cohort expansion phase (Part 2). The study applies a

Bayesian logistic regression model (BLRM) with overdose control to guide dose-escalation decisions. Patients eligible for enrolment must have histologically confirmed mCRPC, evidence of disease progression, and PSMA-positive lesions as confirmed by PSMA PET/CT imaging. Prior treatment with androgen receptor signalling inhibitors or CYP17 inhibitors and at least one taxane-based chemotherapy is required. Patients with extensive PSMA-negative disease are excluded. In Part 1, dose cohorts of 1-3 patients (expanding up to 6) will evaluate ascending dose levels from 1 to 5 MBq to determine the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D). Once the RP2D is established, 18 additional patients will be enrolled in Part 2 to further assess safety and explore early signals of efficacy. The study is currently enrolling patients in Australia and the United States, with sites in Europe expected to open later in 2025. ***Results:*** As of April 2025, one eligible patient has been enrolled and evaluated for safety and dosimetry. Preliminary imaging with [^{111}In]In-FL-020, a surrogate for dosimetry analyses, revealed favourable biodistribution in humans with fast and durable tumor uptake whereas the uptake in salivary glands appeared to be rather low. No unexpected safety signals or dose-limiting toxicities have been observed so far. ***Conclusion:*** These initial findings support the feasibility and tolerability of [^{225}Ac]Ac-FL-020 administration in heavily pretreated mCRPC patients. Preliminary dosimetry indicates organ-specific uptake in line with the intended PSMA-targeting mechanism. Further safety and efficacy data will be shared as enrolment progresses, and additional patients are evaluated.

Evaluation of the safety and efficacy of ^{225}Ac-PSMA-CY313 in metastatic castration-resistant prostate cancer: preliminary results

S. Li[1], *Y. Shi*[1], *J. Liu*[2], *Z. Li*[2], *Y. Wu*[2];
[1]*Department of Nuclear Medicine, Affiliated Hospital of North Sichuan Medical College, Nanchong, CHINA,* [2]*C-Ray Pharmaceuticals (Chengdu) Co. Ltd., Chengdu, CHINA.*

Aim/Introduction: ^{225}Ac-PSMA-CY313 is a novel molecule of targeted alpha therapy (TAT) that delivers alpha-particle radiation specially to prostate cancer cells expressing Prostate-specific membrane antigen (PSMA). In this study, we investigated preliminary safety and efficacy of ^{225}Ac-PSMA-CY313 in mCRPC patients. ***Materials and Methods:*** We are conducting this prospective, open-label, single-arm study in accordance with ICH GCP guidelines. All patients agreed to participate in the trial with written informed consent after the trial was approved by IEC. The study enrolled disease progressive mCRPC patients with PSMA positive lesions imaged by ^{64}Cu-PSMA-CY313 PET/CT scans at baseline after the treatment with one or more approved androgen-receptor-pathway inhibitors (ARPI) with or without taxane regimens. The eligible patients received ^{225}Ac-PSMA-CY313 treatment intravenously at 200 μCi (7.4 MBq) doses administered every 8 weeks per cycle for 4 cycles followed by expanded 4 cycle treatment if the participants continued to benefit from the treatment. The primary endpoint was to assess adverse events by the CTCAE v5.0 grading system. The secondary endpoints included overall survival (OS), Radiographic Progression-Free Survival (rPFS), Overall Response Rate (ORR) per RESIST version 1.1 and PCWG3, and serum Prostate-Specific Antigen (PSA) levels. ***Results:*** From Feb 2024 to Apr 2025 we recruited 13 male participants with mCRPC who received no more than 6 cycles of ^{225}Ac-PSMA-CY313. The mean age was 67 years (range, 54-77). 100% of patients exhibited PSA decline, while 81.8% reached PSA 50 (a decline of 50% or more). The partial response (PR), ORR and stable disease (SD) were 60.0% (6/10), 60.0% (6/10) and 20% (2/10) respectively. Most adverse events (AEs) were Grade 1-2 except for 1 case with grade 3 (anemia). The most common (11/13, 84.6%) AE was dry mouth including one case of Grade 2 and 10 cases of Grade 1 by CTCAE V5.0. No participants withdrew from study due to dry mouth. Other observed AE included anemia, dyspepsia, white blood cell decrease, fatigue, anorexia, diarrhea, and urinary infection. ***Conclusion:*** ^{225}Ac-PSMA-CY313 was safe and well-tolerated, it exhibited preliminary efficacy for mCRPC patients who were resistant to standard lines of approved agents. Overall ^{225}Ac- PSMA-CY313 is a promising radiopharmaceutical agent for the treatment of mCRPC.

OP-672

First-in-Human Study of a Novel PSMA-Targeted Radiotherapeutic Agent: Safety, Preliminary Efficacy, and Dosimetry of [177Lu]Lu-PSMA-XT in Patients with Metastatic Castration-Resistant Prostate Cancer (mCRPC)

Y. Liu[1,2], *H. Wang*[1], *X. Zhang*[1], *W. Zhao*[3], *R. Wang*[1], *B. Xu*[1], *J. Zhang*[1];
[1]*Chinese PLA General Hospital, Beijing, CHINA,* [2]*Chinese PLA Medical School, Beijing, CHINA,* [3]*Sinotau Pharmaceutical Group, Beijing, CHINA.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy has emerged as a promising treatment strategy for metastatic castration-resistant prostate cancer (mCRPC). [177Lu]Lu-PSMA-XT (XT381) is a novel therapeutic agent demonstrating superior cellular internalization in PSMA-positive cells. This multicenter, open-label, dose escalation and extension study conducted in China aims to evaluate the safety, preliminary efficacy and dosimetry of [177Lu]Lu-PSMA-XT in patients with mCRPC. ***Materials and Methods:*** Enrolled participants had PSMA-positive metastatic prostate cancer (confirmed per THERP trial criteria), progression after ≥1 androgen receptor pathway inhibitor, ineligibility or refusal of chemotherapy, and adequate bone marrow/organ function. The dose-escalation phase employed a "3 + 3" design with sequential enrollment into escalating cohorts (1.85-9.25 GBq; up to 6 cycles). Primary endpoints included safety/tolerability, assessed per CTCAE v5.0 criteria (incidence of adverse events [AEs] and serious adverse events [SAEs]). Secondary endpoints comprised preliminary efficacy (PSA50 response, radiographic progression-free survival [rPFS], objective response rate [ORR], disease control rate [DCR]) and dosimetry. Dosimetry analysis followed European Association of Nuclear Medicine (EANM) guidelines utilizing a hybrid planar/SPECT approach. Whole Body planar scintigraphy were performed at 0.5h,4h,24h,48h,72h and 168 hours post-administration of the first administration. ***Results:*** To date, 12 patients were enrolled (9 in escalation, 3 in expansion). Ten completed ≥1 PSA response assessment (3 at 1.85 GBq, 4 at 3.7GBq [3 in escalation,1 in expansion], 1 at 5.55GBq). A PSA decline was observed in 90% patients, with PSA50 and PSA90 response rate of 60% and 40% respectively, and all responders achieved PSA50 responses within 2 cycles. Notably, even the 1.85 GBq cohort achieved high PSA90 rates (PSA90 RR was 67%), suggesting enhanced potency. One patient with measurable disease achieved partial response (RECIST 1.1); among 9 with non-measurable disease, 1 had progressive disease (PCWG3) and 8 maintained stable disease. No Grade≥3 adverse event or salivary toxicity was observed. Dosimetry analysis revealed a tumor absorbed dose of 3.46 ± 1.74 Gy/GBq, with a biological half-life of 200.56 ± 128.21 hours. The absorbed doses to kidneys, red marrow, and salivary glands were 0.67 ± 0.50, 0.05 ± 0.02, and 0.51 ± 0.12 Gy/GBq, respectively. The tumor-to-salivary gland absorbed dose ratio was 7.22. ***Conclusion:*** [177Lu]Lu-PSMA-XT exhibits favorable tolerability and rapid PSA responses at low doses in mCRPC patients. These preliminary findings highlight its potential as a promising therapeutic agent, warranting further investigation in randomized controlled trials.

Head-to-Head dosimetry, safety and preliminary early response evaluation of [^{161}Tb]Tb-SibuDAB versus [^{177}Lu]Lu-PSMA-I&T in patients with mCRPC: PROGNOSTICS Phase Ia

A. Chirindel[1], *G. Nicolas*[1], *F. Westerbergh*[2], *L. McDougall*[1], *D. Schmid*[3], *S. Geistlich*[3], *A. Bauman*[4], *A. Fokkema*[5], *N. Aceto*[5], *P. Bernhardt*[2,6], *N. van der Meulen*[7,3], *C. Müller*[3,8], *R. Schibli*[3,8], *D. Wild*[1]; [1]*Department Theranostics, Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND,* [2]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN,* [3]*PSI Center for Life Sciences, Villigen-PSI, SWITZERLAND,* [4]*Department Theranostics, Radiopharmacy, University Hospital, Basel, SWITZERLAND,* [5]*Department of Biology, Institute for Molecular Health Sciences, ETH Zurich, Zurich, SWITZERLAND,* [6]*Department of Medical Physics and Biomedical Engineering, Sahlgrenska University Hospital, Gothenburg, SWEDEN,* [7]*PSI Center for Nuclear Engineering and Sciences, Villigen-PSI, SWITZERLAND,* [8]*Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.*

Aim/Introduction: The PROGNOSTICS Phase Ia study(NCT06343038) investigates tumor and organ absorbed doses following test injections of [^{161}Tb]Tb-SibuDAB compared to [^{177}Lu]Lu-PSMA-I&T in patients with metastatic castration-resistant prostate cancer(mCRPC). SibuDAB is a novel albumin-binding PSMA-targeted peptidomimetic, developed at PSI, based on a urea-derived PSMA ligand conjugated to (S)-ibuprofen, aiming to enhance blood circulation and, consequently, tumor uptake and retention. ***Materials and Methods:*** In Phase Ia of the study, 10 mCRPC patients received two consecutive test injections of 1 GBq [^{161}Tb]Tb-SibuDAB and 1 GBq [^{177}Lu]Lu-PSMA-I&T, administered three weeks apart in a cross-over, randomized, single-blind design. Quantitative SPECT/CT imaging was conducted (~3, 24, 48, and 168 hours) after each injection to determine tumor and organ absorbed doses using 3D dosimetry based on a Monte Carlo-enhanced OSEM algorithm. For each patient, 3-5 tumor lesions (>1.5cm) were included. Multiple blood samples were collected (~0.5, 1, 3, 24, 48 and 168 hours) for bone marrow dosimetry. Standard laboratory assessments were carried out after 1 and 3 weeks to monitor safety, acute toxicity (CTCAE v5.0), and early PSA response. ***Results:*** Imaging-based dosimetry revealed that the median tumor absorbed dose was 3.5 Gy/GBq (1.5-13.5) following [^{161}Tb]Tb-SibuDAB administration, compared to 1.5 Gy/GBq (0.7-9.7) for [^{177}Lu]Lu-PSMA-I&T. Similarly, median absorbed doses to kidneys were 2.0 Gy/GBq (1.4-2.3) for [^{161}Tb]Tb-SibuDAB and 0.8 Gy/GBq (0.5-1.4) for [^{177}Lu]Lu-PSMA-I&T, while doses to the parotid glands were 0.45 (0.24 - 0.66) and 0.28 (0.11-0.34) Gy/GBq, respectively. Blood-based bone marrow dosimetry yielded 0.092 (0.06-0.22) Gy/GBq for [^{161}Tb]Tb-SibuDAB and 0.014 (0.005-0.025) Gy/GBq for [^{177}Lu]Lu-PSMA-I&T. The effective tumor half-life was 93 and 61 hours, respectively, indicating superior tumor retention for [^{161}Tb]Tb-SibuDAB. Treatment-emergent Grade 1-2 adverse events included anemia (2 vs. 4 patients), leukopenia (1 vs. 1), lymphopenia (5 vs. 3) and creatinine increase (1 vs. 1) following [^{161}Tb]Tb-SibuDAB and [^{177}Lu]Lu-PSMA-I&T, respectively. Grade 3 lymphopenia occurred in 1 patient after [^{161}Tb]Tb-SibuDAB and in 2 patients after [^{177}Lu]Lu-PSMA-I&T. No grade 4 adverse events were recorded. An early measurable PSA response was noted in 6 patients after [^{161}Tb]Tb-SibuDAB and in 4 patients after [^{177}Lu]Lu-PSMA-I&T administration, with partial responses (PCWG3) in 3 and 2 patients, respectively. ***Conclusion:*** The PROGNOSTICS Phase Ia results demonstrate a favorable clinical profile for [^{161}Tb]Tb-SibuDAB in comparison to [^{177}Lu]Lu-PSMA-I&T, with higher tumor doses, prolonged tumor retention and encouraging early PSA responses without evidence of clinical relevant adverse events. PROGNOSTICS Phase Ib (dose escalation study) is currently undergoing to identify the optimal biological dose of [^{161}Tb]Tb-SibuDAB in mCRPC patients.

OP-674

ProstACT Global: A phase 3 study of Lutetium (Lu177) rosopatamab tetraxetan plus standard of care vs standard of care alone in patients with metastatic castration-resistant prostate cancer

J. Roetman[1], *S. Tagawa*[2], *N. Agarwal*[3], *D. Cade*[1], *O. Sartor*[4]; [1]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [2]*Weill Cornell, New York, NY, UNITED STATES OF AMERICA,* [3]*Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, UNITED STATES OF AMERICA,* [4]*Mayo Clinic, Rochester, MN, UNITED STATES OF AMERICA.*

Aim/Introduction: Targeted radionuclide therapy can localize treatment to specific tumor cells to reduce or eliminate damage to normal tissue for patients with prostate cancer (PC). Prostate-specific membrane antigen (PSMA) is an ideal therapeutic target as it is highly expressed by malignant PC cells. Compared to peptide-based, monoclonal antibody-based approaches have high binding specificity, rapid internalization, and long retention. Prior studies have demonstrated a favorable safety profile & efficacy of the radio-antibody drug conjugate (rADC) lutetium (Lu 177) rosopatamab tetraxetan (^{177}Lu-rosopatamab) using a fractionated 2 dose regimen. Thus, ^{177}Lu-rosopatamab is currently being investigated in a Phase 3 study for treatment of patients with PSMA+ metastatic castration resistant PC (mCRPC) who have received prior treatment with one androgen receptor pathway inhibitor (ARPI). ***Materials and Methods:*** This multinational, multicenter, prospective, randomized, open label phase 3 study has 2 parts: a dosimetry and safety lead-in (Part 1; n=30) & a randomized treatment expansion (Part 2; n=490). In Part 1, patients are divided into 3 groups (n=10 each) to receive 2 single intravenous injections of 76 mCi each, 14 days apart, of ^{177}Lu-rosopatamab with standard of care (SoC) combinations with abiraterone, enzalutamide, or docetaxel to characterize biodistribution & safety profiles of ^{177}Lu-rosopatamab + SoC combinations. SoC received is determined prior to treatment with ^{177}Lu-rosopatamab. In Part 2, patients will be enrolled 2:1 to receive SoC (determined pre-randomization) with or without 2 single injections of 76 mCi each of ^{177}Lu-rosopatamab, given 14 days apart. Eligible patients must have PSMA-expressing mCRPC and have experienced disease progression on a minimum 12w prior therapy on their 1st ARPI (abiraterone, apalutamide, darolutamide, or enzalutamide) in metastatic castration-sensitive PC, non-metastatic CRPC, or mCRPC settings. Patients may have received docetaxel in mCSPC setting provided last dose was ≥6m prior to screening. Patients must have PSMA+ disease on ^{68}Ga-PSMA-11 PET/CT imaging. The primary endpoint is rPFS. Key secondary endpoint is OS. Additional secondary endpoints include 5-year OS, tumor objective response rate, time to symptomatic skeletal event, & health-related quality of life. An alpha control & 95% confidence intervals will be used; patients will be randomly assigned to receive ^{177}Lu-rosopatamab + SoC or SoC alone. ***Results:*** This study is currently enrolling; no results available at time of abstract submission. ***Conclusion:*** Combining ^{177}Lu-rosopatamab along with proven patient selection capabilities of ^{68}Ga-PSMA-11 PET provides reasonable justification for further evaluation in a large-scale trial for mCRPC treatment This study is sponsored by Telix Pharmaceuticals.

Médecine Nucléaire, Dijon, FRANCE, [7]Novartis Pharma AG, Basel, SWITZERLAND, [8]Novartis Pharma, East Hanover, NJ, UNITED STATES OF AMERICA, [9]Centre Hospitalier Régional Universitaire de Nancy, Département de Médecine Nucléaire, Nancy, FRANCE.

Aim/Introduction: In VISION, the prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) [^{177}Lu]Lu-PSMA-617 plus standard of care (SoC) significantly prolonged survival of patients with metastatic castration-resistant prostate cancer (mCRPC) versus SoC alone. Compared with the β-emitter ^{177}Lu that induces primarily single-stranded DNA breaks, the α-emitter ^{225}Ac induces primarily double-stranded breaks. ^{225}Ac-labelled PSMA RLT has shown anti-tumour activity in patients with mCRPC and metastatic hormone-sensitive prostate cancer (mHSPC). In at-risk organs, PSMA-R2 has been associated with low radiation-absorbed doses. SatisfACtion (NCT05983198) is a trial-in-progress of [^{225}Ac]Ac-PSMA-R2 (^{225}Ac-PSMA-R2) in patients with PSMA-positive mHSPC or mCRPC. ***Materials and Methods:*** This is an open-label, phase 1/2, multicentre study of ^{225}Ac-PSMA-R2 in adults with progressive PSMA-positive mHSPC or mCRPC, confirmed by [^{68}Ga]Ga-PSMA-11 PET/CT. Patients will be assigned to one of three groups: patients with 1) post-androgen receptor pathway inhibitor (ARPI), post-taxane and post-^{177}Lu-PSMA RLT mCRPC; 2) post-ARPI, ^{177}Lu-PSMA RLT-naive mCRPC; or 3) untreated or minimally treated, ^{177}Lu-PSMA RLT-naive mHSPC. Previous taxane therapy is not required for Groups 2 and 3. Exclusion criteria include treatment with any other radionuclides ≤6 weeks before enrolment or treatment with any other investigational agents or systemic anti-cancer therapy ≤28 days before ^{225}Ac-PSMA-R2 therapy start. In the dose-escalation phase (phase 1), approximately 3-6 participants will be enrolled per dose cohort per group to assess the safety and tolerability of ^{225}Ac-PSMA-R2 and establish the recommended dose for expansion (RDE). Dose escalation will use Bayesian logistic regression models following the escalation with overdose control (EWOC) principle. Participants in Groups 1 and 2 will receive a starting dose of 7 MBq intravenous ^{225}Ac-PSMA-R2 once every 6 (±1) weeks for ≤6 cycles; the dose may be increased to subsequent dose levels providing acceptable safety and tolerability, and that the EWOC principle is satisfied. Latest dose-level data in Groups 1 or 2 will inform the Group 3 starting dose. Additional patients may be enrolled to assess an increased frequency dosing schedule based on data from previous dose levels. Primary endpoints are incidence and severity of dose-limiting toxicities, adverse events and serious adverse events, and dose intensity and treatment modifications. Secondary endpoints include response rates, radiographic progression-free survival, overall survival, time to first symptomatic skeletal event and prostate-specific antigen response. The dose-limiting toxicity evaluation period will be 42 days after the first ^{225}Ac-PSMA-R2 dose.The dose-expansion phase (phase 2) will aim to further characterize the anti-tumour activity of ^{225}Ac-PSMA-R2 at the RDE.

OP-676

Adaptive Design and Dose Optimization in a Phase Ib/IIa Dose Escalation and Expansion Study of ^{212}Pb-ADVC001 in Metastatic Castration-Resistant Prostate Cancer (mCRPC): TheraPb - Phase I/II Study

A. Hansen[1], *A. Karmann*[2], *D. Pattison*[3], *S. Ngai*[1], *L. Katchel*[1], *L. Campbell*[3], *A. Soderholm*[2], *M. Griffiths*[3], *E. O'Mahoney*[1], *J. Brady*[3], *S. Rose*[2], *M. Aim/Introduction: Prostate-specific membrane antigen (PSMA)-directed radioligand therapies (RLT) are evolving to meet unmet patient needs in mCRPC. Traditional dose-finding study designs used for systemic anti-neoplastic agents, however, fail to leverage unique aspects of RLT, while the optimal dosing regimens for even established RLTs have not been fully explored. Adaptive design elements and dose optimization have rarely been included in RLT clinical trials to date. The TheraPb study design incorporates adaptive and dose optimization elements to rigorously and efficiently evaluate optimal dosing strategies of ^{212}Pb-ADVC001, a novel PSMA-targeted radioligand labelled with the potent alpha-emitting payload ^{212}Pb, in mCRPC. ***Materials and Methods:*** This is an ongoing prospective, Phase 1b/2a open-label, non-randomized, multi-centre, dose escalation, dose optimization and expansion study of ^{212}Pb-ADVC001. Primary objectives are selection of the recommended Phase 2 dose and schedule (Phase 1b) and efficacy (Phase 2a) of ^{212}Pb-ADVC001 in patients with PSMA-positive mCRPC who have had exposure to at least one androgen receptor pathway inhibitor. ***Results:*** The Phase 1b dose escalation follows an interval 3+3 design, incorporating Bayesian decision-making and additional design elements that can be modified based on emerging study data to evaluate dosing intervals of ^{212}Pb-ADVC001 administered every 6, 4 or 2 weeks. Number of cycles are tailored to patient response on molecular imaging. Efficient dose escalation leverages routine biodistribution imaging and dosimetry assessment, limiting the number of patients exposed to subtherapeutic doses. If the Phase 1b demonstrates multiple dosing regimens with similar safety, tolerability and anti-tumour activity, the protocol provides the option to include adaptive randomization in Phase 2a expansion to identify an optimized dose and schedule. Phase 2a further includes evaluation of biomarker-driven adaptive dosing regimens in pre-defined cohorts of patients with PSMA-positive mCRPC proceeding in parallel, characterizing the drug profile and development potential in specific indications. ***Conclusion:*** The adaptive design and dose optimization elements of TheraPb aim to identify optimal RLT dosing regimens while reducing exposure of subjects to subtherapeutic doses or suboptimal schedules and improving patient safety and depth and duration of response, ultimately enabling faster patient access to this novel and potentially effective treatment. The trial is currently enrolling at two clinical sites in Australia (NCT05720130).

Dose escalation study for targeted radionuclide therapy with [^{161}Tb]Tb-SibuDAB in mCRPC - PROGNOSTICS Phase Ib study

A. Chirindel[1], *G. Nicolas*[1], *F. Westerbergh*[2], *L. McDougall*[1], *D. Schmid*[3], *S. Geistlich*[3], *A. Bauman*[1], *A. Fokkema*[4], *N. Aceto*[4], *P. Bernhardt*[2,5], *N. van der Meulen*[6,3], *C. Müller*[3,7], *R. Schibli*[3,7], *D. Wild*[1];
[1]Department Theranostics, Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND, [2]Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN, [3]PSI Center for Life Sciences, Villigen-PSI, SWITZERLAND, [4]Department of Biology, Institute for Molecular Health Sciences, ETH Zurich, Zurich, SWITZERLAND, [5]Department of Medical Physics and Biomedical Engineering, Sahlgrenska University Hospital, Gothenburg, SWEDEN, [6]PSI Center for Nuclear Engineering and Sciences, Villigen-PSI, SWITZERLAND, [7]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.

Aim/Introduction: The PROGNOSTICS Phase Ib study (NCT06343038) aims to identify the optimal biological dose of [^{161}Tb]Tb-SibuDAB for targeted radioligand therapy (RLT) in patients with metastatic castration-resistant prostate cancer (mCRPC). SibuDAB is a novel albumin-binding PSMA-targeted peptidomimetic, developed at PSI. It is based on a urea-derived PSMA ligand conjugated to (S)-ibuprofen, in order to prolong blood circulation and, consequently, tumor uptake and retention. ***Materials and Methods:*** This ongoing open-label, prospective

3+3 dose escalation trial includes mCRPC patients with documented disease progression (biochemical, radiologic, and/or clinical) under systemic therapy (anti-hormonal with or without prior chemotherapy), with preserved organ function and PSMA positive disease on pre-therapy PET/CT. Key exclusion criteria include participation in other therapeutic trials, prior treatment with [^{177}Lu]Lu-PSMA RLT, and any other malignancy without complete remission for ≥5 years. Each 3-patient cohort receives a total of 4 therapy cycles, every 6 weeks with same injected activity for every cycle, delivered as a 10-minute short infusion along with 4-hour 1-liter saline hydration. Post-therapy quantitative SPECT/CT imaging is performed at ~3, 24, 48, and 168 h to calculate tumor and organ absorbed doses using a 3D dosimetry using a Monte Carlo-based OSEM algorithm. Blood sampling (~0.5, 1, 3, 24, 48 and 168 hours) is used for bone marrow dosimetry. Additionally, the study incorporates multi-omic profiling (clinical, biochemical, imaging, cellular and transcriptomic) as well as circulating tumor cells and tumor-cell cluster analyses, to explore potential biomarkers for treatment response (PSA per PCWG3) and toxicity prediction (graded by CTCAE v5.0). ***Results:*** The first patient cohort (n=3) has completed two treatment cycles at the initial injected activity of 3 GBq without any infusion-related acute events. Hematologic toxicity was limited to one case of grade 1 leukopenia and two cases of grade 1 lymphopenia, with no additional adverse events. Renal and hepatic function showed no measurable alteration post-treatment. An early PSA decline was observed in one patient, while two patients showed either stable or rising PSA values. ***Conclusion:*** The PROGNOSTICS Phase Ib is an ongoing 3+3 dose escalation study aiming to identify the optimal biological dose of [^{161}Tb]Tb-SibuDAB for RLT in mCRPC patients. Initial findings from the first dose level demonstrate a favorable safety profile with early signs of pharmacological activity. Comprehensive data from the first two cohort - including dosimetry, subacute toxicity and PSA response - will be presented.

OP-678

Dosimetry and Dose-escalation Study of a Novel Long-Acting Radiopharmaceutical [^{177}Lu]Lu-LNC1011 inMetastatic Castration-Resistant Prostate Cancer Patients

J. Wang[1], *R. Wang*[1], *J. Xiang*[1], *X. Chen*[2], *Z. Zhu*[1], *J. Zhang*[2];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: [^{177}Lu]Lu-LNC1011 ([^{177}Lu]Lu-D-Dan-Phe-PSMA) is a novel long-circulating prostate-specific membrane antigen (PSMA) therapeutic radioligand whose structure is based on a labile dansyl group as a relatively weak albumin binder. This study aims to investigate its safety, dosimetry, and initial treatment efficacy of [^{177}Lu]Lu-LNC1011 in patients with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** This study used an open-label, non-randomized design. It adopted a dose-escalation approach, enrolling mCRPC patients who hadpassed a pre-screening PSMA PET/CT. A total of 9 mCRPC patients received [^{177}Lu]Lu-LNC1011 at dose levels of 1.85, 2.78 and 3.70 GBq. ***Results:*** No DLT was observed in any dose group. The effective dose to the whole body was 0.10 ± 0.02 mSv/MBq. The kidneys received the highest expected radiation dose, which was calculated to be 3.33 ± 1.09 Gy/GBq. For salivary glands and red bone marrow, the effective doses were 1.70 ± 1.04 Gy/GBq and 0.11 ± 0. 03 Gy/GBq, respectively. The mean absorbed dose to tumors was 12.29 ± 6.50 Gy/GBq. The effective half-life of [^{177}Lu]Lu-LNC1011 was 49.44 ± 12.58 h in the whole body and 128.3 ± 62.79 h in tumor lesions. After two cycles, the 3.70 GBq cohort demonstrated superior efficacy with 100% PSA reduction (3/3), 66.7% achieving ≥50% PSA decline, and a 33.3% sustained PR rate, while all cohorts maintained 33.3% SD-to-PR conversion and 100% disease control without progression assessed by Response Evaluation Criteria in PSMA PET/CT (RECIP) 1.0 criteria. ***Conclusion:*** The administration of [^{177}Lu]Lu-LNC1011 across three dosing groups in mCRPC patients was well tolerated, with minimal side effects. The treatment delivered a high tumor-absorbed dose and demonstrated prolonged tumor retention. Notably, the 3.70 GBq dose group demonstrated significant therapeutic efficacy. Considering its efficacy, safety, and dosimetric results, we believe that conducting further multi-cycle studies at a dose of 3.70 GBq [^{177}Lu]Lu-LNC1011 is appropriate.

Aim/Introduction: SAFER3, the Phase III, prospective, multicenter, open-label study was designed to evaluate the diagnostic efficacy of a novel ^{18}F-labeled tracer, [^{18}F]SYN2, for myocardial perfusion imaging (MPI) using positron emission tomography (PET) in subjects with suspected coronary artery disease (CAD). ***Materials and Methods:*** The study enrolls male and female participants over 18 years of age who are referred for invasive coronary angiography (ICA) due to suspected CAD. A total of 280 evaluable subjects, accounting for a 15% dropout rate, will be recruited across Europe and the United States, with an adaptive design allowing sample size expansion up to 682 evaluable subjects. The study features an adaptive framework with three unblinded interim analyses to evaluate early efficacy and safety, optimize study conduct, and potentially adjust the sample size. ***Results:*** Participants will receive two [^{18}F]SYN2 injections, one at rest and one during stress, with imaging performed under standardized 1-day protocols. Reference standard diagnostics will include ICA with fractional flow reserve (FFR) or instantaneous wave-free ratio (iwFR) measurements when applicable. The primary objective is to assess [^{18}F]SYN2 PET MPI's ability to detect significant CAD, defined as anatomical stenosis ≥ 90% or functional ischemia in lesions with 40-89% stenosis. Secondary objectives include evaluating quantitative and qualitative imaging performance and assessing the safety of [^{18}F]SYN2 radiotracer. Exploratory objectives will compare [^{18}F]SYN2 PET MPI with other non-invasive imaging modalities. ***Conclusion:*** The clinical trial is already open for recruitment in Europe.

Diagnostic Approach to Microvascular Dysfunction in INOCA: Simultaneous Dual-Perfusion Imaging with ^{13}N-Ammonia and Gadolinium Using an Integrated PET-MR Scanner

R. Wen, *X. Wang;*
The First Affiliated Hospital of University of Science and Technology of China, Hefei, CHINA.

Aim/Introduction: Ischemia with no obstructive coronary arteries (INOCA), a chronic disorder with a poor prognosis, remains diagnostically challenging. Innovative hybrid PET-MR technology enables the concurrent procurement of PET and magnetic resonance (MR) data under precisely the same experimental and physiological circumstances. This study aims to utilize hybrid PET-MR to simultaneously obtain positron emission tomography (PET) and magnetic resonance data of patients, aiming to identify potential predictive factors for the reduction of coronary flow reserve (CFR). ***Materials and Methods:*** We prospectively enrolled 32 patients (14 females and 18 males) with typical angina pectoris and no obvious coronary stenoses shown by angiography. Microvascular dysfunction was defined as CFR < 2. CFR was defined as the ratio of hyperemic MBF (after regadenoson) to resting MBF. The receiver operating characteristic (ROC) curves and diagnostic cutoff values were analyzed to evaluate the predictive value of factors significantly influencing the diagnosis of INOCA. Subsequently, the statistically significant predictive factors were aggregated into the number of risk factors (NRF). ***Results:*** Global CFR (1.56 ± 0.48 vs. 3.10 ± 0.89; P < 0.001) was significantly lower in patients with INOCA than in those with no INOCA. ROC analysis identified the following continuous variables significant for INOCA diagnosis: global radial strain [AUC = 0.929, 95% confidence interval (CI): 0.78 - 0.99, P < 0.001] with a cut-off value of 43.8%; triglycerides (AUC = 0.890, 95% CI: 0.73 - 0.97, P < 0.001), cut-off 1.28 mmol/L; very - low - density lipoprotein (VLDL) (AUC = 0.731, 95% CI: 0.55 - 0.87, P = 0.049), cut-off 0.68 mmol/L; and native T1 maps (AUC = 0.852, 95% CI: 0.86 - 0.95, P < 0.001), cut-off 1213 ms. The categorical variable with statistical significance is late gadolinium enhancement (LGE) (P < 0.001). Based on the aforementioned factors, the NRF for each patient was calculated cumulatively and subsequently input into the ROC curve analysis. The findings revealed that our NRF exhibited excellent diagnostic efficacy for INOCA. Notably, the optimal cut-off value for NRF was determined to be 2 [AUC = 0.992 (95% CI: 0.88 - 1.00), P < 0.001]. ***Conclusion:*** Accumulated risk factors negatively impact CFR. Calculating the NRF in patients with suspected INOCA can effectively predict the probability of microvascular dysfunction among these patients. We propose that patients with NRF ≥ 2 should have their CFR measured via PET.

OP-681

Simultaneous 13N-Ammonia and Gadolinium-Based First-Pass Myocardial Perfusion Using Integrated PET-MRI Imaging: A Comparative Evaluation of Diagnostic Accuracy in Coronary Microvascular Dysfunction

R. Wen, *X. Wang;*
The First Affiliated Hospital of University of Science and Technology of China, Hefei, CHINA.

Aim/Introduction: Absolute quantification of myocardial perfusion and coronary flow reserve (CFR) with positron emission tomography (PET) has demonstrated diagnostic and prognostic value in patients with coronary microvascular dysfunction (CMD). Quantitative magnetic resonance imaging (MRI) perfusion imaging has been recently developed and validated against PET in healthy volunteers. However, no studies have compared MRI and PET perfusion imaging in patients with CMD using integrated PET-MRI imaging. The aim of this study was to assess the quantitative accuracy of cardiac perfusion measurements using MRI with simultaneous ^{13}N-ammonia PET as reference with a fully integrated PET-MRI scanner. ***Materials and Methods:*** Thirty patients with suspected CMD underwent simultaneous MRI and ^{13}N-ammonia PET scans at rest and regadenoson-stress on an integrated PET-MRI scanner. Correlation and agreement between MRI- and PET-derived myocardial blood flow (MBF) and CFR values were evaluated using correlation and Bland-Altman analysis. ***Results:*** MRI measurements of global rest and stress MBF showed moderate correlation to those obtained using ^{13}N-Ammonia PET (r = 0.50; P = 0.005 for rest MBF and r = 0.49; P < 0.006 for stress MBF). Bland-Altman analysis revealed a mean bias of − 0.83 ± 0.47 mL/g/min for rest MBF and −1.84 ± 0.57 mL/g/min for stress MBF. The correlations between regional MBF_{MRI} and MBF_{PET} obtained during rest and stress were only poor to moderate (r = 0.26 and r = 0.43). The limits of agreement were wide for both global and regional MBF, with larger variability for high MBF-values. However, there was good agreement between MRI and PET with regard to global and regional CFR with moderate to strong correlation (r = 0.64, P < 0.001; r = 0.48, P < 0.001). MRI-derived CFR demonstrated an area under the curve (AUC) of 0.85 (95% CI: 0.67 to 0.95) and had an optimal cutoff value of 1.57 for detecting CMD, defined as ^{13}N-Ammonia PET-derived CFR ≤ 2.0 ***Conclusion:*** CFR measurements were concordant between MRI and ^{13}N-Ammonia PET. For detecting significant CMD, CFR_{MRI} and CFR_{PET} demonstrated comparable and high accuracy. Nevertheless, MRI measurements of rest and stress MBF showed only poor to modest agreement to those obtained with ^{13}N-Ammonia PET. Therefore, although quantitative MRI has clinical utility, further refinements are still required.

OP-682

Native T1 Mapping versus Coronary Flow Reserve for Coronary Microvascular Dysfunction in INOCA: PET-MRI Validation

R. Wen, *X. Wang;*
The First Affiliated Hospital of University of Science and Technology of China, Hefei, CHINA.

Aim/Introduction: Ischemia with non-obstructive coronary artery disease (INOCA) is a chronic disorder with a poor prognosis, often caused by coronary microvascular dysfunction (CMVD), which increases morbidity, mortality, and economic burden. Cardiac magnetic resonance imaging (CMR)-derived coronary flow reserve (CFR) is a validated marker for CMVD, but concerns about gadolinium-based contrast agent (GBCA) tissue deposition—especially in the central nervous system with repeated use—highlight the need for non-contrast alternatives. Native T1 mapping, an emerging MRI technique sensitive to myocardial tissue abnormalities (e.g., edema, fibrosis), has not been systematically compared with MRI-derived CFR for detecting CMVD in INOCA. ***Materials and Methods:*** Thirty-three INOCA patients underwent stress/rest PET-MRI, including 3-Tesla native T1 mapping (ShMOLLI sequence) and Gd-DTPA perfusion MRI. Imaging used an integrated 3T PET-MRI system, acquiring cine MRI, native T1 maps, and myocardial perfusion data with 13N-ammonia PET. CFR, defined as hyperemic/resting myocardial blood flow (MBF), was calculated for the left ventricle (LV) and coronary territories. Patients were classified into reference (CFR ≥ 2.0) and CMVD (CFR < 2.0) groups based on PET-derived CFR,

the noninvasive reference standard. ***Results:*** Twelve patients had CMVD (CFR < 2.0) and 21 had preserved CFR. CMVD patients had significantly higher mean global native T1 values (1251.6 ± 22.3 vs. 1207.2 ± 30.7, P < 0.001) and lower stress MBF (0.17 ± 0.03 vs. 0.25 ± 0.07 ml/g/min, P < 0.001) and CFR (1.47 ± 0.35 vs. 2.04 ± 0.39, P < 0.001). Native T1 inversely correlated with PET-derived CFR (r = −0.67, P < 0.001), and MRI-derived CFR correlated with PET-derived CFR (r = 0.63, P < 0.001). Receiver-operating characteristic analysis showed comparable diagnostic accuracy: native T1 (AUC: 0.881) and MRI-derived CFR (AUC: 0.873, P = 0.912). A T1 threshold of 1213 yielded 100% sensitivity and 75% specificity, while CFR_{MRI} ≤ 1.625 had 83% sensitivity and 85% specificity for CMVD. ***Conclusion:*** Elevated native myocardial T1 values inversely associate with PET-derived CFR in INOCA, demonstrating comparable CMVD detection to MRI-derived CFR. This first systematic comparison highlights native T1 mapping as a viable non-contrast alternative for CMVD assessment. If validated in larger studies, it could serve as a gadolinium-free surrogate marker for CMVD severity, enabling safe serial evaluations without GBCA exposure. Mechanistic insights and multicenter validation are needed to optimize its clinical utility.

OP-683

Association between Coronary Microvascular Dysfunction and Diabetic Microvascular complications in Type 2 Diabetes Mellitus: A ^{13}N-Ammonia PET study

J. Ilangovan, *H. Singh, A. Rastogi, A. Sood, B. Mittal;*
PGIMER, Chandigarh, INDIA.

Aim/Introduction: Coronary microvascular dysfunction (CMD) is the impaired ability of the coronary microcirculation to regulate blood flow in response to oxygen demand. Numerous studies have demonstrated that CMD is associated with an increased risk of major adverse cardiac events (MACE). Cardiovascular disease (CVD) remains the leading cause of mortality in patients with diabetes mellitus, highlighting the need for early identification of microvascular abnormalities. This study aimed to evaluate the prevalence of CMD in individuals with type 2 diabetes mellitus (T2DM) without overt coronary artery disease (CAD) using ^{13}N-ammonia PET imaging. The other objective was to compare the prevalence of CMD between T2DM patients with proteinuria and those without proteinuria. ***Materials and Methods:*** Individuals with type 2 diabetes mellitus (T2DM) of at least five years' duration and no prior history of myocardial infarction, heart failure, or coronary revascularisation were prospectively enrolled. Based on the 24-hour urine protein analysis, participants were categorised into two groups: those with proteinuria and those without. All patients underwent a single-day rest/stress cardiac PET scan using ^{13}N-ammonia as the perfusion tracer and adenosine as the pharmacologic stress agent. Additionally, patients were screened for other diabetic microvascular complications, including peripheral neuropathy and diabetic retinopathy. Myocardial flow reserve (MFR) values < 2, were used to define the presence of CMD. ***Results:*** A total of 18 T2DM patients were enrolled in the study. Among them, 13 (72%) were male and 5 (28%) were female. The mean age of the cohort was 59.4 ± 6.9 years. Proteinuria was present in 5 of 18 patients, while the remaining 13 did not exhibit this complication. Among the non-proteinuria group, 3 patients had diabetic foot ulcers secondary to peripheral neuropathy. CMD, indicated by reduced myocardial flow reserve (MFR), was observed in all 5 patients with proteinuria, in 1 of the 3 patients with diabetic foot ulcers, and in only 1 patient without either complication. Overall, T2DM patients with microvascular complications (proteinuria and diabetic foot ulcers) had significantly lower MFR values compared to those without (1.94 ± 0.48 vs. 2.86 ± 0.83; p < 0.005). ***Conclusion:*** Impaired MFR was more frequently observed in T2DM patients with diabetic microvascular complications, especially those with proteinuria. These findings suggest that coronary microvascular dysfunction and diabetic nephropathy may share common underlying mechanisms, pointing to a broader systemic microvascular pathology in diabetes.

Prognostic value of coronary flow capacity by 82Rb PET in a large cohort of patients with suspected and known coronary artery disease

E. Zampella[1], *R. Assante*[1], *T. Mannarino*[1], *A. D'Antonio*[1], *M. Panico*[2], *P. Buongiorno*[1], *V. Cantoni*[1], *R. Green*[1], *A. Cuocolo*[1], *W. Acampa*[1];
[1]*University Federico II, Naples, ITALY,* [2]*3Institute of Biostructure and Bioimaging, CNR, Naples, ITALY.*

Aim/Introduction: Cardiac imaging by positron emission tomography (PET) provides an accurate evaluation of both atherosclerotic burden and vascular function. Coronary flow capacity (CFC) is a comprehensive measure of the entire coronary vascular status, integrating both hyperemic myocardial blood flow (MBF) and myocardial flow reserve (MFR). We aimed to assess the incremental prognostic value of impaired CFC, evaluated by Rubidium-82 (82Rb) PET, in a large cohort of patients with suspected and known CAD. ***Materials and Methods:*** We evaluated 5839 patients who underwent stress/rest 82Rb cardiac PET/CT in our institution. Coronary artery calcium (CAC) score was calculated and categorized as <400 and ≥400. Total perfusion defect (TPD) was considered abnormal when ≥5%. MFR was considered impaired when <2. According to previously defined thresholds, patients were classified as having normal (normal flow or minimally reduced CFC) or abnormal (mildly reduced, moderately reduced, severely reduced CFC and myocardial steal) CFC. The outcome endpoints were cardiac death, myocardial infarction and revascularization procedures. Annualized event rate (AER) was calculated. Cox proportional hazards model was employed to estimate risk of events. A parametric survival model was also used to identify how the variables influenced time to event and to estimate risk-adjusted event rates during the follow-up. ***Results:*** Follow-up was available in 5379 (92%) patients (median age 61±12 years). During a median time of 42±27 months, 780 events occurred (cumulative rate 14%, AER 3.4%). A total of 2037 (38%) patients had abnormal CFC. AER was higher in patients with impaired CFC (AER 7.9%) as compared to those without (AER 1.9%) (p <0.001). At multivariable COX analysis, diabetes, CAC ≥400, TPD ≥5%, MFR<2 and abnormal CFC resulted significant predictor of events (all p<0.001). At incremental analysis the addition of CFC to a model including clinical variables, TPD≥5% and MFR<2 increased the global chi-square from 759 to 840 (p<0.001). At Weibull parametric survival analysis, the highest probability of cardiac events and the major risk acceleration were observed in patients with impaired CFC. ***Conclusion:*** The presence of impaired CFC is associated with a higher risk of cardiac events both in patients with suspected and known CAD.

OP-685

Improved cardiac^{82}Rb-PET functional imaging with 16-gates protocol using a LAFOV PET system

N. Gözlügöl, *H. Sari, F. Aghapour Zangeneh, A. Rominger, F. Caobelli;*
Inselspital Bern University Hospital, Bern, SWITZERLAND.

Aim/Introduction: The evaluation of cardiac function on ^{82}Rb-PET is often limited by low count statistics in gated imaging, which can impair the accuracy of left ventricular (LV) volumes and ejection fraction (LVEF). Although 16 ECG-gated frames could improve accuracy by providing more detailed temporal sampling, low count statistics remain a limiting factor. Hence, 8-gated frames are typically used. Increasing the administered activity may address this, but at the cost of higher radiation exposure. Long axial field-of-view (LAFOV) PET/CT scanners may fit this need by

offering increased sensitivity, enabling high count statistics even at low activity levels. We investigated whether increasing the number of ECG-gated frames from 8 to 16 during ^{82}Rb cardiac PET improves the accuracy of functional parameters compared to transthoracic echocardiography (TTE). ***Materials and Methods:*** Eighty-seven patients who underwent ^{82}Rb-PET with both rest and stress imaging were included. A standard activity of 370 MBq was injected for both acquisitions. PET reconstructions with 8 and 16 gated frames were analyzed for LVEF and end-diastolic and end-systolic values (EDV and ESV, respectively). Corresponding TTE values were collected from clinical reports. Differences between PET- and TTE-derived values were assessed with paired t-test, Pearson-correlation and Bland-Altman analysis. PET-derived values with 8 and 16 gated frames were contrasted with paired t-test after verification of normal distribution. ***Results:*** Mean LVEF at rest was 54.8±13.9% with 8-gated PET, 61.2±11.2% with 16-gated PET, and 58.1±7.8% on TTE. LVEF with 16-gated frames showed close agreement with TTE, with only a slight, non-significant overestimation (p = 0.103, mean difference +2.0%, R=0.47). Conversely, 8-gated PET significantly underestimated LVEF (p = 0.007, mean difference - 4.3%, R=0.28). Considering volume analysis, EDV was accurately evaluated by both 8-gated (mean difference +14.6 mL, p = 0.060) and 16-gated PET (mean difference +10.8 mL, p = 0.067). Conversely, 16-gated PET showed superior accuracy for ESV, with a slight overestimation of +8.8% (p = 0.304), whereas 8-gated PET significantly overestimated ESV by +38.0% (p = 0.013). ***Conclusion:*** ^{82}Rb-PET imaging on LAFOV PET with 16-gated frames demonstrated close agreement with TTE for LVEF, EDV, and ESV, indicating superior accuracy in the assessment of LV functional parameters. Conversely, standard 8-gated PET showed systematic underestimation. Of note, high accuracy was yielded with ultra low activities. These findings support the clinical implementation of 16-gated acquisition protocols on LAFOV PET systems to enhance the accuracy of functional cardiac assessment during myocardial perfusion imaging, while reducing radiation burden.

OP-686

Reduction of acquisition time in [^{15}O]H_2O-myocardial perfusion imaging

K. Thøgersen*, M. Nowak Lonsdale, M. Krakauer;*
Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital – Bispebjerg and Frederiksberg, Copenhagen, DENMARK.

Aim/Introduction: Unlike other perfusion tracers that stay confined in the myocardium, [^{15}O]H_2O is freely diffusible and has an extraction fraction of 1. Therefore, [^{15}O]H_2O-uptake in myocytes is linearly proportional with tissue perfusion and the most crucial time of acquisition is within the first minutes after tracer injection. The usual protocol in myocardial perfusion imaging with Adenosine as vasodilator is intravenous infusion of 140µg/kg/min for 6 minutes with injection of tracer after obtaining maximum vasodilation at 2 minutes followed by at least 4 minutes acquisition time. A reduction in both Adenosine infusion time and acquisition time could reduce patient discomfort and time consumption. The aim of this study was to test if reducing acquisition time with [^{15}O]H_2O as PET-tracer altered myocardial blood flow (MBF). ***Materials and Methods:*** In this retrospective study we included 30 patients suspected of chronic ischemic heart disease. We consecutively included 10 patients in three categories: global stress perfusion below 1.8, between 1.8 and 2.8, and above 2.8ml/g/min. Exclusion criteria were insufficient response to Adenosine or motion artefacts. PET/CT scans were performed on a Discovery 710 (GE Healthcare) with our standard protocol described in detail elsewhere (1). A bolus of 600MBq [^{15}O]H_2O was administered, and PET data acquired for 7 minutes. Adenosine infusion (140µg/kg/min) was started 2 minutes prior to the anticipated arrival of the bolus in the heart. A dynamic series (14×5s, 3×10s, 3×20s, 4×30s) was reconstructed triggered by the arrival of [^{15}O]H_2O to the heart. In addition to the original 280s datasets, 120 datasets were generated by truncating the acquisition at 160s, 190s, 220s and 250s for each patient. Kinetic analysis was conducted using CarimasCE version 1.3.1. (VARHA, Turku, Finland). Volumes of interest were drawn manually by the same physician. Global MBF and regional MBFs (LAD, LCX, RCA territories) were assessed. Full-length scans analysed twice for each patient to assess intra-rater variability. Statistical analyses included paired t-test, intra-class correlation coefficients (ICC) and Bland-Altman plots. ***Results:*** Intra-rater analysis showed no significant difference, e.g., global MBF comparison showed t=0.778, p=0.443. Neither did scan length affect MBF significantly, e.g., global full length versus the shortest showed t=0.402, p=0.691 with high reliability ICC(95%) 0.995(0.991-0.997). Bland Altman plots showed no biases. ***Conclusion:*** Shortening acquisition time by 2 minutes, thus also reducing Adenosine infusion duration, did not affect MBF. This could reduce patient discomfort and time consumption without compromising diagnostic performance. ***References:*** (1) Krakauer M et al. J Nucl Cardiol. 2023 Dec;30(6):2790-2802.

OP-687

Reproducibility of splenic blood flow and splenic switch-off in ^{15}O-water positron emission tomography myocardial perfusion imaging

J. Jou*[1], J. Nordström[2], J. Sörensen[3], M. Lubberink[3], T. Kero[3];*
[1]Department of Medical Sciences, Clinical Physiology, Uppsala University, Uppsala, SWEDEN, [2]Center for Research and Development Uppsala/Gävleborg Country, Gävle, SWEDEN, [3]Molecular Imaging and Medical Physics, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Myocardial perfusion imaging (MPI) with adenosine stress is widely used to diagnose ischemia in coronary artery disease (CAD). However, confirming adequate myocardial vasodilation remains a challenge. Splenic switch-off (SSO) — the reduction in splenic blood flow during adenosine stress— is considered an indirect marker of systemic and coronary vasodilation. A spleen stress/rest ratio (SSR-ratio) below 0.9 has been proposed as a threshold of adequate adenosine effect. Despite its potential, the reproducibility of quantitative splenic perfusion measures is not well established. This study aimed to evaluate the reproducibility of splenic blood flow and SSR-ratio using ^{15}O-water PET. ***Materials and Methods:*** Twenty-one patients with suspected CAD underwent same-day test-retest ^{15}O-water PET MPI at rest and during adenosine stress. All subjects were asked to abstain from caffeine for 24 hours before imaging. Splenic blood flow was quantified at rest and stress using 2D regions of interest (ROIs) in the spleen in full field-of-view parametric blood flow (K1) images. The SSR-ratio was calculated as stress/rest splenic blood flow. Reproducibility was assessed using the repeatability coefficient (RC = 1.96 × SD of differences), mean test-retest differences, and within-subject coefficient of variation (wCV). ***Results:*** Three subjects were excluded from the analysis: two subjects due to suspected caffeine intake between test and retest (a SSO effect and increase in stress myocardial blood flow (MBF) was observed during test, but not during retest); and one subject due to suspected caffeine intake prior to the test (a paradoxical splenic perfusion response —higher splenic blood flow during stress— and low stress MBF and myocardial flow reserve was observed during both test and retest). Eighteen patients (44% female) were thus included in the final analysis. Mean splenic blood flow was 1.13 ± 0.33 and 1.08 ± 0.33 mL/min/g at rest , and 0.20 ± 0.19 and 0.18 ± 0.17 mL/min/g during stress, for test and retest respectively. Mean SSR-ratio was 0.16 ± 0.13 and 0.18 ± 0.16 for test and retest, respectively. SSR-ratios were <0.6 in all patients. The RC of SSR-ratio was 0.38, corresponding to 221% of the mean, with a mean absolute relative difference of 76%, and wCV of 80%. ***Conclusion:*** Splenic blood flow during adenosine stress demonstrates high variability. Nevertheless, SSR-ratios

were <0.6 in all subjects, indicating consistent and optimal SSO and supporting its use as a quantitative biomarker of adequate adenosine response.

Aim/Introduction: Prone positioning in SPECT myocardial perfusion imaging (MPI) is used to reduce attenuation artifacts caused by the diaphragm in the inferior wall and the breast tissue in the anterior and anteroseptal walls. SPECT/CT-based attenuation correction may introduce some artifacts and is not available in all centers. Due to the limitations of prone image acquisition in patients with physical limitations (obesity or large breasts), this technique is not feasible for all patients. Artificial intelligence (AI) has shown promising results in attenuation correction for SPECT MPI. The aim of this study is to use a deep learning model to synthesize prone-position images from supine acquisitions, thereby eliminating the need for acquiring prone images. ***Materials and Methods:*** We employed 7,472 paired supine and prone SPECT MPI scans with ^{99m}Tc-MIBI collected from five centers. Two centers (1,140 cases) were reserved for external test set, while the remaining 6,332 cases were used for model training and validation. PyTomography was used for image reconstruction. A nnUNetv2 model was used for automatic segmentation of the left ventricle (LV), trained on an independent dataset consisting of 540 SPECT MPI scans using 5-fold cross-validation. The trained model was applied to all images for LV delineation, after which each image was cropped to a bounding box surrounding the LV based on the segmentation output. Rigid registration was subsequently performed to align supine images with their corresponding prone images. For model training, we employed SwinUNETR architecture. The synthetic prone images and supine images were compared to the prone images as standard of reference using structural similarity index (SSIM), peak signal-to-noise ratio (PSNR), mean relative error (MRE%), and mean absolute relative error (MARE%) metrics. ***Results:*** The mean Dice and IoU for LV segmentation were 0.91 and 0.84, respectively. The quantitative evaluation demonstrated that the synthetic prone images were more similar to the ground truth prone images in comparison with the original supine images, achieving higher SSIM (90.49 ± 8.46 vs. 87.40 ± 8.23) and PSNR (24.17 ± 2.43 vs. 22.88 ± 2.37), lower MRE% (2.80 ± 19.14 vs. 7.31 ± 21.46) and MARE% (27.58 ± 15.17 vs. 44.23 ± 19.24). ***Conclusion:*** This study demonstrates the feasibility of synthesizing prone SPECT MPI from supine acquisitions. The synthetic prone images have the potential to eliminate the need for additional prone image acquisition, particularly in patients with physical limitations, obesity, or large breasts and providing complementary diagnostic information using only supine imaging.

Aim/Introduction: Deep learning-based PET image reconstruction has gained increasing attention due to its fast reconstruction times and low-count imaging capabilities. Fast reconstruction is particularly valuable for dynamic PET imaging, where multiple frames are needed to capture tracer kinetics. Long axial field-of-view PET scanners enable total-body quantitative blood-flow imaging, allowing measurements across multiple organs of interest beyond the myocardium. This study provides the first systematic evaluation of FastPET(1,2), which uses multi-angular histo-images and attenuation correction factors as inputs to a 3D-UNET to reconstruct PET images in approximately 20 seconds(2), in whole-body 82-Rubidium blood flow imaging. ***Materials and Methods:*** Twenty patients underwent whole-body rest/stress 82-Rubidium PET scans using a LAFOV PET/CT system. List-mode PET data were acquired for 7 minutes at both rest and stress conditions, starting just before administration of 370 MBq of 82-Rubidium. PET data were reconstructed into 35 frames using FastPET and using OSEM to serve as reference reconstructions. Furthermore, static images were reconstructed using FastPET and OSEM

from the last 3.5 minutes. Volumes of interest were segmented semi-automatically in lungs, kidneys, spleen, aorta, liver, and myocardium. Time activity curves (TACs) and mean uptake values were computed using dynamic and static images reconstructed with both methods. Signal-to-noise (SNR) was computed in aorta. TACs were fitted with 1-tissue-compartment model to extract K_1 values. Pearson correlation and paired t-tests were used for statistical comparison. ***Results:*** FastPET and OSEM static images showed close visual resemblance, with FastPET images appearing smoother. The mean SNR was higher in FastPET (6±2 at rest and 5±2 at stress) than in OSEM (3±1 at rest and stress). Uptake value measurements from FastPET static images correlated strongly with OSEM across all organs ($r>0.97, p<0.05$). The mean percentage differences in organ uptake values measured with Fast PET, using OSEM as the reference, ranged from -1.95±1.95 % to 3.08±3.33%. A strong agreement was particularly observed in myocardium values, where the percentage difference in uptake values was -0.65±2.58%(rest) and -0.55±2.41%(stress) with no statistically significant difference (r=0.15 and 0.22 respectively). K_1 estimates with FastPET demonstrated strong correlation with (r=0.97 at rest and r=0.92 at stress, with mean percentage differences of -4.07±7.03% (rest) and -8.51±13.38% (stress). ***Conclusion:*** FastPET reconstruction yields higher SNR and comparable quantitative accuracy to OSEM in dynamic 82-Rubidium PET imaging. Uptake and kinetic parameter (K_1) estimates from FastPET showed strong agreement with OSEM, supporting its potential use for dynamic 82-Rubidium studies. ***References:*** 1)Whiteley W.et al.,IEEE NSS&MIC,2020, 2)Millardet M.et al.,IEEE NSS&MIC,2023.

EPS-222

Feasibility Study of Deep Learning-Based Low-Dose PET and Accelerated MR Imaging in PET/MR

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: Positron Emission Tomography/Magnetic Resonance (PET/MR) imaging requires high doses of radioactive tracers for PET and prolonged MR scanning times to ensure diagnostic accuracy, which raises concerns about radiation exposure risks and patient discomfort. While reducing PET tracer doses shortens radiation exposure, low-dose PET (L-PET) images suffer from increased noise and artifacts. Similarly, accelerated MR scans introduce motion artifacts and reduced spatial resolution, further compromising image quality. Reconstructing high-quality full-dose PET (F-PET) images from L-PET and enhancing accelerated MR scans using deep learning presents a promising solution to address both challenges. ***Materials and Methods:*** In this study, L-PET data were simulated by retaining 10% of the original tracer dose, while accelerated MR data were generated by subsampling 20% of k-space data. A dual-branch deep learning framework, **FusionNet-DSR**, was proposed to simultaneously reconstruct F-PET (100% dose) from L-PET (10% dose) and restore high-resolution MR images from accelerated scans. FusionNet-DSR integrates a transformer-enhanced generative adversarial network (GAN) for PET reconstruction and a deformable convolutional network with spatial-frequency attention for MR super-resolution. The framework was trained on 12,000 paired PET/MR slices from 50 oncology patients and validated on 30 independent cases. Performance was evaluated using peak signal-to-noise ratio (PSNR), structural similarity index (SSIM), and normalized root mean square error (NRMSE) for PET, alongside edge sharpness (ES) and artifact suppression ratio (ASR) for MR. Six state-of-the-art models—ResGAN, U-Net++, 3D-RCAN, CyclePET-MR, and two task-specific networks—were compared. Two radiologists blindly assessed diagnostic consistency between original and reconstructed images. ***Results:*** FusionNet-DSR achieved superior results: PET reconstruction yielded the highest PSNR (31.2±2.9) and SSIM (0.945±0.04), with the lowest NRMSE (0.039±0.011), while MR enhancement attained an ES of 92.4%±3.1 and ASR of 88.7%±2.8, outperforming all competitors. Bland-Altman analysis confirmed narrow limits of agreement (−0.18 to 0.19 for PET SUV; −1.2% to 1.1% for MR spatial accuracy), and paired t-tests revealed no significant differences in radiologists' diagnostic scores ($p > 0.05$) between reconstructed and original images. The dual-branch design effectively preserved metabolic details in PET and anatomical structures in MR, with 40% faster inference than cascaded single-task models. ***Conclusion:*** FusionNet-DSR demonstrates the feasibility of jointly reducing PET tracer doses and shortening MR scan times without compromising diagnostic quality. This approach holds potential to enhance patient safety and operational efficiency in clinical PET/MR workflows.

EPS-223

MlPET: A Fast Localized Machine Learning Approach for Probabilistic PET Image Reconstruction Using Informed Priors - Application to Phantom data

T. M. Hansen[1], *N. L. Christensen*[2], *M. H. Vendelbo*[3,2];
[1]*Department of Geoscience, Aarhus University, Aarhus, DENMARK,* [2]*Department of Nuclear Medicine & PET, Aarhus university Hospital, Aarhus, DENMARK,* [3]*Department of Biomedicine, Aarhus University, Aarhus, DENMARK.*

Aim/Introduction: Positron Emission Tomography (PET) imaging faces inherent limitations in noise and resolution that affect clinical diagnosis, particularly for small lesion detection. This study aims to develop and evaluate MlPET, a novel fast localized machine learning approach for probabilistic PET image reconstruction that addresses these limitations by integrating Point Spread Function (PSF) modeling, spatially correlated noise characterization, and informed Priors. ***Materials and Methods:*** We implemented a neural network-based method that transforms the traditional inverse sampling problem [1] into a computationally efficient local approach. The method incorporates a local neighborhood analysis strategy where posterior statistics are considered for subsets of model parameters using reconstructed PET data around central pixels. This approach was evaluated using phantom data across three different PET scanners (Vision Quadra, Biograph Vision 600, and Discovery MI) with acquisition times ranging from 1 to 900 seconds. Performance was assessed using quantitative metrics including Contrast Recovery Coefficient (CRC), Coefficient of Variation (COV), spatial resolution (FWHM), and visual assessment of lesion detectability. ***Results:*** MlPET achieved substantially improved quantitative performance compared to conventional reconstruction methods. For the smallest spheres (10mm), MlPET reached CRC values approaching 1.0 (0.99 at 900 seconds) compared to 0.56 for conventional PET. Noise characteristics showed approximately tenfold reduction in COV at extended acquisition times. Spatial resolution improved from approximately 2mm FWHM with conventional methods to 0.6mm FWHM with MlPET, representing a 3.5-fold improvement. Most significantly, MlPET at 40-80 seconds acquisition time outperformed conventional PET at 900 seconds across key image quality metrics, suggesting a potential 10-20 fold reduction in required scan time while maintaining or improving diagnostic quality. ***Conclusion:*** The MlPET approach demonstrates significant potential for enhancing PET image quality, particularly for small lesion detection, while enabling shorter scan times or reduced radiation exposure. By integrating PSF modeling, noise characterization, and informed priors through a localized neural network approach, this methodology addresses the traditional trade-off between noise reduction and resolution enhancement. While these phantom-based results represent an idealized scenario with well-matched prior information that may not fully translate to clinical applications, they clearly demonstrate the theoretical boundaries of what could be achieved. These findings suggest MlPET could

improve diagnostic capabilities in oncology applications requiring detection of small lesions, potentially transforming clinical workflows through more efficient scanner utilization. ***References:*** [1] Hansen, T.M., et al. "Probabilistic deconvolution of PET images using informed priors." Frontiers in Nuclear Medicine 2 (2023): 1028928.

EPS-224

Assessment of Deep Learning Attenuation Correction for Myocardial Perfusion Scintigraphy on a Dedicated Cardiac CZT-SPECT Camera: Comparison with [^{82}Rb] PET-CT

M. Westerman[1], *P. Bharadwaj*[1], *G. Keramida*[1], *L. Munemo*[2], *K. Wechalekar*[1], *L. Hossen*[1];
[1]*Royal Brompton Hospital, London, UNITED KINGDOM,* [2]*Auckland City Hospital, Auckland, NEW ZEALAND.*

Aim/Introduction: TruCorr, a deep learning-based attenuation correction method developed for the D-SPECT CZT cardiac camera for Myocardial Perfusion Scintigraphy (MPS), offers potential for attenuation correction (AC) utilising patient emission data. Traditionally 2 imaging positions are acquired, upright and supine, to mitigate attenuation artefacts. This study compares performance of D-SPECT supine [^{99m}Tc]Tetrofosmin MPS data including TruCorr-AC against [^{82}Rb] PET-CT MPS to explore its effectiveness and potential to support single-position D-SPECT imaging. ***Materials and Methods:*** Nineteen patients (15/19 males, age: 48-91, BMI: 20-39.8 kg/m^2) with SPECT and PET-CT scans within one year without major clinical events were selected. Most patients had underlying coronary artery disease. A blinded assessment was performed by two experts comparing D-SPECT stress and rest supine images without AC (Set-1) to D-SPECT stress and rest supine images with TruCorr-AC (Set-2), and to PET dynamic, stress and rest supine images with CT-AC (Set-3). Assessed parameters included image quality, presence, location, and correction of attenuation artefacts, vascular distribution, summed perfusion and reversibility percentages for stress, rest and difference respectively (SS%, SR%, SD%). Statistical analysis included two-tailed sign test, Wilcoxon signed-rank test, and McNemar's test. ***Results:*** Image quality was comparable between Set-2 and Set-3 ($p>0.05$). Attenuation artefacts could be identified in 5/19 Set-1, 14/19 Set-2, and 18/19 Set-3 cases. In absence of AC data, experts faced challenges determining attenuation artefacts in 13/19 cases, resulting in significant differences between Set-1 vs Set-2 ($p=0.0117$) and Set-1 vs Set-3 ($p=0.0005$). This also affected artefact location interpretation between Set-1 and Set-3 ($p=0.0024$). Most artefacts were in the inferior wall, extending to the septum, lateral walls, and some anterior walls. In 4/12 cases, Set-3 appeared to fully correct attenuation artefacts that Set-2 only partially corrected. Although there were observable differences in vascular distribution (e.g. RCA, LAD, CX), no significant statistical differences were found. RCA and LAD were abnormal on Set-1 (RCA: 7/19; LAD: 6/19) and Set-2 (6/19 in both, RCA & LAD) but normal on Set-3. No significant differences were found in SD%, and SS%. However, SR% differed significantly: Set-1 vs Set-3 ($p=0.0093$) and Set-2 vs Set-3 ($p=0.0048$), with PET-CT producing minimal defects. ***Conclusion:*** D-SPECT MPS imaging in supine position with TruCorr-AC improves image quality and confidence compared to SPECT alone for attenuation artifacts. TruCorr-AC gives a conservative correction for attenuation compared to PET-CT. It has the potential for achieving outcomes closer to [^{82}Rb] PET-CT. Further development could support moving to single position supine imaging.

EPS-225

Feasibility Study of Deep Learning-Based Low-Dose PET and CT Imaging in PET/CT

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: Positron Emission Tomography/Computed Tomography (PET/CT) imaging necessitates high doses of radioactive tracers for PET and elevated radiation exposure from CT scans, raising concerns about cumulative radiation risks and patient safety. While reducing PET tracer doses decreases radiation burden, low-dose PET (L-PET) images exhibit amplified noise and quantitative inaccuracies. Similarly, lowering CT radiation doses (L-CT) introduces noise, streak artifacts, and compromised contrast resolution, further degrading diagnostic utility. Reconstructing high-quality full-dose PET (F-PET) images from L-PET and enhancing L-CT scans using deep learning offers a synergistic strategy to mitigate these dual challenges. ***Materials and Methods:*** In this study, L-PET data were simulated by retaining 10% of the original tracer dose, while L-CT data were generated by reducing tube current to 20% of standard protocols. A hybrid deep learning framework, **DualResNet-CTR**, was developed to jointly reconstruct F-PET (100% dose) from L-PET and restore high-fidelity CT images from L-CT. DualResNet-CTR combines a multi-scale residual network with channel attention for PET denoising and a transformer-based U-Net with edge-preserving constraints for CT artifact suppression. The model was trained on 15,000 paired PET/CT slices from 60 oncology patients and validated on 40 independent cases. Performance was evaluated using peak signal-to-noise ratio (PSNR), structural similarity index (SSIM), and standardized uptake value (SUV) error for PET, alongside Hounsfield unit (HU) accuracy, noise reduction rate (NRR), and artifact index (AI) for CT. Five state-of-the-art models—DeepPET, CT-GAN, DenseUNet, JointRecon-Net, and a cascaded single-task network—were benchmarked. Two radiologists performed blinded assessments of diagnostic concordance between original and reconstructed images. ***Results:*** DualResNet-CTR achieved superior performance: PET reconstruction yielded the highest PSNR (32.1±2.5) and SSIM (0.953±0.03), with minimal SUV error (3.8%±1.2), while CT enhancement demonstrated HU accuracy of 98.6%±1.4, NRR of 85.3%±4.1, and AI reduction of 79.5%±3.6, surpassing all competitors. Bland-Altman analysis showed narrow limits of agreement (−0.22 to 0.25 for PET SUV; −2.1% to 1.9% for CT HU values), and Wilcoxon signed-rank tests confirmed no significant differences in radiologists' diagnostic confidence scores ($p > 0.05$) between reconstructed and original images. The integrated architecture effectively preserved metabolic quantification in PET and anatomical fidelity in CT, with 35% faster inference than sequential single-modality models. ***Conclusion:*** DualResNet-CTR validates the feasibility of concurrently reducing PET tracer doses and CT radiation exposure without sacrificing diagnostic accuracy. This approach may significantly enhance patient safety and streamline clinical PET/CT workflows.

EPS-226

Cross-Modal Synthesis of Tau-PET Images from Amyloid-PET Scans Using Deep Learning

Y. Hu[1], *D. E. Peretti*[2], *V. Garibotto*[1], *A. Sanaat*[1], *H. Zaidi*[1];
[1]*Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND,* [2]*Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocenter and Faculty of Medicine, University of Geneva, Geneva, SWITZERLAND.*

Aim/Introduction: The deposition of amyloid-β plaques and the accumulation of neurofibrillary tau tangles are two primary pathological hallmarks of Alzheimer's disease (AD). Studies suggest a complex interplay between tau protein and amyloid plaques. Flortaucipir (FTP) PET imaging is crucial for

understanding AD progression and surpasses Amyloid-PET in predicting cognitive decline. However, the clinical application of FTP-PET is hindered by high costs and limited availability. This study proposes a deep learning framework leveraging SwinUnetR to synthesize FTP-PET images from Amyloid-PET scans, aiming at reducing patient burden, minimize radiation exposure, and improve diagnostic efficiency. ***Materials and Methods:*** A dataset from the Alzheimer's Disease Neuroimaging Initiative (ADNI) and hospital university Geneva (HUG) memory center comprising 415 patients with Amyloid-PET tracers including ^{18}F-Florebetaben (FBB), ^{18}F-Florbetapir (FBP), and ^{18}F-Flutemetamol (FMM) was used to develop a cross-modal synthesis model. The model was trained using five-fold cross-validation with mean squared error loss. Given the regional accumulation patterns of tau protein, a CenTauR mask including relevant regions was generated and multiplied by PET images to focus the model on these regions. The synthesized FTP-PET images were evaluated using quantitative metrics, including peak signal-to-noise ratio (PSNR), structural similarity index (SSIM), mean relative error (MRE), mean relative absolute error and absolute error. ***Results:*** The model successfully synthesized realistic FTP-PET images for all tracers (FBB, FBP, FMM) (Figure 1). As shown in Table 1, the MRE for FTP generated using FBB images was 0.23 ± 1.02%, 0.2 ± 1.27% for FTP generated using FBP, and 0.28 ± 1.11% for FTP generated using FMM. Figure 2 presents regional error analyses, demonstrating minimal error values: FTP from FBB had errors ranging from -0.025 to 0.005 standardized uptake value ratio (SUVR), FTP from FBP had errors ranging from -0.005 to 0.005 SUVR, and FTP from FMM had errors ranging from -0.03 to 0.01 SUVR. ***Conclusion:*** This study proposes and validates a cross-modal image generation method that synthesizes accurate FTP-PET from Amyloid-PET images without requiring additional PET scans, thus simplifying AD diagnostic workflows.

EPS-227

Deep Learning Model for Denoising and Positron Range Correction for Clinical Gallium-68 PET/CT Scanning

P. Gavriilidis[1,2,3], *R. Wierts*[1], *F. M. Mottaghy*[1,4], *M. Koole*[3];
[1]*Maastricht UMC+, Maastricht, NETHERLANDS,* [2]*Maastricht University, Maastricht, NETHERLANDS,* [3]*KU Leuven, Leuven, BELGIUM,* [4]*RWTH Aachen University Hospital, Aachen, GERMANY.*

Aim/Introduction: Gallium-68 (^{68}Ga) features larger positron range than Fluorine-18 (^{18}F), which can be compensated via positron range correction (PRC), as was demonstrated in a previous patient study [1]. Meanwhile, deep learning models (DLMs) have been employed to denoise PET images, thus enabling a reduction in scan time or injected activity. In this study, a DLM was developed to perform both ^{68}Ga-specific PRC and denoising on clinical ^{68}Ga-PET/CT data. ***Materials and Methods:*** List-mode PET/CT data from 76 patients scanned with ^{68}Ga-DOTATOC (1.5 MBq/kg) were split into 50% count subsets. High-count data were reconstructed using Q.Clear including Point-Spread-Function (PSF) modeling and Time-of-Flight (ToF) information, both with and without a tissue-independent PRC (β=600 and β=700, respectively) [1]. Low-count data were reconstructed with Q.Clear, including PSF and ToF but without PRC (β=700). A DLM based on U-Net was trained to map reconstructed low-count PET data without PRC to their corresponding high-count PET data with PRC. The scans were divided into training (54), validation (10), and test (12) sets. Model performance was evaluated by comparing the coefficient of variation (COV) in liver, as a measure for noise levels between the low-count, DLM and high-count PET data. Additionally, the maximum standardized uptake value (SUV_{max}) and contrast-to-noise ratio (CNR) of corresponding tumor lesions between low-count, DLM and high-count PET images were compared. Statistical analysis was performed using the Wilcoxon signed-rank test (α=0.05), with Bonferroni correction for multiple comparisons. ***Results:*** The low-count PET data without PRC demonstrated significantly higher noise levels (28.2%, p=0.002), reduced SUV_{max} (-10.6%, p=0.002), and lower CNR (-20.5%, p<0.001) compared to the high-count PET images with PRC. The DLM achieved noise levels comparable to high-count PET data with and without PRC, as no statistically significant COV differences were observed (p=1). For soft tissue lesions (23), the DLM resulted in a reduced SUV_{max} (-8.7%, p<0.001) and similar CNR (p=0.5) compared to high-count PET data with PRC. When compared to high-count PET data without PRC, the DLM increased the CNR (7.6%, p=0.005), while no statistically significant difference was observed for SUV_{max} (p=1). ***Conclusion:*** The DLM provided sufficient denoising performance to enable a 50% reduction in acquisition time for clinical ^{68}Ga PET/CT imaging while maintaining image quality. However, addressing simultaneously the longer positron range of ^{68}Ga with a DLM appears to be less effective than incorporating a PRC directly into the high-count ^{68}Ga-specific PET reconstruction of patient scans. ***References:*** [1] Gavriilidis P, et al., EJNMMI, 2025.

EPS-228

Image quality and lung nodule detectability in LAFOV PET: quantitative and qualitative evaluation

A. Spataro*, A. Franchini, S. Capitanio, A. Scarale, L. Airo' Farulla, G. Cabrini, E. Gay, C. Rossetti;*
Nuclear Medicine Unit, Dipartimento Ematologia, Oncologia e Medicina Molecolare, ASST Niguarda, Milan, ITALY.

Aim/Introduction: Large Axial Field-of-View (LAFOV) PET/CT systems offer increased sensitivity and enable ultra-fast acquisitions with lower injected activity. This opens new possibilities for faster, lower-dose protocols, especially relevant in the evaluation of solitary pulmonary nodules, where lesion detectability and image quality are essential. In this study, we aimed to assess how different reconstruction methods, including both standard and AI-based techniques, perform in a LAFOV PET setting, using various acquisition durations. ***Materials and Methods:*** In this retrospective study, data were collected from 40 patients (21 men and 19 women; mean age 67.6 years) who underwent [^{18}F]FDG PET/CT for characterization of indeterminate pulmonary nodules between January 1 and March 31 2025. Patients were all scanned 60 minutes after FDG injection on a LAFOV PET/CT system featuring 148 cm Axial Field of View. A 3-minute acquisition was performed on each patient, and 4 image sets were reconstructed: standard OSEM algorithm at 3 minutes, a new iterative algorithm (Hyper iterative) at 30 seconds, a deep learning-based algorithm (DPR) at 3 minutes and the same DPR algorithm at 30 seconds. For every reconstruction, we analyzed SUVmax, SUVmean, SUVpeak, signal-to-noise ratio (SNR), and tumor-to-background ratio (TBR). A total of three nuclear medicine physicians analyzed all sets of images, blinded to reconstruction method, scoring overall image quality, background noise, and nodule definition on a four-point scale. Inter-reader agreement was determined using Fleiss' kappa. We further examined the relationship between visual scores and quantitative imaging metrics using Pearson's correlation coefficient. ***Results:*** DPR at 30 seconds provided the best TBR and SNR results, significantly outperformed standard OSEM at 3 min reconstruction ($p < 0.001$) and showed statistically and clinically significant improvements, enhancing lesion visibility, visual scores and interpretability, especially in small nodules. The visual assessment also favored the DPR reconstructions, during which the DPR 3 minutes and DPR 30 seconds demonstrated the highest average scores. Inter-reader agreement was very good for all visual criteria (kappa: 0.77-0.94). Of the visual features, nodule definition correlated the most with quantitative parameters, particularly SUVmax ($R = 0.70$), SUVpeak ($R = 0.58$), and TBR ($R = 0.66$). SUVpeak values showed excellent consistency across all reconstruction methods ($R > 0.99$). ***Conclusion:*** DPR-based reconstruction, even with just 30 seconds of acquisition, provides excellent image quality and

lesion detectability, outperforming standard protocols. SUVpeak and nodule definition proved to be the most reliable indicators. These results support the clinical adoption of AI-based methods, enabling faster, lower-dose PET imaging without compromising diagnostic performance.

EPS-229

Study of Different Partial Volume Correction Methods in Tau PET Imaging for Alzheimer's Disease

A. Rohmah[1], *K. Lin*[2], *I. Hsiao*[1,2];
[1]*Chang Gung University, Taoyuan, TAIWAN,* [2]*Department of Nuclear Medicine, Chang Gung Memorial Hospital, Taoyuan, TAIWAN.*

Aim/Introduction: Partial volume effect (PVE) leads to the degradation of the quantitative accuracy of the PET imaging. This study compares different partial volume correction (PVC) methods in [18F] APN-1607 ([18F]-Florzolotau) to assess their impact on image quantification for Alzheimer's Disease. ***Materials and Methods:*** A total of 149 subjects, including 42 normal control (NC), 43 mild cognitive impairment (MCI), and 64 Alzheimer's disease (AD), underwent [18F] APN-1607 tau PET and MRI imaging. The T1 MRI images were co-registered with the corresponding PET images, segmented using FastSurfer, and merged into 48 regions. All PET images were corrected by Muller-Gartner (MG), Multi-Target Correction (MTC), Region-Based Voxel-Wise Correction (RBV), Iterative Yang (IY), Richardson-Lucy (RL), and Van-Cittert (VC) methods using the PETPVC toolbox. The crus was used as the reference region to generate the standardized uptake value ratio (SUVR). The percentage of group differences between uncorrected and corrected SUVR and Cohen's d-effect sizes of the Braak stage VOIs were evaluated. ***Results:*** The result showed increasing in SUVR values after PVC in all groups. MG led the highest percentage, with increased SUVR by 9%, 14%, and 18% in NC; 19%, 26%, and 30% in MCI; and 28%, 41%, and 46% in AD for Braak stage I/II, III/IV, and V/VI, respectively. A similar trend in the MTC, with increases of 5%, 10%, and 11% in NC; 12%, 20%, and 21% in MCI; and 19%, 33%, and 32% in AD. In MCI vs NC, the effect sizes before PVC were 0.66, 0.74, and 0.60 for Braak stage I/II, III/IV, and V/VI, respectively. After PVC, MG led the largest effect size in Braak stage I/II (0.86), Braak stage III/IV (0.92), and Braak stage V/VI (0.86). In AD vs NC, the effect sizes before PVC were 1.13, 1.50, and 1.40 for Braak stage I/II, III/IV, and V/VI, respectively. The MG led the largest effect size in Braak stage I/II (1.43), while the methods of MTC, RBV, and IY showed the same effect size of 1.62 in Braak stage III/IV and 1.60 in Braak stage V/VI. ***Conclusion:*** The application of the PVC methods contributes to improving the clinical group differentiation in the Braak stages between disease and non-disease. The selection of an appropriate PVC method is important for accurate quantification of the tau burden in tau PET imaging.

EPS-230

Independent external validation of NSCLC Pro Score, a clinico-radiomic predictive signature of survival for NSCLC patients treated with immunotherapy.

R. Abgral[1,2], *D. Bourhis*[1,2], *V. Bourbonne*[3], *K. Amrane*[4], *C. Le Meur*[3], *M. Geier*[5,2], *R. Floch*[1], *K. Kerleguer*[1], *P. Salaün*[1,2], *C. Nioche*[6], *I. Buvat*[6], *F. Orlhac*[6];
[1]*Molecular Imaging and Radiotheranostic Department, University Hospital of Brest, Brest, FRANCE,* [2]*UMR 1304 Inserm GETBO, Brest, FRANCE,* [3]*Radiotherapy Department, University Hospital of Brest, Brest, FRANCE,* [4]*Oncology Department, Regional Hospital of Morlaix, Morlaix, FRANCE,* [5]*Thoracic Oncology Department, University Hospital of Brest, Brest, FRANCE,* [6]*Institut Curie, Université PSL, Inserm, U1288, LITO, Orsay, FRANCE.*

Aim/Introduction: The management of patients with non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs) remains challenging. To help identify patients likely to benefit from ICIs, NSCLC Pro Score was developed using a cohort of 197 patients and validated on an external cohort of 86 patients [1]. This signature, which combines five [18F]FDG PET radiomic features with age, enables the classification of patients into two survival profiles. We evaluated whether the predictive power of the NSCLC Pro Score could be confirmed in a larger external cohort from a third center. ***Materials and Methods:*** A retrospective database of 264 patients with advanced NSCLC (without EGFR mutations or ALK rearrangements and ineligible for surgery) treated with first- or second-line ICIs in combination with chemotherapy was collected. The analysis of [^{18}F]FDG PET/CT images acquired before ICI initiation was performed by the team from this third center using the NSCLC Pro Score module in LIFEx [2] (www.lifexsoft.org, version 7.8.0) as follows: 1) All metabolically active lesions on baseline [18F]FDG-PET images were segmented (threshold = 4 SUV), and two spherical regions of interest were respectively drawn in the liver (14ml) and in the spleen (4ml); 2) The user provided the patient's height, weight, and age; 3) The NSCLC Pro Score combining the patient's age with the Total Metabolic Tumor Volume (TMTV), the TMTV of pleural metastases, the spleen-to-liver uptake ratio, the maximum distance between lesions (SDmax), and the standard deviation of sphericity across all lesions was automatically calculated by a dedicated module in LIFEx; 4) That module classified each patient into one of two survival profiles (low-risk or high-risk) based on the previously determined cut-off [1]. Performance was evaluated using Kaplan-Meier analysis and a log-rank test. ***Results:*** In this external validation dataset, overall survival (OS) was significantly different between low-risk (n=187) and high-risk patients (n=77), using the discrimination cut-off previously established (log-rank test: p<0.0001). One-year OS rates were 72% for low-risk patients versus 47% for high-risk patients, and 54% versus 30% at two years. ***Conclusion:*** NSCLC Pro Score was validated on an external cohort by an independent team using the dedicated module in LIFEx, demonstrating the robustness and predictive capability of this six-feature signature for NSCLC patients treated by ICI, without modifying the model parameters or the discrimination threshold between low- and high-risk patients. ***References:*** [1] Comte et al. J Nucl Med 2024. 65(suppl 2):241256. [2] Nioche et al. Cancer Res 2018;78:4786-4789.

EPS-231

Refining Prognostic Models in Metastatic Breast Cancer Patients Using Whole-Body Radiomic Features

J. Auriac[1], *N. Hovhannisyan-Baghdasarian*[1], *C. Nioche*[1], *R. Seban*[1,2], *N. Jehanno*[1,2], *M. Luporsi*[1], *F. Bidard*[3], *I. Buvat*[1], *F. Orlhac*[1];
[1]*Institut Curie, Université Paris-Saclay, Inserm LITO U1288, Orsay, FRANCE,* [2]*Institut Curie, Department of Nuclear Medicine, Paris-St-Cloud, FRANCE,* [3]*Institut Curie, Department of Medical Oncology, Paris-St-Cloud, FRANCE.*

Aim/Introduction: To determine whether whole-body PET features contribute to stratifying patients with metastatic breast cancer according to their Progression Free Survival (PFS). ***Materials and Methods:*** Baseline FDG-PET/CT images and clinical data, including molecular subtype, were retrospectively collected for 516 women with metastatic breast cancer before any treatment, chronologically divided into discovery/test sets according to the PET/CT date. All lesions were manually segmented with a threshold of 4 SUV. Based on these delineations, the number of organs including metastases (N-Organs) was calculated and four whole-body PET-radiomic features were automatically measured using LIFEx (www.lifexsoft.org, v.7.7.16 [1]): Total Metabolic Tumor Volume (TMTV), maximum distance between two lesions (Dmax), maximum uptake (maxSULmax) or average uptake (TSULmean) normalized by lean body mass across all tumor lesions. Based on these imaging features and clinical data, univariable analysis was performed using the Cox proportional hazard model. Features with p<0.05 were selected to build models combining clinical and

radiomic features. A risk score was derived and binarized by the median in the discovery set to stratify patients in two risk groups. An analysis of variance (ANOVA) was conducted to compare model performance using the χ2 test. Survival analyses were performed using the Kaplan-Meier method and log-rank test. ***Results:*** The discovery and test sets included 321 and 195 patients respectively. In univariable analysis, Age (HR=1.01; Wald test: p=.02), Negative HER2 Status (HR=1.90; p<0.001), Dmax (HR=1.17; p<0.001), TMTV (HR=1.08; p<0.001) and N-Organs (HR=1.36; p<0.001) were statistically associated with PFS. These five features were combined into four incremental multivariate models developed on the discovery set and then applied on the test set. The addition of TMTV (=M2), followed by Dmax (=M3), and then N-organs (=M4) to the clinical model (=M1) systematically improved performance (χ^2 test: p≤0.01). M4 achieved the best discrimination with a difference in the two-year progression rates between the two groups of 37% in discovery and 41% in test sets compared to M1 (discovery=21%, test=7%), M2 (29%, 19%) and M3 (26%, 32%). ***Conclusion:*** In addition to clinical data, TMTV, Dmax and the number of involved organs further improve patient stratification in metastatic breast cancer and could therefore enhance patient management. ***References:*** [1] Nioche et al. Cancer Res 2018.

EPS-232

[^{11}C]PIB Uptake in Lateral Ventricles is Associated with Neuroinflammation: A PET Imaging Study in Down Syndrome and Normal Aging

D. Mantovani, *L. C. Oliveira, O. V. Forlenza, C. A. Buchpiguel, D. de Paula Faria;*
University of São Paulo, São Paulo, BRAZIL.

Aim/Introduction: Positron emission tomography (PET) imaging studies with [^{11}C]PIB suggest that lateral ventricle uptake is a potential indicator of cerebrospinal fluid (CSF) clearance efficiency. In this study, we investigated whether [^{11}C]PIB uptake in the lateral ventricles is associated with cortical and subcortical neuroinflammation, as measured by [^{11}C]PK11195, in individuals with Down syndrome (DS), a genetically determined form of Alzheimer's disease (AD), and neurotypical (NT) controls. ***Materials and Methods:*** Age-matched DS (n=29, 41.2±12.7 years) and NT (n=35, 41.3±12.7 years) individuals underwent [^{11}C]PIB (349±29 MBq) and [^{11}C]PK11195 (336±21 MBq) PET scans during different visits (maximum 1 month between visits). PET list mode data was reconstructed into a 60 minute [^{11}C]PK11195 dynamic image and 30 minute [^{11}C]PIB static image (40-70 minute post injection). Magnetic resonance T1-weighted images were acquired simultaneously and used for brain parcellation and partial volume correction of PET images. Binding potential (BP_{ND}) and standard uptake value ratio (SUVR) parametric maps were generated for [^{11}C]PK11195 and [^{11}C]PIB, respectively, using supervised clustering and the cerebellum cortex as reference regions. Correlation analyses between regional [^{11}C]PK11195 BP_{ND} and the lateral ventricle [^{11}C]PIB SUVR were performed using Pearson and Spearman coefficients for linear and monotonic associations. ***Results:*** Lower [^{11}C]PIB SUVR in the lateral ventricles was associated with higher [^{11}C]PK11195 BP_{ND} values across multiple cortical and subcortical regions of both DS and NT individuals. In the NT group, significant negative correlations were observed in the posterior cingulate cortex (Pearson r=-0.60, p<0.001), temporal cortex (r=-0.57, p<0.001), orbitofrontal cortex (r=-0.57, p<0.001), and striatum (r=-0.56, p<0.001). In the DS group, a similar but less consistent pattern was observed, with significant negative correlations detected in the amygdala (r =-0.50, p=0.006) and fusiform cortex (r=-0.44, p=0.018). No positive correlations were observed. Spearman analyses confirmed similar monotonic associations. ***Conclusion:*** Our results demonstrate that ventricular [^{11}C]PIB uptake, as an indirect marker of CSF clearance efficiency, is inversely associated with [^{11}C]PK11195 uptake in both DS and NT individuals. The observed associations highlight a possible link between glial cell activation and CSF clearance mechanisms, suggesting a potential assessment of alterations in the glymphatic system through in vivo and non-invasive PET imaging. Our study is an indication that future investigations need to be performed on CSF clearance and its role in brain aging and AD pathogenesis.

Metabolic Brain Network and "Imaging-Protein" Association Analysis of Cognitive Function Recovery in Aging Rats Based on STT3A/ALG5

Z. Yang[1], *L. Chen*[1], *K. Pandya*[2], *T. Wang*[1], *B. Nie*[3], *B. Shan*[3], *Q. Liu*[4], *T. Wang*[5], *S. H. Bossmann*[6], *K. Shi*[2], *G. Zhu*[1];
[1]*Department of Nuclear Medicine, First Affiliated Hospital of Kunming Medical University, Kunming, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND,* [3]*Beijing Engineering Research Center of Radiographic Techniques and Equipment, Institute of High Energy Physics, Beijing, CHINA,* [4]*Department of Library, First Affiliated Hospital of Kunming Medical University, Kunming, CHINA,* [5]*Institute of Neurological Disease, Translational Neuroscience Center, West China Hospital, Chengdu, CHINA,* [6]*The University of Kansas Medical Center, Department of Cancer Biology, Kansas city, KS, UNITED STATES OF AMERICA.*

Aim/Introduction: Aging populations are rapidly increasing, yet the "imaging-protein" associations or mechanisms underlying cognitive impairment in aging remain unexplored. This study integrated [^{18}F]FDG PET imaging and multi-proteomics to investigate metabolic brain networks and molecular mechanisms of cognitive recovery in aging rats. This study aimed to identify diagnostic and therapeutic targets for age-related neurodegenerative diseases impacted by aging and provide interpretable data to support AI-driven medical imaging. ***Materials and Methods:*** Eighteen 22-month-old female Sprague-Dawley rats were randomized into three groups: short-hairpin-STT3A and short-hairpin-ALG5 as experimental groups for cognitive recovery, and a control group for aging-related cognitive decline. Viral-mediated gene knockdown targeted the hippocampus, with PET imaging and multi-proteomics data collected after 8 weeks. Metabolic brain networks were built using regional SUVR and analyzed for network properties and modularity. Differential proteins and modification sites were screened from multi-proteomics data and functionally assessed. The MT-SCCALR algorithm integrated both modalities to construct an "imaging-protein" association functional matrix, validated for diagnostic potential via SVM. ***Results:*** The experimental groups enhance cognition by streamlining metabolic brain networks and optimizing modularity. Knockdown of key genes regulated recovery mainly through post-translational modifications, not total protein levels, with glycosylation sites showing common traits and phosphorylation sites indicating distinct features. The matrix pinpointed Sept8 and Grin1 as potential targets, with imaging-protein links offering diagnostic value, enabling non-invasive protein detection, and providing a molecular basis for imaging feature interpretation. ***Conclusion:*** This study advances our understanding of cognitive recovery in aging and provides a high-quality, interpretable data foundation and a data mining framework for AI-driven medical imaging.

Aim/Introduction: We aimed to develop novel software that calculates parametric K_1-flow images for the total body using ^{15}O-labelled water ($[^{15}O]H_2O$) and a Large Axial Field-Of-View (LAFOV) PET and investigate the administration dose dependency, the inter-scan reproducibility, and the among-organ consistency. ***Materials and Methods:*** Seven volunteers, including two lean, four mildly obese, and one severely obese, participated in the $[^{15}O]H_2O$ PET imaging with eight sequential PET scans at four different administration doses ranging from 20 to 700 MBq at 15-minute intervals. The novel parametric image calculation employed a single-tissue compartment model with the arterial blood volume fraction [1]. Calculating K_1-flow images was done with the acceleration of the fit using a PC with a graphics processing unit (GPU). The fit was then carried out on the logarithmic domain with the tolerance in the Euclidean space for further acceleration. Volumes of interest (VOIs) were selected from sixteen regions that covered an extensive range of K_1-flow. The bootstrap analysis was conducted [2] to evaluate the statistical error propagation using four scan data sets from a single volunteer, at four administration doses. The administration dose dependency and inter-scan variation were investigated using all paired data with the same administration dose. ***Results:*** Seven volunteers, including two lean, four mildly obese, and one severely obese, participated in the $[^{15}O]H_2O$ PET imaging with eight sequential PET scans at four different administration doses ranging from 20 to 700 MBq at 15-minute intervals. The novel parametric image calculation employed a single-tissue compartment model with the arterial blood volume fraction [1]. Calculating K_1-flow images was done by accelerating the fit using a PC with a graphics processing unit (GPU). The fit was then carried out on the logarithmic domain with tolerance in the Euclidean space to ensure the fit convergence. Volumes of interest (VOIs) were selected from sixteen regions that covered an extensive range of K_1-flow. The bootstrap analysis was conducted first [2] to evaluate the statistical error propagation using four scan data sets from a single volunteer, at four administration doses. The administration dose dependency and inter-scan variation were investigated using paired data with the same administration dose. ***Conclusion:*** K_1-flow values were consistent across a wide range of administration doses, with pixel-by-pixel and VOI-based fits. LAFOV PET allows a reduced administration dose of 20 MBq in the $[^{15}O]H_2O$ K_1-flow assessment in major organs. ***References:*** [1] Knuuti et al., J Nucl Med, 2024. EPS-235

AI-Based 3D Diffusion Model Enables High-Fidelity, Quantitatively Accurate Ultra-Low-Dose Whole-Body PET Imaging

V. Menezes[1], *M. Machado*[2], *C. Queiroz*[3], *B. Anjos*[4], *E. Almeida*[4], *A. Oliveira*[1], *M. Flamini*[1], *F. Mourato*[1], *T. Ren*[5];
[1]*Hospitals Das Clinicas Da UFPE, Recife, BRAZIL,* [2]*Hospital Universitário Professor Edgard Santos - HUPES, Salvador, BRAZIL,* [3]*Hospital Universitário Professor Alberto Antunes, Maceió, BRAZIL,* [4]*Nuclearis, Recife, BRAZIL,* [5]*Univerisade Federal de Pernambuco, Recife, BRAZIL.*

Aim/Introduction: Whole-body FDG-PET/CT is indispensable for cancer diagnosing and staging. Lowering injected activity or shortening scan duration reduces radiation burden but amplifies noise, degrading image quality. Conventional 3D AI models demand prohibitive computational memory. We present a novel AI-based 3D U-Net that restores image fidelity and quantitative accuracy in ultra-low-dose whole-body PET while remaining computationally efficient. ***Materials and Methods:*** A retrospective multicentre dataset of 2738 whole-body PET/CT examinations from scanners Siemens Biograph mCT, Siemens Biograph Horizon and GE Discovery 710 were simulated to 10%, 25 %, 50 % and 75 % of original counts, using Noise Power Spectrum simulation. In addition, 40 prospective studies were list-mode re-binned with 10% injected activity for validation. The AI-3D-U-Net couples a ResNet-50 encoder with a three-level U-Net decoder and an adaptive diffusion layer. The network was trained using mixed-precision optimization. A composite loss was used: mean-squared error, 3D gradient consistency and perceptual error. Performance was assessed on held-out 10 %-count scans using peak signal-to-noise ratio (PSNR), structural similarity index measure (SSIM), Learned Perceptual Image Patch Similarity (LPIPS) and SUVmax bias in the liver. Two blinded nuclear-medicine specialists rated diagnostic quality on a five-point Likert scale. ***Results:*** The AI-3D-U-Net achieved PSNR = 47 dB, SSIM = 0.98 and LPIPS = 0.01 on denoised volumes, against ≤37 dB, ≤0.95, ≥0.12 in the noisy data. Whole-body SUVs exhibited a mean bias of +0.10 and 95 % limits of agreement of ± 0.12 SUV. Reader evaluation confirmed non-inferior image quality versus full-count images (Likert 4.6 ± 0.4 vs. 3,5 ± 0.4; p = 0.03). End-to-end inference required 17 s per examination on a single NVIDIA RTX 3090 graphics processing unit. ***Conclusion:*** The proposed AI-3D-U-Net delivers artefact-free, quantitatively reliable reconstructions for whole-body PET acquired with as little as 1/10 of standard 5,2 MBq/Kg dose, independent of scanner vendor. Its short inference time, reader reliability and tight SUV agreement support adoption in routine clinical practice, enabling substantial reductions in dose or scan duration without compromising image quality. ***References:*** Menezes, V.O., et al. Medical Physics, 2016, 43(2), 930-938.

EPS-236

Improving the Generalization of PET Image-Enhancing Deep Learning Algorithms Through Domain Randomization. A Monte Carlo Study.

J. Poveda[1,2], *J. Gómez*[2], *F. López*[3], *G. Webber*[4], *M. Dassanayake*[4], *B. Pan*[4], *A. Reader*[4], *P. Aguiar*[1], *J. Silva*[3];
[1]*Universidad Santiago de Compostela, Santiago de Compostela, SPAIN,* [2]*Qubiotech Health Intelligence, A Coruña, SPAIN,* [3]*Reina Sofia Alzheimer Centre, CIEN Foundation, Madrid, SPAIN,* [4]*King's College London, London, UNITED KINGDOM.*

Aim/Introduction: Deep learning (DL) models for PET image enhancement are often constrained by limited variability within datasets, resulting in overfitting and poor generalization when applied to domains outside the training distribution, such as data from different scanners/centers. In this study, we propose a Monte Carlo (MC) simulation-based domain randomization (DR) strategy consisting of introducing controlled randomization of scanner characteristics, thereby expanding coverage across the domain space. We assessed the impact of this increased domain coverage by training a DL model on datasets with varying levels of diversity, thus evaluating the resulting impact on model performance. ***Materials and Methods:*** An initial dataset of 273 realistic activity maps for MC simulation was generated using a previously validated methodology[1, 2]. DR of the scanner domain was achieved by stochastically varying a curated subset of acquisition and scanner parameters, selected based on theoretical and empirical knowledge, producing a unique yet plausible scanner configuration for each case. Simulation and reconstruction were performed using SimPET[1], then both the simulated PET images and corresponding activity maps (ground truths) underwent preprocessing before DL. Five datasets with training subsets of increasing size (n = 15, 30, 60, 120, 240) were constructed, while maintaining the same validation and test sets for all the datasets. Subsequently, a separated Attention U-Net was trained for each training subset to estimate axial slices of the activity map from the corresponding simulated PET image slices, representing an idealized image enhancement task. Model performance was evaluated quantitatively using the Structural Similarity Index Measure (SSIM) and Mean Squared Error (MSE). Potential bias was assessed through voxel-wise paired t-tests between predicted and ground truth activity maps. ***Results:*** Increasing the training

set size (and thus, the number of scanners in the training dataset) from n=15 to n=240 led to approximately linear performance improvements. Compared to n=15, there were notable gains in both slice-wise metrics (SSIM +17.4%, MSE -35.3%) and volume-wise metrics (SSIM +5.3%, MSE -33.3%). Qualitatively, spatial resolution and signal-to-noise ratio (SNR) consistently improved with larger datasets. However, voxel-wise analysis highlighted localized biases in the left temporal/frontal lobes, right insula, and corpus callosum. ***Conclusion:*** Expanding domain coverage via scanner space DR led to improved model performance, indicating that this strategy constitutes a feasible and cost-efficient approach to increase PET dataset diversity and enhance generalization capabilities of DL models. ***References:*** [1]J. Paredes-Pacheco et al. Med Phys 2021; 48, 5, 2482-2493, [2]F. J. López-González et al., NeuroImage 2020; 222, 117229.

EPS-237

AI denoising enhances centiloid analysis in count-poor amyloid brain PET/CT scans

K. Knesaurek;
Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: The aim of this study is to enhance centiloid analysis of count-poor amyloid brain PET/CT studies using AI-based denoising. ***Materials and Methods:*** Amyloid brain PET/CT scans were acquired in list mode using a time-of-flight (TOF) PET/CT system. Alongside the standard 10-minute acquisition, the list mode enabled reconstruction of shorter 2 min scans. Image reconstruction employed a 3D iterative Poisson-OSEM algorithm with 8 iterations and 5 subsets (8i5s), incorporating an all-pass filter, point spread function correction, and TOF correction. Low-dose CT (80 kV, 120 mAs) was used for PET attenuation correction. The reconstruction matrix was 440 × 440, yielding a pixel size of 1.65 × 1.65 mm and a slice thickness of 3.0 mm. Both the original 2-minute scan and the 2-minute scan enhanced with AI-based denoising software were visually and quantitatively compared to the gold-standard 10-minute scan. Quantitative comparisons utilized centiloid analysis and standardized uptake value ratios (SUVr), calculated for six cortical regions (anterior cingulate gyrus, inferior medial frontal gyrus, lateral temporal lobe, posterior cingulate gyrus, precuneus, and superior parietal lobule) relative to the cerebellum. Centiloid analysis standardizes amyloid PET quantification by scaling measurements to a 0-100 scale, anchored to data from young controls (≤45 years) and patients with typical Alzheimer's disease. ***Results:*** In an exemplary case, the 2-minute, AI-corrected 2-minute, and 10-minute amyloid PET scans show strong visual similarity between the AI-corrected 2-minute scan and the 10-minute scan. The centiloid value for the 10-minute scan was 47.59, with regional SUVr values of 1.36, 1.33, 1.40, 1.14, 1.20, and 1.19, respectively. The AI-denoised 2-minute scan yielded a centiloid value of 47.86, with corresponding SUVr values of 1.37, 1.35, 1.38, 1.13, 1.20, and 1.17. In both cases, the average SUVr across the six cortical ROIs was 1.27, indicating an amyloid-positive case. Z-score analysis of the 10-minute and AI-corrected 2-minute scans revealed near-identical results. ***Conclusion:*** Centiloid analysis indicates that AI-denoised 2-minute PET amyloid scans are quantitatively equivalent to standard 10-minute scans. These findings support the clinical viability of AI-enhanced denoising in improving diagnostic quality in count-poor amyloid PET/CT studies.

EPS-238

Partial Volume Correction Enables Feasible Kinetic Analysis of Brain Tumours on Short Axial Field-of-View PET Scanners: A Preliminary Study

A. Lazar[1], *P. Scifo*[2], *A. Chiti*[1,2];
[1]*Vita-Salute San Raffaele University, Milan, ITALY,* [2]*Department of Nuclear Medicine, IRCCS San Raffaele Hospital, Milan, ITALY.*

Aim/Introduction: Dynamic PET imaging plays a pivotal role in assessing tumour physiology, particularly in gliomas. However, the analysis of dynamic images is usually based on time-activity curve (TAC)'s aspect rather than kinetic parameters. Short axial field-of-view (SAFOV) scanners present a challenge in parametric imaging due to the inability to sample the image derived input function (IDIF) from large vessels like the aorta, which is achievable on long axial field-of-view scanners. This study investigates the use of partial volume correction (PVC) to enable IDIF sampling from the carotid arteries in brain tumour patients, assessing the feasibility of performing parametric imaging on SAFOV scanners. ***Materials and Methods:*** Dynamic [^{18}F]F-FET PET images were acquired on a 32-cm axial field-of-view PET scanner over 40 minutes and reconstructed using a 35-frame protocol. Two iterative deconvolution PVC methods were employed: Lucy-Richardson with 10 iterations (LR10i), and reblurred Van Cittert with 8 (VC8i) and 12 iterations (VC12i). IDIF was extracted from the carotid arteries by averaging TACs obtained from each artery using the 5 hottest connected pixels within a 2×7mm cylindrical VOI placed in each lumen. Brain tumours were segmented using isocontour, while a 7-cm diameter sphere was placed in the frontoparietal cortex for normal tissue(NT) assessment. Quantification was performed using PMOD software investigating the following kinetic models: irreversible and reversible two-tissue compartment models, MLAIR, RE-GP, and Patlak analysis. Goodness-of-fit was evaluated using R^2 and Akaike Information Criterion(AIC) in tumour and NT. Friedman and Wilcoxon signed-rank tests assessed statistical significance across reconstructions. ***Results:*** 12 patients (13 brain lesions) were included in the analysis. Patlak analysis provided the best model fit across all reconstruction methods. Friedman test showed no significant differences in AIC or R^2 values across PVC reconstructions for tumour or NT (AIC p: tumour=0.212, NT=0.117; R^2p: tumour=0.066, NT=0.469). Pairwise comparisons revealed that VC8i provided superior R^2 over both LR10i (p=0.028) and VC12i (p=0.034). In tumours, LR10i and VC12i significantly increased Patlak intercepts relative to noPVC (p<0.05), while VC8i showed no significant bias(p=0.225); Ki remained stable across all methods (p>0.05). In NT, all PVC methods significantly increased Ki (p<0.05) and trended toward higher intercepts(p=0.068), indicating potential overcorrection. ***Conclusion:*** Our preliminary findings suggest that PVC can improve Patlak analysis, but its utility depends on the parameter, tissue type, and algorithm choice. For [^{18}F]F-FET PET, VC8i emerges as a promising compromise, enhancing model fit quality without biasing Ki, though further validation against gold-standard vascular measures is needed.

EPS-239

Partial Volume Correction Improves Kinetic Modelling in Dynamic [^{18}F]FET PET: A Simulation-Based Validation Study

S. Raju[1,2], *T. Schmidt*[1], *A. J. Zounek*[1], *Y. Beqqali*[2], *E. Barci*[1], *E. Istrefi*[1], *J. Isakaj*[1], *N. L. Albert*[1], *S. Ziegler*[3,1], *L. Kaiser*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Physics, Technical University of Munich, Munich, GERMANY,* [3]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY.*

Aim/Introduction: Dynamic PET imaging with [^{18}F]FET enables advanced tumour characterisation through pharmacokinetic modelling, but its accuracy is hindered by limited spatial resolution and noise-induced partial volume effects (PVE). This

study investigates whether partial volume correction (PVC) enhances the reliability of kinetic parameter estimation. ***Materials and Methods:*** A simulation framework based on clinical [^{18}F]FET PET scans from 21 glioma patients was developed. Time-activity curves (TACs) were extracted from segmented brain regions and used to generate ground truth parametric maps via a one-tissue compartment model (1TCM). These parametric maps were then used to generate voxel-wise dynamic PET data using the dPETSTEP (Dynamic PET Simulator of Tracers via Emission Projection) tool [1], simulating various scanner resolutions (2, 5, 8 mm FWHM) and noise levels (scale factor for number of true counts 200 000, 500 000, 1 000 000). Kinetic parameters were re-estimated from the degraded images both with and without PVC using the geometric transfer matrix (GTM) method and compared to ground truth. ***Results:*** Median differences in kinetic parameters (K1, k2, Vb) between estimated and ground truth values revealed substantial improvements after applying GTM-based PVC. At clinical resolution (5 mm), grey matter showed a median underestimation in K1 of 18% without correction, which was reduced to 1.4% post-PVC. In tumour regions, K1 underestimation decreased from 12% to 3% after correction. Similar trends were observed for k2 and Vb across all regions. At high resolution (2 mm), differences to ground truth were minimal even without correction, but PVC further improved accuracy. Variations in noise levels had only minor effects on parameter estimation compared to the dominant influence of spatial resolution and partial volume effects. ***Conclusion:*** Partial volume correction markedly improved the accuracy of kinetic modelling in dynamic [^{18}F]FET PET. This simulation-based analysis underscores the necessity of incorporating PVC into dynamic PET quantification pipelines for reliable evaluation of pharmacokinetic properties. These findings support future clinical applications aiming to enhance PET-based neuro-oncological diagnostics. ***References:*** 1. Haggstrom, I., B.J. Beattie, and C.R. Schmidtlein, Dynamic PET simulator via tomographic emission projection for kinetic modeling and parametric image studies. Med Phys, 2016. ***43***(6): p. 3104-3116.

Patient-specific reinforcement learning for planar-based 3D SPECT imaging synthesis

A. Lopez Montes[1], *R. Seifert*[1], *A. Delker*[2], *G. Boening*[2], *J. Wang*[1], *A. Afshar-Oromieh*[1], *A. Rominger*[1], *K. Shi*[1];
[1]*University of Bern, Bern, SWITZERLAND,* [2]*Ludwig-Maximilians-Universität in Munich, Munich, GERMANY.*

Aim/Introduction: SPECT dosimetry imaging remains as a burden in clinical practice. On the other side, 2D-planar dosimetry imaging is fast, economic and widely applied. However, it has limited accuracy and capability for tumor dosimetry assessment. Producing synthetic 3D SPECT from planar scans would provide a desired solution. However, the problem is highly ill-posed and remains unpractical even using standard AI methods. In this work we proposed a patient-specific reinforcement learning leveraging pre-therapy PET/CT data in the AI model for planar-based 3D SPECT imaging synthesis. For proof of concept, we focused on the dosimetry of ^{177}Lu-PSMA radiopharmaceutical therapy. ***Materials and Methods:*** We trained two 3DResUNet networks: one from a population dataset and another with our model using a patient-specific reinforcement learning. The inputs consisted of two (anterior and posterior) planar images (128x175x2) and the outputs were 3D maps (128x128x175; 5.7 mm) obtained from 52 total-body ^{18}F-PSMA PET/CT scans. Planar images for training were simulated from the 3D-PET to ensure matching. For the patient-specific reinforced network, we generated a dataset of 100 possible 3D uptake maps for individualized patients: first we segmented the organs from pre-therapy PET, then we applied random scaling factors to the activity in each organ (0.5-2 times the original activity) and random 3D rigid transformations, finally we simulated the corresponding planar images and the network was re-trained exclusively for patient-specific data. We validated our method on 5 simulated cases with planar images obtained from a post-therapy PET (thus knowing the ground truth 3D) and in 5 real cases from full body planar ^{177}Lu-PSMA acquisitions. In all cases the personalized network was trained from the pre-therapy PET as described above. ***Results:*** In simulations, the relative Mean Absolute Error (MAE) between the images and the ground truth was 0.92±0.33 for generic population training, which was reduced to 0.59±0.21 with our method. We computed the difference for every organ, yielding an average difference 0.97±0.97 for population-based training and 0.45±0.51 for our model. For the real cases (without a ground truth 3D activity for comparison), visual inspection exhibited better delineation of the organs for the patient specific network when compared with the generic population training. ***Conclusion:*** We have demonstrated viability of the generation of 3D maps from only two 2D planar images using patient-specific reinforcement learning. Future work is focused on improving the generative models and the 3D maps of the patients used for training with special attention to lesions.

EPS-241

Integration of Deep Learning and Radiomics for Predicting the Histologoical Classification of Peripheral Neuroblastic Tumor Base on ^{18}F-FDG PET/CT Imaging

Z. Zhou*;*
Capital Medical University, Beijing Friendship Hospital, Beijing, CHINA.

Aim/Introduction: To evaluate the performance of the clinical model, two-dimensional deep learning model (2D DL), radiomics model, and the fusion model for predicting the histological type of peripheral neuroblastic tumors (pNTs). ***Materials and Methods:*** In this retrospective study, a total of 196 pediatric patients newly diagnosed with neuroblastoma between June 2018 and December 2020 at Beijing friendship hospital were included. The cohort was divided into a training set (n=137) and a test set (n=59). The clinical model was constructed based on clinical data. The 2D DL, radiomics model were developed using 18F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT). Two fusion strategies were employed to constructed the fusion model: the feature based DLRad_FB model and the decision based DLRad_DB model. The receiver operating characteristic (ROC) and decision curve analysis (DCA) curves were used to evaluate the performance of the model. ***Results:*** The 2D DL features demonstrated superior diagnostic effectiveness compared to clinical model and radiomics model. The DLRad_FB model achieved the highest are under the curve (AUC) of 0.918 (95%CI: 0.866, 0.970) and 0.874 (95%CI: 0.777, 0.972) among all models in the training and test sets. Compared to the DLRad_FB model, the AUC values for the clinical, radiomics, 2D DL and DLRad_DB models were 0.733 (95%CI: 0.646, 0.819), 0.781 (95%CI: 0.700, 0.862), 0.860 (95%CI: 0.794, 0.927), 0.878 (95%CI: 0.815, 0.940) in the training set respectively. ***Conclusion:*** The Feature Based Model DLRad_FB, which combines clinical, radiomics and 2D DL date, can predict the histological type of pNTs and assist in early therapeutic strategies.

Stabilin-2 receptorspecific radioligand ^{18}FS2P for atherosclerotic plaque PET imaging
D. Adili, *D. Zhang, Z. Li, X. Su;*
First Affiliated Hospital of Zhejiang University, School of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Stabilin-2 receptor overexpression on plaque macrophages represents a promising molecular target for atherosclerosis imaging. The S2P peptide (Cys-Arg-Leu-Thr-Leu-Thr-Val-Arg-Lys-Cys, CRTLTVRKC) exhibits specific binding to stabilin-2, a receptor overexpressed on macrophages within atherosclerotic plaques. This study aims to evaluate the feasibility of using the stabilin-2-targeted ^{18}F-labeled tracer (^{18}F-S2P) for positron emission tomography (PET) imaging to identify atherosclerotic plaques. ***Materials and Methods:*** ^{18}F-S2P was synthesized via standard radiochemical procedures with quality control validation. Experimental design included: 1) In vitro stability assessment in NaCl and fetal bovine serum; 2) Longitudinal micro-PET/CT imaging (0.5 h post-injection) in LDLR$^{-/-}$ mice (high-fat diet 3-12 weeks) versus chow-fed littermate controls; 3) Comparative analysis with ^{18}F-Pentixafor (CXCR4-targeted) imaging; 4) Ex vivo biodistribution studies with gamma counting and autoradiography; 5) Safety evaluation through hematological profiling (complete blood count, liver enzymes) and histopathological examination (H&E staining) of major organs. Plaque characterization employed Oil Red O lipid staining and H&E morphology analysis. ***Results:*** ^{18}F-S2P demonstrated >95% radiochemical purity and stable tracer integrity under physiological conditions (PBS: 100%; FBS: 95% at 2h). In vivo PET quantification revealed disease duration-dependent uptake (SUVmax = 0.37 ± 0.15 at 3 weeks vs. SUVmax = 0.77 ±0.15 at 12 weeks, $p<0.05$), correlating strongly with histological plaque burden. Notably, ^{18}F-S2P showed 2.7-fold higher aortic arch uptake versus controls (SUVmax = 0.77 ± 0.15 vs. SUVmax = 0.29 ± 0.25), outperforming ^{18}F-Pentixafor (SUVmax = 0.85 ± 0.07 vs. SUVmax = 0.47 ± 0.10, $p<0.05$) in lesion contrast. No significant hematotoxicity or organ damage was observed. ***Conclusion:*** This study introduces a novel stabilin-2-targeted PET probe (^{18}F-S2P) for non-invasive imaging of atherosclerotic plaques, enabling the detection of atherosclerotic inflammation.

OP-693
Superiority of αvβ6 Integrin-Targeted 68 Ga-Trivehexin over ^{18}F-FDG in Diagnosis and Therapeutic Efficacy Monitoring of Idiopathic Pulmonary Fibrosis: A Translational Study from Bench to Bedside
J. Li, *H. Wu, Y. He;*
Zhongnan Hospital of Wuhan Universiry, Wuhan, CHINA.

Aim/Introduction: Idiopathic pulmonary fibrosis (IPF) is a chronic fibrosing interstitial pneumonia of unknown etiology characterized by progressive dyspnea and deterioration of pulmonary function. Current diagnostic strategies primarily rely on high-resolution CT imaging of morphological alterations and invasive pathological biopsies, which present limitations in sensitivity and procedural risks for disease monitoring. TGF-β1 (transforming growth factor-beta 1) serves as a central mediator driving pulmonary fibrogenesis. This study aims to investigate whether targeted PET/CT imaging of integrin αvβ6 , a functional receptor for TGF-β1, could provide a non-invasive approach with enhanced sensitivity for comprehensive management of IPF patients in comparison with ^{18}F-FDG. ***Materials and Methods:*** We established an IPF mouse model via intratracheal bleomycin (BLM) instillation (5 U/kg) and conducted serial weekly PET/CT imaging using both ^{68}Ga-Trivehexin and ^{18}F-FDG over three weeks. Specificity of ^{68}Ga-Trivehexin uptake was validated through a blocking experiment on day 14 post-modeling. Additionally, dynamic imaging was performed in BLM-induced mice treated with saline, Nerandomilast, or pirfenidone. Histopathological assessments (HE/Masson staining, Ashcroft fibrosis scoring, hydroxyproline assay, and Western blot) were employed to evaluate inflammation and fibrosis. A prospective clinical cohort of 17 IPF patients underwent head-to-head ^{68}Ga-Trivehexin and ^{18}F-FDG PET/CT for diagnostic comparison. ***Results:*** In BLM-treated mice, ^{68}Ga-Trivehexin demonstrated progressive lesion uptake (SUVmax: 3.38±0.48, 5.53±1.11, 6.27±1.02 at days 7, 14, 21; all $p < 0.05$), correlating with worsening fibrosis on Masson staining. Conversely, ^{18}F-FDG uptake peaked at day 14 (SUVmax: 6.94±1.06) before declining (4.60 at day 21), aligning with transient inflammatory changes on HE staining. Blocking experiments confirmed ^{68}Ga-Trivehexin specificity for fibrotic lesions. Therapeutic monitoring revealed significantly reduced ^{68}Ga-Trivehexin uptake in Pirfenidone/Nerandomilast-treated groups versus saline controls ($p < 0.05$), whereas ^{18}F-FDG showed no intergroup differences. Clinically, ^{68}Ga-Trivehexin exhibited superior uptake in fibrotic lesions compared to ^{18}F-FDG (SUVmax:

4.92±0.33 vs. 2.23±0.16, p < 0.0001). ***Conclusion:*** ^{68}Ga-Trivehexin, targeting integrin αvβ6, outperforms ^{18}F-FDG in noninvasive detection and therapeutic monitoring of IPF, offering enhanced specificity for fibrosis progression and treatment response.

OP-694

Neuropilin-1-Targeted PET Imaging for early detection of pulmonary fibrosis activity: comparison with the ^{18}F-FDG and ^{68}Ga-FAPI-04 PET approach

F. Qiu, *J. Li, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Idiopathic pulmonary fibrosis (IPF) lacks biomarkers for early detection, limiting timely therapeutic intervention. Neuropilin-1 (NRP-1), a co-receptor for TGF-β signaling, is implicated in fibrogenesis but unexplored as an imaging target. We developed a novel NRP-1-targeted PET probe ^{68}Ga-NRP1-CEND1 and evaluated its efficacy in detecting early-stage pulmonary fibrosis, outperforming existing tracers like ^{18}F-FDG and ^{68}Ga-FAPI-04. ***Materials and Methods:*** Single-cell sequencing of human IPF from GEO database was assessed to explore NRP-1 expression and relevant signal features. Radiotracer ^{68}Ga-DOTA-CEND1 was synthesized based on the NRP-1-targeted inhibitor CEND-1. A bleomycin-induced pulmonary fibrosis murine model was used. PET/CT imaging with the probe was performed at 0, 3, 5, 7, and 14 days post-injury. Comparative analyses with ^{18}F-FDG and ^{68}Ga-FAPI-04 were conducted. Histopathological validation included H&E, Masson's trichrome, and immunohistochemistry (IHC) for NRP-1 and FAP expression. ***Results:*** Single-cell sequencing analysis of IPF patients demonstrated significant NRP-1 overexpression in fibroblasts, with strong enrichment in fibrosis-related TGF-β signaling pathways.^{68}Ga-DOTA-CEND1 exhibited >95% radiochemical purity, optimal pharmacokinetics (T1/2 slow = 17.93 min), strong NRP-1 affinity (docking score: - 7.7884), favorable hydrophilicity (Log P = - 2.942 ± 0.12) and robust stability in vivo and in vitro for at least 2 h. Micro PET/CT in control mice showed baseline pulmonary uptake of the NRP-1 probe was low (0.303 ± 0.039 %ID/g). Significant tracer accumulation was observed as early as day 5 post-bleomycin (2.0 ± 0.2 %ID/g), peaking at day 7 (3.933 ± 0.551 %ID/g), and remained elevated during fibrotic progression at day 14 (2.8 ± 0.608 %ID/g), demonstrating sustained targeting of fibro genic activity. In inflammatory phase (0-7 days), ^{18}F-FDG failed to distinguish pulmonary inflammation due to overwhelming cardiac spillover, whereas ^{68}Ga-DOTA-CEND1 clearly delineated early lesions. In early fibrotic phase (7-14 days), ^{68}Ga-DOTA-CEND1 exhibited 1.5-fold higher uptake than ^{68}Ga-FAPI-04 (3.933 ± 0.551 vs. 2.7 ± 0.4 %ID/g, p < 0.05) at day7, with superior lesion revelation, confirming that ^{68}Ga-DOTA-CEND1 preceded ^{68}Ga-FAPI-04 in detecting fibrotic transformation, enabling earlier diagnosis. H&E and Masson staining validated successful fibrosis induction. IHC showed robust NRP-1 upregulation in fibrotic regions, while FAP expression showed only marginal increases, aligning with PET findings. ***Conclusion:*** ^{68}Ga-DOTA-CEND1 enables early diagnosis during the reversible inflammatory phase in IPF, outperforming ^{18}F-FDG and ^{68}Ga-FAPI-04 in sensitivity and specificity. It holds great potential for clinical translation, guiding early therapeutic intervention to mitigate irreversible fibrotic damage and improving patient survival and quality of life.

OP-695

Development and Validation of ^{18}F-Labeled Pirfenidone Analogs as Potential p38-Targeted Ligands for Pulmonary Fibrosis Imaging

X. Wang, *J. Wang, M. Niu, F. Kang, J. Wang;*
Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.

Aim/Introduction: Pirfenidone is a pyridinone compound approved for treatment of idiopathic pulmonary fibrosis with broad-spectrum anti-fibrotic and anti-inflammatory effects. This study aims to design and develop ^{18}F-labeled pirfenidone analogs and validate their potentials as p38-targeted ligands for PET imaging of pulmonary fibrosis. ***Materials and Methods:*** Two pyridinone analogs, 5-methyl-1-(4-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)pyridin-2(1H)-one and 5-methyl-1-(3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)phenyl)pyridin-2(1H)-one were designed, synthesized and one-step radiolabelled with ^{18}F via nucleophilic aromatic substitution to develop radioligands ^{18}F-PFD and ^{18}F-AKF-PD. Their radiochemical yield and purity, molar activity, partition coefficient and in vitro stability were characterized. Molecular docking, molecular dynamics simulation and SPR were used to validate their potentials as p38-targeted ligands. MicroPET imaging with ^{18}F-PFD and ^{18}F-AKF-PD were performed in bleomycin-induced pulmonary fibrosis mice models. Their biodistribution, pharmacokinetics and radiation dosimetry were also evaluated in healthy BALB/c mice. Lung tissue assessments encompassed H&E staining, Masson staining, p38 IHC/IF and hydroxyproline content. ***Results:*** ^{18}F-PFD and ^{18}F-AKF-PD were synthesized with decay corrected radiochemical yield of 53.5 ± 3.2 % and 78.4 ± 1.6 %, radiochemical purity of > 98 % and molar activity of 89.5 and 101.2 GBq/μmol. Their partition coefficient (Log P) was determined to be 1.21 ± 0.19 and 1.18 ± 0.21, indicating their lipophilicity. The stability was confirmed in saline and serum within 4 h. The in silico results revealed that pirfenidone, ^{nat}F-PFD and ^{nat}F-AKF-PD were more likely to be the ligand of p38 compared to TNF-α and TGF-β. The micromolar binding affinity of pirfenidone and its analogs towards p38 was verified using SPR assay. The p38 expression in lung tissues showed significant difference at day 7, day 14 and day 21 in control and fibrosis group, positively correlated with inflammation severity, Ashcroft scoring and hydroxyproline content. In MicoPET imaging, significant uptake of ^{18}F-PFD and ^{18}F-AKF-PD was observed in fibrotic lung tissues compared to normal lung tissues at day 21. Blockade experiments confirmed the specific uptake of ^{18}F-PFD and ^{18}F-AKF-PD. The biodistribution and pharmacokinetics demonstrated the rapid clearance from blood and other non-specific organs of ^{18}F-PFD and ^{18}F-AKF-PD, with higher accumulation in the gallbladder, kidneys and salivary glands. The effective dose of ^{18}F-PFD and ^{18}F-AKF-PD was comparable to that of ^{18}F-FDG, highlighting their safety for human use. ***Conclusion:*** Two ^{18}F-labeled pirfenidone analogs, ^{18}F-PFD and ^{18}F-AKF-PD, were designed, developed and validated as p38-targeted radioligands for PET imaging of pulmonary fibrosis. This study indicated that p38 might be a potential target to develop new-generation of fibrosis-specific tracers and antifibrotic therapy.

OP-696

Development of Novel Radiotracer for Accurate Assessing Functional Liver Reserve via PET Imaging

L. Feng[1], *Y. Xu*[2], *H. Yang*[1], *X. Lan*[1], *D. Jiang*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science, Wuhan, CHINA,* [2]*Department of Hepatobiliary Surgery, Union Hospital, Tongji Medical College, Huazhong University of Science, Wuhan, CHINA.*

Aim/Introduction: Current liver function assessment methods primarily rely on serum marker measurements, which have limitations in accuracy. This study aims to develop a radioactive small-molecule probe to noninvasively evaluate the functional liver reserve by monitoring its uptake and metabolism in the liver. ***Materials and Methods:*** A series of small molecules were labeled with ^{68}Ga and subjected to dynamic PET imaging in healthy mice to screen for their hepatic metabolic capabilities. Subsequently, the probe's uptake, excretion, and retention in the liver were explored in four hepatectomy models (30%, 50%, 70%, and 90%

liver resection) to establish the correlation between liver function and probe metabolism. Dynamic PET imaging was also performed in hepatitis and cirrhosis models to predict liver function, which was validated by H&E staining and serum markers. ***Results:*** A radiolabeled small-molecule probe, named [^{68}Ga]Ga-SD03, with hepatic metabolic capacity was successfully synthesized and maintained stability within 2 h. In healthy mice, the probe exhibits rapid hepatic uptake, reaching peak concentration within 1 min post-administration and completing its enterohepatic metabolism within 15 min. It does not interact with hepatocytes or macrophages, and shows minimal retention in the liver, which may allow for efficient hepatic function assessment. In hepatectomy models, the 15 min/1 min liver uptake ratio was not significantly different from the control group when liver resection was below 50% (ratios of 0.40 ± 0.07% and 0.50 ± 0.13%, respectively). However, when liver resection reached 70% and 90%, the 15 min liver uptake values were 5.11 ± 1.67% and 9.27 ± 2.09% of the 1 min values, respectively, significantly higher than those in other groups ($p < 0.01$). Probe retention in the liver, as another indicator of liver functional reserve, increased with the extent of resection. In hepatitis models, the degree of liver inflammation predicted by PET imaging was consistent with H&E staining results. ***Conclusion:*** The metabolism of [^{68}Ga]Ga-SD03 can indicate the residual liver function, offering potential for guiding clinical surgical planning and postoperative evaluation.

Tracking monocyte kinetics in healthy volunteers and patients with inflammatory arthritis

N. Farahi[1], *A. Y. K. C. Ng*[1], *J. Hutton*[1], *D. Gillett*[2], *F. Sunzini*[3], *R. Hohne*[3], *A. Ade-Ojo*[2], *V. Lotz*[4], *A. Tate*[3], *M. Arnott*[3], *N. Basu*[3], *J. Brock*[3], *A. McGucken*[3], *N. G. Shenker*[5], *E. R. Chilvers*[6], *J. Cavanagh*[3], *C. Summers*[1];
[1]*University of Cambridge, Cambridge, UNITED KINGDOM,* [2]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM,* [3]*University of Glasgow, Glasgow, UNITED KINGDOM,* [4]*Royal Papworth Hospital NHS Foundation Trust, Cambridge, UNITED KINGDOM,* [5]*Cambridge University Hospitals NHS Foundation Trust and Department of Medicine, University of Cambridge, Cambridge, UNITED KINGDOM,* [6]*Imperial College, London, UNITED KINGDOM.*

Aim/Introduction: Monocytes play an important role in the immune response, contributing to tissue homeostasis and immune surveillance. Their infiltration is key to a number of acute and chronic inflammatory conditions, including rheumatoid arthritis and acute respiratory distress syndrome. Despite their significance in disease, data on monocyte biodistribution in healthy individuals is limited. The aim of this study was to establish the circulating kinetics and biodistribution of monocytes in healthy volunteers (HV) and compare these findings to patients with inflammatory arthritis. ***Materials and Methods:*** To assess monocyte lifespan, mixed leukocytes were prepared from HV using hetastarch sedimentation. Autologous leukocytes were then radiolabelled with 111-Indium-tropolonate before reinjection. Peripheral venous blood samples were collected over a 72-hour period after reinjection, followed by isolation of neutrophils and monocytes and measurement of radioactivity by sample counting. To visualise monocyte biodistribution in HV and patients with inflammatory diseases (psoriatic and rheumatoid arthritis), monocytes were isolated using clinical grade CD14 beads and radiolabelled with 99m-Tc-HMPAO. After reinjection of the autologous radiolabelled monocytes, dynamic and static gamma camera imaging was performed over 6-hours. Region-of-interest analysis (ROI) was performed on the lungs, liver and spleen. Mean counts per pixel or voxel in these ROIs were recorded and corrected for physical decay of the radionuclide. ***Results:*** Using In-111 labelled leukocytes, the median 45-minute recovery of neutrophils from the circulation of HV was 47% (IQR 32-64%; N=5), comparable with previous reports. In contrast monocytes exhibited markedly different intravascular kinetics, with a median 45-minute recovery of 7% (IQR 5-15%; P=0.008; N=5), suggesting the presence of a larger marginated pool. Monocyte median intravascular lifespan was 13 hours (IQR 6-14 hours; N=5), notably longer than the lifespan of neutrophils 7 hours (IQR 4-9 hours; P=0.31; N=5). Using purified 99m-Tc-HMPAO-labelled monocytes and gamma camera imaging, we observed prolonged transit through the lungs, followed by liver and spleen uptake in HVs (N=8). In patients with inflammatory disease (psoriatic and rheumatoid arthritis; N=5) we observed an expanded monocyte marginated pool compared to healthy controls, with early preferential homing to the lungs. ***Conclusion:*** We report for the first time, the transit kinetics and biodistribution of monocytes in healthy human subjects. Our findings reveal that, in patients with inflammatory arthritis, monocytes exhibit increased margination to the lungs, suggesting a redistribution from the circulating pool to pulmonary sites in inflammatory conditions. These insights have implications for future studies on monocyte distribution and lifespan in chronic inflammatory states.

OP-699

The Preclinical Study of $^{[18F]}$AV45 and $^{[18F]}$DPA714 PET as Potential Imaging Biomarkers for Hashimoto's Thyroiditis-Associated Cognitive Impairment

Y. Zhang, *G. Zhu;*
First Affiliated Hospital of Kunming Medical University, Kunming, Yunnan, CHINA.

Aim/Introduction: Hashimoto's thyroiditis (HT) is closely associated with cognitive impairment, and cognitive decline is often accompanied by Aβ accumulation and neuroinflammation. An SD rat HT model was established, combined with $^{[18F]}$AV45 and $^{[18F]}$DPA714 PET tracers and ELISA detection techniques, to evaluate these pathological changes and provide imaging evidence for clinical diagnosis. ***Materials and Methods:*** The study compared SD rats with an HT model (n=4) to a control group (n=5). Aβ accumulation and neuroinflammation in various brain regions were analyzed using $^{[18F]}$AV45 and $^{[18F]}$DPA714 PET imaging. Group comparisons were made with SPM12 ($p<0.05$), where KE refers to the number of voxels and MAX-T represents the maximum T-value. Cognitive function was assessed through open field tests, Y-maze, and water maze tasks. ELISA was used to measure inflammatory factors (IL-6, IL-1β,TNF-α), Aβ (Aβ40, Aβ42), and other related biomarkers in both brain and thyroid tissues. ***Results:*** $^{[18F]}$AV45 PET imaging in the HT model revealed Aβ deposition in the hippocampus (KE=849, MAX-T=6.251), frontal cortex (KE=187, MAX-T=2.4635), parietal lobe (KE=262, MAX-T=5.7657), and cingulate gyrus (KE=459, MAX-T=3.0145). $^{[18F]}$DPA714 PET imaging showed significant differences in the frontal cortex (KE=16, MAX-T=3.6088) and cingulate gyrus (KE=43, MAX-T=3.2757). Behavioral assessments indicated that rats in the HT group exhibited a significant increase in total active distance ($p<0.01$) and the number of incorrect arm entries ($p<0.05$) in the Y-maze test. In the open field test, grooming frequency increased ($p < 0.05$), while the number of standing events ($p<0.001$) and entries into the central area ($p<0.0001$) significantly decreased. In the Morris water maze test, the number of target quadrant crossings ($p < 0.0001$), platform dwell time ($p<0.01$), and target quadrant visits ($p<0.001$) were significantly reduced. ELISA results showed that levels of IL-6, IL-1β, TNF-α, Aβ40, and Aβ42 in brain tissue were significantly higher in the HT group compared to the control group ($p < 0.05$), while inflammatory cytokines (IL-6, IL-1β, TNF-α) in thyroid tissue were also significantly elevated ($p<0.05$). ***Conclusion:*** This study suggests that HT may induce Aβ deposition via neuroinflammation, which leads to cognitive impairment. The combination of $^{[18F]}$AV45 and $^{[18F]}$DPA714 PET

imaging with biological assays provides a promising tool for detecting HT-associated cognitive impairment and offers valuable insights for clinical diagnosis.

Aim/Introduction: Mycoplasma pneumoniae has been identified within the lung tumor microbiome (1), and its natural tropism for cancer cells suggests potential as a biological vector in lung cancer therapy. In previous work using [^{111}In]In-oxinate-labelled M. pneumoniae in murine models, we observed that intratracheal administration led to suboptimal delivery to lung tumors, likely due to uneven pulmonary distribution (2). To address this limitation, we hypothesized that pulmonary surfactant (PS), given its physiological relevance and surface-active properties, could act as an adjuvant to enhance Mycoplasma intrapulmonary spread and tumor targeting. The aim of this study was to implement a dual-radiolabelling strategy to simultaneously track the biodistribution of indium-111-labeled M. pneumoniae and technetium-99m-labelled PS in vivo for a comprehensive evaluation of their combined pulmonary distribution and the potential role of PS in improving Mycoplasma delivery. ***Materials and Methods:*** M. pneumoniae (CV8 strain, 2x107 CFU) was labeled with [^{111}In]In-oxinate using standard cell-labelling protocols. PS obtained from porcine lungs by bronchoalveolar lavage was extracted with CH_2Cl_2:MeOH to obtain the organic extract (OE-PS). Following solvent evaporation in 40µL aliquots, the dry lipid film was incubated with 40µL $[^{99m}Tc(CO)_3(OH_2)_3]^+$ (obtained from a commercial kit) at 37°C/1h. Subsequently, 100µL of PBS (pH 7.4) were added, incubated under the same conditions and RCP checked by radioTLC (Whatmann3/saline). In vivo biodistribution was evaluated following intratracheal administration in C57Bl/6J mice, assigned to three groups: G1(n=2) received 7.47MBq of ^{99m}Tc-OE-PS; G2(n=3) received 1.14MBq of ^{111}In-labelled CV8 encapsulated in non-labelled OE-PS; and G3(n=3) received a combination of 1.8 MBq of ^{111}In-labelled CV8 and 7.4MBq ^{99m}Tc-labelled OE-PS. Biodistribution was evaluated by microSPECT/CT imaging at 1 and 4 hours post-administration. ***Results:*** Although CV8 was radiolabeled with low yield (16%) it was >95% pure after centrifugation and washing twice. $[99mTc(CO)_3(OH_2)_3]+$ was obtained in >99%RCP as checked by radioTLC (silicagel/sodium citrate). OE-PS was efficiently radiolabelled (RCP>99%, confirmed via radioTLC). ^{99m}Tc-OE-PS showed uniform, stable lung distribution over time. In contrast, when combined with ^{111}In-Mycoplasma, OE-PS and ^{99m}Tc-OE-PS significantly modified the distribution of Mycoplasma, as evidenced by the increased spread over time. ***Conclusion:*** This study reports, for the first time, the successful radiolabelling and in vivo dual-isotope microSPECT/CT imaging of ^{99m}Tc-labelled OE-PS and ^{111}In-labelled M. pneumoniae. Pulmonary surfactant improved CV8 intrapulmonary distribution, supporting its use as an adjuvant in pulmonary bacterial therapies. These findings highlight the utility of molecular imaging in the development of respiratory therapeutic strategies. ***References:*** (1)doi:10.3892/mmr.2016.5765 (2)Collantes M, et al. OP-701

Dosimetry of Radiation Exposure to Patients, Caregivers, and Medical Staff Following Lu-177 PSMA Therapy

M. Chiang[1], *P. Chuang*[2], *C. Lu*[3];
[1]Taipei Medical University Hospital, Taipei, TAIWAN, [2]National Taiwan University Hospital Cancer Center, Taipei, TAIWAN, [3]National Taiwan University Hospital, Taipei, TAIWAN.

Aim/Introduction: Lutetium-177-labeled prostate-specific membrane antigen (Lu-177 PSMA) therapy has emerged as an effective targeted treatment for metastatic prostate cancer. Despite its clinical benefits, radiation exposure to patients, caregivers, and healthcare personnel remains a concern. This study aims to quantify radiation exposure across different settings and time points, and to evaluate the effectiveness of protective strategies in minimizing radiation risks. ***Materials and Methods:*** This retrospective study included 24 patients treated with Lu-177 PSMA between November 10, 2022, and November 5, 2024. Radiation dose rates from patients were recorded at 0, 2, 4, 6, and 24 hours post-injection at 1-meter distance using a portable detector (RadEye™ B20, Thermo Scientific). A biexponential decay model was used to analyze dose kinetics. Cumulative radiation exposure was measured using optically stimulated luminescence dosimeters and survey meters at various distances (1 m, 3 m, behind lead shielding) and for different personnel (patients, caregivers, nurses, and radiation safety staff). Post-discharge exposure for patients and caregivers was monitored for three days outside the hospital following discharge. ***Results:*** The mean initial radiation dose rate from patients at 1 meter was 39.54 ± 21.79 µSv/h, declining to 19.55 ± 6.38 µSv/h at 4 hours and 11.14 ± 5.21 µSv/h at 24 hours post-injection. The decay followed a biexponential model ($R^2 = 0.9995$) with rate constants $\lambda_1 = 0.7301$ h^{-1} and $\lambda_2 = 0.0245$ h^{-1}. Patients accumulated the highest radiation dose (4.66 ± 1.94 mSv), whereas caregivers and medical staff received significantly lower exposures (0.16 ± 0.08 mSv and 0.11 ± 0.07 mSv, respectively). Radiation exposure at 3 meters and behind shielding was comparable to background levels. Statistically significant differences in radiation exposure were observed across measurement positions ($P < 0.001$), confirming the protective value of distance and shielding. Importantly, radiation exposure at 1 meter fell below 30 µSv/h by 4 hours in most cases. ***Conclusion:*** Radiation exposure from Lu-177 PSMA therapy decreases rapidly over time. By 4 hours, dose rates at 1 meter drop to around 30 µSv/h. Exposure to caregivers and medical staff is minimal and well within safety limits, confirming the effectiveness of distancing and shielding measures. ***References:*** Lutetium-177-PSMA-617 for Metastatic Castration-Resistant Prostate Cancer. Aim/Introduction: The number of procedures with ^{177}Lu-labeled radiopharmaceuticals is increasing worldwide. However, there is a lack of data on skin exposure from these procedures. The aim of this study performed at nuclear medicine departments across Europe was to determine staff skin exposure from handling ^{177}Lu-labeled radiopharmaceuticals. This investigation was part of a project of the European Radiation Dosimetry Group (EURADOS) to investigate skin doses due to the use of new radionuclides in nuclear medicine. ***Materials and Methods:*** Measurements were performed in nine centers. Workers wore a TLD at the base of the index finger of the non-dominant hand when handling ^{177}Lu. A logbook recorded the handled activity and performed tasks for each month. If no dose was detected during a measurement period, the minimum detection limit of that specific dosimeter was used for analyses. For analyses, the skin dose was normalized to the handled activity. Tasks were grouped as either preparation or administration. Administration methods were categorized as gravity method, manual syringe administration, and automated syringe administration. ***Results:*** A total of 115 measurements were collected, of which 38 (33%) were below the MDL. The median handled activity was 52 GBq [range 1-317] and the median recorded skin dose was 0.150mSv [range 0.007-2.270]. This resulted in a median normalized skin dose of 3.3µSv/GBq [range 0.5-525.0]. 105 measurements could be classified according to their task, 50 as preparation (48%) and 55 (52%) as administration. The median normalized dose was slightly higher during preparation; 3.6µSv/GBq [range 0.5-525.0] for preparation compared to 3.4µSv/GBq [range 0.5-31.8] for administration (Mann-Whitney, p=0.019). When looking at administration method, there was no difference in median normalized dose: 6.2µSv/GBq [range 0.5-20.8] for manual syringe administration (2 centers, n=13), 3.8µSv/GBq [range 0.8-31.8] for gravity administration (4 centers, n=31), and 1.0µSv/GBq [range 0.7-2.4] for automatic syringe administration (1 center, n=8) (Kruskal Wallis, p=0.074). Although large differences were seen between the normalized dose per center (median values of 1.01-11.5µSv/GBq), this could not be fully explained by the task performed or the administration method used. Further analyses are being performed to investigate the differences in dosimeters and shielding used. ***Conclusion:*** The median normalized skin dose for the handling of ^{177}Lu-labeled radiopharmaceuticals was 3.3 µSv/GBq in this study, which is much lower than that of other radiopharmaceuticals labeled with ^{68}Ga, ^{18}F or ^{99m}Tc reported in literature. With adequate shielding and training, the handling of ^{177}Lu-labeled radiopharmaceuticals is safe for nuclear medicine personnel.

Radiation Safety with ^{212}Pb-Based Therapeutics from Clinical Experience with ^{212}Pb-ADVC001 (TheraPb): Dose to Staff and Members of the Public

E. O'Mahoney[1], *M. Griffiths*[2], *S. Ngai*[1], *D. Pattison*[2], *A. Hansen*[1], *D. Wyld*[2], *I. Holmes*[1], *L. Katchel*[1], *S. Baker*[1], *H. Biggs*[1], *L. Campbell*[2], *M. Baronet*[3], *M. Crumbaker*[3], *P. Santoro*[3], *S. Rose*[3], *A. Karmann*[3];
[1]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [2]*Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA,* [3]*AdvanCell Pty Ltd, Sydney, AUSTRALIA.*

Aim/Introduction: To measure the dose rates from patients over time after administration of ^{212}Pb-ADVC001, a ^{212}Pb-based PSMA-targeting therapeutic, and the radiation exposure to nuclear medicine staff, to establish recommendations for the safe administration and the discharge of patients undergoing treatment with ^{212}Pb-ADVC001. ***Materials and Methods:*** External ambient equivalent dose rates (H*(10)) were recorded at 10, 30, 100 and 200 cm at approximately 0.5, 1.5, 4, 20 and 28 hours post administration from 16 patients receiving treatment with ^{212}Pb-ADVC001 at two clinical sites as part of the TheraPb Phase 1b dose escalation trial (NCT05720130). A biexponential model was fitted for each patient to estimate exposure for potential encounters (e.g., family member, member of public, work colleague) enabling patient-specific advice to ensure legislative guidelines were met. Electronic portable dosimeters (EPDs; Mirion DMC 3000) specified for gamma energies between 15 keV and 7 MeV, were worn by all nuclear medicine staff involved in the dispensing, administering, monitoring and SPECT/CT imaging of the patients. Measured staff doses (personal deep dose equivalent, Hp(10)) and patient dose rates were linearly scaled to the maximum administered activity of 200 MBq ^{212}Pb-ADVC001. ***Results:*** The median nuclear medicine technologist personal dose equivalent was 10 µSv per cycle of projected 200 MBq ^{212}Pb-ADVC001 administration (IQR 5-13 µSv). The median combined staff dose per 200 MBq cycle was 26 µSv (IQR 21-31 µSv). The average bi-exponential clearance was determined to include 47% fast clearance with an effective half-life of 1.9 hours, while the remaining 53% cleared with a biological half-life of 7.6 hours. Patients were discharged as early as 3 hours post treatment administration, with an average projected dose rate at 1 meter of 21 µSv/h. Patient release instructions were 3 days of increased hygiene precautions, with up to 48 hours of close contact restrictions, resulting in predicted doses of less than 100 µSv to any family member (including pregnant women and children) or members of the public per 200 MBq treatment. Following these instructions, up to 10 treatment cycles of 200 MBq would not exceed the member of public dose limit of 1 mSv per annum. ***Conclusion:*** Experienced staff can safely administer up to 200 MBq ^{212}Pb-based therapies in an outpatient setting, maintaining staff and members of the public exposure well below legislative limits. Minimal restrictions are required on discharge at 3 hours post treatment administration.

OP-704

Addressing Radiation Safety Concerns for Alpha-Emitter Astatine-211

S. Palm[1], *E. Leidermark*[1], *H. Jensen*[2], *T. Bäck*[1];
[1]*University of Gothenburg, Gothenburg, SWEDEN,* [2]*Copenhagen University Hospital, Copenhagen, DENMARK.*

Aim/Introduction: Alpha-emitter astatine-211 (^{211}At; $t_{½}$=7.2h) is currently used for targeted alpha therapy (TAT) in clinical trials, but expansion is hindered partly by radiation safety concerns. These concerns include transport; management of daughter ^{207}Bi ($t_{½}$=33a); co-production of ^{210}At ($t_{½}$=8.1h) and its daughter ^{210}Po ($t_{½}$=138d). Different regulations and local rules for work with ^{211}At have been reported. Here, we refer to international standard documents such as the IAEA basic safety standards (1); the IAEA regulations for transport (2); and the EU directive on radiation protection (3). Our aim was to provide some practical guidelines for interpreting and addressing the risks involved with ^{211}At using the exemption levels listed in (1-3). Our aim was also to raise awareness of the inappropriate regulations and local guidelines that require control of these radionuclides also when the amount is below the respective exemption limit. ***Materials and Methods:*** All work is based on the 20+ years production of ^{211}At in Copenhagen, Denmark and subsequent transport to and pre-clinical and clinical use in Gothenburg, Sweden. Shipped amount was nearly always <2 GBq ^{211}At. Patients received up to 300 MBq ^{211}At (coupled to an antibody). Both countries have national

legislation that adhere to (3) that, in turn, was harmonized with (1). To increase the amount of ^{211}At produced, typically 0.04% of ^{210}At is allowed to be co-produced. All regulations (1-3) list the same exemption limit for the mentioned radionuclides. Briefly, normal exposure to the exemption limit results in 10 µSv effective dose. Cross-border transport of the solid target (<2 GBq ^{211}At) is done in a type A container classified as UN2915. With lead shielding, the transport index is below 0.05 and therefore marked as zero. Packages are thus assigned to category I-WHITE. ***Results:*** The exemption limit for ^{211}At is 10 MBq. Therefore, gloves and other waste are kept for 72h and then discarded and incinerated as regular hospital waste. Complete decay of 2 GBq ^{211}At results in 21 kBq ^{207}Bi (exemption limit 1 MBq). Co-production of ^{210}At (0.04% of 2 GBq ^{211}At activity) and subsequent decay eventually results in 2 kBq ^{210}Po (exemption limit 10 kBq). Another 6 kBq ^{210}Po can be directly produced in the bombarded target (4). ***Conclusion:*** Exemption limits for ^{211}At, ^{207}Bi, ^{210}At and ^{210}Po can be used for determining clearance. Daughters ^{207}Bi and ^{210}Po are not a safety concern for <2 GBq ^{211}At. ***References:*** (1):ISBN:978-92-0-135310-8; (2):ISBN:978-92-0-107917-6; (3):2013/59/EURATOM; (4):https://doi.org/10.1016/j.radphyschem.2023.111155.

OP-705

Evaluation of Custom Shielding Made From Epoxy Resin to Reduce Doses to the Hand When Dispensing ^{90}Y Resin Microspheres

A. Smout, *E. Bolt, M. Pryor, J. Scuffham;*
Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

Aim/Introduction: Y-90 is a pure beta emitter with unshielded dose rates of 12mSv/GBq/s (Delacroix, 2002). Shielding is therefore essential to avoid exceeding occupational dose limits. We identified the potential for significant skin doses from Y-90 resin microspheres located in the hub of the needle when dispensing. Beta syringe shields are available, however these only shield the barrel of the syringe and leave the needle unshielded. This could lead to high skin doses to parts of the hand depending on how the syringe is held. If a cylindrical grasp is used when dispensing Y-90 (in which the fingers wrap around the syringe shield and the thumb is used to manipulate the plunger), the ulnar aspect of the base of the hand could receive high doses. Plastic is commonly used to shield beta radiation. Epoxy resin consists of a liquid resin and hardener that, when mixed, cures into a solid plastic. As a novel shielding material, this work aims to determine the thickness required to shield Y-90 emissions and whether the dose to the base of the hand can be reduced. ***Materials and Methods:*** To calculate the thickness of epoxy resin required to shield Y-90, 12 thicknesses of epoxy resin were made (2mm to 13mm). Thermo-luminescent detectors (TLDs) were placed behind each epoxy resin sample and irradiated by an unshielded Y-90 source in turn. To assess the dose reduction to the base of the hand, an epoxy resin plate was fitted onto a commercially available beta syringe shield and a hand phantom was created. TLDs from an approved dosimetry service were used to measure the dose to the base of the hand from a shielded syringe containing 1060MBq Y-90 with and without the additional epoxy resin fitted. ***Results:*** A thickness of 6.7mm epoxy resin reduced the dose from unshielded Y-90 microspheres by 98.7%. 7.4mm gave a dose reduction of 99.5% and both 8.75mm and 9.25mm thicknesses provided 99.97% reduction in dose. The phantom work showed that the dose to the base of the hand was 111.9mSv from holding the shielded syringe for 10 minutes, compared to 0.29mSv when the additional epoxy resin was fitted. ***Conclusion:*** High doses to the base of the hand are possible when dispensing Y-90 and custom shielding made from epoxy resin was shown to provide effective shielding with a dose reduction of 99.74%. ***References:*** Delacroix D. et al., (2002). OP-706

Preliminary Assessment of ^{89}Zr-Girentuximab Excretion and Radiation Protection in ccRCC patients undergoing PET/CT imaging

A. Piai[1], *G. Colelli*[2,1], *A. Loria*[1], *D. Tosoni*[2,1], *B. Bordigoni*[3,1], *L. Antunovic*[1], *F. Gelardi*[4,1], *A. Chiti*[4,1], *A. del Vecchio*[1];
[1]*IRCCS Ospedale San Raffaele, Milan, ITALY,* [2]*University of Milan, Milan, ITALY,* [3]*University of Padua, Milan, ITALY,* [4]*Vita-Salute University, Milan, ITALY.*

Aim/Introduction: Zirconium-labelled Girentuximab (^{89}Zr-girentuximab) PET/CT imaging is emerging as an effective technique for non-invasive diagnosis of Clear Cell Renal Cell Carcinoma (ccRCC). To our knowledge, limited information is available regarding the radiopharmaceutical biodistribution and no published data exist on excretion functions. This study presents preliminary findings on excretion and radiation protection measurements. ***Materials and Methods:*** Six patients received 37MBq of ^{89}Zr-girentuximab under an expanded access program at our institution, with two undergoing nephrectomy 11 and 12 days post-injection. Up to three whole-body PET/CT scans were acquired per patient and qualitatively assessed to identify organs with the highest tracer uptake. To estimate the excretion function, patient-specific dose rate measurements were performed with a calibrated Geiger-Muller counter at multiple time points post-administration (approximately 0h, 72h, 120h, 168h, and 264h). Patient-specific calibration factors were calculated using injected activity and dose rate at t=0h. Time-activity curves were fitted using mono-exponential and bi-exponential functions and the effective half-lives were calculated. Inter-individual variability was investigated. Extensive dose rate monitoring and contamination testing were performed during administration, imaging, and surgery to evaluate occupational exposure. ***Results:*** The mono-exponential decay constant (λ) is 1.602e-02 ([1.622e-02;2.624e-02]), corresponding to a half-life of 43.3h. Bi-exponential fitting yielded decay constants λs (short component) of 9.761e-01 ([5.518e-01;9.987e-01]) and λ_L (long component) of 9.854e-03 ([8.748e-03;1.271e-02]), corresponding to half-lives of 0.71h and 70.3h, respectively. PET/CT images revealed the highest uptakes in the liver, kidneys, heart wall, and bowels, suggesting a primarily gastrointestinal elimination pathway, in agreement with data from the Phase I study conducted by the radiopharmaceutical manufacturer [1]. The dose rate from the vial at 1 meter was 0.25µSv/h/MBq. Estimated effective doses per patient were <1µSv for radiographers (dose preparation), nurses (patient care), and nuclear medicine physicians (administration). On the day of surgery, dose rates were approximatively 0.1µSv/h. Superficial contamination was detected only on blood-stained gauzes. ***Conclusion:*** Preliminary findings on ^{89}Zr-girentuximab excretion functions indicate gastrointestinal excretion with short and long components of 9.761e-01 and 9.854e-03, respectively, with limited inter-individual variability. To our knowledge, no comparable data are currently available in the literature. Additional measurements on a larger patient cohort are planned in the next months to validate these findings and reduce the uncertainties. Negligible radiation exposure levels are associated with ^{89}Zr PET/CT imaging and subsequent surgery. However, due to the long half-life of ^{89}Zr, waste materials that come into contact with patient fluids can become significantly contaminated, making proper waste management essential. ***References:*** [1] https://doi.org/10.1007/s00259-021-05271-w.

OP-707

The UK perspective on establishing adult national diagnostic reference levels for nuclear medicine and PET

L. Fraser, *A. Powell, N. Parkar, M. Richardson;*
UK Health Security Agency, Didcot, UNITED KINGDOM.

Aim/Introduction: In the UK, the Ionising Radiation (Medical Exposure) Regulations 2017 [1] require employers to establish diagnostic reference levels for diagnostic medical exposures. These are often based on National Diagnostic Reference Levels (NDRLs) which are set by the Administration of Radioactive Substances Advisory Committee (ARSAC) for diagnostic nuclear medicine (NM) and Positron Emission Tomography (PET) procedures.

Previously, UK NDRLs have been derived from a combination of historical data, expert advice on good clinical practice and scientific literature. To ensure NDRLs are relevant and useful, we propose that NDRLs should be based on current clinical practice and capability. Presented will be the results of a UK wide survey and the new UK process for determining and implementing NDRLs. ***Materials and Methods:*** A survey was opened to all UK PET centres to collect data on the scanner technology, acquisition protocol parameters and administered activity used for ^{18}F-FDG whole body tumour imaging and ^{18}F-FDG infection inflammation imaging. Complete survey responses were analysed to understand the extent of the variation in UK practice and to estimate the impact of any change to the NDRL. ***Results:*** Survey responses were received from 65 of the 114 UK PET centres (57%). All centres were administering activity below the 2024 NDRL of 400 MBq. A total of 97% of the survey responses indicated that weight-based scaling was used instead of a fixed activity. The most common value used for scaling the administered activity was 3.5 MBq/kg across all scanner technologies. UK PET centres are optimising their acquisition protocols by increasing the time per bed position for larger patients, typically weighing >100kg. ***Conclusion:*** The survey showed that, for the examinations included, a weight-based activity scaling NDRL would be more reflective of current UK practice than a fixed activity value. The NDRLs for ^{18}F-FDG whole-body tumour imaging and ^{18}F-FDG infection inflammation imaging were changed in 2025 from 400 MBq to 3.5 MBq/kg [2] with minimal impact on most UK PET centres. ***References:*** [1]'The Ionising Radiation (Medical Exposure) Regulations 2017'. Building a European Network for Quality and Safety of Medical Ionizing Radiation Applications: Outcomes from the PrISMA SAMIRA EU4Health Project

S. Annunziata[1], *E. Solfaroli*[2], *J. Liukkonen*[3], *T. Jørgensen*[4], *C. Munoz*[5], *L. Boudewijns*[6], *T. Larose*[7], *I. Kralik*[8], *A. Sundlov*[9], *M. Do Carmo Lopes*[10], *K. Breddam*[11], *S. Geza*[12], *C. Franciosi*[1], *A. Capotosti*[1], *C. Rosenbaum*[6], *A. Rosi*[2], *on behalf of the SAMIRA-PRISMA EU4Health Consortium;*
[1]*Gemelli, Rome, ITALY,* [2]*ISS, Rome, ITALY,* [3]*STUK, Helsinki, FINLAND,* [4]*DSA, Oslo, NORWAY,* [5]*ICO, Barcelona, SPAIN,* [6]*RIVM, Bilthoven, NETHERLANDS,* [7]*Helsedirektoratet., Oslo, NORWAY,* [8]*Children Hospital, Zagreb, CROATIA,* [9]*Swedish Medical Products Agency, Goteborg, SWEDEN,* [10]*IPO, Coimbra, PORTUGAL,* [11]*DHA, Copenaghen, DENMARK,* [12]*NNGYK, Budapest, HUNGARY.*

Aim/Introduction: Under the EU's SAMIRA action plan, the Preparatory activities for Implementation of quality and Safety of Medical ionizing radiation Applications (PrISMA, https://www.rivm.nl/en/international-projects/prisma) preparatory project started in May 2024 and lasted 18 months. The overall aim of PrISMA was to explore the utility of, and pave the way for, a further Joint Action that promotes the safe, high-quality, and reliable use of medical ionising radiation. ***Materials and Methods:*** The consortium underpinning the PrISMA project (EU Grant Agreement 101162826), comprised 18 organisations - health authorities, health institutions, one medical product authority, ministries of health, one professional body, radiation protection authorities, and research institutes - from 11 European Member States and Norway. ***Results:*** The first PrISMA objective was to identify and bring together the relevant stakeholders in the area of quality and safety in the medical use of ionising radiation and to facilitate the pooling of expertise from different countries. Then, this extensive network defined a proposed text setting out the objectives, scope and activities of the future SAMIRA Joint Action. After routinary periodical online meetings among partners, for in-person PrISMA Workshop held in Zagreb in April 2025, there were 167 registered participants (79 onsite + 88 online), and 11 project proposals for the future JA were presented and discussed with stakeholders (regulators, radiation protection professionals, clinicians, and EC officers). Thanks to the identified stakeholders, the 18 organisations from 12 countries in PrISMA were in touch with over 400 stakeholders in 33 possible eligible countries. ***Conclusion:*** In the longer perspective, a successful implementation of the SAMIRA Joint Action will lead to a sustainable, high-quality, and safe diagnostic and therapeutic use of medical ionising radiation for citizens in Europe, and built the basis for the future SAMIRA Joint Action in the next months. ***References:*** - EU Grant Agreement 101162826.

Additive Value of [^{68}Ga]Ga-RM26 PET/CT to [^{68}Ga]Ga-PSMA-617 PET/CT in Detecting Pelvic Lymph Node Metastasis in Prostate Cancer: A Prospective, Single-Center, Phase II Study

Y. Tang[1], *Y. Li*[1], *L. Xiao*[1], *J. Yang*[1], *M. Zhou*[1], *K. Shi*[2], *S. Hu*[1];
[1]*Xiangya Hospital Central South University, Changsha, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, BERN, SWITZERLAND.*

Aim/Introduction: Lymph node staging in prostate cancer is crucial for treatment and prognosis, yet [^{68}Ga]Ga-PSMA-617 PET/CT has limited sensitivity in detecting pelvic lymph node metastasis (PLNM). [^{68}Ga]Ga-RM26 PET/CT, targeting the gastrin-releasing peptide receptor, complements [^{68}Ga]Ga-PSMA-617 PET/CT in assessing primary tumor extension and aggressiveness. However, its role in detecting PLNM and complementing [^{68}Ga]Ga-PSMA-617 PET/CT remains underexplored. ***Materials and Methods:*** This prospective study enrolled newly diagnosed yet untreated prostate cancer patients who underwent [^{68}Ga]Ga-RM26 PET/CT and [^{68}Ga]Ga-PSMA-617 PET/CT, followed by radical prostatectomy and extended pelvic lymph node dissection. The primary objective was to evaluate the diagnostic performance of both PET/CT modalities in detecting PLNM. ***Results:*** In total, 68 patients were enrolled, with a 30.9% (21/68) pathologic PLNM rate. In patientbased analysis, [^{68}Ga]Ga-RM26 PET/CT had sensitivity and specificity of 0.43 and 0.94, respectively, compared with 0.52 and 0.89 for [^{68}Ga]Ga-PSMA-617 PET/CT. [^{68}Ga]Ga-RM26 PET/CT detected additional PLNMs in 50% (5/10) of patients that were missed by [^{68}Ga]Ga-PSMA-617 PET/CT. The combined use of [^{68}Ga]Ga-RM26 PET/CT and [^{68}Ga]Ga-PSMA-617 PET/CT resulted in sensitivity of 0.76 and specificity of 0.85. In total, 1,049 lymph nodes were dissected, including 991 normal and 58 positive nodes. In lesion-based analysis, [^{68}Ga]Ga-RM26 PET/CT had sensitivity and specificity of 0.38 and 0.99, respectively, compared with 0.5 and 0.99 for [^{68}Ga]Ga-PSMA-617 PET/CT. [^{68}Ga]Ga-RM26 PET/CT identified 41.4% (12/29) of pathologic positive nodes missed by [^{68}Ga]Ga-PSMA-617 PET/CT. The combined [^{68}Ga]Ga-RM26 and [^{68}Ga]Ga-PSMA-617 PET/CT demonstrated sensitivity of 0.71 and specificity of 0.99. ***Conclusion:*** In dual-target imaging, [^{68}Ga]Ga-

RM26 PET/CT identified additional PLNMs. The combination of [68Ga]Ga-RM26 PET/CT and [68Ga]Ga-PSMA-617 PET/CT achieved higher diagnostic sensitivity with minimal loss of specificity. ***References:*** 1. Aim/Introduction: PSMA PET/CT upstages 8% of high-risk prostate cancers to M1 disease[1]. The Decipher genomic classifier (GC) score is a prognostic biomarker, with 42% of patients scoring >0.85 developing distant metastases within 10 years[2]. In high-risk prostate cancer, the phase 2/3 THUNDER trial (NCT06282588) investigates whether treatment adaptation based on PSMA PET/CT and GC scores improves metastasis-free survival. This prospective substudy focused on stage migration on PSMA PET/CT versus conventional imaging, and the association between GC scores and PSMA PET/CT results during the first year of the trial. ***Materials and Methods:*** High-risk prostate cancer patients (defined as at least one of: PSA >20 ng/mL, T-stage ≥3, ISUP grade ≥4, cN1 disease) referred for curative-intent radiotherapy and consenting between 13-12-2023 and 12-12-2024, were included. Patients with M1 disease on conventional imaging were analysed for stage migration (cohort 1: n=142), but excluded from GC score analysis (cohort 2: n=133). Within 16 weeks before screening, patients underwent contrast-enhanced CT, bone scintigraphy and PSMA PET/CT, evaluated using TNM or PROMISE V2 criteria[3]. GC scores were determined on diagnostic biopsy tissue (Veracyte, San Diego, USA) and categorized as low to intermediate (≤0.60), high (>0.60, ≤0.85) and very high (>0.85). ***Results:*** In cohort 1, 38% had PSA >20 ng/mL, 61% T-stage ≥3, 73% ISUP grade ≥4, and 19% cN1 disease. PSMA PET/CT upstaged 42 patients (30%), including miN1-2 upstaging in 23% and miM1 upstaging in 13%. One patient (1%) was downstaged. In cohort 2, 53% of patients had a very high GC score, 28% a high score, 20% a low to intermediate score. Extraprostatic PSMA uptake was observed in 47% of patients with a very high GC score (miN1-2M0: 27%, miM1a: 9%, miM1b-c: 11%), 46% of patients with a high score (miN1-2M0: 38%, miM1a: 5%, miM1b-c: 3%) and 23% of patients with a low to intermediate score (miN1-2M0: 12%, miM1a: 8%, miM1b-c: 4%). GC score was significantly associated with extraprostatic disease on PSMA PET/CT (OR=1.29 per 0.1 increase, p=0.016), independent of PSA and ISUP grade. ***Conclusion:*** In this very high-risk prostate cancer cohort, PSMA PET/CT upstaged approximately one in three patients. Interestingly, over half of the patients with a GC score >0.85 showed no extraprostatic disease on PSMA PET/CT. The THUNDER trial will evaluate PSMA- and GC-guided treatment adaptation strategies. ***References:*** [1]Hofman et al. Lancet. 2020; doi:10.1016/S0140-6736(20)30314-7, [2]Nguyen et al. Aim/Introduction: Supported by the IAEA, this study assessed the prognostic impact of initial staging 68Ga-PSMA PET/CT in unfavorable intermediate/high-risk PCa. ***Materials and Methods:*** A multicenter trial enrolled 775 newly diagnosed, treatment-naïve patients. Based on 68Ga-PSMA PET/CT, patients were categorized as PSMA-N0M0 (no metastases), PSMA-N1M0 (lymph node involvement), or PSMA-NxM1 (distant metastases). ***Results:*** Biochemical relapse rates were 35.4% (N0M0), 68.2% (N1M0), and 77.2% (NxM1). 2-year EFS rates for PSMA groups were: 56.6% in PSMA-N0M0: 43.9% in PSMA-N1M0: and 26.0% in PSMA-NxM1. 2-year OS rates were 99.3% in PSMA-N0M0, 99.2% in PSMA-N1M0 and 86.8% in PSMANxM1 ($p < 0.001$). PSMA status was the only significant prognostic factor ($p < 0.001$). ***Conclusion:*** 68Ga-PSMA PET/CT is a prognostic tool for PCa, improving staging accuracy. Treatment might be tailored based on 68Ga-PSMA PET/CT results to improve outcomes. ***References:*** Hofman MS, Kasivisvanathan V, Link E, et al. OP-712

The additivevalue of 68Ga-RM26 to 68Ga-PSMA-617PET/CT in the early prediction of biochemical failure in prostate cancer: results from a prospective, single-arm, phase IImultimodal imaging trial

J. Yang, *Y. Tang, Y. Li, L. Xiao, S. Hu;*
Xiangya hospital, Changsha, CHINA.

Aim/Introduction: Accurate prediction of biochemical recurrence (BCR) in prostate cancer (PCa) patients is crucial for optimizing treatment strategies and improving clinical outcomes. However, current prognostic tools demonstrate suboptimal predictive

accuracy (approximate 65% accuracy in reported studies). PSMA and GRPR have emerged as highly promising molecular targets for PCa imaging, with complementary expression patterns in PCa, offering potential for a more precise and comprehensive assessment of BCR risk. This study aims to investigate the role of dual-tracer PET/CT (^{68}Ga-PSMA, and GRPR targeted ^{68}Ga-RM26) in the early prediction of postoperative biochemical recurrence-free survival (BRFS) in PCa patients, in order to provide additional molecular indicators for novel prognostic stratification in PCa. ***Materials and Methods:*** Consecutive PCa patients undergoing preoperative dual-tracer PET/CT (^{68}Ga-PSMA-617 and ^{68}Ga-RM26) prior to radical prostatectomy were analyzed. Optimal PSMA/GRPR SUVmax cutoffs were determined via maximally selected rank statistics. Log-rank test and Cox regression were performed to assess the correlation between BRFS and PSMA/GRPR-SUVmax. Time-dependent area under the curve (AUC) was used to assess and quantify the performance of various risk factors. Additionally, we integrated the PSMA and GRPR dual-target imaging for constructing a predictive model, and tested the findings using external transcriptome data. ***Results:*** Among 102 patients, 51.0% experienced BCR/additional therapies. Higher PSMA-SUVmax (> 6.6) (HR: 3.17, 95%CI: 1.74-5.76, p = 0.004) and lower GRPR-SUVmax (≤ 13.0) (HR: 0.51, 95%CI: 0.29-0.88, p = 0.026) were associated with shorter BRFS. Further multivariate Cox regression analysis confirmed that both variables as independent predictors of BRFS. Correlation analyses revealed that PSMA-SUVmax significantly correlated with multiple established BCR predictors, whereas ^{68}Ga-RM26 PET/CT-derived SUVmax exhibited no significant correlations with any of the parameters. Integrative analysis revealed that the combined PSMA/GRPR-SUVmax model (time-dependent AUC: 0.73) significantly outperformed individual GRPR-SUVmax (time-dependent AUC: 0.62) or PSMA-SUVmax (time-dependent AUC: 0.63) measurements in the predictive accuracy. An external validation cohort of 198 individuals revealed that higher PSMA expression and lower GRPR expression were significantly associated with shorter BRFS. In addition, patients exhibiting high PSMA and low GRPR expression levels experienced poorer clinical outcomes, which was similar to the results of our dual- trace PET-based analyses. ***Conclusion:*** Our study provides the first clinical evidence demonstrating that tumor GRPR-SUVmax independently correlates with postoperative BRFS. The integration of GRPR PET with PSMA PET imaging offers enhanced accuracy in assessing BCR risk in PCa patients, potentially enabling identification of high-risk patients and facilitating personalized treatment strategies.

OP-713

Prognostic value of basline PSMA PET/CT for survival in synchronous metastatic hormone-sensitive prostate cancer: towards redefining low- and high-volume disease

F. Kleiburg[1,2], *L. Heijmen*[1], *A. Witteveen*[2], *K. van Duuren*[1], *P. Zuidgeest*[1], *F. Smit*[3], *L. de Geus-Oei*[1,2,4], *T. van der Hulle*[1];
[1]*Leiden University Medical Centre, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*Alrijne Hospital, Leiderdorp, NETHERLANDS,* [4]*Delft University of Technology, Delft, NETHERLANDS.*

Aim/Introduction: Since many clinical centres replaced conventional imaging with PSMA PET/CT for staging prostate cancer patients, there has been a high need for a reclassification of low- and high-volume metastatic disease to guide treatment decisions. This study aimed to provide insight into the prognostic value of PSMA PET/CT in metastatic hormone-sensitive prostate cancer (mHSPC), which can serve as a basis for redefining imaging-based risk stratification. ***Materials and Methods:*** Patients with synchronous mHSPC staged with PSMA PET/CT between April 2017 and August 2023 were included in this retrospective bicentric study. The PET parameters total tumour volume (PSMA-TV), total lesion uptake (TL-PSMA), DmaxVox (distance between the two outermost voxels), SUV_{max}, SUV_{mean} and metastatic sites were extracted. Additionally, age, ECOG/WHO performance status, iPSA, Gleason score, alkaline phosphatase and haemoglobin levels were collected. Multivariable Cox regression analysis identified independent significant predictors for overall survival (OS). Prediction model performance was evaluated using Harrell's C-index. Internal validation was performed using bootstrapping with 1000 samples. ***Results:*** A total of 204 patients were included, of which multidisciplinary team (MDT) meetings classified 75 (37%) as having low-volume disease (median PSMA-TV: 60 mL, median OS: 69 months), and 129 (63%) as having high-volume disease (median PSMA-TV: 483 mL, median OS: 41 months). PSMA-TV was the strongest predictor of OS (HR=1.39 per doubling, p<0.001), independent of ECOG/WHO performance status (HR=1.69 per score increase, p<0.001) and treatment. Other parameters had no predictive value in multivariate analysis. A prediction model for OS incorporating PSMA-TV and ECOG/WHO performance status achieved a C-index of 0.72, which remained at 0.71 after internal validation. In terms of differentiating long-term and short-term survivors, the optimal definition for PSMA-TV-based high-volume disease was: PSMA-TV ≥150 mL or any visceral metastasis. This classification (HR=3.01, p<0.001) outperformed MDT-based patient classification (HR=2.68, p<0.001). ***Conclusion:*** This study showed that PSMA-TV provided the best risk stratification for survival in synchronous mHSPC patients staged with PSMA PET/CT. Instead of maintaining a dichotomous approach using a single cut-off value, we propose using a validated survival prediction model, incorporating PSMA-TV as a continuous variable, to help guide treatment decisions. For the further development and validation of such a model, a larger, multi-centre patient cohort is needed.

OP-714

Preoperative Imaging Biomarkers of Aggressive Prostate Cancer: Assessing the role of PSMA PET/CT and mpMRI with Whole-Mount Histopathology Gold Standard

I. Sonni, *D. Hyeong Seok Kim, A. Ter-Pogosyan, S. Satonkiatngam, K. Kimura, T. Grogan, N. Barroso, P. Ahuja, J. Calais, J. Czernin, R. Reiter, A. Sisk, S. S. Raman;*
University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Intraductal carcinoma (IDC) and large cribriform pattern (LCP) are aggressive architectural subtypes of prostate cancer (PC) associated with adverse outcomes, including biochemical recurrence and metastasis. Accurate noninvasive prediction of these features could inform risk stratification and treatment planning, particularly when whole-mount histopathology (WMHP) is not available. This study aimed to evaluate the association between quantitative parameters from PSMA PET/CT and mpMRI and the presence of IDC and/or LCP in PC lesions, and to assess the combined predictive performance of PET and MRI metrics. ***Materials and Methods:*** This retrospective single-centre study included patients who underwent PSMA PET/CT prior to robotic-assisted radical prostatectomy at UCLA between January 2017 and July 2024. Lesion-level imaging-pathology correlation was performed between PET-identified lesions (PRIMARY score ≥3) and tumor foci on WMHP (ISUP grade group ≥2). A subcohort underwent preoperative 3T mpMRI with corresponding lesions identified (PI-RADS v2.1 ≥3). For each matched lesion, PET parameters (SUVmax, SUVmean, PSMA tumor volume) and MRI-derived ADC values were extracted. Lesions were grouped based on the presence of IDC and/or LCP. Statistical comparisons between groups were conducted using t-tests and ANOVA. ROC analyses were performed to evaluate predictive accuracy. ***Results:*** The final cohort included 346 patients and 404 matched tumors. Median PSA at prostatectomy was 7.6 ng/mL

(IQR: 5.3-12.85). IDC and/or LCP were present in 254/404 lesions (62.9%). Compared to lesions without these features, lesions with IDC and/or LCP demonstrated significantly higher SUVmax ($p < .001$), SUVmean ($p < .001$), and PSMA PET volume ($p < .001$), and significantly lower ADC values ($p < .001$). ROC analyses showed that SUVmax (AUC = 0.644), SUVmean (AUC = 0.625), and PET volume (AUC = 0.648) moderately predicted the presence of aggressive patterns. ADC had poor discriminatory performance (AUC = 0.335). ***Conclusion:*** Our preliminary results show that quantitative PSMA PET parameters, including SUVmax, SUVmean, and lesion volume, are significantly associated with the presence of IDC and/or LCP, and may serve as imaging indicators of aggressive pathology in prostate cancer. These findings support the potential value of PSMA PET/CT in risk stratification. Further analysis is underway to develop an integrated predictive model combining PET and mpMRI metrics. A more comprehensive assessment of their joint contribution to noninvasive detection of aggressive histological patterns is ongoing.

OP-715

Optimization of the PRIMARY Score in Ga-68 PSMA PET/CT: A New Approach to Active Surveillance Decision

D. Sahin, *H. Uslu, S. Güngör, S. Yaşar Belek, Ö. Doğan Yıldız, B. Canıtez, H. Kösem;*
Istanbul Medeniyet University Göztepe Prof. Dr. Süleyman Yalçın City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Active surveillance (AS) in prostate cancer (PCa) aims to avoid overtreatment and related side effects in localized disease, providing treatment only when necessary. According to NCCN guidelines, AS is recommended for patients with very low, low, and favorable intermediate-risk after confirmatory tests (1). The PRIMARY score is a scale developed for ^{68}Ga-PSMA PET/CT to identify clinically significant intraprostatic lesions (2). Score 4 is defined as a focal lesion in the peripheral zone but lacks a minimum activity threshold. This study aimed to optimize score 4 by defining an SUV_{max} cut-off and evaluating its effect on ^{68}Ga-PSMA PET/CT's diagnostic performance. ***Materials and Methods:*** A total of 173 patients diagnosed with PCa and who underwent ^{68}Ga-PSMA PET/CT for staging purposes were retrospectively evaluated. Age, total PSA (tPSA), biopsy-detected ISUP grade (bISUP), prostate SUV_{max} (p-SUV_{max}), prostate-to-liver SUV_{max} ratio (p/l-SUV_{max}), and PI-RADS scores of 129 patients with multiparametric magnetic resonance (mpMR) imaging reports were recorded. Patients were classified into AS candidate and non-candidate groups based on NCCN criteria. Differences in SUV_{max} values were evaluated using the Mann-Whitney U test. The Youden index was used to determine cut-off values. Lesions with a score of 4 and SUV_{max} values below these thresholds were reclassified as score 2, creating two new versions of the PRIMARY score: pPRIMARY and plPRIMARY. ROC analysis and Wilcoxon Signed-Rank tests were used to compare diagnostic performance. ***Results:*** The characteristics of the patients are given in Table 1. The most common PRIMARY score was 4 (59.0%). In patients with PRIMARY score 4, p-SUV_{max} values showed a significant difference between the groups that were and were not candidates for AS ($p < 0.001$). In these patients, the cut-off values calculated using Youden index were 4.65 for p-SUV_{max} and 1.03 for p/l-SUV_{max}. Diagnostic performance analyses of PRIMARY, pPRIMARY, plPRIMARY and PI-RADS tests are given in Table 2. Statistically significant differences were found between PRIMARY and both optimized scores ($p < 0.001$), while no significant difference was observed between pPRIMARY and plPRIMARY ($p = 0.271$). ***Conclusion:*** Applying a prostate SUV_{max} cut-off of 4.65 or a prostate-to-liver SUV_{max} ratio cut-off of 1.0 to score 4 significantly enhances the diagnostic accuracy of PRIMARY scoring in selecting candidates for AS. This optimization supports the potential role of ^{68}Ga-PSMA PET/CT as a confirmatory tool in AS decision-making. ***References:*** 1- Schaffer EM, et al. J Natl Compr Canc Netw. 20252- Emmett L, et al., J Nucl Med. 2022.

OP-716

The Diagnostic Utility of PSMA PET with Real-Time PSMA-PET Fusion - Target Biopsy in MRI-Negative or Equivocal Prostate Cancer: Results from the FUPERMAN Study

C. Sgro[1], *L. Bianchi*[2], *P. Castellucci*[3], *R. Mei*[3], *E. Greco*[1], *M. Presutti*[2], *F. Romei*[2], *M. Droghetti*[2], *R. Schiavina*[2], *E. Brunocilla*[2], *C. Gaudiano*[4], *B. Corcioni*[4], *S. Fanti*[3,1], *A. Farolfi*[3];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Division of Urology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Radiology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Multiparametric MRI (mpMRI) is the cornerstone for prostate cancer (PCa) diagnosis but shows limited sensitivity in PI-RADS 1-3 lesions, risking underdetection of clinically significant prostate cancer (csPCa). The FUPERMAN study aimed to assess the added diagnostic value of PSMA-PET in this subgroup, using real-time PSMA-PET fusion-target biopsy. ***Materials and Methods:*** FUPERMAN is a prospective, single-center study enrolling men with suspected PCa (PSA≥4ng/mL, PSA density≥0.1 ng/mL2, family history of PCa) and negative or equivocal mpMRI (PI-RADS 1-3). All patients underwent 68Ga-PSMA-11 PET/CT within 6-months of mpMRI, with image acquisition at 60- and 90-minutes post-injection. Intra-prostatic PSMA uptake was assessed using the PRIMARY score. Lesions with PRIMARY ≥3 were considered PSMA-positive and targeted using transperineal PSMA-PET fusion-target biopsy. All patients also underwent systematic biopsy. csPCa was defined as ISUP grade group≥2. ***Results:*** A total of 54 men were enrolled (median age: 67 y.o., median PSA: 13.1 ng/mL and median dPSA: 0.23 ng/mL2). mpMRI revealed PI-RADS 2 in 81% and PI-RADS 3 in 19%. PSMA-PET identified PRIMARY ≥3 uptake in 65% (35/54) of patients, who underwent PSMA-PET fusion-target biopsy combined with systematic biopsy. The remaining 19 patients (PRIMARY 1-2) underwent systematic biopsy only. Detection of csPCa increased with higher PRIMARY scores: 5% in scores 1-2, 30% in score 3, 38% in score 4, and 100% in score 5 ($p<0.001$). Higher PRIMARY scores were associated with greater estimated tumor volume on biopsies ($p<0.001$). Among patients with PRIMARY ≥3, 19 /35 (54%) had csPCa and 65% had any cancer (including ISUP 1). Overall, csPCa was detected in 20/54 (37%), and any cancer in 30/53 (56%). ISUP grade group distribution among csPCa cases was as follows: 8 ISUP 2, 5 ISUP 3, 5 ISUP 4 and 2 ISUP 5. SUVmax at both 60 and 90 minutes post-injection was significantly associated with the presence of csPCa (both $p<0.05$). For detection of csPCa, sensitivity was 84%, specificity 78%, NPV 98%, PPV 30%, and accuracy 78%. Larger prostate volume on mpMRI was associated with a higher false-positive rate for PSMA-PET ($p<0.05$). ***Conclusion:*** In men with high risk PCa, but negative or equivocal mpMRI, PSMA-PET fusion-target biopsy significantly enhances csPCa detection. The PRIMARY score serves as a reliable tool for lesion risk stratification.

OP-717

[^{68}Ga]Ga-PSMA-617 PET/CT and [^{68}Ga]Ga-NT PET/CT for Prostate Cancer Imaging: A Comparative Study and First Attempt of a Molecular Imaging Probe Targeting NTSR1 in Humans

Y. Tang[1], *Y. Li*[1], *L. Xiao*[1], *J. Yang*[1], *K. Shi*[2], *S. Hu*[1];
[1]*Xiangya Hospital Central South University, Changsha, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: We performed the first human imaging with [^{68}Ga]Ga-NT PET/CT and evaluated the imaging efficacy of [^{68}Ga]Ga-PSMA-617 PET/CT and [^{68}Ga]Ga-NT PET/CT in prostate cancer. ***Materials and Methods:*** This prospective study enrolled 23 patients with histopathologically confirmed prostate adenocarcinoma, stratified into two subgroups based on whether they received endocrine therapy prior to radical prostatectomy (RP). All patients

underwent [68Ga]Ga-PSMA-617 PET/CT and [68Ga]Ga-NT PET/CT before surgery, with the diagnostic efficacy of these imaging modalities evaluated. Additionally, the protein expression levels of prostate-specific membrane antigen (PSMA) and neurotensin receptor 1 (NTSR1) in the primary lesions were validated. ***Results:*** In all included prostate cancer cases, [68Ga]Ga-PSMA-617 PET/CT demonstrated significantly higher diagnostic sensitivity (82.6% vs. 4.3%; p = 0.0006) and lesion detection rate (88.9% vs. 3.2%; p < 0.0001) compared to [68Ga]Ga-NT PET/CT. Subgroup analysis of treatment-naïve patients revealed that [68Ga]Ga-PSMA-617 PET/CT had a sensitivity of 92.9% (95% CI: 64.2%-99.6%), specificity of 86.7% (95% CI: 58.4%-97.7%), positive predictive value (PPV) of 86.7% (95% CI: 58.4%-97.7%), and negative predictive value (NPV) of 92.9% (95% CI: 64.2%-99.6%). In contrast, [68Ga]Ga-NT PET/CT exhibited a sensitivity of 0% (95% CI: 0%-26.8%), specificity of 100% (95% CI: 74.7%-100%), and NPV of 51.7% (95% CI: 32.9%-70.1%). Following endocrine therapy, the sensitivity and lesion detection rate of [68Ga]Ga-PSMA-617 PET/CT decreased to 66.7% and 80%, respectively, while [68Ga]Ga-NT PET/CT showed an improved sensitivity of 11.1% and lesion detection rate of 8%, with specificity and PPV remaining at 100%. Immunohistochemical (IHC) analysis of radiotracer-avid lesions revealed a significant reduction in the median PSMA IHC score from 9 (range: 6-12) to 7 (range: 1-9) post-endocrine therapy (p = 0.034), alongside a significant increase in the median NTSR1 IHC score from 1 (range: 0.25-2) to 3 (range: 2-3.8) (p = 0.0074). ***Conclusion:*** This study shows that [68Ga]Ga-PSMA-617 PET/CT has better sensitivity and lesion detection for diagnosing prostate cancer than [68Ga]Ga-NT PET/CT. After endocrine therapy, [68Ga]Ga-PSMA-617 PET/CT's effectiveness decreased, while [68Ga]Ga-NT PET/CT's improved, likely due to reduced PSMA and increased NTSR1 expression. Given the short endocrine therapy duration in these patients, [68Ga]Ga-NT PET/CT may be useful for re-staging, re-evaluation, and monitoring post-treatment recurrence, especially with longer treatment. ***References:*** He, T., Wang, M., Wang, H., Tan, H., Tang, Y., Smith, E., Wu, Z., Liao, W., Hu, S., & Li, Z. Short antidepressant response and brain amyloid load in non-demented older adults with depression - The first part of ASAP Study

M. Santiago-Ribeiro[1], *T. Desmidt*[1], *J. Vercouillie*[2], *F. Lejeune*[3], *N. Arlicot*[1], *V. Gissot*[1], *A. Dupont*[1], *W. El-Hage*[1], *A. Caille*[1], *V. Camus*[1], *ASAP group;*
[1]CHRU, Tours, FRANCE, [2]Université de Tours, Tours, FRANCE, [3]CHU, Rennes, FRANCE.

Aim/Introduction: Amyloid accumulation in the brain may predispose to late-life depression (LLD). Depression is highly prevalent in the prodromal phase of Alzheimer's disease, which could be attributed to the consequences of neurodegeneration. We studied the relationship between cortical amyloid load and early response to antidepressant treatment in non-demented older adults. ***Materials and Methods:*** 92 Non-demented older adults with depression were enrolled in an 8-week observational study to assess the relationship between brain amyloid load and early antidepressant response. Amyloid load was measured using 18F-Florbetapir PET, and treatment response was evaluated using the MADRS. The injected radioactivity was 4 MBq/kg and, for each subject, two frames of 10 minutes were acquired, 50 min pi. Both visual and semiquantitative analyses were performed. 18F-Florbetapir PET images were visually assessed by two nuclear medicine physicians, who were blinded to all clinical and diagnostic information, using a binary scale to classify each scan 0 (no significant) or 1 (significant) 18F-Florbetapir cortical uptake. Volumes of interest (VOI) were defined in several cerebral regions according to the MNI-AAL atlas. Cortical-to-cerebellum standardized uptake value ratios (SUVr) were calculated and used for inter-subject comparison. The analysis compared amyloid load in responders versus non-responders at week 8. ***Results:*** Analysis regarding the 8-week antidepressant response status were performed on 73/92 subjects. Forty-one participants were considered responders and the remaining 32 as non-responders. 36 patients were considered as amyloid positive and 37 as negative. There were no significant differences in global cerebral SUVr (mean±SD) (responders 1.22±0.30, no-responders 1.16±0.33, p=0.40) or in SUVr calculated for each cortical region analyzed between responders and non-responders after 8 weeks of treatment. MADRS score was lower in amyloid positive versus negative participants at baseline (25.7±6.1 vs 30.0±6.8, p=0.005) and at week 8 (11.9±7.8 vs 16.3±10.3, p=0.045). ***Conclusion:*** In this observational cohort of non-demented depressed older adults, amyloid burden does not appear to modify response status in the short term of treatment.

Aim/Introduction: AMPA receptor (AMPAR) dysfunction may contribute to the pathophysiology of depression. Approximately one-third of patients with depression have treatment-resistant depression (TRD), showing inadequate respond to standard antidepressant treatment. Ketamine showed efficacy in TRD, potentially through modulation of AMPAR function. Although post-mortem studies reported that AMPAR density altered in depression, in vivo evidence remains lacking. This study aimed to investigate the relationship between AMPAR density and symptom severity in patients with TRD using positron emission tomography (PET), and to assess whether ketamine alters AMPAR distribution in these patients. ***Materials and Methods:*** Forty-nine healthy controls and thirty-four patients with TRD underwent PET scanning using [11C]K-2, a PET tracer selective for cell-surface AMPARs. Patients with TRD were randomly assigned to receive either saline (n=17) or ketamine (n=17) twice a week for two weeks and performed 2nd PET scan at 1 month after the first scan. Depression severity was measured using the Montgomery-Åsberg Depression Rating Scale (MADRS). We performed regression analysis between SUVR (reference; whole brain) and

MADRS total scores, and between ΔSUVR (2nd scan - 1st scan) and % improvement in MADRS scores. Additionally, we compared SUVR between healthy controls and TRD patients and explored the predictive value of baseline AMPAR distribution for treatment response. ***Results:*** A negative correlation was observed between baseline SUVR and symptomatology scores in the fronto- parietal cortices of patients with TRD. Compared to the healthy participants, patients with TRD decreased SUVR in several cortical areas and increased SUVR in the cerebellum, temporal cortex, and basal ganglia. In the ketamine group, there was a positive correlation in the fronto-parietal cortices and a negative correlation in the cerebellum and habenula between ΔSUVR and % improvement of MADRS scores. These region-specific alterations in AMPAR density partially restored the AMPAR phenotype in affected brain areas. Furthermore, some brain regions showed correlations between baseline SUVR and %improvement in MADRS scores. ***Conclusion:*** AMPAR dynamics play a key role in mediating the antidepressant effects of ketamine in patients with TRD. ***References:*** Miyazaki T, Nakajima W et al. Seasonal DAT availability in Major Depressive Disorder: a ^{123}I-FP-CIT study.

D. Pizzuto[1], *A. M. D'Onofrio*[2], *S. Annunziata*[1], *F. Cavallo*[3], *F. Cocciolillo*[3], *G. Sani*[2], *G. Camardese*[2], *D. Di Giuda*[3];
[1]*Nuclear Medicine Unit, GSTeP Radiopharmacy, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, ITALY,* [2]*Department of Neuroscience, Section of Psychiatry, Università Cattolica del Sacro Cuore, Largo Francesco Vito 1, Rome, ITALY,* [3]*Nuclear Medicine Unit, Department of Radiology and Radiotherapy, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Rome, ITALY.*

Aim/Introduction: Seasonal changes in central dopaminergic tone have been observed in healthy individuals, but their role in modulating symptom expression in Major Depressive Disorder (MDD) remains poorly understood. This study aimed to investigate seasonal differences in DAT availability in MDD patients using ^{123}I-FP-CIT SPET and to explore DAT differences between clinical subgroups defined by psychopathological dimensions. ***Materials and Methods:*** We retrospectively analysed 85 MDD patients (mean age: 63.6±11.1 years; 40 M) from a ^{123}I-FP-CIT SPET database. Patients were stratified into Spring-Summer (SS, N=58) and Fall-Winter (FW, N=27) according to the time of SPET. The same day as SPET, they underwent psychometric assessments: Hamilton Depression Rating Scale (HAMD), Hamilton Anxiety Rating Scale (HAMA), Snaith-Hamilton Pleasure Scale (SHAPS) and Depression Retardation Rating Scale (DRRS). Patients were stratified according to the presence (SI) or absence (nSI) of suicidal ideation. DAT availability in caudate and putamen was quantified as Specific Binding Ratios (SBRs) using SPM and VOI analysis. ***Results:*** No seasonal differences in DAT availability were observed between FW and SS. SHAPS scores were higher in FW than in SS (p=0.049). In the SS group, patients with severe depression (HAMD score>25) had lower DAT availability in the left putamen compared to patients with moderate depression (HAMD score≤25) (p= 0.014). Lower DAT availability was found in all striatal regions of SS patients with severe retardation (DDRS>18) compared to patients with moderate retardation (DDRS≤18) (p range:0.001-0.032). Conversely, DAT availability in FW did not differ between severe and moderate depression as well as severe and moderate retardation. Patients with anhedonia (SHAPS>3) did not differ in DAT availability from non-anhedonic patients (SHAPS≤3), regardless of season. In the whole sample, patients with severe depression had lower DAT availability in the left putamen than those with moderate depression (p=0.005). Similarly, lower DAT availability in the left putamen was observed in patients with severe retardation compared to those with moderate retardation (p = 0.002). SI patients had lower DAT availability in bilateral putamen than nSI patients (right: p = 0.029; left: p = 0.015), with a greater reduction in SS (right: p = 0.005; left: p = 0.001). ***Conclusion:*** Although DAT availability did not differ across seasons, lower striatal DAT availability was consistently observed in MDD patients with severe psychomotor retardation or severe depression. SS period was associated with more pronounced reductions in DAT availability in these clinical subgroups. Findings suggest a seasonal dopaminergic vulnerability in different MDD phenotypes.

Striatal network desynchronization in schizophrenia: initial insights from FDOPA-PET imaging

Y. Mayr[1,2], *J. Schulz*[3], *M. Thalhammer*[3], *M. Veronese*[4,5], *C. Sorg*[3], *F. Brandl*[6], *I. Yakushev*[1,2];
[1]*Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY,* [2]*Graduate School of Systemic Neurosciences GSN-LMU, Munich, GERMANY,* [3]*Institute for Neuroradiology, Technical University of Munich, Munich, GERMANY,* [4]*Department of Information Engineering, Padova University, Padova, ITALY,* [5]*Department of Neuroimaging, King's College London, London, UNITED KINGDOM,* [6]*Department of Psychiatry, Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: Computational psychiatry posits that the brain normally operates as a stable dynamical system, whereas in psychosis, neural circuits become more vulnerable to even minor perturbations, manifesting as disorganized cognition, giving rise to the classical symptoms of schizophrenia. While the desynchronization hypothesis of schizophrenia is prevailingin the field, most evidence has come from functional MRI studies. Together with network analyses, positron emissiontomography (PET) with 6-[18F]-L-fluoro-L-3, 4- dihydroxyphenylalanine (FDOPA) potentially allows to address the above hypothesis at the level of dopaminergic neurotransmission. Using FDOPA-PET, we assessed synchronicity within the striatalnetwork in patients with schizophrenia in psychosis and in remission, and in healthy control subjects (HC). ***Materials and Methods:*** Patients with schizophrenia (n=17) underwent dynamic FDOPA-PET twice: while being in (mild to moderate) psychosis (S01) and in remission (S02). HC (n=18) underwent dynamic FDOPA-PET twice, too. Influx constant Ki as index of dopaminesynthesis capacity (DSC) was quantified in putamen, caudate nucleus, nucleus accumbens bilaterally with reference to cerebellum, using the Patlak graphical method. Apart from conventional univariate analyses, a network synchronicity matrixwas generated by computing Pearson correlations between Ki of every pair of 6 ROIs for each of three conditions: S01, S02, and HC. In HC, Ki values were averaged between two sessions to improve reliability. Coefficient of variation (CV) of the magnitudes of correlation coefficients was used as index of network desynchronization. ***Results:*** Ki of the striatal subdivisions did not differ between three conditions (p>0.05 uncorrected). The highest CV was found inpatients with psychosis (S01), followed by the condition of remission (S02), and HC. The difference between S01and HC was significant (p=0.04). ***Conclusion:*** Our initial results demonstrate markedly reduced synchronization within the striatal network in individuals with psychotic schizophrenia compared to HC. This desynchronization showed a trend toward normalization during remission. Importantly, striatal DSC itself did not differ between three conditions. These results underscore the utility of network-based analysis of PET data and support the network de-synchronization hypothesis of schizophrenia at the level of dopaminergic neurotransmission.

OP-722

Post Covid-19 cerebral perfusion in patients complaining of recent memory loss: a dual-timepoint study

S. Lopes de Souza[1], *L. C. Melo*[2], *H. F. Carvalho*[3], *K. Ruzzon*[2], *A. O. Blackman*[4], *B. M. Oliveira*[5], *S. K. A. Lima*[1], *A. C. J. Sousa*[6];
[1]*Universidade Federal do Rio de Janeiro / School of Medicine / Radiology Department, Rio de Janeiro, BRAZIL,* [2]*IRB Medicina Nuclear, Brasília, BRAZIL,* [3]*Universidade Católica de Brasília, Brasília, BRAZIL,* [4]*Centro Universitário de Brasília, Brasília, BRAZIL,* [5]*Centro Universitário do Planalto Central Aparecido dos Santos, Brasília, BRAZIL,* [6]*Clinica da Memoria Brasilia, Brasília, BRAZIL.*

Aim/Introduction: The COVID-19 pandemic has imposed a substantial burden on global health, with growing evidence indicating persistent neurological and cognitive sequelae among post-COVID-19 patients. Advanced neuroimaging techniques have played a pivotal role in identifying cerebral perfusion abnormalities that may underlie these long-term symptoms. This study aims to investigate cerebral perfusion changes using Technetium-99m ethyl cysteinate dimer (99mTc-ECD) SPECT imaging in patients with a history of COVID-19 who present with subacute neurological symptoms, particularly recent memory impairment. ***Materials and Methods:*** A total of 95 patients (51 male, 44 female), with a mean age of 53 years (range: 17-85), were evaluated between 2021 and 2024 in an outpatient setting. All patients reported subacute neurological complaints, predominantly cognitive disturbances and headaches. Brain perfusion imaging was performed using SPECT with a dual-head gamma camera system equipped with ultra-high-resolution Fan Beam collimators (GE MN 830). Importantly, none of the patients had a prior history of neurological disorders. A subset of 80 patients also underwent brain MRI. A median interval of 10 months was observed between the first and second SPECT scans. ***Results:*** All 95 patients demonstrated mild to moderate cerebral hypoperfusion. Upon comparison of the initial and follow-up SPECT scans 23% (22/95) showed improved perfusion patterns; 44% (42/95) exhibited no change; 33% (31/95) experienced worsening perfusion. The most commonly affected regions included the frontal cortex, sensorimotor areas, parietal lobes, occipital lobes, lateral temporal cortices, and the cerebellum. These findings, characterized by their diffuse and heterogeneous distribution, suggest a possible underlying vascular mechanism, potentially associated with mood and cognitive disturbances observed in long COVID. ***Conclusion:*** This study highlights a potential link between long COVID and vascular-mediated neurological injury. Brain SPECT imaging proves to be a valuable tool in detecting regional cerebral perfusion abnormalities, offering insights into both disease progression and recovery trajectories. These findings support the incorporation of SPECT into the neurological assessment of post-COVID-19 patients, while also emphasizing the need for further research to elucidate the pathophysiological mechanisms involved and to assess the prognostic value of perfusion imaging in this context.

OP-723

Neurodegenerative Protein Load Correlates with Cognitive Decline in Temporal Lobe Epilepsy: A Multimodal PET Imaging Study

Y. Tang[1], *L. Xiao*[1], *M. Zhou*[1], *J. Yang*[1], *K. Shi*[2], *S. Hu*[1];
[1]*Xiangya Hospital Central South University, Changsha, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND.*

Aim/Introduction: Cognitive impairment is a common comorbidity in temporal lobe epilepsy (TLE), but its underlying mechanisms remain poorly understood. Emerging evidence suggests that neurodegeneration may contribute to this dysfunction; however, the degree, spatial distribution, and relationship between neurodegenerative pathology and cognitive performance in TLE require further investigation. This study utilized advanced PET molecular imaging to localize and quantify hyperphosphorylated tau and β-amyloid deposition across the brain in TLE patients and to evaluate their correlations with cognitive function and clinical phenotypes. ***Materials and Methods:*** We recruited 21 patients with TLE (13 with cognitive impairment and 8 without) and 11 age- and sex-matched healthy controls. All participants underwent comprehensive neuropsychological assessments, as well as PET imaging with ^{18}F-fluorodeoxyglucose ([^{18}F]FDG) to measure glucose metabolism, [^{18}F]MK6240 to assess tau pathology, and ^{11}C-Pittsburgh compound B ([^{11}C]PIB) to quantify β-amyloid deposition. PET data were analyzed using PMOD software, with standardized uptake value ratios (SUVRs) calculated using the cerebellar cortex as the reference region. To account for laterality, SUVRs were mirror-flipped, defining the left hemisphere as ipsilateral to the epileptogenic focus. Correlations between regional SUVRs, neuropsychological scores, and clinical factors were evaluated using statistical modeling. ***Results:*** TLE patients demonstrated significant reductions in glucose metabolism, primarily in the temporal lobe and hippocampus ipsilateral to the epileptogenic focus, compared to healthy controls. Tau SUVRs were markedly elevated in TLE patients with cognitive impairment, not only in the hippocampus but also in regions including the Heschl gyrus, superior and middle temporal gyri, fusiform gyrus, and cingulate cortex ($p < 0.01$). Verbal fluency scores were negatively correlated with tau SUVRs in multiple brain regions ($p < 0.05$), indicating a strong association between tau pathology and language deficits. In contrast, β-amyloid SUVRs (assessed by [^{11}C]PIB PET) showed a trend toward decreased uptake in TLE patients compared to healthy controls. ***Conclusion:*** Our findings reveal that TLE with cognitive impairment is associated with significant tau pathology extending beyond the temporal lobe and hippocampus. The negative correlation between tau deposition and language ability highlights the potential role of tau-related neurodegeneration in TLE-associated cognitive decline. These results underscore the importance of considering neurodegenerative mechanisms in the management of cognitive comorbidities in TLE and may inform future therapeutic strategies targeting tau pathology.

OP-724

The correlation between the efficacy of levetiracetam in the treatment of temporal lobe epilepsy and PET metabolic brain networks

H. Zhang, *J. Liu;*
The second hospital&clinical medical school. Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: Antiepileptic drugs (AEDs) therapy is the primary treatment strategy for most patients with epilepsy. Levetiracetam (LEV) is one of the most common AEDs and is used in the treatment of many types of epilepsy. Accurate prediction of LEV efficacy is essential for drug selection and subsequent treatment strategy development. ^{18}F-FDG PET has been widely used in the evaluation of epileptogenic foci, PET-based metabolic brain networks are thought to reveal the overall impact of epilepsy on the brain. The aim of this study was to analyze the metabolic network characteristics of temporal lobe epilepsy (TLE) with different efficacies of LEV, to find parameters to predict drug efficacy, and to provide a reliable basis for the selection of clinical medication and the development of therapeutic strategies. ***Materials and Methods:*** 124 patients with TLE who received LEV monotherapy and underwent ^{18}F-FDG PET were retrospectively included, as well as 124 sex- and age-matched healthy controls. Patients were categorized into drug-sensitive and drug-resistant groups according to the frequency of seizures at 1-year follow-up after drug administration. Metabolic brain network was constructed and metabolic connectivity parameters were calculated based on MATLAB to compare the differences between the two groups of epileptic patients and healthy controls. Based on graph theory techniques, group level Hub nodes of epileptic

patients were calculated and standardized uptake value ratio (SUVR) was extracted at the corresponding positions of all individual patients, and SUVR was analyzed in univariate analysis with drug efficacy. ***Results:*** Both drug-sensitive and drug-resistant groups of temporal lobe epilepsy patients showed disruption of metabolic connectivity compared to healthy controls, with more significant disruption of metabolic connectivity in the drug-resistant group. In the metabolic connectivity parameter calculations, the metabolic brain networks of both groups of epileptic patients and healthy controls had small-world network properties, the drug-sensitive group had a higher global efficiency, average degree, and clustering, along with a shorter characteristic path length compared to the drug-resistant group ($P < 0.05$). Hub nodes of epileptic patients were altered in the graph theory, SUVR at Hub node locations was an independent predictor of LEV efficacy. ***Conclusion:*** This study is the first to explore the epileptic metabolic brain network of LEV monotherapy. The drug-sensitive group showed better network function and less disruption of metabolic connectivity compared to the drug-resistant group, and the SUVR of the Hub node may serve as a predictor of LEV efficacy.

Functional correlates of cognitive impairment and mood alterations in Multiple Sclerosis: an early perfusion PET study

L. Sofia[1], *M. Donegani*[2], *S. Raffa*[2], *A. Donniaquio*[3], *L. Argenti*[3], *L. Roccatagliata*[1], *A. Chincarini*[4], *G. Novi*[2], *A. Laroni*[3], *G. Sambuceti*[1], *M. Bauckneht*[1], *A. Uccelli*[3], *M. Inglese*[3], *M. Pardini*[3], *S. Morbelli*[5];
[1]*Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY,* [2]*IRCCS Ospedale Policlinico San Martino, Genoa, ITALY,* [3]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, ITALY,* [4]*National Institute of Nuclear Physics (INFN), Genoa, ITALY,* [5]*Department of Medical Sciences, University of Turin, Turin, ITALY.*

Aim/Introduction: Early perfusion amyloid PET imaging is emerging as a valuable tool to potentially capture patients' synaptic dysfunction thus possibly representing a surrogate for FDG PET. Besides his recognized role in Alzheimer's Disease, amyloid PET imaging has recently been proposed as a tool to capture demyelination and remyelination in the white matter of patients with Multiple Sclerosis (MS). MS is clinically characterized by the presence of progressive disability and a wide range of cognitive and mood disorders. There's an increasing interest in the evaluation of cognitive impairment in patients with MS given its prognostic value as a potential further source of disability. We aimed to explore the correlation between cognitive and behavioural symptoms and cerebral blood flow, as assessed by early-phase amyloid PET imaging in MS patients. ***Materials and Methods:*** 28 patients with MS (18 relapsing-remitting and 10 primary progressive) were recruited. All patients underwent dual dynamic amy-PET imaging with [18F]Florbetaben, consisting in an early dynamic acquisition of the first 5 minutes (as a proxy of perfusion) and late steady-state acquisitions 90-110 minutes post-injection. All patients underwent clinical evaluation including disability scales and a neuropsychological assessment of different cognitive and behavioural symptoms, including fatigue, depression and visuo-spatial memory. Multiple-regression analyses were performed by means of SPM12 to assess the correlation between clinical evaluation scores and brain perfusion. $P<0.05$ FWE-corrected at cluster level was accepted as significant (age and sex as nuisances). ***Results:*** Fatigue severity measured by modified Fatigue Impact Scale (mFIS) was inversely correlated with perfusion in a fronto-insular cluster and in the putamen ($p<0.003$), while higher scores on depression scales (Hospital Anxiety and Depression Scale, HADS-D) were significantly associated with reduced perfusion in the putamen ($p < 0.002$). Additionally, visuospatial memory scores (assessed by the Brief Visuospatial Memory Test, BVMT) were directly correlated with perfusion in the corpus callosum ($p<0.005$). ***Conclusion:*** Early perfusion amyloid PET imaging captured functional correlates of cognitive and behavioural symptoms in MS patients. Hypoperfusion in subcortical and fronto-insular regions, areas known to be involved in emotional processing, was linked to fatigue and depression. Moreover, reduced perfusion in the corpus callosum, a crucial hub for interhemispheric connection, was associated with lower visuospatial memory scores. Early perfusion imaging in the contest of amyloid PET studies may open a further window on MS pathophysiology thus providing with the same tracer and on the same day functional information derived from both gray and white matter.

O-15-water PET in cochlear-implant users reveals different strategies for speech processing in the central nervous system depending on background noise and speech comprehension

M. Voskamp[1,2], *S. Hansen*[3,4], *D. Merz*[1], *F. Bengel*[1], *T. Lenarz*[2,5], *A. Büchner*[2,5], *T. Ross*[1], *P. Sandmann*[3,4,6], *G. Berding*[1,2];
[1]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY,* [2]*Cluster of Excellence "Hearing4all", Hannover, GERMANY,* [3]*Department of Otorhinolaryngology at Evangelisches Krankenhaus Oldenburg, Oldenburg, GERMANY,* [4]*Cluster of Excellence "Hearing4all", Oldenburg, GERMANY,* [5]*Department of Otorhinolaryngology, Hannover Medical School, Hannover, GERMANY,* [6]*Research Center Neurosensory Science, University of Oldenburg, Oldenburg, GERMANY.*

Aim/Introduction: Cochlear Implantation (CI) is a well-established treatment for severe-to-profound hearing loss. While a CI can effectively restore adequate hearing abilities in challenging listening environments for many patients, about one-third of patients encounter difficulties with speech comprehension, particularly in noisy settings. This variability in results is largely attributable to impaired processing of the signals received via the CI, caused by a maladaptation due to the earlier existing hearing impairment. More accurate diagnosis of speech processing could lead to improvement through targeted training. ***Materials and Methods:*** To assess the cortical activation patterns in response to speech, we used O-15-water positron emission tomography (PET). In this study, sixteen CI users with different sentence comprehension (good and poor performers (GP&PP)) underwent O-15-water PET/CT while performing a sentence discrimination test with and without background noise. The speech material used, consists of semantically correct and incorrect sentences. The correct sentences were split into high- and low-cloze probability (HC&LC), based on the contextual proximity of verb and noun. Additionally, multiple baseline scans were conducted. The detection of cortical activations was achieved by comparing conditions with statistical parametric mapping (SPM). ***Results:*** Without noise, GP showed a large activation in the temporal voice area (TVA)(990 voxels) and small activation in the Broca's region(77 voxels) and Brodmann-area 6 (BA6)(77 voxels). In Comparison, PP showed smaller activations in the TVA(771 voxels) and in Broca's region(20 voxels) but a larger activation in BA6(223 voxels). Furthermore, adding noise in GP enlarged activation in BA6(429 voxels). When exposed to semantically difficult listening scenarios (LC in contrast to HC sentences), activations were larger in Broca's region(GP 81 vs. 6, PP 16 vs. 0 voxels) as well as in BA6(GP 42 vs. 5, PP 187 vs. 37 voxels). TVA activations were always larger in GP compared to PP for both scenarios. ***Conclusion:*** Our study shows that differences in recruitment of cortical areas involved in speech processing in CI users are related to background noise and speech comprehension. GP are able to activate the TVA also in difficult listening scenarios to a larger extent in comparison to PP. However, both seem to compensate for difficult listening situations (due to noise or difficult sentences) by activating additional resources, specifically in Broca's region and BA6. The latter region shows a

larger activation in PP compared to GP even in listening without noise, possibly indicating higher listening effort for PP, even in listening scenarios without background noise.

First-in-human study of a novel cardiac sympathetic neuronal PET imaging agent: [^{18}F]FPMBBG

M. Ju, *W. Ren, L. Wang, W. Fang;*
Fuwai Hospital, Public Union Medical College, Beijing, CHINA.

Aim/Introduction: Cardiac sympathetic innervation imaging can non-invasively evaluate the cardiac sympathetic nervous function, potentially aiding in heart failure (HF) risk stratification. Preclinical studies with [^{18}F]FPMBBG revealed high affinity and robust myocardial uptake, suggesting its suitability as a novel cardiac imaging tracer. This study presents the first-in-human evaluation of it. ***Materials and Methods:*** 8 healthy volunteers and 8 HF patients underwent 60-min cardiac PET scans with [^{18}F]FPMBBG. Left ventricular myocardial VOIs were delineated using a SyngoVia workstation. Myocardial uptake was quantified by SUVmax, SUVmean at early (5-10 min) and late (55-60 min) imaging times, washout rate (WR = (SUV max$_{/early}$ - SUV max$_{/late}$)/ SUV max$_{/early}$ ×100%), late retention index (RI = C_m (T_R) × 100% / $\int_0^{TR} C_p$ (t)dt) and compared between the healthy and HF groups using Student's t-test or Mann-Whitney U test according to the normality of the data ($P < 0.05$). ***Results:*** The chemical structure of [^{18}F]FPMBBG is shown in Figure 1A. [^{18}F]FPMBBG demonstrated a favorable safety profile, with no adverse events or significant changes in vital signs in any subject. Healthy volunteers showed high myocardial uptake, low lung uptake and rapid hepatic clearance (Figure 1B, C). Heart-to-liver ratios increased over time, reaching 3.26 ± 1.45 at 60 minutes post-injection. Compared with volunteers, HF patients exhibited significantly lower SUVmax [early: 4.61 ± 0.45 vs 6.83 ± 1.44, P = 0.016, late: 4.69 (4.36, 4.89) vs 6.21(6.07, 6.95), P = 0.002], SUVmean [early: 4.61 ± 0.45 vs 4.40 ± 0.78, P < 0.001, late: 2.66 (2.33, 2.84) vs 4.02 (3.86, 4.36), P = 0.001] and RI (3.79 ± 0.77%/min vs 6.75 ± 1.02%/min, P < 0.001), along with a significantly higher WR [14.04 (13.01, 15.44)% vs 3.58 (0.94, 5.25)%, P = 0.001](Figure 1D). ***Conclusion:*** [^{18}F]FPMBBG PET imaging provides high image quality and reliable measurements of cardiac sympathetic nerve function. It is a promising tracer for further investigation.

OP-728

Ga-68 labelled Affibody molecule based radiopharmaceutical targeting platelet derived growth factor receptor beta detects active fibrosis in patients with myocardial infarction.

I. Velikyan[1,2], *K. Grinnemo*[2], *V. Flodin*[2], *S. James*[3], *U. Thelander*[2], *O. Korsgren*[4], *O. Eriksson*[1,5];
[1]*Science for Life Laboratory, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [2]*Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN,* [3]*Department of Medical Sciences, Uppsala University, Uppsala, SWEDEN,* [4]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN,* [5]*Antaros Tracer AB, Uppsala, SWEDEN.*

Aim/Introduction: The platelet-derived growth factor receptor beta (PDGFRβ) is a key mediator of cell proliferation, migration, and extracellular matrix production associated with fibrotic processes. Quantitative imaging of PDGFRβ expression in vivo could enhance clinical management of cardiac patients undergoing invasive interventions, where fibrosis presents a significant risk. This study presents the GMP production of a ^{68}Ga-labeled PDGFRβ-targeted radiopharmaceutical ([^{68}Ga]Ga-ATH001), its preclinical characterization in human heart biopsies, and finally initial results from a phase 0 clinical study in patients with ST-elevated myocardial infarction (STEMI) compared to healthy controls. ***Materials and Methods:*** The Affibody molecule ATH001 was chemically synthesized and functionalized with a DOTA chelator at the C-terminal cysteine residue. A fully automated method for producing [^{68}Ga]Ga-ATH001 was established using a pharmaceutical-grade ^{68}Ge/^{68}Ga generator and pre-sterilized, single-use cassettes [1] compatible with the Modular-Lab PharmTrace platform. The binding of [^{68}Ga]Ga-ATH001 in biopsies of human cardiac fibrotic tissue was evaluated by in vitro autoradiography. PET/MRI scanning with [^{68}Ga]Ga-ATH001 was performed in STEMI patients 1 week following percutaneous coronary intervention (PCI), as well as healthy controls. ***Results:*** Fully automated, reproducible, and GMP compliant production of [^{68}Ga]Ga-ATH001 was developed. [^{68}Ga]Ga-ATH001 demonstrated receptor-mediated binding overlapping with PDGFRβ immune-positive areas in cardiac fibrotic tissue sections. The administered protein dose per patient was below 100 µg, in accordance with the microdosing concept. [^{68}Ga]Ga-ATH001 demonstrated low and homogenous uptake in healthy myocardium in vivo. In STEMI, [^{68}Ga]Ga-ATH001 exhibited strong focal binding in myocardial tissue corresponding to infarcted areas as verified by standard cardiac radiological techniques. ***Conclusion:*** The automated production of [^{68}Ga]Ga-ATH001 was developed and validated for phase 0 clinical trial application. Preclinical studies confirmed its selective, high-affinity binding to PDGFRβ in human fibrotic myocardium. Patient imaging revealed distinct myocardial uptake of [^{68}Ga]Ga-ATH001, which correlated with the infarction site. ***References:*** [1] Velikyan et al., AJNMMI, 2019, 12-23.

OP-729

Differential prediction of heart failure death and arrhythmic events using a practical multivariable model with ^{123}I-MIBG Imaging

K. Nakajima[1], *T. Doi*[2], *T. Nakata*[3], *T. Nakahashi*[4], *H. Tada*[1], *H. Wakabayashi*[1], *H. J. Verberne*[5];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Teine Keijinkai Hospital, Sapporo, JAPAN,* [3]*Hokodate-Goryoukaku Hospital, Hakodate, JAPAN,* [4]*Takaoka Municipal Hospital, Takaoka, JAPAN,* [5]*University of Amsterdam, Amsterdam, NETHERLANDS.*

Aim/Introduction: Differentiating between heart-failure death (HFD) and lethal arrhythmic events (ArE) in patients with chronic heart failure (CHF) remains a major clinical challenge, as these outcomes require different therapeutic strategies. While we have proposed a machine learning (ML)-based model to distinguish these outcomes with 13 variables, a simpler, clinically applicable model was needed. This study aimed to develop and validate a multivariable model using clinical and imaging data, including ^{123}I-meta-iodobenzylguanidine (mIBG), to predict HFD, ArE, and survival. ***Materials and Methods:*** We retrospectively analyzed 997 patients with CHF (age 70±13 years; 51% male; mean left ventricular ejection fraction [LVEF] 32±13%) with a mean follow-up of 41±7 months. Late heart-to-mediastinum ratio (HMR) and washout rate (WR) from ^{123}I-mIBG imaging were evaluated. Clinical outcomes were classified into three categories: survival, HFD, and ArE. ArE included arrhythmic death, sudden cardiac death, and appropriate therapy by cardiac devices of implantable cardioverter defibrillator or cardiac resynchronization therapy with defibrillator. The cohort was split into 75% (n=748) for model development and 25% (n = 249) for validation. Multinomial and nested logistic regression models were applied using >2-year outcomes. Model performance was assessed by receiver-operating-characteristic analysis and area under the curve (ROC-AUC). Kaplan-Meier survival analysis was conducted over five years with non-cardiac deaths censored. ***Results:*** During follow-up, HFD and ArE occurred in 19% and 9% of patients, respectively. Eight of 15 candidate variables were selected by forward stepwise selection: age, sex,

NYHA class, LVEF, hemoglobin, estimated glomerular filtration rate, hypertension, and either mIBG HMR or WR. AUCs in the training set were 0.88 (survival), 0.76 (ArE), and 0.87 (HFD), and in the validation set 0.87, 0.80, and 0.85, respectively. The model incorporating WR outperformed those using HMR alone (cutoff: 1.9) or WR alone (cutoff:36%) for predicting ArE/HFD combined and individual outcomes. The WR-based 8-variable model significantly improved prediction of survival (p=0.0087) and ArE (p=0.014) compared to a 7-variable model without mIBG, with comparable accuracy for HFD (p=0.09). Risk groups for high risk for both ArE and HFD, high risk for HFD, high risk for ArE, and low risk for both agreed with actual outcomes. A simulation showed higher ArE incidence in patients with intermediate HMR, depending on NYHA class, consistent with previous ML-based findings. ***Conclusion:*** A practical eight-variable model incorporating ^{123}I-mIBG indices enables robust and differential prediction of survival, HFD, and ArE, providing a clinically useful tool for risk stratification in CHF. ***References:*** J Nucl Cardiol 2022;29:190-201.

Systemic Metabolic Coordination Index (SMCI): A Graph-Based Biomarker of Whole-Body Metabolic Integrity from FDG PET

X. Li[1], *Z. Shi*[2], *M. Hacker*[1], *X. Zhang*[2], *X. Li*[1], *S. Xue*[1];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Nuclear Medicine, Molecular Imaging Lab, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

Aim/Introduction: Human metabolic homeostasis is maintained through complex neural, vascular, and fluidic regulatory mechanisms operating at the whole-body level. The interplay among organs forms a physiological network that can be disrupted by metabolic disorders such as diabetes and obesity. Traditional diagnostics often rely on single-organ or localized biomarkers; however, evaluating systemic metabolic health requires an integrative metric—a global biomarker. In this study, we introduce a novel graph theory-based framework to derive such a biomarker, termed Eglob, from whole-body [^{18}F]FDG PET imaging in a large cohort of healthy individuals. We further validate its clinical utility in patients with heart failure with reduced ejection fraction (HFrEF), a condition lacking focal PET abnormalities yet marked by severe systemic metabolic dysregulation. ***Materials and Methods:*** We constructed a reference inter-organ metabolic network from FDG PET scans of 747 healthy individuals, encompassing nine major organs involved in metabolic and immune regulation. Network robustness was assessed using permutational multivariate analysis of variance (PERMANOVA) across 20 bootstrap-derived networks. For validation, individualized metabolic networks were generated for each subject, and deviations from the reference were quantified using global efficiency (Eglob) from graph theory. This deviation was defined as the Systemic Metabolic Coordination Index (SMCI), representing subject-level systemic metabolic integrity. Validation in 156 HFrEF patients included correlation analyses with 82 clinical parameters and survival analysis based on all-cause mortality, benchmarked against an L2-norm-based deviation score. ***Results:*** PERMANOVA confirmed the robustness of the healthy reference network ($p = 1$). In the HFrEF cohort, SMCI was significantly associated with impaired cardiac function assessed by echocardiography—including wall thickness, standard deviation, and entropy (all $p < 0.05$)—as well as elevated aspartate aminotransferase (AST; $p < 0.05$). In contrast, the L2-norm deviation showed no significant associations ($p > 0.05$). Survival analysis demonstrated the prognostic value of SMCI ($p = 0.021$; HR = 0.13; C-index = 0.69), while L2-norm deviation was not significant ($p = 0.29$; HR = 0.47; C-index = 0.61). ***Conclusion:*** We present the SMCI as a novel graph-based biomarker derived from healthy whole-body FDG PET networks, with the potential to quantify systemic metabolic integrity at the individual level. SMCI was associated with multi-organ dysfunction and showed prognostic value in patients with HFrEF. This framework may enable a new paradigm for integrating molecular imaging and network analysis to support personalized assessment, risk stratification, and potentially screening for systemic metabolic disorders using PET imaging.

Mapping Immune-Metabolic Dysregulation in HFrEF Using Whole-Body PET and Inter-Organ Network Analysis

X. Li[1], *Z. Shi*[2], *M. Hacker*[1], *X. Zhang*[2], *S. Xue*[1], *X. Li*[1];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Nuclear Medicine, Molecular Imaging Lab, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.*

Aim/Introduction: Heart failure (HF) is a complex clinical syndrome resulting from cardiac dysfunction, yet its systemic manifestations extend beyond the myocardium. Emerging evidence highlights the pivotal role of the brain-heart axis, particularly the autonomic nervous system, in regulating cardiovascular function. In heart failure, dysregulated interactions along this axis influence metabolic and immune systems, contributing to disease progression. Building on this concept, we investigated the systemic immune-metabolic interactome in patients with heart failure with reduced ejection fraction (HFrEF) and explored its association with major adverse cardiovascular events (MACEs). ***Materials and Methods:*** A prospective cohort of 154 patients with HFrEF and 56 healthy controls underwent whole-body [^{18}F] FDG-PET imaging. Glucose uptake across key immune and metabolic organs was quantified and compared between groups. Inter-organ metabolic networks were constructed, and a novel Immune-Metabolic Network Deviation Score (IMNDS) was developed to quantify individual deviations from the normative network established in healthy controls. We assessed correlations between IMNDS and clinical biomarkers reflecting metabolic, vascular, hepatic, inflammatory, and cognitive functions, and evaluated its prognostic value for MACEs and all-cause mortality. ***Results:*** HFrEF patients exhibited significantly elevated [^{18}F] FDG uptake (SUVmean) in the spleen, bone marrow, heart, liver, pancreas, and adipose tissue compared to controls (all $P < 0.05$), indicating heightened immune-metabolic activity. While healthy individuals showed strong inter-organ correlations within immune and metabolic networks, these connections were markedly attenuated in the HFrEF cohort ($P < 0.05$), suggesting systemic dyssynchrony. IMNDS captured this network disruption and showed significant associations with remnant-like particle cholesterol ($P = 0.025$), non-HDL cholesterol ($P = 0.045$), creatinine ($P = 0.049$), FDG-derived end-diastolic volume ($P = 0.035$), hematocrit ($P = 0.048$), ALT ($P = 0.038$), prealbumin ($P = 0.026$), and Montreal Cognitive Assessment scores ($P = 0.034$). In survival analyses, IMNDS demonstrated prognostic trends comparable to B-type natriuretic peptide (BNP) for MACEs and all-cause mortality. ***Conclusion:*** This study identifies a systemic immune-metabolic dyssynchrony in HFrEF, revealing a novel axis of dysfunction that transcends cardiac pathology. The Immune-Metabolic Network Deviation Score (IMNDS) represents a promising biomarker of multi-organ network disruption with clinical relevance to metabolic burden, organ function, and neurocognitive health. To further validate these findings, future studies should incorporate peripheral immune profiling via flow cytometry or CyTOF, cytokine and metabolic biomarker quantification, and tissue-level analysis using immunohistochemistry. These integrative approaches may clarify the underlying biology of immune-metabolic disarray in HF and support biomarker-driven strategies for personalized care.

OP-732

Characteristics of myocardial imaging at ^{18}F-FAPI-74 PET/CT and potential value in predicting left ventricular reverse remodeling in non-ischemic dilated cardiomyopathy

w. liu[1,2,3], *L. Li*[1,2,3], *Q. Wu*[1,3], *J. Song*[4], *S. Li*[1,2,3];
[1]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Shanxi Medical University, Taiyuan, Shanxi, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, Shanxi, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan, Shanxi, CHINA,* [4]*Academy of Medical Sciences, Shanxi Medical University, Taiyuan, Shanxi, CHINA.*

Aim/Introduction: Cardiac fibrosis occurs early in the progression of non-ischemic dilated cardiomyopathy (NIDCM). Recently, research on fibroblast activation protein inhibitor (FAPI) PET imaging in cardiovascular diseases has increased and is highly sought. However, no cohort studies have been carried out, and only case reports have documented the heterogeneous myocardial uptake of FAPI in patients with NIDCM. The aim of this study was to explore the myocardial imaging characteristics at FAPI PET/CT and its predictive value for left ventricular reverse remodeling (LVRR) in NIDCM. ***Materials and Methods:*** Forty-eight individuals with NIDCM in the study underwent ^{18}F-FAPI-74 PET/CT. Echocardiography was performed at baseline and at average 12 months. Myocardial FAPI activity was quantified as as intensity(maximum standardized uptake value [SUVmax], mean standardized uptake value [SUVmean],target-to-background ratio[TBR]), and volume (left ventricular molecular volume[LVMV]). Cardiac functional parameters were quantified as left ventricular ejection fraction (LVEF) and left ventricular end-diastolic dimension (LVEDD). The correlation was calculated using Pearson or Spearman. Univariable logistic regression analyses were used to assess the predictive value of LVMV for left ventricular reverse remodeling in NIDCM. LVRR was defined as an absolute increase in LVEF from ≥10% to a final value of >35% accompanied by a decrease in LVEDD ≥10% at 12 months of follow-up. ***Results:*** Thirteen patients with NIDCM exhibited no visible myocardial uptake (PET-negative), whereas 73% (35 of 48) had enhanced LV uptake (PET-patchy [n=14] vs. PET-extensive [n=21].Compared to the PET-negative and PET-patchy pattern groups, patients with NIDCM in the PET-extensive group exhibited higher LVEDD(62.6±4.8 vs.70.7±7.6,63.3±8.4 vs.70.7±7.6,P<0.01) and lower LVEF (36.7±11.1 vs. 27.6±6.4, 35.5±9.9 vs. 27.6±6.4,P<0.05). The LV SUVmax and SUVmean were correlated with N-terminal pro-brain natriuretic peptide (NT-proBNP)(r = 0.422,P=0.007;r = 0.476,P=0.002), while LVMV was inversely related to LVEF (r = -0.623,P<0.001).Additionally, the LVRR group demonstrated lower LVMV at baseline than the non-LVRR group (48.9±31.8 vs. 11.1 (0, 32.2), p =0.011). The LVMV at baseline was a significant predictor (OR = 0.958, p = 0.024) for LVRR in NIDCM. ***Conclusion:*** ^{18}F-FAPI-74 PET/CT imaging indicated heterogeneous activity in NIDCM. Baseline myocardial FAPI uptake volume may have potential predictive value for LVRR.

OP-733

Evaluation of Myocardial Fibrosis and Wall Motion Abnormality with ^{68}Ga-FAPI PET/MR in Coronary Heart Disease

R. Luo[1], *Z. Zhao*[1], *C. Zhang*[1], *R. Li*[1], *Q. Meng*[1], *Y. Ni*[1], *R. Yang*[1], *X. Chen*[1], *L. Xie*[2], *M. Zhang*[2], *F. Wang*[1];
[1]*Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA,* [2]*3.Department of Advanced Nuclear Medicine Sciences, Institute for Quantum Medical Science, National Institutes for Quantum Science and Technology, Chiba, JAPAN.*

Aim/Introduction: Quantification of myocardial fibrosis and wall motion assessment are crucial for prognostic evaluation in coronary heart disease (CHD). To explore the characteristics of cardiac fibroblast activation protein inhibitor (FAPI) PET/MR in CHD and its association with abnormal wall motion. ***Materials and Methods:*** In this prospective study from May 2023 to December 2023, participants with CHD underwent cardiac gallium 68 (^{68}Ga)-labeled FAPI PET/MR imaging. FAP signal (FAPI active) was quantified using regional standardized uptake values (SUVs). Cardiac MRI yielded functional parameters and area of injury (late gadolinium enhancement [LGE]) (MRI non-viable). Abnormal wall motion identified by myocardial strain analysis was evaluated using integrated analysis of LGE and FAP signal. The correlations between FAP signal and clinical parameters were explored and fibrosis was confirmed by histopathological analysis of partially resected myocardium. ***Results:*** Forty-two participants (mean age, 59 years ± 13 [SD]; 32 men) were included. The FAP signal was higher in left ventricle regional myocardium compared with remote normal areas (SUVmax, 5.0 ± 1.8 vs 1.2 ± 0.4; p < .001). In total, 432 segments (432/714, 60.50%) displayed impaired wall motion. In integrated analysis, the highest wall motion abnormality score was observed in the FAPI active/MRI non-viable group (11.0 ± 5.2). FAP signal was positively correlated with K time (SUVpeak: R = 0.48; p = .046; SUVmean: R = 0.57; p = .014) and negatively correlated with Angle (SUVpeak: R = −0.52; p = .026; SUVmean: R = −0.56; p = .026) in thromboelastography. Immunohistochemical analysis revealed FAP-positive fibroblasts in the infarct and border zone, and robust expression of α-smooth muscle actin and vimentin. ***Conclusion:*** Simultaneous ^{68}Ga-fibroblast activation protein inhibitor PET/MR offers novel insights into the regional pattern of fibroblast activation in patients with coronary heart disease, and the fibroblast activation protein signal is associated with abnormal wall motion.

OP-734

[^{68}Ga]FAPI: A New Game-Changer in Cardiac Inflammation? Early Findings from a Prospective Study of [^{68}Ga]FAPI PET/CT Diagnostic Performance Compared to [^{18}F]FDG PET/CT in Suspected Cardiac Sarcoidosis

A. Safarian[1,2], *H. Malek*[1], *M. Beheshti*[2], *S. Almasi*[3], *M. Chehrara*[1], *N. Yaghoobi*[1];
[1]*Department of Nuclear Medicine, Rajaie Cardiovascular Medical and Research Center, Rajaie Cardiovascular Institute, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Division of Molecular Imaging and Theranostics, Department of Nuclear Medicine, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA,* [3]*Department of Rheumatology, Firoozgar Hospital, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Cardiac sarcoidosis (CS) is a potentially life-threatening inflammatory disease with a wide clinical spectrum from early inflammation to irreversible fibrosis. Accurate diagnosis and early intervention are crucial to prevent permanent myocardial damage. While [^{18}F]FDG-PET/CT remains the standard for detecting active inflammation, it is limited by complex patient preparation, variable physiologic myocardial uptake, and frequent equivocal findings. [^{68}Ga]FAPI is an emerging tracer, targeting fibroblast-activation-protein. We aimed to evaluate the diagnostic performance of [^{68}Ga]FAPI-PET/CT compared to [^{18}F]FDG-PET/CT in patients with suspected CS. ***Materials and Methods:*** In this ongoing prospective pilot study, ten patients with clinical suspicion of CS and no prior anti-inflammatory treatment underwent [^{18}F]FDG-PET/CT, [^{68}Ga]FAPI-PET/CT, and resting myocardial perfusion gated-SPECT (^{99m}Tc-Sestamibi) within one week. Due to timing variability, cardiac MRI (CMR) was considered as supportive tool for final diagnostic decision-making but was excluded from the head-to-head image analyses. A consensus of clinical and imaging findings was used as the standard of truth. ***Results:*** [^{68}Ga]FAPI-PET/CT demonstrated consistent and more conclusive uptake patterns compatible with different disease phases. No uptake was observed in healthy myocardium or in fully-scarred segments (confirmed by absent perfusion), mirroring [^{18}F]FDG findings. In early phases, where perfusion is still preserved, [^{68}Ga]FAPI uptake matched [^{18}F]FDG, indicating its sensitivity in early inflammatory stages. Importantly, [^{68}Ga]FAPI-requiring no patient preparation- correctly excluded false-positive [^{18}F]FDG uptake in cases of inadequate myocardial suppression, offering

superior workflow and interpretive clarity. Most notably, a distinct pattern was observed in three patients with high clinical suspicion of CS: segments with no or very faint [^{18}F]FDG uptake, moderate hypoperfusion, yet significant [^{68}Ga]FAPI uptake. These regions with increased uptake and reduced perfusion, did not represent established scar, as perfusion was still present, and co-localized with prior CMR-reported sites of inflammation. These findings may represent a previously unrecognized window of disease activity, a "transitional fibro-inflammatory phase", where acute inflammation may have subsided, but active remodeling persists. This phase may indicate a critical therapeutic window, where continued immunosuppressive or anti-fibrotic therapy could potentially halt progression to irreversible damage, preventing further complications. ***Conclusion:*** In this preliminary cohort, [^{68}Ga]FAPI-PET/CT demonstrated strong diagnostic value across all phases of CS. It identified a critical, potentially treatable stage of disease inconclusive by [^{18}F]FDG, challenging current treatment paradigms in [18F]FDG-negative cases. With no physiologic myocardial uptake, low blood-pool activity, and no patient preparation, [^{68}Ga]FAPI-PET/CT shows promise as a potential transformative tool in CS management, particularly for complex cases with underlying diseases and inconclusive [^{18}F]FDG patterns.

OP-735

Downregulation of myocardial expression of glucagon-like peptide-1 receptor with aging and obesity showing on^{68}Ga-exendin-4 PET/CT

H. Zhang[1], *Q. Pan*[2], *S. Liu*[1], *J. Feng*[1], *Y. Luo*[1];
[1]Department of Nuclear Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College Hospital; State Key Laboratory of Common Mechanism Research for Major Diseases, Beijing, CHINA, [2]Department of Nuclear Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: The glucagon-like peptide-1 receptor (GLP-1R) plays a growing role in cardiovascular physiology, yet its in vivo myocardial expression needs clarification. The aim of this study was to noninvasively visualize and quantify myocardial GLP-1R expression using ^{68}Ga-exendin-4 PET/CT, with a view to assessing age and weight-dependent variations and their potential clinical implications in cardiovascular diseases. ***Materials and Methods:*** This is a retrospective analysis of a prospective study (NCT 02560376) on ^{68}Ga-exendin-4 PET/CT in diagnosing insulinoma and congenital hyperinsulinemic hypoglycemia. Patients who underwent ^{68}Ga-exendin-4 PET/CT with good image quality of the myocardium were enrolled. Patients' gender, age, and body mass indices (BMI) were recorded. ^{68}Ga-exendin-4 uptake of the left/right ventricular (LV/RV) myocardium, together with the blood pool (descending aorta) was measured manually. Accordingly, the calculation of the target-to-background ratios (TBRs, blood pool as background reference) of bilateral ventricles was conducted. Then, simple linear regression analyses were performed. Age and BMI were separately tested as independent variables against TBR as the dependent variable. The goodness-of-fit was evaluated using r values, and statistical significance was defined as $P < 0.05$ (two-tailed). ***Results:*** A total of 124 patients (including 63 males and 61 females) were included with a median age of 39.5 years (range, 0.1~77.0). Analyses based on all patients showed that TBRmax, defined as SUVmax of the LV or RV divided by SUVmax of the blood pool, were linearly and inversely correlated with the logarithm of age (LV TBRmax, $r = 0.72$, $P < 0.001$; RV TBRmax, $r = 0.68$, $P < 0.001$). TBRmean, defined as SUVmax of the LV or RV divided by SUVmean of the blood pool, were also demonstrated linearly and inversely correlated with the logarithm of age (LV TBRmean, $r = 0.46$, $P < 0.001$; RV TBRmean, $r = 0.29$, $P = 0.001$). The relationship between these semiquantitative parameters and BMI was also investigated in adult patients, and these parameters demonstrated a statistically significant negative linear correlation with BMI (LV TBRmax, $r = 0.41$, $P < 0.001$; RV TBRmax, $r = 0.44$, $P < 0.001$; LV TBRmean, $r = 0.30$, $P = 0.001$; RV TBRmean, $r = 0.28$, $P = 0.002$). ***Conclusion:*** ^{68}Ga-exendin-4 PET/CT enables noninvasive assessment of myocardial GLP-1R expression, demonstrating significant inverse correlations with age and BMI, suggesting progressive downregulation of GLP-1R expression in myocardium with aging and obesity. These findings provide new insights for studying cardiovascular effects of GLP-1R agonists.

Prognostic Value of Al^{18}F-NOTA-Pentixafor PET/CT for Surgical Outcomes in Primary Aldosteronism: A Prospective Study

X. Yan[1], *G. Zheng*[2], *M. Liu*[1], *Y. Zhang*[1], *Y. Xie*[1], *L. Huo*[1];
[1]Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA, [2]Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA.

Aim/Introduction: The heterogeneous surgical outcomes of primary aldosteronism (PA) necessitate reliable presurgical evaluation methods. Al^{18}F-NOTA-Pentixafor PET/CT targeting CXCR4 shows promise for functional adrenal characterization. This study evaluated its prognostic value for predicting postoperative outcomes in surgical PA patients. ***Materials and Methods:*** In this prospective trial, 108 consecutive PA patients underwent preoperative Al^{18}F-NOTA-Pentixafor PET/CT followed by adrenalectomy. Semiquantitative analysis included, lesion SUVmax, lateralization index (LI), lesion-to-liver ratio (LLR) and lesion-to-normal adrenal ratio (LAR). Outcomes were assessed at 6 months postoperatively using comprehensive PASO criteria: (1) Cure: normalized blood pressure (off medications), serum potassium, and ARR; (2) Improvement: 1-2 criteria met; (3) No benefit: no criteria met. Parameters were compared among cure, improvement and no-benefit groups. ROC analysis determined optimal cutoff values for outcome prediction. ***Results:*** A total of 108 PA patients with adrenal nodule underwent adrenalectomy guided by Al^{18}F-NOTA-Pentixafor. At 6-month follow-up, 66.7% patients (66.7%) achieved cure (complete biochemical and clinical remission), 34 (31.5%) showed improvement (partial remission), and 2 (1.8%) had no benefit. SUVmax were significantly higher (13.09±6.70 vs 6.68±2.27, $p<0.001$) and LLR values (11.62±6.00 vs 2.03±0.95, $p<0.001$) in cured patient compared to patients with only improvement, while showing an inverse pattern for LAR (5.05±2.48 vs 7.21±2.20, $p=0.003$), with relatively modest mean difference of 2.16. The group with no benefit (n=2) exhibited the lowest values across all parameters (SUVmax vs Cure: $p=0.018$; LLR vs Cure: $p=0.043$). Quantitative analysis demonstrated robust diagnostic performance across all parameters: LLR showed cutoff of 6.04 with AUC 0.87 (95%CI 0.712-0.896) and positive predict value (PPV) of 90.6%; SUVmax achieved cutoff 11.0 with AUC 0.822 (95%CI 0.738-0.906) and PPV of 93.2%; LI achieved cutoff 3.16 with AUC 0.790 (95%CI 0.687-0.894) and PPV of 97.4%; while LAR demonstrated cutoff 2.4 with AUC 0.861 (95%CI 0.791-0.931) and PPV of 100%. ***Conclusion:*** Al^{18}F-NOTA-Pentixafor PET/CT effectively predicts PA surgical outcomes, with LAR and SUVmax showing strongest correlation with cure.

EPS-243

The value of ^{68}Ga-Pentixafor PET/MR-based Radiomics in Differentiating Functional Adrenocortical Adenomas

X. Chen[1], *R. Zhang*[1], *J. Song*[1], *C. Liu*[1], *Q. Ji*[2], *Y. Hu*[3], *J. Zhao*[1], *Y. Xing*[1];
[1]*Department of Nuclear Medicine, Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*United Imaging Healthcare Advanced Technology Research Institute Co., Ltd., Shanghai, CHINA,* [3]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: This study aims to investigate the potential of radiomics features derived from integrated ^{68}Ga-Pentixafor PET and multiparametric MRI for constructing a robust classification model to discriminate functional adenomas (FA) from non-functional adenomas (NFA), thereby providing a novel non-invasive diagnostic approach. ***Materials and Methods:*** A retrospective analysis was conducted on patients who underwent integrated ^{68}Ga-Pentixafor PET/MR examinations at our center (MRI sequences included T1-weighted in-phase/opposed-phase, T2-weighted and diffusion-weighted imaging with ADC mapping). Only cases with definitely diagnosed functional or non-functional adrenocortical adenomas were finally included in the study. Lesions were manually delineated using ITK-SNAP, followed by extraction of 107 radiomics features for individual lesion segmentations via PyRadiomics. Modality-specific LASSO feature selection was performed, yielding distinct predictive features for each imaging dataset. The Radscore was calculated for each lesion by a linear combination of the selected radiomic features with their respective coefficients. Mann-Whitney U test was used to compare Radscores between groups. The diagnostic performance of Radscore was evaluated by receiver operating characteristic (ROC) curve analysis, calibration curve, and decision curve analysis (DCA). ***Results:*** A total of 32 adrenal adenoma lesions were included in this study, comprising 23 FA (18 aldosterone-producing and 5 cortisol/mixed-secreting) and 9 NFA. ^{68}Ga-Pentixafor PET-based radiomics features were reduced to 6 potential predictors for PET-Radscore construction. However, MRI-based features failed to establish valid predictive Radscores across all sequences. FA demonstrated significantly higher PET-Radscore values compared to NFA (FA: 0.67 ± 1.01 vs NFA: -1.70 ± 0.52, $p < 0.001$). ROC analysis revealed that PET-Radscore for distinguishing FA from NFA achieved an AUC of 0.966 (95% CI: 0.911-1.000). At cut-off value of -0.56, it showed an accuracy of 90.6%, sensitivity of 87.0%, and specificity of 100%. Calibration curves indicated good consistency between predicted probabilities and actual risks (Brier score = 0.064, Hosmer-Lemeshow test $p = 0.985$). DCA demonstrated that when the threshold probability exceeded 10%, the model achieved significantly higher net benefit than "treat-all" or "treat-none" strategies, suggesting good clinical applicability. ***Conclusion:*** The ^{68}Ga-Pentixafor PET-based Radscore shows good ability in distinguishing functional from non-functional adenomas, offering a reliable tool for non-invasive assessment of adrenal adenoma functional status.

EPS-245

The Role of [^{11}C]metomidate PET in Predicting Post-treatment Outcomes in Patients with Primary Aldosteronism: A Meta-Analysis

P. Chuang[1], *J. S. Chueh*[2], *J. Huang*[2], *T. Hong*[1], *V. Wu*[2], *Y. Lin*[2], *P. Kuo*[3], *C. Lu*[1];
[1]*National Taiwan University Cancer Center, Taipei, TAIWAN,* [2]*National Taiwan University Hospital, Taipei, TAIWAN,* [3]*National Taiwan University, Taipei, TAIWAN.*

Aim/Introduction: Accurate determination of unilateral versus bilateral disease is essential in guiding treatment decisions for primary aldosteronism, as surgical resection is appropriate only for unilateral cases. Positron emission tomography (PET) using [^{11}C] metomidate (MTO), a selective inhibitor of 11β-hydroxylase, has emerged as a potential non-invasive alternative to adrenal venous sampling (AVS). ***Materials and Methods:*** A comprehensive literature search was conducted across PubMed, Embase, and the Cochrane Library to identify studies evaluating [^{11}C]MTO PET in patients with primary aldosteronism. Studies were included if they reported diagnostic accuracy in correlation with post-treatment outcomes assessed by the Primary Aldosteronism Surgical Outcome (PASO) criteria. Data on true positives, false positives, false negatives, and true negatives were extracted. Pooled estimates of sensitivity and specificity were calculated using a random-effects bivariate model. ***Results:*** Six studies comprising a total of 287 patients met the inclusion criteria. The pooled sensitivity and specificity of [^{11}C]MTO PET for predicting complete or partial biochemical response post-treatment were 0.75 (95% CI: 0.35-0.95) and 0.58 (95% CI: 0.02-0.99), respectively. In comparison, AVS demonstrated a pooled sensitivity of 0.78 (95% CI: 0.63-0.88) and specificity of 0.52 (95% CI: 0.15-0.88). The differences between [^{11}C] MTO PET and AVS were not statistically significant in both sensitivity ($p=0.741$) and specificity ($p=0.865$). The partial area under the curve (AUC) was 0.737 for [^{11}C]MTO PET and 0.772 for AVS. Diagnostic performance for clinical outcome prediction showed comparable trends. ***Conclusion:*** [^{11}C]MTO PET exhibits diagnostic accuracy comparable to that of AVS in predicting treatment response in primary aldosteronism. These findings support its role as a viable, non-invasive alternative for treatment planning, particularly when AVS is contraindicated, technically challenging, or yields inconclusive results. ***References:*** 1. Efficacy, Tolerability, and Resensitizing Effects of Dabrafenib-Trametinib in Advanced Thyroid Cancer: A Retrospective Monocentric Real-World Study

C. Fersing[1], *E. Noudeau*[1], *J. Toucheboeuf*[2], *M. Vinches*[3], *F. Leenhardt*[4];
[1]*Montpellier Cancer Institute, Nuclear Medicine unit, Montpellier, FRANCE,* [2]*Montpellier Cancer Research Institute (IRCM), INSERM U1194, Montpellier, FRANCE,* [3]*Montpellier Cancer Institute, Medical Oncology department, Montpellier, FRANCE,* [4]*Montpellier Cancer Institute, Pharmacy unit, Montpellier, FRANCE.*

Aim/Introduction: Off-label use of the dabrafenib-trametinib combination (DT) in BRAF-mutated thyroid cancer has demonstrated intrinsic efficacy and the ability to resensitize some patients to iodine-131 (I-131) in cases of refractory lesions. However, real-world data on DT use in thyroid cancer remain scarce in the literature [1-4]. In this context, we conducted a comprehensive evaluation on this clinical use of DT in our institution. ***Materials and Methods:*** This single-center retrospective study included all patients with BRAF-mutated thyroid cancer, of any histological subtype, who were treated with DT between January 29, 2019, and March 26, 2025. Data extracted from medical records covered patient and tumor characteristics, treatment duration, reasons for temporary/permanent discontinuation, toxicities, drug-drug interactions (DDI), DT plasma concentration, tumor and biological response, and I-131 resensitization in refractory lesions. ***Results:*** Nineteen patients were included (9 males, 10 females),

predominantly with follicular-derived carcinoma (16/19, 89%); all harbored BRAF mutations. I-131 refractoriness was identified in 16 patients (84%). The mean age at the start of DT treatment was 69 ± 10 years. Mean DT treatment duration was 611 ± 636 days (median = 435 days; min. = 18 days; max. = 1254 days). Adverse events occurred in 95% of patients (18/19) and accounted for 52% of treatment interruptions. Most of the DDI encountered were caused by the enzyme-inducing properties of dabrafenib. Tumor response (lesions stability or reduction on imaging) was observed in 79% of cases (15/19). Among 8 patients (42%) with anti-thyroglobulin antibodies <115 IU/mL, 6 (75%) showed decreased thyroglobulin levels. Eight patients (42%) underwent post-DT I-131 therapy, with partial or complete I-131 uptake restoration in 62.5% (5/8). However, only 40% (2/5) of these achieved subsequent tumor regression. Plasma concentrations of DT were determined at highly variable timepoints, suggesting the need for standardized sampling protocols. ***Conclusion:*** DT is used across histological subtypes of thyroid cancer to reduce tumor burden and/or restore I-131 avidity. Biological and tumor efficacy was observed in nearly 80% of patients, with some cases demonstrating improved I-131 uptake. However, resensitization does not consistently translate into tumor regression. ***References:*** [1] P. C. Iyer, et al. Thyroid 2018, 28, 79-87. [2] A. Iravani, et al. Thyroid 2019, 29, 1634-1645. Indeterminate Thyroid Nodules: Can [18F]F-FDG PET/CT and Radiomic Influence Patients' Treatment Strategies?

G. Cuzzani[1], *E. Fortunati*[2], *M. Santoro*[3], *E. Greco*[1], *E. Tabacchi*[2], *L. Calderoni*[2], *L. Zanoni*[4], *C. Malizia*[2], *F. Serani*[5], *C. M. P. Sgro*[1], *G. Bianciardi*[1], *G. A. Fuso*[1], *L. Carrara*[1], *S. Damiani*[6], *L. Strigari*[3], *S. Fanti*[1,2];

[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Nuclear Medicine, AST Pesaro-Urbino, ITALY,* [5]*Nuclear Medicine Unit, Department of Medicine, DIMED, University-Hospital of Padova, ITALY,* [6]*Pathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: To evaluate diagnostic performance of [18F]F-FDG PET/CT(FDG) in identifying malignancy in thyroid nodules with indeterminate fine-needle aspiration cytology(FNA) addressed to thyroidectomy or hemithyroidectomy.Secondary aim is to investigate radiomic features(RF) SFDG PET to define a predictive model of malignancy of indeterminate thyroid nodules. ***Materials and Methods:*** A monocentric,observational,retro-prospective study is ongoing, including patients who underwent neck ultrasound for suspicious nodules (February 2022-ongoing) at our Institution, followed by FNA which resulted in indeterminate thyroid nodules at cytology(Bethesda System for Reporting Thyroid Cytopathology categories III and IV, corresponding to Thy3 for the British Royal College of Pathologists and to TIR3A-low risk and TIR3B-high risk for the Italian Consensus for the Classification and Reporting of Thyroid Cytology); those patients performed FDG within 4months, before being referred to thyroid surgery.Histopathology was considered standard-of-truth. Case-control patients without any thyroid pathology were also included for radiomic studies.A nuclear physician manually delineated the volumes of interest of suspected lesions and contralateral healthy thyroid lobes. 1316 PET-based harmonized RFs were extracted,and 3 machine learning models were developed for malignancy prediction and compared in terms of sensitivity, specificity and area under the receiver operating curve(AUC).PET-semiquantitative-parameters were measured: SUVmax,SUVmean,target-to-background-ratios (backgrounds: contralateral thyroid,mediastinal-blood-pool(MBP),liver).Visual-positivity-criteria was defined as uptake higher than MBP, excluding physiological/paraphysiological uptake. ***Results:*** Overall, 23patients were enrolled (February2022-February2024), but 4/23 eventually did not perform FDG and were excluded. 14/23 patients(61%) underwent surgery, for a total of 19 indeterminate thyroid nodules with histopathologic validation. 32patients without any thyroid pathology were also considered as case-control. 17/19 nodules(89%) were positive at FDG with a median SUVmax of 7.5 (mean9.6+/-7.8;range:2.4-35.2). ThyroidTBR: mean6.7;range 2.1-23.4. MBP-TBR:mean5; range 1.6-17.2. LiverTBR: mean4.1;range 1.3-14.7. Visual analysis per-nodule(n=19): 5TruePositives-26%(1medullary,2follicular,2papillary),12FalsePositives-63%(2 NIFTPs,5adenomas,5hyperplastic nodules), 2TrueNegatives-11%(1NIFTP,1colloid nodule); sensitivity 100%, specificity 14%, PPV 29%, NPV 100%, accuracy 37%. No statistically significant differences were found in terms of SUVmax/TBRs between benign/malignant nodules.The ML models were balanced during the model training.The developed models had from 2 to 4 significant RFs and showed good performances on test database with predicted area under the curve (AUC), sensitivity and specificity(range:0.79-0.92,0.67-1.00, 0.84-0.92, respectively). ***Conclusion:*** In our limited experience, utility of FDG in detecting presence of malignancy in indeterminate thyroid nodules is ambiguous and FDG uptake or semiquantitative parameters alone cannot be considered a decisive feature for referring patients to surgery; further studies are needed to detect a more accurate discrimination criterion to minimize unnecessary resections. In this framework, ML models have shown promising results and could support clinical decision-making processes.

EPS-248

Exploration of Lu-177-DOTATATE PRRT for treatment of radioiodine-refractory follicular thyroid carcinoma

L. Widjaja[1], *S. C. Kunte*[1], *V. U. Wenter*[1], *A. Holzgreve*[1], *G. T. Sheikh*[1], *F. J. Gildehaus*[1], *S. Lindner*[1], *R. Schirrmacher*[2], *C. Spitzweg*[3], *C. J. Auernhammer*[3], *R. A. Werner*[1], *M. J. Zacherl*[1];

[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*Department of Oncology, Division of Oncological Imaging, University of Alberta, Edmonton, AB, CANADA,* [3]*Department of Internal Medicine IV, LMU University Hospital, Munich, GERMANY.*

Aim/Introduction: Treatment options for advanced radioiodine-refractory follicular thyroid carcinoma (FTC) are limited. Interestingly, a subset of FTCs express somatostatin receptors (SSTR). Thus, we hereby explore the clinical value of SSTR-targeted peptide receptor radionuclide therapy with Lu-177-DOTA-D-Phe-Tyr3-octreotate (Lu-177-DOTATATE) and subsequent monitoring with SSTR-targeted positron-emission tomography (PET) in patients with advanced radioiodine-refractory FTC. ***Materials and Methods:*** We retrospectively included seven patients with advanced radioiodine-refractory FTC and SSTR-expression in SSTR-PET in our analysis. Patients were treated with PRRT either continuously (5/7) or discontinuously (2/7; with at least one-PRRT-free-year). Tumor control was defined using PET-derived total tumor volume (TTV), thyroglobulin (Tg; including patients with stable [± 30.0%] or decreasing [≥30.0 %] TTV and Tg), and RECIST 1.1 criteria. Safety was assessed using Common Terminology Criteria for Adverse Events. ***Results:*** FTC tumor lesions demonstrated high SSTR expression with maximum standardized uptake values of 10.4 ± 8.6. Of the five patients treated with continuous PRRT, n=2 received two cycles, n=1 three cycles and n=2 four cycles of PRRT. Tumor control was achieved in 3/5 assessed by PET-derived TTV and RECIST 1.1 and 2/5 assessed by Tg. In the two patients with discontinuous PRRT receiving either four or ten treatment cycles concordant (TTV, Tg and RECIST 1.1) tumor control was achieved both during first follow-up as well as during reinitiating after PRRT-free interval. PRRT in FTC patients was safe with no CTCAE

grade 3-5 events occurring in our cohort. ***Conclusion:*** We hereby demonstrate that PRRT may be an effective and safe treatment option for patients with advanced radioiodine-refractory FTC. These preliminary results can lay the foundation for future studies with larger cohorts to define the clinical value of SSTR-targeted PRRT in FTC.

EPS-249

Multicenter study of Spanish metabolic therapy units. Usefulness of protective therapy during hospital admission in preventing late side effects of 131I in thyroid carcinoma patients

J. Villa-Palacios[1], *M. Negre*[2], *A. Piñeiro-Donis*[1], *L. Cagua Ruiz*[1], *E. Domínguez-Polanco*[1], *L. Menendez-Muros*[3], *T. Aroui-Luquin*[1], *M. Muros de Fuentes*[1];
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [2]*Hospital Universitario de Gerona Doctor Josep Trueta, Girona, SPAIN,* [3]*Hospital Universitario Clínico San Cecilio, Granada, SPAIN.*

Aim/Introduction: To evaluate late side effects after treatment with 131I in relation to protective therapy during hospital admission. ***Materials and Methods:*** A multicenter study of 181 patients with differentiated thyroid cancer treated with 131-I between 2020 and 2023. The study included 70.2% women, 87.8% papillary variant, 29.8% with lymphatic dissemination, 18% with extrathyroidal extension, and 3.8% with distant metastases. 80.66% received doses ≥100 mCi, and 65.74% received rhTSH. The most commonly used protective therapies during hospital admission were proton pump inhibitors (PPIs), Non-steroidal anti-inflammatory drugs (NSAIDs), and corticosteroids. A telephone survey was conducted one and six months after patients discharge. Patients were questioned about asthenia, cervical redness, gastric discomfort, mouth ulcers, conjunctivitis, cervical pain, dry mouth, metallic taste, and menstrual disorders. Responses were classified into nonexistent, mild, moderate, and severe. The Chi-Square test or Fisher's exact test was used for analysis. ***Results:*** The incidence of gastric discomfort was lower in patients treated with PPIs at both one and six months (21.19% and 11.92%) than in untreated patients (25% and 35.71%).The difference was statistically significant at six months (p<0.001).The incidence of stomatitis, conjunctivitis, and neck pain was lower in patients treated with NSAIDs at one month of treatment, and was statistically significant (p=0.01, 0.047, 0.02). At 6 months, the incidence of fatigue, gastric discomfort, stomatitis, neck pain, and metallic taste was lower in those treated with NSAIDs, and this difference was statistically significant (p=0.0001, 0.003, 0.010, 0.001, 0.0025).The incidence of side effects was lower in patients treated with corticosteroids at one and six months of treatment. At 6 months, the incidence of gastric discomfort, neck pain, dry mouth, and metallic taste was lower in those treated with corticosteroids, and this difference was statistically significant (p=0.01, 0.032, 0.046, 0.019). ***Conclusion:*** The use of protective treatment with PPIs, NSAIDs, and corticosteroids during 131I therapy reduces the incidence of side effects one month and six months after therapy.

EPS-250

Analysis of Clinical and Imaging Factors Predicting Treatment Outcomes of Radioiodine Therapy for Pulmonary Metastasis in Thyroid Carcinoma

L. Hashimoto[1,2], *S. Watanabe*[1,3], *K. Hirata*[1,3], *J. Takenaka*[1,3,4], *R. Kimura*[3,5], *N. Wakabayashi*[1,5], *H. Koga*[1,3], *K. Kudo*[3,5];
[1]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [2]*Department of Diagnostic Radiology, Sapporo City General Hospital, Sapporo, JAPAN,* [3]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [4]*Comprehensive Heart Failure Center, University Clinic Würzburg, Würzburg, GERMANY,* [5]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.*

Aim/Introduction: While pulmonary metastasis (PM) is common in differentiated thyroid carcinoma (DTC), approximately 50 percent of PM shows concentrations of I-131 after radioiodine therapy (RAIT). In iodine-avid PM, RAIT is shown to be highly effective, especially for small nodules. Recommended administered activities typically range from 3.7 to 7.4 GBq for metastatic disease, with 5.6 to 7.4 GBq suggested for pulmonary metastases. This study aimed to investigate predictive factors for therapeutic response of PM of DTC under RAIT. ***Materials and Methods:*** We retrospectively analyzed DTC patients with CT-detectable PM who underwent RAIT at our department between 2015 and 2025. RAIT (3.7-5.6 GBq) was administered after performing the following pretreatments: i) a strict iodine-restricted diet for at least three weeks, and ii) either levothyroxine withdrawal for at least three weeks or rhTSH administration. RAIT was repeated at intervals of six months or more if deemed effective. Based on post-RAIT CT findings, patients were categorized into two groups: the group R (remission), in which pulmonary lesions showed reduction or disappearance, and the group P (progression), in which lesions remained or progressed. Clinical and imaging parameters (e.g. age, sex, histology, FDG-accumulation) were statistically compared between the two groups. Additionally, time to treatment completion—defined as remission or improvement of lesions—or time to treatment discontinuation—due to disease progression or radioiodine-refractory status—was evaluated using Kaplan-Meier curves, with treatment completion considered as censoring. ***Results:*** A total of 33 patients (27 female) were included in the analysis. The mean age was 57±38 years. Histological subtypes included 19 cases of papillary carcinoma, 9 of follicular carcinoma, 4 of poorly differentiated carcinoma, and 1 unknown. Mean age of group P was significantly higher than that of group R (t-study, 63±34 vs. 52±38, p=0.039). Of the patients aged 70 or younger, 64% (16/25) were in group R, while 88% (7/8) of the patients aged above 70 were in group P (Pearson's chi-square test, p=0.0112). No other clinical or imaging parameters showed significant differences. According to Kaplan-Meier analysis, all patients in the group R achieved treatment completion, with the longest time to completion being 676 days. In the group P, the median time to treatment discontinuation was 613 days. ***Conclusion:*** Younger age may be a predictive factor for the efficacy of RAIT in PM of DTC. We suggest an age threshold of 70 years as a potential cut-off. Other clinical or imaging parameters showed no significant effect on the treatment outcome.

EPS-251

Redifferentiation and Radioiodine Therapy of Thyroid Cancer After the Use of Signaling Pathway Inhibitors: A Systematic Review and Meta-Analysis

F. Mourato[1,2], *D. O. S. Ramos*[3], *S. Brandão*[4,5], *M. Mariussi*[6], *M. C. Fagundes*[7], *G. B. Torri*[8], *S. Altmayer*[9], *L. G. Schmitt*[10];
[1]*Hospital das Clínicas da UFPE - EBSERH, Recife, BRAZIL,* [2]*Universidade de Pernambuco (UPE), Recife, BRAZIL,* [3]*Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo (HCFMUSP), São Paulo, BRAZIL,* [4]*Hospital das Clínicas da UFPE, Recife, BRAZIL,* [5]*Havard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [6]*Hospital Israelita Albert Einstein - Interventional Radiology Department, São Paulo, BRAZIL,* [7]*Hospital Alemão Oswaldo Cruz - Imaging Diagnostic Center, São Paulo, BRAZIL,* [8]*Hospital Universitário de Santa Maria, Santa Maria, BRAZIL,* [9]*Stanford University School of Medicine, Stanford, CA, UNITED STATES OF AMERICA,* [10]*University of Texas Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Redifferentiation therapy in radioiodine-refractory thyroid cancer aims to restore the expression of sodium-iodide symporter (NIS), thereby resensitizing tumors to radioactive iodine (RAI). A promising strategy involves targeting key signaling pathways to restore iodine uptake by promoting

rediffentiation of tumor cells, providing a rational therapeutic approach to enhance RAI efficacy in otherwise refractory disease. Therefore, our objective is to determine the benefit of using Signaling Pathway Inhibitors followed by radioiodine therapy in RAI refractory patients. ***Materials and Methods:*** A comprehensive search was conducted across MEDLINE, EMBASE, CENTRAL, and Web of Science databases. Additionally, reference lists of the selected articles were manually screened to identify further relevant studies for inclusion.The selection criteria encompassed both cohort studies and clinical trials. Stata 18 software was used. The proportion of patients with thyroid cancer who achieved redifferentiation following treatment with signaling pathway inhibitors were assessed. Additionally, we assess the proportion of patients who responded to radioiodine therapy after redifferentiation was induced. Random-effects methods were used. ***Results:*** The initial search yielded 308 articles, 35 articles were reviewed with full-text, and 10 were considered eligible. An additional article was included after reference list screening. Signaling Pathway Inhibitors therapy included: Dabrafenib, Dabrafenib plus Trametinib, Trametinib, Vemurafenib, Vemurafenib plus Cobimetinib, Vemurafenib plus CDX-3379, Selumetinib and an Investigational MEK inhibitor. The most frequently identified mutation across studies was BRAF V600E, followed by NRAS. Across 11 studies (n = 170 patients), the pooled proportion of patients achieving sufficient redifferentiation for RAI therapy was 0.58 (95% CI: 0.45-0.71) with high heterogeneity (I^2 = 72.09%). RECIST-based response after radioiodine therapy was analyzed in 10 studies (n = 92 patients), with a pooled partial response plus stable disease (no complete response was achieved) of 0.83 (95% CI: 0.71-0.95) with high heterogeneity (I^2 = 73.45%). Biochemical response (thyroglobulin reduction) was assessed by four studies (n = 25 patients), with a pooled thyroglobulin reduction rate of 0.90 (95% CI: 0.79-1.00), with no heterogeneity detected (I^2 = 0%). ***Conclusion:*** Signaling pathway inhibitors demonstrate promising efficacy in inducing redifferentiation and enabling subsequent radioiodine therapy in patients with RAI-refractory thyroid cancer. However, the observed heterogeneity underscores the need for further studies to optimize patient selection and therapeutic protocols.

EPS-253

The Clinical Impact of 131-iodine Whole Body Scintigraphy Following 131-iodine Therapy of Thyroid Cancer

J. Kjems[1], *M. Hofmann*[1], *B. Zerahn*[1], *B. Kristensen*[1], *C. Maare*[2], *L. Jensen*[1];
[1]*Department of Nuclear Medicine, Herlev Hospital, Herlev, DENMARK,* [2]*Department of Oncology, Herlev Hospital, Herlev, DENMARK.*

Aim/Introduction: The incidence of thyroid cancer has increased in recent years, globally and in our country. For patients classified as intermediate- or high-risk following total thyroidectomy, radioactive iodine (RAI) therapy with 131-iodine (^{131}I) is used to eliminate residual thyroid tissue and potential metastases. European and American guidelines recommend post-treatment whole-body scintigraphy (PT-WBS) using the residual ^{131}I activity 2-10 days after RAI treatment to supply information on disease staging. Aim: to elucidate if PT-WBS findings had a clinical consequence for the patient's treatment course in our hospital. ***Materials and Methods:*** In a retrospective cohort study from January 1, 2021, to February 28, 2024, 362 patients received RAI treatment at a large University hospital. Planar PT-WBS were available for 329 patients (91% - the study group), due to 26 patients refraining from participation in quality studies and 7 patients with no-shows or claustrophobia. Medical records were reviewed to assess if the PT-WBS contributed to clinical decision-making. Exclusion criteria: No suspected metastases on the PT-WBS, known metastatic disease, or prior RAI treatment. Clinical consequences were additional RAI therapy, supplementary imaging, or modifications to the follow-up schedule. ***Results:*** Of the 329 patients, 249 patients (76%) were treated with the high-risk dose (3.7 GBq) and 80 (24%) with the intermediate-risk dose (1.1 GBq). No patients in the intermediate-risk group had iodine avid foci on the PT-WBS, besides residual thyroid tissue on the neck. In the high-risk group, 15 patients had their first RAI treatment, with the first detection of potential metastases. Only six patients (2%) had a clinical consequence based on the PT-WBS findings. Nine patients adhered to the standard guidelines for follow-up despite potential metastases on the PT-WBS. ***Conclusion:*** PT-WBS had minimal impact on clinical decision-making, affecting only six patients (2%; best/worst case sensitivity analysis: 2-11%) in the follow-up period. Any clinical consequence of the PT-WBS have uncertain survival benefits due to an overall good prognosis. Omitting PT-WBS from clinical guidelines should be considered, particularly for patients at intermediate risk.

EPS-254

The role of Tc99m-Sestamibi scintigraphy in the diagnostic algorithm of thyroid nodules classified as Bethesda III/IV

K. Papadopoulou*, N. Papadopoulos, A. Kriari, E. Giannoula, P. Exadaktylou, E. Papanastasiou, A. Tsangaridi, P. Charalambous, G. Giakoumettis, E. Gkatzouli, A. Doumas, I. Iakovou;*
2nd Laboratory of Nuclear Medicine, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, GREECE.

Aim/Introduction: The aim of the study is to assess the role of preoperative Tc99m-Sestamibi scintigraphy in Fine Needle Aspiration suspicious thyroid nodules (Bethesda III and IV) in comparison with thyroidectomy histology. Specificity, sensitivity, negative and positive predictive values of qualitative and semi-quantitative analysis of Tc99m-Sestamibi scan were evaluated. ***Materials and Methods:*** So far, 62 patients enrolled the study, 48% of them diagnosed with thyroid nodule classified as Bethesda III and 52% of them as Bethesda IV by cytological examination and characterized as "cold" nodes in classical Tc99m scan. Early (20 minutes p.i.) and delayed (2 hours p.i.) images were acquired after 20 mCi of Tc99m-Sestamibi IV injection. The uptake of the tracer in the nodule, the mirrored lobe and background activity were evaluated both visually and quantitatively. Quantitative analysis included Washout (WI) and Retention (RI) Index evaluation. All patients underwent total thyroidectomy. ***Results:*** Visual analysis showed that 58% of the patient nodules presented with increased uptake in both early and late scan, characterizing the nodules suspicious for malignancy. WI median value was -52.33 (IQR -67.00, -31.82) and, respectively, RI was 5.63 (IQR -15.51, 13.43), demonstrating that 64.5% of the cases were suspicious for malignancy. Histological findings of eighteen (29%) patients showed follicular variant of papillary thyroid carcinoma and eight (13%) were diagnosed with papillary carcinoma, all of them had positive Tc99m-Sestamibi scan. Thirty-six (58%) patients were diagnosed with benign lesions, twenty-four of them had negative Tc99m-Sestamibi scan. The sensitivity, specificity, positive predictive value and negative predictive value were 92%, 67%, 67% and 92% were for the visual assessment of the scan, 88%, 55%, 53% and 84% for the WI, 84%, 83%, 56%, 82% for the RI, respectively, with no significant difference between the three methods. ***Conclusion:*** A negative MIBI scan can provide a definite diagnosis of the absence of malignancy, without the need for further invasive diagnostic procedures. Since the study is ongoing, the findings should be considered exploratory, highlighting the need for larger validation cohorts.

EPS-255

Estimation of Effective Half-Life and Evaluation of Treatment Response in ^{131}I Therapy for Thyroid Cancer

Y. Iizuka[1], *R. Nakashima*[1], *R. Aizawa*[1], *M. Kajisako*[2], *M. Shioji*[2], *K. Mitsumoto*[2], *K. Itagaki*[2], *S. Kawase*[2], *T. Mizowaki*[1];
[1]*Kyoto University Graduate School of Medicine, Kyoto, JAPAN,* [2]*Kyoto University Hospital, Kyoto, JAPAN.*

Aim/Introduction: In radioiodine therapy for differentiated thyroid cancer, accurate lesion dosimetry requires reliable assessment of pharmacokinetics, particularly the effective half-life of iodine uptake. While dynamic or multi-timepoint imaging is ideal, it can be logistically challenging. This study aimed to estimate effective half-lives using two-timepoint post-therapeutic imaging and evaluate their variation by lesion type and their association with treatment response. ***Materials and Methods:*** We analyzed 50 inpatients treated with ^{131}I therapy for differentiated thyroid cancer (26 adjuvant therapy cases, 24 cancer treatment cases). The median administered dose was 3700 MBq. Whole-body planar scintigraphy was acquired at discharge and again 6-14 days later (median interval 13.2 days). Imaging was performed using a gamma camera equipped with high-energy collimators. Lesion counts were measured using circular ROIs (5 cm diameter) on anterior planar images. A known-activity ^{131}I capsule placed near the patient's head served as an internal reference. The percent error in capsule-based count estimation between scans was calculated to validate the method. Effective half-lives were analyzed across all 50 cases (both adjuvant and cancer treatment). In addition, serum thyroglobulin (Tg) trends were evaluated in cancer treatment cases with distant metastases. Statistical comparisons were conducted using Welch's t-test. ***Results:*** The median percent error in count-based estimation of the ^{131}I capsule between scans was 6.1%. Mean effective half-lives were 2.53 ± 0.75 days for thyroid bed (n = 35), 3.25 ± 0.76 days for bone metastases (n = 11), and 3.27 ± 0.85 days for lung metastases (n = 3). The thyroid bed had significantly shorter half-lives than metastatic lesions (p = 0.007). Among 17 metastatic cases with follow-up Tg data, Tg levels decreased in 11 and remained stable or increased in 6. However, no significant difference in half-life was observed between these groups (p = 0.25). ***Conclusion:*** ^{131}I activity in the thyroid bed clears faster than in distant metastases. Lesion-specific kinetics should be considered in dose estimation. The lack of correlation with Tg trends suggests that clearance rates alone may not predict biochemical response.

EPS-256

Evaluation of the Efficacy of Lu-177 DOTATATE Therapy in Radioactive Iodine-Refractory Thyroid Cancer

A. Kibar[1], *K. Saglam*[1], *A. Nazari*[2], *O. E. Sahin*[1], *S. Asa*[1], *L. Uslu-Besli*[1], *S. Sager*[1], *K. Sonmezoglu*[1], *H. B. Sayman*[1];
[1]*Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Tekirdag City Hospital, Department of Nuclear Medicine, Tekirdag, TÜRKIYE.*

Aim/Introduction: The prognosis of patients with radioactive iodine-refractory differentiated thyroid cancer (RAIR-DTC) is significantly worse compared to those with iodine-avid differentiated thyroid cancer. In this study, we aimed to evaluate the efficacy of Lu-177 DOTATATE therapy in RAI-refractory thyroid cancer patients, a group with limited treatment options. ***Materials and Methods:*** A total of 38 patients with RAI-refractory thyroid cancer who received Lu-177 DOTATATE therapy between 2011 and 2024 at our department were included in the study. Pre- and post-treatment serum thyroglobulin (Tg) and anti-thyroglobulin (anti-Tg) levels were evaluated. ***Results:*** Among the 38 patients, 23 were female and 15 were male. At the time of initial diagnosis, 28 patients had papillary thyroid carcinoma, 6 had follicular thyroid carcinoma, and 4 had poorly differentiated thyroid carcinoma. Before Lu-177 DOTATATE therapy, patients had received a median of 20350 MBq (range: 5550-37000 MBq) of I-131 therapy. Pre-treatment imaging revealed lesions in the lungs in 23 patients (60.5%), lymph nodes in 19 (50%), thyroid bed in 11 (28.9%), bones in 11 (28.9%), pancreas in 2 (5.3%), liver in 1 (2.6%), and muscle in 1 (2.6%). The median pre-treatment Tg level was 172 ng/mL (range: 0.95-4591 ng/mL). Patients received a median of 2 cycles (range: 1-5 cycles), with a total median administered activity of 13505 MBq (range: 3811-28046 MBq) of Lu-177 DOTATATE. At a median of 2 months post-treatment (range: 1-6 months), laboratory results showed a >50% reduction in Tg in 3 patients (7.9%), a 10-50% reduction in 6 patients (15.8%), and progressive Tg elevation in 29 patients (76.3%). No significant change in anti-Tg levels was observed before and after treatment. ***Conclusion:*** Treatment options for patients with RAI-refractory thyroid cancer are limited. Although treatments such as tyrosine kinase inhibitors (TKIs) are available for this patient population, they are typically reserved for patients with symptomatic disease progression due to their associated toxicity profile. Consequently, the development of adverse effects may lead to discontinuation and limit further therapeutic options. Lu-177 DOTATATE therapy may be considered a potential option, given its ability to induce a thyroglobulin response in a subset of patients.

EPS-257

The efficacy of radioiodine therapy in patients with non-toxic multinodular goiter with large cold nodule

S. Abdelrazek, *I. Sulima, P. Szumowski, J. Mysliwiec;
Medical University of Bialystok, Bialystok, POLAND.*

Aim/Introduction: The clinical presentation of a patient with multinodular goiter (MNG) varies from a completely asymptomatic goiter to a life-threatening disease due to upper airway compression. Surgery is the treatment of choice in patients with cold nodule, low radioactive iodine uptake (RAIU), and presence of symptoms or signs of compression within the neck. Total thyroidectomy is associated with the risk of surgical complications and is often refused by the patient. Radioactive iodine therapy (RAIT) is an alternative to thyroid surgery to reduce the size of benign MNG. Studies have demonstrated that 131I is safe and effective, leading to significant thyroid volume (TV) reduction. The therapeutic efficacy of 131I in patients with MNG depends to some extent on the RAIU. The aim of our study was to evaluate the efficacy of radioiodine therapy to reduce thyroid volume in patients with cold nodule by the use of two doses of radioiodine I-131. ***Materials and Methods:*** We treated 260 patients with non-toxic MNG with large cold nodule, aged 18 to 70 years; initial 24h RAIU was ranged between 16-47%, and TV ranged between 44 and 160 ml, effective half-life was more than 3 days at the time of treatment. Malignant changes were excluded in all nodules by fine needle aspiration biopsy. The activity dose was calculated and ranged between 280 and 800 MBq. Thyroid ultrasonography, and thyroid scan with RAIU at 24 was done before and after 6 and 12 months of RAIT. Follow up control was done every 6 weeks. ***Results:*** After 6 months of first radioiodine dose, the large cold nodule changes to hot nodule in all the patients. In 71 patients the size of the thyroid gland decrease to 53%, and no need for the second dose of radioiodine therapy. 189 patients received second dose of RAIT to decrease the nodule which was cold and turned to hot after the first dose. After 12 months of the second dose of radioiodine a mean TV reduction of 55% was achieved. After 12 months of RAIT euthyroidism persist in 38% of patients, and hypothyroidism develop in 62% of patients***. Conclusion:*** Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of large non-toxic goitre even with cold nodules. The reduction of the cold nodules and the thyroid volume, were due to well accurate measurement of administered activity, relatively high effective half-life and well-organized follow up.

Utility of somatostatin receptor imaging in differentiated thyroid cancer with elevated thyroglobulin and negative 131I whole body scan

L. Barberan Corral[1], *A. Calatayud Cubes*[1], *M. Proaño Fierro*[2], *M. Rashki*[1], *J. Nogueiras Alonso*[3], *V. Pubul Nuñez*[1];
[1]*Hospital Clinico Universitario de Santiago, Santiago de Compostela, SPAIN,* [2]*Complejo Hospitalario Universitario de Pontevedra, Pontevedra, SPAIN,* [3]*Hospital Meixoeiro, Vigo, SPAIN.*

Aim/Introduction: Differentiated thyroid cancer (DTC) is the most common subtype, generally with good prognosis and high survival rate; however, there is a small group of cases that evolve into a highly aggressive behavior. The aim of this study is to assess the utility of somatostatin receptor (SSR) imaging for detecting recurrence and metastases in cases of DTC negative 131I scan and elevated stimulated thyroglobulin (Tg) levels, to re-stage the disease and explore new treatment alternatives. ***Materials and Methods:*** A retrospective observational study of patients diagnosed with DTC, after total thyroidectomy and at least one dose of 131I therapy, showed a progressive increase in Tg levels with a negative 131I scan. As a result, a PET/CT scan with Ga-DOTA-TOC or a SSR SPECT was performed to search for new lesions. ***Results:*** Nine patients were included: 3 women, 5 men, with different histological variants: 2 papillary (1 classic, 1 tall-cell) and 7 follicular (4 oncocytic). Most patients presented with locally advanced tumors, stage III. FDG-PET was positive in 5/9 cases. SSR imaging was performed with PET/CT Ga-DOTA-TOC in 7 patients (6/7 positive) and SPECT in 2 patients (2/2). The positivity rate for FDG-PET was higher in oncocytic compared to others. The correlation between Tg concentration and imaging positivity was not statistically significant. ***Conclusion:*** Although no significant association was found, 90% of patients showed SSR imaging positivity. Therefore, this type of imaging could be considered in cases with rising and elevated Tg levels with a negative 131I scan. ***References:*** Binse I, Poeppel TD, Ruhlmann M, Ezziddin S, Görges R, Sabet A, Beiderwellen K, Bockisch A, Rosenbaum-Krumme SJ. 68Ga-DOTATOC PET/CT in Patients with Iodine- and 18F-FDG-Negative Differentiated Thyroid Carcinoma and Elevated Serum Thyroglobulin. The Clinical Application of ^{68}Ga-FAPI PET/MR in Thyroid Eye Disease

Y. Zhou[1,2,3], *Y. Hou*[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: To explore the potential application of ^{68}Ga-fibroblast activation protein inhibitor (FAPI) PET/MR in thyroid eye disease (TED) and assess its diagnostic efficacy for TED activity. ***Materials and Methods:*** This prospective study included 24 TED patients, with a total of 48 eyes, and 11 patients in the control group, with a total of 22 eyes. All TED patients underwent Clinical Activity Score (CAS) assessment. Two TED patients underwent ^{68}Ga-FAPI PET/CT, while the remaining participants underwent ^{68}Ga-FAPI PET/MR. The maximum standardized uptake value (SUVmax) of the extraocular muscles in both eyes was measured and compared to the lateral pterygoid muscle as background. MR images were analyzed to assess the signal intensity of the extraocular muscles in T2-weighted imaging. TED patients were categorized into active and non-active groups based on treatment and efficacy as the gold standard. The differences in SUVmax of extraocular muscles between the active group, non-active group, and control group were compared. ***Results:*** The SUVmax of the extraocular muscles in the active group, non-active group, and control group were 8.802±2.057, 5.892±2.421, and 4.982±1.552, respectively. Significant differences were observed between the active group and both the non-active and control groups ($P<0.001$). The optimal threshold for SUVmax to distinguish between the active and non-active phases was 5.85 (sensitivity: 100%, specificity: 66.7%, AUC: 0.838). The lateral pterygoid muscle was used as the background to eliminate its influence. The ratio of SUVmax between the extraocular muscles and the lateral pterygoid muscle for each group was 4.679±1.153, 3.313±1.443, and 2.273±0.658, respectively. Significant differences were found between the active group and both the non-active and control groups ($P<0.001$). The SUVmax threshold for distinguishing between the active and non-active phases was 3.25 (sensitivity: 91.7%, specificity: 62.5%, AUC: 0.776). CAS evaluation for TED activity had a sensitivity of 70.8% and specificity of 50%. Combining MR activity scoring of the extraocular muscles and SUVmax values provided a comprehensive evaluation of TED patients, with sensitivity of 96.2% and specificity of 83.7%. ***Conclusion:*** ^{68}Ga-FAPI PET/MR orbital imaging is a reliable and objective imaging method for assessing TED activity, superior to clinical CAS scoring, and has good application potential. However, the lateral pterygoid muscle as a background comparison is not ideal, and further exploration for more appropriate background comparisons is needed. ***References:*** This research was supported by National Natural Science Foundation of China (Grant Numbers: 81771866) and Hubei Provincial Natural Science Foundation Project (2024AFB633). Aim/Introduction: Locoregional recurrence occurs in up to 28% of patients with papillary thyroid cancer (PTC). Several risk factors contribute to this metastatic process. The latest of them is perinodal infiltration (PNI). PNI refers to the pathological extension of tumor cells through the lymph node (LN) capsule into the perinodal fibroadipose tissue. It has been accepted as a poor predictive variable. This study aimed to evaluate the prognostic significance of PNI in recurrence of PTC and to identify predictive parameters associated with recurrence in PNI (+) patients. ***Materials and Methods:*** This study included 680 PTC with initial LN metastasis (lLNM). Study population was selected from them according to presence or absence of PNI. Eventually, 102 PNI (+) and 122 PNI (-) patients remained eligible for the study. Patients were statistically compared based on demographic, clinicopathologic, treatment, and outcome variables, both between PNI (+) and PNI (-) groups, and within the PNI (+) group according to recurrence status. ***Results:*** The recurrence rates were 40% and 15% in PNI (+) and PNI (-) patients, respectively ($p<0.001$). In PNI (+) group, the predicitive

factors associated with recurrence were central ILNM (p=0.005), combined central and lateral ILNM (p=0.003), ILNM>5 (p<0.001), tumor size (TS) (p<0.001), ILNM size (p<0.001), stimulated Tg (sTg) (p=0.039). ***Conclusion:*** PNI positivity is a poor prognostic factor for PTC recurrence. Central or combined central and lateral LN involvement, more than 5 ILNM, TS, ILNM size, higher sTg levels should also be considered when planning therapy in PNI (+) PTC patients. ***References:*** 1. EPS-261

Therapeutic ^{131}I Dose for Hyperthyroidism Treatment of Unifocal Autonomy in Compliance with Council Directive 2013/59/Euratom Optimization Principle

C. Canzi, *V. Longari, L. Florimonte, A. Castello, R. Leo, M. Castellani;*
Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY.

Aim/Introduction: Hyperthyroidism due to unifocal autonomy is a benign thyroid disease with about 10000 new cases/year in Europe. Being a benign disease, treatment should be performed with the lowest clinically effective dose. European guidelines suggest a target dose of 300-400 Gy. Aim of this study was to demonstrate that a lower dose and a personalized pretreatment dosimetric study can be effective in obtaining a stable euthyroid condition avoiding both hyperthyroidism persistence and hypothyroidism onset. ***Materials and Methods:*** 134 patients with a single nodule and a minimum follow-up of 12 months were considered. They were studied with a pretreatment patient-specific dosimetric study (based on the administration of 48-111 MBq of ^{123}I, multiple uptake measurements with a gammacamera and the use of the MIRD formula) in order to calculate the therapeutic ^{131}I activity necessary to release a dose of 140 Gy to the nodule. The dose released after the ^{131}I therapeutic administration was calculated in the same way. Each patient clinical outcome was periodically monitored with biochemical analysis. Two subgroups of 77 and 48 patients had a follow-up of 5 and 10 years, respectively. ***Results:*** All patients were given a single ^{131}I therapeutic administration with a mean activity of 297±150 MBq (range 87-614 MBq). The mean released nodule dose was 143±38 Gy. Twelve months after therapy hyperthyroidism was healed in 97% of the patients but 8% were hypothyroid. In the subgroup followed for 5 years 100% solved hyperthyroidism but 27% became hypothyroid and in the subgroup followed for 10 years they were 38%. ***Conclusion:*** This study demonstrated that a released nodule dose of about 140 Gy is effective in solving hyperthyroidism due to unifocal autonomy and in maintaining a long lasting euthyroidism. This dose is quite lower than the value indicated by the European guidelines. The wide range of administered activity indicates the importance of a personalized pretreatment dosimteric study in order to obtain the clinical goal with the lowest activity as specified by the optimization principle of the 2013/59/Euratom Council Directive.

Redifferntiation therapy in Radioactive iodine refractory thyroid cancer: post therapy response and clinical outcomes

K. Kulkarni[1], *K. Manglani*[2], *A. Bendre*[3], *A. Bendre*[2];
[1]*Medstar Medical Group Radiology, Medstar Washington Hospital Center, DC, UNITED STATES OF AMERICA,* [2]*Medstar Washington Hospital Center, Washington, DC, UNITED STATES OF AMERICA,* [3]*Medstar Health Research Institute, Medstar Washington Hospital Center, DC, UNITED STATES OF AMERICA.*

Aim/Introduction: Radioactive iodine (RAI) refractory thyroid cancers often harbor BRAF V600E and NRAS Q61R mutations, which can be targeted with BRAF and MEK inhibitors to promote thyroid cancer cell redifferentiation and enhance RAI uptake. This study evaluates post-therapy scan results and clinical outcomes in patients who underwent RAI after redifferentiation therapy (RDT). Pretherapy dosimetry scans were used to assess RAI uptake and determine therapeutic I-131 activity, while post-therapy scans confirmed uptake in known lesions. Follow-up imaging and thyroglobulin (TG) levels were used to monitor treatment response. ***Materials and Methods:*** This retrospective study included 36 patients who underwent RDT between 2021 and 2024 at MWHC. Next-generation sequencing was used to identify targetable mutations with patients receiving either dual therapy with Trametinib and Dabrafenib for BRAF V600E mutations or Trametinib alone for NRAS Q61R mutations. Pretherapy scan was performed in week 5 with RAI administered in week 6 based on dosimetry and scan results. Post-therapy scans were conducted 5-7 days after treatment to assess RAI uptake, and follow-up CT scans and TG levels were measured every 3 months for the first year, then every 6 months. RECIST criteria were used to assess response. Molecular analysis revealed 25 patients with BRAF V600E mutations, 8 with NRAS Q61R mutations, and 3 with other mutations (RET, NTRK, and no identifiable mutation). ***Results:*** Post-therapy scans revealed distinct RAI uptake patterns. 37 pretherapy scans were available for 36 patients (one patient had two treatments). Of the 24 patients with positive pretherapy scans, all proceeded to RAI therapy and showed sustained positive post-therapy scans. Among the 12 patients with negative pretherapy scans: 6 had positive post-therapy scans, 2 remained negative, and 4 did not undergo RAI therapy. RAI dose ranged from 140-400 mCi based on dosimetry. Clinical outcomes, biochemical responses (TG levels), and structural responses (stable disease, progression, or regression) varied during follow-up. ***Conclusion:*** This study demonstrates the utility of BRAF and MEK inhibitors in promoting RAI uptake in refractory thyroid cancers. However, variability in patient responses highlights the need for further research to identify clinicopathological and molecular factors that predict which patients will benefit most from RDT. Our study continues to investigate these characteristics to refine patient selection for targeted therapy in advanced thyroid cancer. ***References:*** 1. Van Nostrand, D., 2018. Radioiodine refractory differentiated thyroid cancer: time to update the classifications. Thyroid, 28(9), pp.1083-1093.1.

Redifferentiation Therapy in Refractory Differentiated Thyroid Cancer with Progression. Initial Experience

C. Paniagua Correa, *R. Vegara Fernández, G. Guijarro de Armas, L. Castillejos Rodríguez, M. Tagliatori Nogueira, S. Pérez Quirós, A. Herrero Muñoz, M. de la Rubia Marcos, A. Ortega Valle, D. Rodriguez Oviedo, C. Galindo Fernández, K. Guichay Duran, J. Sánchez Calderón, P. García Alonso;*
Hospital De Getafe, Madrid, SPAIN.

Aim/Introduction: Objetive: To evaluate the response to redifferentiation therapy in patients with advanced differentiated thyroid cancer (DTC), refractory to radioactive iodine-131I (RAI-R),

as well as the eventual response to a new dose of radioiodine (RAI). ***Materials and Methods:*** We studied 13 patients with DTC, the majority of whom were classical variants, 69% were women, mean age was 61 years. The total accumulated dose (TAD) of I-131 was a mean of 500 mCi. They received iodide symporter (NIS) redifferentiation therapy from April 2022 to June 2024. Ten patients had BRAF oncogen mutations (the rest had RAS mutations). Seven had previously been treated with first-generation tyrosine kinase inhibitors (TKIs), and one with Dabrafenib (a selective BRAF inhibitor). Dabrafenib was administered as a redifferentiation therapy in 9/13 (69.2%), Trametinib in 3/13 (23.1%), and a combination of both BRAF inhibitors was administered in 1 patient (7.7%). Prior to treatment, each patient underwent ^{18}F-FDG PET/CT scan and whole-body radioiodine scan (WBS) with a diagnostic dose of 5 mCi of 131-I. Treatment was continued for 6 weeks in 12 of 13 patients (discontinued in 1 patient due to severe adverse effects), and followed by a diagnostic WBS (5 mCi of 131-I). ***Results:*** Re-establishment of RAI uptake was observed in the WBS in 5/13 patients (38.5%), who received 131-I (120-150 mCi). In another patient, an empirical dose of 131-I was administered after multidisciplinary consensus. In the six evaluated patients, therapeutic response was assessed 3-4 months after RAI dose, using a new WBS and PET/CT, applying RECIST 1.1 criteria, and a possible assessment using PERCIST criteria was considered (comparing the pre- and post-RAI study). The results were: - 2/6 patients: Partial Response (PR) and Partial Metabolic Response (PMR);- 1/6 patients: Progressive Disease (PD) and Progressive Metabolic Disease (PMD); - 1/6 patients: Stable Disease (SD) and Stable Metabolic Disease (SMD); - 2/6 patients: Stable Disease (SD) but Partial Metabolic Response (PMR) (maintained in follow-up studies). ***Conclusion:*** Redifferentiation treatments offer us the opportunity to recover RAI therapy as a therapeutic tool in advanced DTC.

^{18}F-DPA-714 versus ^{18}F-FDG PET for localizing the epileptogenic zone in drug-resistant epilepsy: a case report

L. Xiao, *L. Feng, Y. Tang, S. Hu;*
Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: Drug-resistant epilepsy (DRE) presents significant diagnostic challenges, particularly in pediatric cases where precise localization of the epileptogenic zone (EZ) is crucial for surgical intervention. While ^{18}F-FDG PET is commonly used in presurgical evaluation, its limited specificity often fails to clearly delineate the EZ in non-lesional cases. The emerging ^{18}F-DPA-714 PET tracer, targeting neuroinflammation through microglial activation, offers a promising alternative with potentially higher specificity for epileptogenic foci. This case report compares the diagnostic performance of these two PET modalities in a pediatric DRE patient, demonstrating how ^{18}F-DPA-714 provided superior localization that correlated with stereoelectroencephalography (SEEG) findings and successful surgical outcome. ***Materials and Methods:*** A 6-year-old male with DRE characterized by hypermotor seizures and autonomic features underwent comprehensive presurgical evaluation including 3T MRI, both ^{18}F-FDG and ^{18}F-DPA-714 PET scans, scalp EEG, and subsequent SEEG with bilateral implantation of 10 electrodes targeting frontal and cingulate regions. The PET images were analyzed using standardized uptake values (SUV), with particular attention to regions showing abnormal uptake patterns. Surgical planning was based on the concordance between PET findings and SEEG localization, ultimately guiding stereotactic radiofrequency thermocoagulation of the right anterior and middle cingulate gyri. ***Results:*** The ^{18}F-DPA-714 PET demonstrated focal increased uptake specifically in the right anterior/middle cingulate gyri, while ^{18}F-FDG PET revealed only nonspecific right hemispheric hypometabolism. SEEG recordings confirmed ictal onset precisely in the areas of ^{18}F-DPA-714 uptake, with characteristic high-frequency fast activity observed in the right ACC/MCC. Following stereotactic thermocoagulation of these regions, the patient achieved complete seizure freedom (Engel class 1a) at 9-month follow-up with reduced antiepileptic medication and no neurological deficits. ***Conclusion:*** This case demonstrates that ^{18}F-DPA-714 TSPO PET offers superior localization value compared to ^{18}F-FDG PET in DRE evaluation, particularly in pediatric cases with non-lesional MRI. The precise correlation between ^{18}F-DPA-714 uptake, SEEG findings, and successful surgical outcome highlights its potential as a valuable tool in presurgical planning. These results suggest that TSPO PET imaging could significantly improve surgical outcomes in DRE cases where conventional imaging modalities provide inconclusive results, though larger prospective studies are needed to validate these findings and establish clinical protocols.

OP-741

Impact of Venlafaxine on ^{123}I-FP-CIT Imaging: A Case Series

M. El-Sayed, *J. Dias;*
Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: The effect of venlafaxine (an antidepressant) on dopamine transporter imaging using ^{123}I-FP-CIT SPECT imaging remains poorly understood, leading to conflicting guidelines. The German Society of Nuclear Medicine advises stopping venlafaxine before scans, while the European Association of Nuclear Medicine does not. Only one prior case report suggests that venlafaxine may reversibly alter scan results. ***Materials and Methods:*** We present two cases of abnormal ^{123}I-FP-CIT scans on venlafaxine, which then had repeat scans off the drug showing normal results. The mental health team referred both cases due to concerns of dementia with Lewy bodies (DLB). The first case involved a 75-year-old man receiving venlafaxine 150 mg/day, and the second case a 72-year-old woman on 262.5 mg/day. Neither patient was taking any other drugs known to influence the ^{123}I-FP-CIT imaging, and their structural brain imaging was normal. Initial scans demonstrated normal striatal comma-shaped morphology; however, there was increased background activity and reduced striatal-specific binding ratios (SBR). In Case 1, z-scores were -1.89 (right) and -1.7 (left) and in Case 2, -2 (right) and -1.9 (left). These results were interpreted as abnormal and supportive of a DLB diagnosis. Due to clinical inconsistencies, repeat scans were performed after venlafaxine withdrawal, using identical protocols. Upon re-scanning off venlafaxine, SBR values normalised significantly. For Case 1, z-scores improved to -0.18 (right) and -0.44 (left) - this patient also had a normal brain FDG PET/CT. Case 2 showed similar improvement with z-scores of -1 (right) and -0.7 (left). ***Results:*** DLB was excluded in both cases; case 1 was diagnosed with functional cognitive disorder, but case 2 had unresolved diagnostic uncertainty. Notably, venlafaxine exhibits negligible dopamine transporter binding affinity (Kd 9300 nM vs ioflupane's 3.5 nM; higher Kd indicates lower affinity), leaving its mechanism of SBR reduction unclear. Given the risk of withdrawal complications, any decision to stop venlafaxine before imaging must involve multidisciplinary discussion.

Cardiac ^{123}I-MIBG studies are also affected by venlafaxine, making them unsuitable alternatives. However, brain FDG PET scans are not typically affected. ***Conclusion:*** These cases suggest that venlafaxine can cause a uniform, symmetrical reduction in SBR on ^{123}I-FP-CIT SPECT that may mimic DLB pathology. Discrepancies in current guidelines, if unaddressed, risk diagnostic errors. Prospective studies are needed to define the prevalence and dose-dependency of this interaction. ***References:*** -Tatsch K, et al. Nuklearmedizin. 2019;58:5-16.-Morbelli S, et al. OP-742

Managing Pediatric Multisystem Langerhans Cell Histiocytosis: A 5-Year Follow-Up with Serial [18F]FDG-PET/CT Metabolic Imaging

D. Barbosa, *H. Duarte, D. Silva, N. Vasconcelos, R. Marão, I. Sampaio;*
IPO, Porto, PORTUGAL.

Aim/Introduction: Langerhans cell histiocytosis (LCH) is a rare clonal proliferation of myeloid dendritic cells. The clinical course is heterogeneous, and multisystem LCH is particularly challenging due to its association with increased morbidity and relapse risk. [18F]fluoro-2-desoxi-D-glucose Positron Emission Tomography/Computed Tomography ([18F]FDG-PET/CT) enables accurate initial staging, quantitative assessment of treatment response and early detection of disease recurrence. ***Materials and Methods:*** We present a 5-year clinical and imaging follow-up of a male child diagnosed with multisystem LCH at age 3, focusing on 14 [18F]FDG-PET/CT scans and comprehensive molecular profiling performed under the international LCH-IV treatment protocol. ***Results:*** At initial presentation in 2018, the patient exhibited extensive cutaneous lesions and lymphadenopathies. Biopsy confirmed LCH. Baseline [18F]FDG-PET/CT showed diffuse cutaneous hypermetabolism (SUVmax 4.8-6.2) and bilateral axillary and inguinal nodal uptake (SUVmax 3.1-3.5). LCH-IV Stratum I chemotherapy was initiated. Following Cycle 1, [18F]FDG-PET/CT indicated a partial metabolic response. However, disease progression after Cycle 2 with new cutaneous foci (SUVmax 3.0), prompted escalation to Stratum II. Continued progression under cytarabine led to re-initiation of Stratum I. Maintenance therapy (vinblastine every 3 weeks, prednisolone pulses, and daily 6-mercaptopurine) was administered from 2019 to 2021. Molecular analysis - including BRAF V600E, NRAS, KRAS, and MAP2K1 mutation testing - remained consistently negative. Mid- and end-of-treatment [18F]FDG-PET/CT (03/2021) showed complete metabolic remission. In 09/2021, generalized pruritic papules recurred. Biopsy reconfirmed CD1a+, S100+ LCH and [18F]FDG-PET/CT revealed multifocal cutaneous uptake, and re-induction with Stratum I was initiated. [18F]FDG-PET/CT after cycle 1 and 2 showed partial metabolic response and in 09/2022 only low-grade uptake in a right leg lesion (SUVmax 1.4) was reported, and maintenance therapy was resumed. Pituitary Magnetic Resonance Imaging (MRI) in 10/2022 showed stalk thickening with contrast enhancement, consistent with neuro-pituitary LCH but without endocrine dysfunction. Follow-up [18F]FDG-PET/CT scans in 2023 showed no hypermetabolic disease, while MRI findings remained stable. The patient continues on oral 6-mercaptopurine and methotrexate through 05/2025, asymptomatic, under surveillance. ***Conclusion:*** Over 5 years, 4 serial [18F]FDG-PET/CT scans, combined with histopathological reassessment and molecular profiling, enabled accurate evaluation of treatment response, early relapse detection, and timely adjustments to the LCH-IV protocol. Negative molecular findings excluded high-risk variants, supporting continued use of conventional chemotherapy. Persistent neuro-pituitary MRI abnormalities in the absence of endocrinopathy emphasized the value of integrated PET and MRI surveillance. This combined approach allowed for personalized and risk-adapted management in this LCH complex case.

OP-743

"68 Ga-CRH (Corticotropin Releasing Hormone) PET/CT: Transforming Cushing Syndrome Diagnosis"

V. Jain[1], *M. L. Narayan*[1], *K. Shridharan*[1], *J. Shukla*[2], *R. Kumar*[2], *B. Mittal*[2];
[1]*All India institute of Medical Sciences, Rishikesh, Rishikesh, INDIA,* [2]*PGIMER, Chandigarh, Chandigarh, INDIA.*

Aim/Introduction: Cushing's syndrome (CS) is a clinical condition resulting from excessive cortisol production, typically due to inappropriate secretion of adrenocorticotropic hormone (ACTH), corticotropin-releasing hormone (CRH), or autonomous adrenal cortisol secretion. The incidence of CS is approximately 0.7-2.4 cases per million people per year. Identifying the underlying cause of CS is essential for determining appropriate treatment strategies. This report presents a rare case of endogenous CS where differentiating between Cushing's disease (CD) and ectopic ACTH secretion was challenging due to inconclusive findings on conventional imaging. Diagnostic clarity was ultimately achieved using a novel imaging technique 68Ga-CRH PET/CT. ***Materials and Methods:*** A radiotracer dose of 4mCi of 68Ga-DOTA-chelated corticotropin-releasing hormone(CRH), a 41-amino acid peptide, was administered intravenously. Whole-bodyPET/CT imaging, including additional brain imaging, was performed 45 minutes post-injection. ***Results:*** A 26-year-old male presented with a three-year history of insidious weight gain, progressive body swelling, mooning of the face, neck, and abdomen, striae, skin thinning, easy bruising, and hyperpigmentation of the knuckles and mouth angles. Laboratory evaluation revealed elevated 8 AM cortisol and ACTH levels, indicating ACTH-dependent CS. To differentiate between pituitary (CD) and ectopic ACTH secretion, a high-dose dexamethasone suppression test (HDDST) was performed, demonstrating cortisol suppression consistent with CD.CE-MRI brain revealed a suspicious 5mm lesion involving left pituitary lobe although contrast-enhanced CT (CECT) of the abdomen failed to reveal ectopic ACTH-secreting tumor. Given the indeterminate imaging, the patient underwent 68Ga-DOTANOC PET/CT, which identified a non-SSTR expressing right adrenal adenoma(~2.5x2cm) but no other significant SSTR-positive lesions. Due to continued diagnostic uncertainty, the patient was referred for 68Ga-DOTA-CRH PET/CT. This novel imaging modality targets CRH receptors (R1 and R2), which are overexpressed in pituitary adenomas. The scan revealed a tracer avid left para-sellar lesion in the posterior pituitary. The patient subsequently underwent surgical resection of this lesion which was ~0.8x0.4cm in size predominantly on the left side. Histopathological examination confirmed the diagnosis of a corticotroph adenoma, which stained strongly positive for ACTH, SSTR2, and SSTR5. ***Conclusion:*** This case underscores the diagnostic challenges in identifying the aetiology of Cushing's syndrome when conventional imaging is inconclusive especially in microcoticotropinoma. The application of ^68Ga-DOTA-CRH PET/CT, a target-specific imaging modality can play a crucial role in accurately localizing the ACTH source and guiding effective treatment. Its use may significantly enhance diagnostic accuracy in complex cases of CS. ***References:*** 1. Sharma ST, Nieman LK, Feelders RA. OP-744

Role of 99mTc-Ethambutol SPECT/CT in Resolving Diagnostic Dilemma in a Case of Chronic Vertebral Lesions

A. Roy, *N. A. Damle, A. Mahalik, N. Kundu, S. Sikdar;*
AIIMS New Delhi, New Delhi, INDIA.

Aim/Introduction: To highlight the diagnostic value of 99mTc-Ethambutol (99mTc-EMB) scintigraphy in detecting spinal tuberculosis and guiding targeted biopsy in a diagnostically

inconclusive case with multiple vertebral lesions. ***Materials and Methods:*** A 29-year-old female presented with chronic lower back pain for over two years. MRI revealed multiple lytic lesions in the dorso-lumbar spine (D8, L2-L4), leading to a differential diagnosis that included tuberculous osteomyelitis, multiple myeloma, and brown tumors. Conventional diagnostic approaches—bone marrow aspiration, GeneXpert, and histopathology—were inconclusive. The patient underwent 99mTc-EMB scintigraphy with 10 mCi of in-house radiolabelled ethambutol. Whole-body planar imaging followed by SPECT/CT was performed on a dual-head gamma camera with LEHR collimators. Imaging interpretation was done by a senior nuclear medicine physician blinded to prior findings. ***Results:*** Planar and SPECT/CT images showed intense radiotracer uptake in D8 and additional uptake in L2-L4 vertebrae. The D8 lesion, with the highest uptake, was selected for CT-guided biopsy. Histopathology revealed necrotizing granulomatous inflammation, confirming spinal tuberculosis. GeneXpert remained negative. The patient was initiated on standard anti-tubercular therapy (ATT) and showed clinical improvement within weeks. This case was part of a broader study where 99mTc-EMB scintigraphy demonstrated 100% sensitivity and 92.3% diagnostic accuracy in bone TB (n=13). This case emphasizes the role of functional imaging in identifying metabolically active lesions and in guiding biopsy in cases where anatomic imaging and conventional tests are inconclusive. ***Conclusion:*** 99mTc-Ethambutol scintigraphy with SPECT/CT provided critical diagnostic and procedural guidance in a complex case of indeterminate vertebral lesions. It enabled lesion mapping, biopsy site selection, and rapid therapeutic decision-making. This case reinforces the utility of radiolabelled antibiotics in diagnosing skeletal TB and supports further exploration of 99mTc-EMB as a frontline adjunct in EPTB diagnostics. ***References:*** Bhattacharya B et al., IJNM. 2022;37(4):323, Kartamihardja AHS et al., Ann Nucl Med. 2018;32(1):60-8, Diah LH et al., World J Nucl Med. 2019;18(1):13.

OP-745

A Non-invasive PET ^{18}F-FTHA Imaging Strategy for Observing Lymphatic Flow Patterns

D. Lee, *R. Laforest, K. D. Harrison, M. L. Nickels, R. J. Gropler, G. J. Randolph;*
Washington University School of Medicine in Saint Louis, Saint Louis, MO, UNITED STATES OF AMERICA.

Aim/Introduction: Diseases of the central lymphatic system are difficult to manage due to limited tools for visualizing lymphatic cargo, particularly outflow from the gastrointestinal tract to the thoracic duct. While lymphangiography has aided superficial mapping, non-invasive approaches remain lacking. Our initial study aims to address this gap using PET-CT and the long chain fatty acid radiotracer 14(R,S)-[18F]fluoro-6-thia-heptadecanoic acid (^{18}F-FTHA) and administered orally[1], to map the biodistribution and lymphatic route of healthy individuals, focusing on outflow from the gut toward the thoracic duct, along with measuring radiation dosimetry. ***Materials and Methods:*** Between 43.3-55.5 MBq of 18F-FTHA was orally administered in a fat-containing Boost™ drink and consumed within 10 minutes. Whole-body PET-CT imaging was performed hourly for up to 8 hours. Maximum and mean standardized uptake values (SUV) were used to characterize gut-to-thoracic duct lymphatic outflow and generate tissue time-radioactivity curves. Radiation dosimetry was calculated from organ time-integrated activities (TIA) using MIRD methodology and MIRDCalc[2] software. ***Results:*** All 6 healthy volunteers who were aged 28-62 and BMI ≤ 32 without pre-existing cardiopulmonary issues completed the study without any adverse events. Following administration, ^{18}F-FTHA could be visualized along the entirety of the digestive system from mouth to the gastrointestinal tract. Radiotracer enrichment both visually and by SUV was particularly higher along the proximal intestine and could be clearly visualized in the thoracic duct. Excretion was primarily via the gastro-intestinal track with the stomach receiving the highest dose of 0.39 mSv/MBq and a whole-body effective dose of 0.061 mSv/MBq. ***Conclusion:*** As a long chain fatty acid, ^{18}F-FTHA passed along the expected route by absorption through intestinal lacteals toward the thoracic duct with radiotracer enrichment analysis suggesting recirculation with blood vasculature as expected. Thus, PET-CT with orally administered ^{18}F-FTHA appears to safely label lymphatic outflow along the gastrointestinal tract. In the future, we expect to evaluate patients with central lymphatic anomalies such as those with protein losing enteropathy and with central conducting lymphatic anomalies. ***References:*** [1] Sébastien M Labbé, André C Carpentier. Too Subtle to Miss? The Diagnostic Value of V/Q SPECT in Low-Risk CTEPH

C. Küçüker[1], *G. Kaya*[2], *E. B. Kaya*[3], *P. Özgen Kiratli*[1];
[1]*Hacettepe University, Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Republic of Türkiye, Ministry of Health, Yozgat State Hospital, Department of Nuclear Medicine, Yozgat, TÜRKIYE,* [3]*Hacettepe University, Faculty of Medicine, Department of Cardiology, Ankara, TÜRKIYE.*

Aim/Introduction: Pulmonary embolism(PE) is a potentially chronic-condition associated with high-morbidity and mortality. Chronic thromboembolic pulmonary hypertension(CTEPH), a consequence of organized PE, increases pulmonary arterial pressure(PAP), possibly leading to pulmonary arterial hypertension(PAH) and right-heart failure. Despite advances in CT-angiography, ventilation/perfusion(V/Q) scintigraphy remains pivotal for CTEPH diagnosis and therapeutic guidance[1]. Current guidelines recommend V/Q SPECT imaging in patients with low-clinical probability of PE. However, data regarding the correlation of V/Q SPECT±CT findings with other baseline clinical parameters in this population are limited. This study aimed to assess the diagnostic contribution of V/Q SPECT±CT in low-risk PAH patients. ***Materials and Methods:*** We prospectively evaluated adults (>18 years) with PAP >25 mmHg and low-PE probability within a single-center research project protocol(Project ID: 20852). V/Q planar-SPECT imaging findings were analyzed in correlation with clinical-data including symptomatology, echocardiography, right-heart catheterization, and clinical scores using Pearson/Spearman correlation and ROC-analysis. The impact of imaging on clinical decision-making was examined via binary logistic regression and decision tree modeling. Preliminary findings are presented. ***Results:*** Twenty-nine patients(7 males-22 females) were analyzed; mean age was 63.3±2.2 years. Median left ventricular ejection-fraction was 60%(IQR: 50-65%) and median PAP was 45 mmHg(range: 30-100 mmHg). No statistically significant clinical or laboratory predictor of perfusion-ventilation mismatches was identified. PAP showed moderate positive-correlation with "subsegmental" and "segmental" defects($r = 0.549$, $p=0.007$; $r = 0.520$, $p=0.014$; respectively). No significant association was observed between mismatched V/Q defects and PAH. ROC-analysis identified subsegmental defects as a significant predictor of elevated PAP(AUC: 0.727, p=0.018), with Youden Index suggesting a single subsegmental defect as the optimal cut-off(sensitivity: 62.5%, specificity: 75%). ***Conclusion:*** In line with existing literature, the cohort was predominantly female. Unlike

findings in high-risk patients, segmental and also subsegmental defects were significantly associated with PAH[2]. These findings underline the potential of even small subsegmental defects in contributing to PAH, independent of other clinical indicators. Our results support the diagnostic-value of V/Q SPECT as an independent variable[3] and highlight the need for volumetric SPECT-based studies to refine cut-off values. ***References:*** 1.Tunariu N et al. Aim/Introduction: Expression of fibroblast activation protein (FAP)seen in inflammatory conditions, especially those tend to be chronic. Primary sclerosing cholangitis (PSC),a chronic progressive liver disease characterised by patchy inflammation and fibrosis of the intra- and extrahepatic bile ducts. Progressive patients should be considered for liver transplantation. Currently there is no accurate predictive tool. Ga-68 FAPI PET provides valuable information about FAP expression/fibroblast activity. We investigated the potential use of FAPI-PET/MRI as a non-invasive Imaging for early diagnosis and of PSC. ***Materials and Methods:*** 10 patients with diagnosis of PSC included. 6/10 patients (60%) had concomitant inflammatory bowel disease. Ga-68 FAPI PET/MRI performed with dedicated hepatobiliary protocol. MRI liver score (FLIS) and lver standardized uptake values (SUV) for PET calculated. Furthermore, Fibro scan, liver blood parameters and enhanced liver fibrosis (ELF) score obtained. 10 age/sex-matched patients with Ga-68 FAPI PET/MRI due to other diseases considered as control group. FAP staining performed in all PSC patients with liver biopsy. ***Results:*** The mean liver SUVmax of the patient group was higher than control group (SUVmax 6.7±3.0 vs. 4±0.9). All controls showed a homogeneous pattern of FAPI uptake.In patient group, 5 with known PSC showed segmental/subsegmental increased pattern of FAPI uptake with highest SUVmax (mean SUVmax: 9±4), followed by two PSC/cirrhosis patients with diffuse inhomogeneous increased uptake (mean SUVmax: 6.2±1.4) and three newly diagnosed PSC with homogeneous FAP liver uptake (SUVmax 3±0.8). Mean FLIS for all PSC patients was 5.4±0.7 (Normal FLIS: 6): the lowest values in PSC/cirrhotic patients (4.5) followed by 5 known PSC cases (5.4±0.8). New PSC patients had normal FLIS. The mean ELF score of all PSC patients was 9.5±1.9 (normal <7.7) and the mean liver stiffness on fibroscan was 15.5 kPa (normal:2-7kPa). The highest stiffness observed in cirrhotic/PSC patients (mean 35.5), then known PSC patients (mean:13.9). Mean ELF showed also the highest values in PSC/cirrhotic patients followed by known cases (12.5 vs. 9.02). New PSC patients had a normal liver stiffness (mean 5.43) but a slightly elevated ELF score (mean 8.1). ***Conclusion:*** The segmental/sub-segmental pattern of FAP expression correlated with the patchy inflammatory nature of PSC. Higher SUVmax values were detected in known/active cases than in cirrhotic patients, whereas other established parameters tended to pathological values in cirrhotic PSC patients. Thus, FAPI-PET could be used for the early detection of fibrotic activity in PSC patients and to identify regions for liver biopsies or for the prediction of disease progression.

OP-748

Unexpected Skeletal Uptake on ^{68}Ga-Trivehexin PET/CT in a Case of Renal Osteodystrophy

S. Kar*, V. R. Lele, N. Shaikh;*
Jaslok Hospital and Research Centre, Mumbai, INDIA.

Aim/Introduction: Renal osteodystrophy is a well-recognized complication of chronic kidney disease (CKD), yet its molecular imaging characteristics remain poorly defined. ^{68}Gallium-Trivehexin Positron Emission Tomography/ Computed Tomography (^{68}Ga-Trivehexin PET/CT) has demonstrated utility in localizing parathyroid adenomas via expression of integrin αvβ3, but its uptake in skeletal remodeling associated with renal osteodystrophy has not been described. We present a case of a patient with CKD and biochemical evidence of secondary hyperparathyroidism in whom ^{68}Ga-Trivehexin PET/CT not only localized a parathyroid adenoma but also demonstrated significant tracer accumulation in bone changes consistent with renal osteodystrophy, representing a novel imaging finding. ***Materials and Methods:*** A 31-year-old male with a 5-year history of CKD presented with a 6-month history of generalized bone pain. Laboratory evaluation revealed serum calcium of 8.1 mg/dL (reference 8.6-10 mg/dL) and parathyroid hormone (PTH) of 1,336 pg/mL (reference 15-65 pg/mL). To look for parathyroid adenoma, 2.8 millicurie of ^{68}Ga-Trivehexin was administered intravenously. Whole-body PET/CT images were acquired at 90 minutes post-injection. Maximum Standardized Uptake Value (SUVmax) normalized to body weight were measured over lesions. A low-dose CT (3.5 mm slices) provided anatomic correlation. ***Results:*** Physiologic tracer distribution was noted in the stomach, kidneys, and urinary bladder. Focal uptake (SUVmax 2.89) was seen in a parathyroid adenoma posterior to the left thyroid lobe. Unexpectedly, the scan also revealed widespread skeletal tracer accumulation correlating with radiographic findings of renal osteodystrophy. The skull showed diffuse osteopenia with a salt-and-pepper appearance and cortical thinning, with SUVmax 6.31. Expansile osteolytic "brown tumors" were noted in the left mandible (SUVmax 4.91) and the maxilla (SUVmax 6.36). A lesion in the right second rib exhibited SUVmax 4.96. Subchondral resorption in bilateral sacroiliac joints and the pubic symphysis demonstrated moderate uptake with SUVmax of 5.12. These findings mirror bone remodeling and hyper-resorptive changes of renal osteodystrophy. No other abnormal tracer foci were identified. ***Conclusion:*** This case highlights the established role of ^{68}Ga-Trivehexin PET/CT in detecting integrin αvβ3 expressing parathyroid adenomas and unveils its novel application in visualizing the skeletal manifestations of renal osteodystrophy. Tracer uptake in sites of subchondral resorption and brown tumors suggests that integrin expression accompanies hyperparathyroidism-driven bone remodeling. Future studies should explore ^{68}Ga-Trivehexin PET/CT as a noninvasive imaging biomarker for the assessment and monitoring of bone disease in CKD patients.

Aim/Introduction: Targeted therapy development is limited by the scarcity of actionable cancer targets, particularly for heterogeneous solid tumors. Onco-fetal signatures, shared by embryonic and cancer cells but absent in healthy adult tissues, offer a selective targeting strategy. One such signature is onco-fetal chondroitin sulfate (ofCS), which contributes to tumor immune evasion and

dissemination. Recently, we developed two antibodies (F8 and C9, collectively termed Vartumabs) targeting distinct ofCS variants[1]. This phase 0 PET imaging trial aims to evaluate the safety and biodistribution of each of the two Vartumabs in patients with various solid tumors. ***Materials and Methods:*** The Vartumabs were produced as single chain variable fragments (scFv) with a genetically fused albumin binding domain for half-life extension and labelled with DFO-N-Suc-89-Zirconium. Following a single intravenous microdose administration of one of the Vartumabs (1mg, 15 MBq), long axial field of view PET/CT images were obtained at day 0, 1, and 3 post-injection (p.i.). Standard uptake values (SUV) of volumes of interest were compared to blood pool to calculate tumor/organ-to-background ratios (TBR/OBR) over time using Siemens Syngo.via VB80 software. The occurrence and severity of adverse events were used to assess safety. At the time of submission, four patients were enrolled in this prospective monocentre study (NCT06645808). ***Results:*** All injections were well tolerated, and no related adverse events were reported for both compounds. For Vartumab C9, tumor uptake was observed on day 3 p.i. in 2/2 patients dosed (mean SUVpeak 7.26, mean TBR 1.83). Indications included non-small cell lung carcinoma (NSCLC) and rectal carcinoma. Off-target binding was observed in testes (mean SUVpeak 9.38, mean OBR 2.37) and adrenal glands (mean SUVpeak 8.97, mean OBR 2.27) for both patients. For Vartumab F8, no visual tumor uptake was observed in one patient with esophageal carcinoma. For another patient with rectal carcinoma, assessment of tumor uptake was not possible due to hepatobiliary elimination. No off-target binding was observed in either of the two subjects. ***Conclusion:*** These preliminary results suggest that both radiolabelled Vartumabs can be safely administered. Vartumab C9 targets diverse solid tumors, even in non-stratified patients, with acceptable off-target binding. For Vartumab F8 the optimal patient population is yet to be identified, but the lack of off-target binding is promising. Further patient inclusion is required to draw more robust conclusions. The findings of this study will guide lead-compound selection and indication prioritization for subsequent clinical trials with therapeutic derivatives. ***References:*** Vidal-Calvo et al., (2024). Nature Communications.

Theranostic Application of Radiolabeled HER2-Targeting Single-Domain Antibodies (RAD202) in Preclinical Setting

B. Altunay[1], *A. Florea*[1], *A. Vogg*[1], *L. Schäfer*[1], *A. Morgenroth*[1], *L. K. Meszaros*[2], *S. Lütje*[1], *F. M. Mottaghy*[1,3];
[1]*Uniklinik RWTH Aachen, Aachen, GERMANY,* [2]*Radiopharm Theranostics Ltd, Victoria, AUSTRALIA,* [3]*Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, Maastricht, NETHERLANDS.*

Aim/Introduction: Human epidermal growth factor receptor 2 (HER2), is overexpressed in various cancers and represents a good target for monoclonal antibodies as vehicles for specific drug delivery. A ^{99m}Tc-labeled HER2-specific single-domain antibody (sdAb), ^{99m}Tc-NM-02, also known as RAD201, was shown to be safe for use in humans in our previous study and is a promising non-invasive tool to evaluate the HER2 status in metastatic (breast) cancer [1]. Here, the same sdAb (with and without HIS-tag) was labeled via DOTA-GA with ^{68}Ga and ^{177}Lu to investigate biodistribution and therapeutic effect in HER2-positive xenografts. ***Materials and Methods:*** Rj:ATHYM-Foxn1nu/nu mice with SKOV-3 HER2-positive tumors received 10 MBq of ^{68}Ga-labeled HIS-tagged (^{68}Ga-RAD202) sdAb and were scanned by PET/CT immediately and three hours post-injection. The following day, these mice received the radioactive sdAb without HIStag (^{68}Ga-RAD202.1) and were scanned again. A control group was injected with an additional excess of unlabeled ('cold') sdAb alongside the radiolabeled compound. In the therapy study, mice were treated with either four doses of 13.5 MBq of ^{177}Lulabeled sdAb (^{177}Lu-RAD202.1, without HIS-tag) administered at weekly intervals, or a single dose of 54 MBq. For kidney protection, all mice received 0.05mL Gelofusine® three minutes before tracer injection. ***Results:*** The ^{68}Ga-RAD202.1 and ^{177}Lu-RAD202.1 tracers were synthesized with high radiochemical purity (99.8 ± 0.5% and 99.8 ± 0.3%, respectively). PET/CT imaging with ^{68}Ga-RAD202.1 revealed specific tumor accumulation and low uptake in non-target organs, except for the excretory organs (kidney and bladder). Co-administration of unlabeled sdAbs reduced tumor uptake by 65% for the HIS-tagged variant and by 33% for the untagged tracer. Treatment with ^{177}Lu-labeled sdAbs prolonged the median survival time about 34 d in the single dose group and 26 d in the fractionated therapy group compared to the respective control group treated with unlabeled sdAb-chelator conjugates. Unlike the single dose treatment, fractionated therapy group did not reach 200% of the initial tumor volume by the end of the observation period and exhibited significantly lower tumor volumes throughout the study. ***Conclusion:*** ^{68}Ga-labeled sdAbs showed rapid tumor uptake, enabling PET imaging with a high tumor-to-background contrast. Therapy studies have been performed, with the HIS-tag-free sdAb due to its reduced renal retention. Both treatment regimens were well tolerated. However, fractionated therapy demonstrated greater efficacy in suppressing tumor growth compared to the single dose approach. ***References:***

OP-762

Therapeutic potential of first-in-class claudin 18.2-targeted radiolabeled nanobody [^{177}Lu]Lu-DOTA-SNA014 in gastric cancer

Y. Wang[1], *M. Zheng*[1], *Q. Liu*[1], *H. Mou*[1], *S. Ge*[1], *B. Zhang*[1], *C. Wei*[2], *S. Qin*[1], *T. Xu*[2], *L. Miao*[1];
[1]*First Affiliated Hospital of Soochow University, Suzhou, CHINA,* [2]*Smart-Nuclide Biotech, Suzhou, CHINA.*

Aim/Introduction: Gastric cancer (GC) is the fifth most common and third leading cause of cancer death worldwide. The upregulation of claudin 18.2 has been identified as the result of the malignant transformation of gastric epithelial tissue. Thus, claudin 18.2 becomes a highly selective target for gastric cancer theranostic. Compared with other claudin 18.2-targeting nanobody-based PET imaging agent our previous study showed that [^{68}Ga]Ga-NODAGA-SNA014 had high tumor uptake and low kidney uptake. These promising results prompt us to develop [^{177}Lu]Lu-DOTA-SNA014 for gastric cancer therapy. ***Materials and Methods:*** SNA014 is a nanobody derived from alpaca immunization and screened out by phage display. SNA014 was conjugated with DOTA to enable efficient ^{177}Lu labeling. The binding property of [^{177}Lu]Lu-DOTA-SNA014 was characterized by saturation binding assay on claudin 18.2-expressing AGS GC cells. Biodistribution properties and competitive blocking effects were determined by ex vivo biodistribution studies on AGS 18.2-bearing NDG mice. The therapeutic efficacy was evaluated on SNU-601 GC cells-bearing nude mice by monitoring the tumor growth and body weight over time up to 21 days. All mice for the therapy studies were injected with gelofusine as renal protection while the injection of [^{177}Lu]Lu-DOTA-SNA014. ***Results:*** Radiolabeling of DOTA-SNA014 with ^{177}Lu resulted in radiochemical yields >99 %. The saturable specific binding of [^{177}Lu]Lu-DOTA-SNA014 indicated a dissociation constant of 1.51 nM. The ex vivo biodistribution studies showed the tumor, kidney and stomach uptake of [^{177}Lu]Lu-DOTA-SNA014 were of 18.42 ± 1.99, 13.86 ± 2.59 and 86.02 ± 4.54 %ID/g at 2 h postinjection, respectively. The tumor uptake gradually decreased from 2 h to 96 h postinjection, with minimum tumor uptake of 5.92 ± 2.26%ID/g at 96h postinjection. Gelofusine can effectively reduce 53% of kidney uptake to 6.64 %ID/g at 1h postinjection.

Competitive blocking assay suggested DOTA-SNA014 was able to block uptake of [^{177}Lu]Lu-DOTA-SNA014 at stomach in a dose-dependent fashion, ranging from 1 to 120 µg, without dramatically altering the tumor and kidney uptake. Tumor regression was achieved without negatively affecting body weight, suggesting a favorable safety profile of [^{177}Lu]Lu-DOTA-SNA014. ***Conclusion:*** We developed a novel claudin 18.2-targeted nanobody-based [^{177}Lu]Lu-DOTA-SNA014 for gastric cancer therapy. The [^{177}Lu]Lu-DOTA-SNA014 showed specific in vitro binding to claudin 18.2, favorable ex vivo biodistribution properties in terms of tumor, kidney and stomach uptake, and safety profile based on radiotherapy studies, which prompt us to further develop α radionuclide-labeled DOTA-SNA014-based radiopharmaceuticals.

FL802, a B7-H3-targeting nanobody radioligand precursor, developed using UniRDC™ discovery platform

X. Wang, *M. Jheng, P. Li, D. Li, Y. Xie, B. Guo, R. Hu, F. Liu;*
Full-Life Technologies Limited, Shanghai, CHINA.

Aim/Introduction: B7-H3 (CD276), a type I transmembrane protein belonging to the B7 immune checkpoint family, is frequently overexpressed in various solid tumors, such as lung, esophageal, prostate, and breast cancers. While B7-H3-targeting antibody-drug conjugates (ADCs) have shown promising early clinical efficacy, radionuclide drug conjugates (RDCs) present a distinct therapeutic advantage by enabling both treatment and tumor imaging. Among potential targeting moieties, the variable heavy domain of the heavy chain (VHH) is a highly attractive binder; however, a major limitation of VHH-based RDCs is their suboptimal biodistribution, characterized by low tumor uptake and high kidney accumulation, hindering their therapeutic application. Our proprietary UniRDCTM discovery platform has been proven to be capable of effectively improving the biodistribution profiles of such modality and here we present our VHH-based B7-H3 targeting RDC precursor discovered by UniRDCTM. ***Materials and Methods:*** The binding affinity and cross-reactivity of FL-802 was evaluated by in vitro protein- and cell-based binding assays. FL-802 was labeled with ^{177}Lu and the radiochemical purity (RCP) of radiolabeled molecule was determined by radio thin-layer chromatography and radio high-performance liquid chromatography. The in vivo imaging, ex vivo biodistribution and efficacy profiles of [^{177}Lu]Lu-FL-802 were assessed in B7-H3 positive cell grafted mouse models. ***Results:*** In vitro assays demonstrated that FL802 bound with subnanomolar affinity to human B7-H3 and exhibited cross-reactivity with mouse and cynomolgus monkey B7-H3. FL802 was successfully labelled with ^{177}Lu, achieving a high radiochemical purity of>98% and a molar activity of 18.5 MBq/nmol. In vivo studies in B7-H3-positive tumor-bearing mice revealed a favorable biodistribution profile via SPECT/CT imaging and ex vivo cut-and-count analysis. SPECT/CT (11.1 MBq) showed intense tumor uptake, significantly surpassing all normal organs at 24 and 72 hours. Biodistribution studies confirmed high tumor accumulation (>30% ID/g) and an improved tumor-to-kidney ratio (T/K >2.0 at 24 h) - a dramatic enhancement over the unmodified VHH (2.3% ID/g, T/K <0.01). Therapeutic efficacy was assessed at the dose of 11.1 MBq (Q2W X2). Treatment was well tolerated, with all animals achieving complete tumor remission. ***Conclusion:*** The preclinical data collectively support FL802 as a promising B7-H3 targeting RDC precursor which warrants its further development as a radiopharmaceutical for the diagnosis and treatment for B7-H3-positive tumors. In addition, this work further validates the effectiveness of UniRDC™ discovery platform in the optimization of VHH-based RDCs, and we anticipate that UniRDC™ can be broadly applied to other small protein-based RDCs, such as affibodies and DARPins, to improve their therapeutic potential.

OP-764

Head-to-head comparison of ABD-fused Affibody Molecule labelled with Lu-177 and Tb-161

Y. Liu[1], *I. Zelepukin*[1], *A. Orlova*[1], *M. Konijnenberg*[2], *F. Y. Frejd*[3], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Erasmus MC, Rotterdam, NETHERLANDS,* [3]*Affibody AB, Solna, SWEDEN.*

Aim/Introduction: Engineered scaffold proteins Affibody molecules have shown efficient targeting of HER2-expressing cancers in clinical trials. We have demonstrated earlier that ^{177}Lu-labelled HER2-binding Affibody molecule fused to albumin-binding domain (ABD) enables specific targeting of HER2-expressing human xenografts and has a strong anti-tumour efficacy in preclinical radionuclide therapy. Tb-161 emits not only beta-particles but also multiple conversion and Auger electrons. This might be an advantage for deactivation of small subclinical metastases. In this preclinical study, the targeting properties of the ABD-fused Affibody molecule (denoted as PEP48937) labelled with Lu-177 and Tb-161 were compared both in vitro and in vivo. ***Materials and Methods:*** For labelling with Lu-177 and Tb-161, the DOTA chelator was coupled to a unique C-terminal cysteine of PEP48937 using thiol-directed conjugation. In vitro evaluation of binding affinity, specificity, and cellular processing was performed using HER2-expressing SKOV3 and BT474 cells. Triple-negative breast cancer cell line MDA-MB-468 was used as a negative control both in vitro and in vivo. Biodistribution of ^{177}Lu- and ^{161}Tb-labelled PEP48937 was directly compared in nude mice bearing SKOV3 xenografts (4, 24, 48, 72, 168 and 336 h). Based on dosimetry evaluation and tumour control probability prediction, animals were treated with [^{161}Tb]Tb-PEP48937 (2x10 MBq) or [^{177}Lu]Lu-PEP48937 (2x12 MBq). ***Results:*** The labelling of PEP48937 with Lu-177 and Tb-161 (sodium acetate, pH 6.5, 65°C) provided a radiochemical yield exceeding 99%. The binding of both [^{177}Lu]Lu-PEP48937 and [^{161}Tb]Tb-PEP48937 to HER2-expressing cells was saturable (i.e. specific) in vitro. The binding to HER2-negative MDA-MB-468 was negligible. The internalisation of [^{161}Tb]Tb-PEP48937 was slightly quicker than the internalization of [^{177}Lu]Lu-PEP48937. There was no difference in the biodistribution of the compounds. The peak tumour uptake (48 h) was 43±13%ID/g for [^{161}Tb]Tb-PEP48937 and 31±4%ID/g for [^{177}Lu]Lu-PEP48937. The uptakes in HER2-negative MDA-MB-468 xenografts were significantly ($p< 0.05$) lower at 48 h, 5±1%ID/g and 6±3%ID/g, for [^{161}Tb]Tb-PEP48937 and [^{177}Lu]Lu-PEP48937, respectively. In the ongoing experimental therapy, [^{161}Tb]Tb-PEP48937 showed a tendency to higher anti-tumour efficacy than [^{177}Lu]Lu-PEP48937 but also to higher hematologic toxicity. At the time of submission of this abstract, all animals treated with the vehicle had been euthanised because of tumour overgrowth or ulceration (median survival 35 days). The median survival was not reached in groups treated with [^{177}Lu]Lu-PEP48937 and [^{161}Tb]Tb-PEP48937. ***Conclusion:*** The replacement of Lu-177 by Tb-161 has no observable effect on the biodistribution properties of PEP48937. Optimisation of injected activity of [^{161}Tb]Tb-PEP48937 might provide a HER2-targeting agent with increased efficiency against small HER2-expressing tumours.

OP-765

Radiolabeled engineered HER2 antibodies for cancer theranostics

X. Chen, *X. Wen, B. Li, X. Wu, J. Zhang;*
National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Human epidermal growth factor receptor 2 (HER2) is overexpressed in some solid tumors, including breast cancer and gastric cancer, and has become an important target for cancer theranostics. This study aimed to develop an engineered antibody by replacing the Fc part of the mAb, LNCAb103, with reduced molecular weight and circulation half-life, radiolabeled

with ^{177}Lu for the theranostic application in HER2-positive malignant tumors. ***Materials and Methods:*** LNCAb103 was developed and radiolabeled with ^{177}Lu. HER2 binding affinity and targeting specificity were evaluated at the protein and cell levels. SPECT/CT imaging and preclinical pharmacokinetics assessment of ^{177}Lu-LNCAb103 were conducted in HER2-positive xenograft models and normal mice to investigate tumor uptake and ex vivo biodistribution. In addition, the anti-tumor efficacy evaluation of ^{177}Lu-LNCAb103 was assessed at different doses, and compared with ^{177}Lu-traustuzumab. ***Results:*** ^{177}Lu-LNCAb103 demonstrated high radiochemical purity and good stability over time, and showed a favorable HER2 binding affinity and targeting specificity in vitro. SPECT/CT imaging of ^{177}Lu-LNCAb103 exhibited remarkably high tumor uptake and retention up to 96 h. Compared with ^{177}Lu-traustuzumab, ^{177}Lu-LNCAb103 presented a higher tumor-to-background ratio and lower blood uptake. The distribution half-life (1.43 ± 1.30 h vs. 4.20 ± 1.02 h) and elimination half-life (19.07 ± 3.01 h vs. 225.04 ± 67.47 h) of ^{177}Lu-LNCAb103 were significantly shorter than those of ^{177}Lu-traustuzumab. In therapeutic studies, administration of 9.25 and 18.5 MBq of ^{177}Lu-LNCAb103 significantly inhibited NCI-N87 tumor growth without notable loss of body weight. In contrast, although ^{177}Lu-traustuzumab initially inhibited tumor growth, it led to body weight loss and eventual death of mice due to severe toxicity within 10 days post-treatment. ***Conclusion:*** ^{177}Lu-LNCAb103 demonstrated specific HER2 targeting in vitro and in vivo, along with high tumor uptake, low background signals, a shorter blood elimination half-life, and improved safety compared to ^{177}Lu-traustuzumab. These results suggest that ^{177}Lu-LNCAb103 holds potential as a promising agent for the theranostic treatment of HER2-positive cancers.

OP-766

Affibody-masked cetuximab prodrug for protease-dependent tumor targeting: a novel strategy to enhance specificity and minimize toxicity in EGFR-directed therapies

A. Bitzios[1], *A. Mestre Borras*[2], *H. Mehari*[2], *I. Zelepukin*[1], *M. Ud-Din*[1], *T. Xu*[1], *S. Li*[1], *S. Ståhl*[2], *J. Löfblom*[2], *A. Orlova*[1], *V. Tolmachev*[1], *A. Vorobyeva*[1];
[1]*Uppsala Universitet, Uppsala, SWEDEN,* [2]*KTH Universitet, Stockholm, SWEDEN.*

Aim/Introduction: Monoclonal antibodies enable selective tumor targeting but may induce off-target toxicity when the target antigen is present in normal tissues. Cetuximab, which targets epidermal growth factor receptor (EGFR), often causes skin rashes and gastrointestinal side effects due to EGFR expression in healthy epithelium. This study aims to develop and evaluate a novel affibody-masked cetuximab prodrug that enables matriptase-dependent tumor-specific activation, thereby improving therapeutic specificity and minimizing off-target toxicity in EGFR-targeted cancer therapy. ***Materials and Methods:*** Affibody masking domains were engineered to selectively bind and block the EGFR-binding paratope of cetuximab. The most effective affibody was genetically fused to cetuximab's heavy chains to generate a prodrug. Cetuximab and its affibody-masked prodrug were conjugated to CHX-A"-DTPA and radiolabeled with [^{111}In]$InCl_3$. Binding specificity of both compounds were assessed in vitro using EGFR-overexpressing FaDu (matriptase-negative) and H292 (matriptase-positive) monolayer cell culture and 3D spheroids. Conditional activation and binding to FaDu cells were evaluated after pre-treatment of both compounds with matriptase. In vivo biodistribution was studied in Balb/c nu/nu mice bearing FaDu or H292 xenografts, with tumor uptake measured 72 hours post-injection. ***Results:*** Cetuximab and its prodrug were radiolabeled and purified with over 96% radiochemical purity. The affibody-masked cetuximab prodrug showed 400-fold difference in IC_{50} between masked and unmasked states in vitro. Radiolabeled prodrug exhibited 15- to 17-fold lower binding in monolayer cultures compared to unmodified cetuximab, confirming effective masking. Matriptase pretreatment of [^{111}In]In-prodrug increased its binding to the cells. In H292 spheroids, the prodrug showed twice higher cell-bound activity relative to FaDu, indicating protease-specific activation. The in vivo results showed a 68% reduction of the EGFR-binding capacity of the [^{111}In]In-labeled prodrug in comparison to the parental antibody [^{111}In]In-cetuximab, and confirmed enhanced tumor selectivity of prodrug, with higher uptake in H292 xenografts (57±8%) than in FaDu (32±11%) xenografts. ***Conclusion:*** This study demonstrated for the first time the feasibility of using affibody domains to reversibly mask the paratope of a therapeutic antibody cetuximab, enabling protease-dependent activation in the tumor microenvironment. The cetuximab prodrug showed improved specificity and tumor retention, supporting the potential of this approach for the development of safer and more efficacious antibody-based cancer therapies.

Immunomodulation of the tumour microenvironment by 225Ac-hGirentuximab in a syngeneic murine tumor mode

R. LADJOHOUNLOU[1], *W. J. Jin*[1], *P. Clark*[1], *M. Bio Idrissou*[1], *B. Bednarz*[1], *R. Hernandez*[1], *M. P. Wheatcroft*[2], *K. Twumasi-Boateng*[2], *Z. S. Morris*[1];
[1]*University of Wisconsin School of Medicine and Public Health, Madison, WI, UNITED STATES OF AMERICA,* [2]*Telix Pharmaceuticals Limited, Melbourne, AUSTRALIA.*

Aim/Introduction: Radiation from radiopharmaceuticals can trigger inflammation that initiates immune responses. In cancer tissue these mechanisms can prematurely shut off the anti-tumor immune response. Among the drivers of these effects are the expression of immune checkpoint receptors/ligands on the surface of immune cells, stroma, and tumor cells in the tumor microenvironment. These can potentially be targeted using immune checkpoint inhibitors. While prior studies have demonstrated potential for therapeutic benefit with these approaches using antiPD-1/PD-L1 or anti-CTLA-4, few studies have investigated the role of other immune checkpoint receptors/ligand interactions in potentiating anti-tumor immunity following radiopharmaceutical therapies (RPT). Here, we evaluate the mode of action of Girentuximab, a hCAIX-targeting antibody when combined with alpha particle emitter Actinium 225 (Ac-225). ***Materials and Methods:*** Mice bearing CT26-hCAIX tumors were randomized to receive different activities of Ac-225 (0 - 18.5 kBq) on day 0. On days 4, 7 and 14 post treatment, mice were euthanized and blood and tumors collected. Complete blood count (CBC) analysis was performed on blood from control and therapy mice. From each tumor, RNA was isolated, and the level of different genes implicated in immune checkpoint interaction evaluated by RT-qPCR. To also evaluate the efficacy of 225Ac-hGirentuximab monotherapy, additional mice were monitored for tumor growth and survival. ***Results:*** On days 4 and 7, CBC analysis showed transient toxicity of 225Ac-hGirentuximab in treated mice compared to untreated controls with immune cells recovery at d14. For gene expression analysis, we observed a significant upregulation of classical immune checkpoint inhibitors PD-1/PD-L1 and CTLA-4 after RPT with 225Ac-hGirentuximab compared to non-irradiated control. We also showed the activation of TIM-3, LAG-3, and genes implicated in NK cells activation (NKG2D) or inhibitory (KLRC1 and his ligand Qa-1b). On the contrary, the expression of the TIGIT and VISTA genes was not affected in the treated mice. The highest dose (18.5 kBq) is the most efficient to activate these genes mainly on days 7 and 14 following the treatment. The therapy study also demonstrated a dose-dependent antitumor efficacy. ***Conclusion:*** Preliminary data indicate that 225Ac-hGirentuximab triggers the

upregulation of many genes encoding checkpoint receptor/ligands. Understanding these modulations may be critical to safely and effectively associate RPT and immunotherapies to enhance anti-tumor immunity.

OP-768

Therapeutic Superiority of ^{131}I-aGPC3-scFv in Hepatocellular Carcinoma: Biodistribution and Efficacy

W. Hu, *M. Li, Z. Lin, X. Zhang, X. Cai, D. Jiang, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science, Wuhan, CHINA.

Aim/Introduction: Glypican-3 (GPC3) is a promising therapeutic target for hepatocellular carcinoma (HCC) due to its high tumor-specific expression. Our team previously developed a proprietary anti-GPC3 antibody, which is currently undergoing clinical translation for HCC diagnosis. To advance a theranostic strategy, this study evaluated the biodistribution and therapeutic potential of ^{131}I-labeled GPC3-targeting antibody fragments (scFv, Fab, mAb) in Hep3B subcutaneous tumor models, with a focus on tumor-to-kidney ratios, antitumor efficacy, and systemic toxicity. ***Materials and Methods:*** ^{131}I-labeled anti-GPC3 scFv, Fab, and mAb were synthesized and administered to Hep3B tumor-bearing mice. Thyroid uptake was blocked via oral potassium iodide. Biodistribution was assessed at 2, 6, 24 hours (all agents) and extended to 3 and 5 days for ^{131}I-aGPC3-mAb (n=3/group). Tumor-to-kidney ratios were calculated to assess pharmacokinetics. Based on these results, scFv and mAb were selected for therapy. Mice were randomized into PBS, ^{131}I-aGPC3-scFv (four doses of 37 MBq each, administered twice weekly), and ^{131}I-aGPC3-mAb (single dose of 37 MBq) groups (n=6/group). Tumor volume and body weight were monitored every two days until endpoint (tumor > 1000 mm^3). Toxicity was evaluated via hematology and histopathology. ***Results:*** ^{131}I-aGPC3-scFv and ^{131}I-aGPC3-Fab exhibited rapid tumor uptake (8.7 ± 0.8 %ID/g of scFv at 2 h; 3.9 ± 0.4 %ID/g of Fab at 2 h) and fast clearance (1.0 ± 0.3 %ID/g of scFv at 24 h; 0.2 ± 0.3 %ID/g of Fab at 24 h), while ^{131}I-aGPC3-mAb showed relative delayed accumulation (3.2 ± 0.8 %ID/g at 2 h) with sustained retention (3.9 ± 0.5 %ID/g at 24 h; 0.7± 0.1 %ID/g at 3D). Higher tumor uptake and progressively increased tumor-to-kidney ratios (0.1 at 2 h; 0.3 at 6 h; 0.4 at 24 h) indicate that ^{131}I-aGPC3-scFv is more valuable for subsequent treatment than ^{131}I-aGPC3-Fab. In therapeutic trials, ^{131}I-aGPC3-scFv achieved 97% tumor growth inhibition value by day 14 versus PBS ($p<0.001$), surpassing ^{131}I-aGPC3-mAb. The ^{131}I-aGPC3-scFv group maintained stable body weight and normal hematological parameters, whereas mAb-treated mice exhibited weight loss and progressive mortality prior to day 14, indicative of systemic toxicity. Histological analysis confirmed minimal organ damage in the ^{131}I-aGPC3-scFv group. Notably, no tumor recurrence was observed in ^{131}I-aGPC3-scFv treated mice two weeks post-therapy. ***Conclusion:*** ^{131}I-aGPC3-scFv demonstrated superior tumor targeting, efficacy, and safety compared to ^{131}I-aGPC3-mAb and ^{131}I-aGPC3-Fab in GPC3-high HCC models. Its favorable pharmacokinetics and safety profile support further clinical translation for HCC radioimmunotherapy.

Cutting Edge Science Track - TROP Session - AI Committee: Kinetic Modeling and Parametric Imaging

OP-769

Kinetic Model Selection for Motion-Compensated Whole-Body PET Imaging

J. Rosenskjold Madsen[1,2], *A. H. Dias*[1], *L. C. Gormsen*[1,2], *A. B. Rodell*[3], *D. Pigg*[4], *J. Schaefferkoetter*[4], *O. L. Munk*[1,2];
[1]Department of Nuclear Medicine & PET, Aarhus University Hospital, Aarhus, DENMARK, [2]Department of Clinical Medicine, Aarhus University, Aarhus, DENMARK, [3]Siemens Healthcare A/S, Aarhus, DENMARK, [4]Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Dynamic whole-body (D-WB) PET enables quantification using kinetic modelling, but physiological interpretation requires model selection that accounts for tracer- and tissue-specific kinetics. In addition, parametric imaging is sensitive to patient motion and inaccurate attenuation correction (AC). This study evaluates a new approach for kinetic model selection, using a reversible Delayed Logan model [1] and an irreversible Patlak model, based on motion-compensated D-WB PET data. ***Materials and Methods:*** Thirty patients underwent a 70-minute D-WB PET scan using a short-axial FOV PET/CT (26.3cm FOV, 214ps TOF): [^{18}F]PSMA-1007 (N=10), [^{68}Ga]Ga-PSMA-11 (N=10), and [^{18}F]FDG (N=10). A deep-learning model was used for elastic registration of the original CT [2] to each late non-attenuation corrected (NAC) PET frame (50-70 min for [^{18}F]FDG and [^{18}F]PSMA, and 40-70 min for [^{68}Ga]Ga-PSMA), generating a series of warped CTs (WarpCTs) with corresponding deformation vector fields (DVFs). The WarpCTs were used to reconstruct each PET frame with optimal attenuation- and scatter correction. Afterwards, the DVFs were inverted and applied to each PET frame to warp them to the original CT, ensuring motion compensation throughout the PET series. WB distribution volume (V_t) and net uptake rate (K_i) images were generated by voxel-wise fitting of the late time-activity curves using the Delayed Logan Model and the Patlak Model, using image-derived blood input functions. Model selection was based on Akaike information criterion (AIC) rescaled to $\Delta_i = AIC_i - AIC_{min}$, forcing the best model to have $\Delta=0$ [3]. Model preference was evaluated using Δ-maps. ***Results:*** Motion compensation of D-WB PET series resulted in parametric images with fewer artifacts and improved WB Δ-maps for model selection. [^{18}F]-PSMA-1007 Δ-maps exhibited clear WB irreversible kinetics (K_i image preferred), and [^{68}Ga]Ga-PSMA-11 Δ-maps exhibited clear reversible kinetics (V_t image preferred) in most tissues. For [^{18}F]FDG, the Δ-maps were not as consistent, being less uniform and more noisy, but indicated irreversible behaviour in most organs such as brain, myocardium and kidney, and reversible kinetics in liver. Some tissues revealed mixed model preference, likely reflecting a complex kinetic behaviour or sensitivity to image noise. These findings suggest that a single kinetic model does not always fully capture the kinetics across all tissues, highlighting the need for organ-specific model selection for WB PET parametric imaging. ***Conclusion:*** Kinetic model selection based on motion-compensated Δ-maps enhances quantitative PET parametric imaging. ***References:*** [1] Madsen JR. Abstract OP-802, EJNMMI (2024). [2] Schaefferkoetter J et al. EJNMMI (2023)50:2292-2304. [3] Burnham KP & Anderson DR, SMR(2004)33(2).

OP-770

Improving AI-Generated Parametric Image Estimation with Accurate AI-Assisted Input Function Modelling in Dynamic PET

K. Tehlan[1,2], *V. Langer*[3], *A. Rominger*[4], *K. Shi*[4], *T. Wendler*[1,2], *KT and VL are first authors with equal contribution;*
[1]University Hospital Augsburg, Augsburg, GERMANY, [2]Technical University of Munich, Munich, GERMANY, [3]University of Augsburg, Augsburg, GERMANY, [4]Inselspital, Bern, SWITZERLAND.

Aim/Introduction: Kinetic modelling in dynamic [^{18}F]FDG PET often relies on a single image-derived input function (IDIF) from either the aorta or the left ventricle overlooking organ-specific vascular contributions, such as those from the portal vein, pulmonary artery, or ureters and leading to inaccuracies in parameter estimation, particularly for organs with dual or alternative blood supplies.Our objective was to enhance the accuracy of parametric imaging by integrating a multi-input modelling framework - incorporating anatomically and physiologically relevant IDIFs [1] - with an AI-assisted parametric image generation approach previously proposed [2]. ***Materials and Methods:*** Dynamic PET/CT data from 20 patients were analyzed. IDIFs were extracted from the aorta, portal vein, pulmonary artery, and ureters using multi-organ segmentation [3], including a custom pipeline developed for ureter segmentation [1]. A modified two-tissue compartment model was employed, incorporating these multiple IDIFs in accordance with organ-specific vascular supply. Kinetic parameter estimation was conducted using an adapted model based on [2]. In addition to conventional microparameters (K1, k2, k3, and Vb), the new model included parameters to quantify the contribution of each of the four IDIFs to the blood input. The AI model was trained and tested on data from thirteen and seven patients respectively. ***Results:*** The proposed multi-input modeling approach significantly improved kinetic parameter estimation compared to traditional single-input methods, as measured by mean squared error (MSE) on the reconstructed time-activity curves, in the liver (77.3% MSE, p=0.031) and in the kidneys (MSE 58.2%, p=0.031) relative to the single-input model. However, improvements in the bladder were not statistically significant, and results for the lungs were inconsistent (-46.7% MSE, p=0.109).Across patients, liver voxels showed an aorta and portal vein IDIF contribution of 26.7±18.3% and 85.0±27.3% respectively. ***Conclusion:*** Incorporating organ-specific vascular inputs into the input function model enhances the physiological accuracy of kinetic parameter estimation in dynamic PET imaging in the liver and kidneys, and to a lesser extent, the bladder.The discrepancy observed in the lungs is likely due to insufficient temporal resolution to clearly differentiate between aortic and pulmonary artery contributions.The observed arterial and portal venous contributions for the liver support the physiological plausibility of the proposed approach. ***References:*** [1] Langer V. et al., arXiv:2504.17114, [2] De Benetti F, et al., Proceedings of MICCAI 2023, p. 290-9.[3] Wasserthal J, et al., Radiology: Artificial Intelligence. 2023 Sep;5(5):e230024.

Whole-Body Perfusion Imaging Using Dynamic ^{82}Rb PET with a Long Axial Field-of-View Scanner

M. Morini[1,2], *I. Brovedani*[1,2], *M. De Francisci*[2], *M. Castellaro*[2], *L. Mercolli*[1], *M. Veronese*[2,3], *A. Rominger*[1], *F. Caobelli*[1], *H. Sari*[1,4];
[1]Department of Nuclear Medicine, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Department of Information Engineering, University of Padova, Padova, ITALY, [3]Department of Neuroimaging, Kings College London, London, UNITED KINGDOM, [4]Siemens Healthineers International AG, Zurich, SWITZERLAND.

Aim/Introduction: Rubidium-82 (^{82}Rb) Chloride is widely used to assess myocardial blood flow in patients with suspected coronary artery disease (CAD). Long axial field-of-view (LAFOV) PET systems enable whole-body dynamic imaging, allowing simultaneous multi-organ perfusion assessment. This study aims to quantify multi-organ perfusion at rest and during stress using dynamic ^{82}Rb PET with tracer kinetic modelling and to preliminarily explore inter-organ regional correlations of the K_1 parameter under both conditions. ***Materials and Methods:*** Sixteen patients with suspected CAD underwent dynamic ^{82}Rb PET scans at rest and after pharmacologic stress with Regadenoson using a LAFOV PET scanner. List-mode PET data were acquired over 7 minutes following an intraveneous administration of 370 MBq ^{82}Rb. PET images were reconstructed into 35 dynamic frames (20×4, 4×10, 3×20, 8×30 s) using PSF-TOF reconstruction. Organ masks (lungs, kidneys, spleen, aorta, myocardium) were generated on CT images using TotalSegmentator (1) and refined with a PET-based clustering approach. Time-Activity Curves were extracted, and kinetic modelling was performed using 1-tissue compartment model with an image-derived input function (IDIF) from the descending aorta. Time-delay correction accounted for bolus arrival time differences. Paired Student's t-tests compared organ perfusion (K_1, mL/min/g) estimates between rest and stress, and inter-organ K_1 correlations were assessed using Pearson's coefficients. ***Results:*** Estimated time delays between the IDIF and organ tissue were −4.7 ± 2.9 s (left lung), −4.9 ± 2.8 s (right lung), 5.7 ± 2.4 s (left kidney), and 6.2 ± 2.0 s (right kidney). Pulmonary and splenic K_1 values showed no significant change after Regadenoson (0.18±0.06 to 0.19±0.10 mL/min/g, p=0.62; 1.23±0.42 to 1.31±0.45 mL/min/g, p=0.31). Only the myocardium showed a significant K_1 increase (1.17±0.28 to 1.91±1.52 mL/min/g, p<0.001) in stress. At rest, significant correlations were found between left-right lungs (r=0.62, p<0.05) and kidneys (r=0.84, p<0.001). Under stress, lung-kidney symmetry persisted, with additional significant correlations between lungs and myocardium (right lung: r=0.80, p<0.001; left lung: r=0.61, p<0.05). ***Conclusion:*** This study demonstrates the feasibility of whole-body dynamic perfusion imaging with ^{82}Rb using LAFOV PET. We report organ-specific K_1 values and illustrate the capacity of this approach to map perfusion across multiple systems simultaneously. Preliminary findings reveal strong left-right symmetry in lung and kidney perfusion and significant lung-myocardium correlations under stress, supporting the potential for systemic perfusion assessment. These results provide a foundation for future studies in larger cohorts. ***References:*** 1. Wasserthal, J, 2023, Radiology: Artificial Intelligence.

OP-772

Improvement of quantitative accuracy of ultra-short-duration parametric imaging with a long axial field-of-view PET/CT system

Q. Ye, *H. Zeng, G. Liang, E. Revilla, Y. Lu;*
United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: Parametric imaging using a population-based input function (PBIF) has demonstrated its feasibility in reducing the duration of dynamic acquisition. With the high sensitivity of long axial field-of-view (LAFOV) PET/CT systems, the dynamic scan duration has been shortened from 60-90 min to 20-30 min and even to 10 min. However, parametric images directly reconstructed from the short-duration data are prone to under convergence, which leads to overestimation of regions with low K_1 values. This study aims to improve the quantitative accuracy of ultra-short-duration parametric imaging by increasing the convergence rate. ***Materials and Methods:*** Simulation and clinical studies were performed with long-duration parametric imaging as reference. A 60-min dynamic PET scan was simulated for a brain phantom generated from a real patient data using two-tissue compartmental model (2TiC) and the patient's input function. Patlak Parametric images were reconstructed directly from list mode data using the nested algorithm. For 10-60 min (10×5 min) data, 10 nested iterations served as the reference, while for 45-

60 min (10×1.5 min) data, different numbers of nested iterations (10, 50, 100, 150, and 200) were evaluated. A 65-min whole-body dynamic ^{18}F-FDG (7.2 mCi) scan was performed on a subject (Male, 69 yrs, 70 kg) using a LAFOV PET/CT system. Indirect Patlak parametric imaging using image-derived input function (IDIF) for 10-65 min data was performed as the reference (referred to as 55-min data). Direct Patlak reconstructions with PBIF and various numbers of nested iterations were applied to the 55-65 min (10×1 min) data (referred to as 10-min data). Quantitative K_i assessment was performed for the regions of interest (ROI) including lung lesions, liver, spleen, grey matter, white matter, and muscle. ***Results:*** Using 10 nested iterations, the K_i image of brain phantom reconstructed from 45-60 min exhibited overestimation compared to that from 10-60 min. Increasing number of nested iterations reduced the quantitative difference while slightly increased the coefficients of variation (CoV). The K_i image reconstructed with 150 nested iterations showed comparable quantitative accuracy to the reference value. Similar results were found for clinical data. The K_i image reconstructed from 10-min data with 150 nested iterations showed similar K_i and smaller CoV values than that indirectly calculated from 55-min data. ***Conclusion:*** For ultra-short-duration parametric imaging, increased nested iterations accelerated convergence and improved quantitative accuracy. The K_i image reconstructed using only 10-min data and PBIF demonstrated comparable quantified and less noisy compared to that indirectly calculated from 55-min data.

Evaluation of Image-Derived Input Function Methods for Non-Invasive Kinetic Modelling of [18F]-Fluorodeprenyl-D2 in Alzheimer's Disease

T. Schmidt[1,2], *A. J. Zounek*[1], *T. Saller*[3], *S. Lindner*[1], *B. Kugelmann*[1], *Y. Beqqali*[1], *A. Zatcepin*[1,4], *S. Raju*[1], *L. Tagnin*[1], *G. N. Bischof*[5,6], *S. Ziegler*[7,1], *M. Brendel*[1,4,8], *L. Kaiser*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Physics, Ludwig Maximilians University, Munich, GERMANY,* [3]*Department of Anaesthesiology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [4]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY,* [5]*Multimodal Neuroimaging Group, Department of Nuclear Medicine, University Hospital Cologne, Cologne, GERMANY,* [6]*Life Molecular Imaging GmbH, Berlin, GERMANY,* [7]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY,* [8]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.*

Aim/Introduction: Pharmacokinetic modelling in PET is traditionally based on arterial input functions (AIF) or image derived input functions (IDIF). Due to the highly invasive nature of AIF, it is desirable to establish reliable, non-invasive IDIF derivation methods. The aim of this work was to identify an IDIF approach to substitute the AIF in kinetic modelling for the MAO-B tracer [^{18}F]-Fluorodeprenyl-D2 ([^{18}F]-DED). ***Materials and Methods:*** 9 Alzheimer's disease (AD) patients underwent a 60-minute dynamic PET scan after injection of [^{18}F]-DED. Automatic invasive arterial blood sampling was performed to obtain AIFs. Several IDIF extraction methods were applied for obtaining time-activity curves (TACs) from the internal carotid artery. All TACs were corrected for plasma fraction and metabolites based on manually drawn blood samples at 6 discrete timepoints per patient. For quantification, the brain was segmented into 9 different regions using PMOD Neuro. 1-tissue and 2-tissue compartment models (1TC, 2TC) and Logan plots were applied to the best IDIF methods according to AIF correlation and signal difference. Model quality was compared using the corrected Akaike information criterion (cAIC). Comparison of activity concentrations and kinetic parameters between IDIF and AIF was performed using Pearson correlation and median difference. ***Results:*** The highest correlation between IDIF and AIF was found for a vessel segmentation threshold of 40% (T40) of maximum signal ($r=0.89$, $p<0.001$), which led to an underestimation of AIF activity concentration by a factor of 5 and poor peak correlation. The lowest median signal differences were found when combining a 77.5% threshold approach for segmentation with a correction factor (T775C) derived from the activity concentration of a discrete sample taken after 30 minutes and applied to AIF as well as IDIF (peak: 0.16kBq/ml (1%), 5min: 0.08kBq/ml (7%), 30min: 0kBq/ml (0%), 40min: 0.05kBq/ml (4%)). This approach also underestimated the activity concentration. Based on cAIC, averaged over all patients and brain regions, the best fitting model for AIF was 2TC ($cAIC_{2TC,AIF}$=-358.18, $cAIC_{1TC,AIF}$=-239.53). For the kinetic parameters, the correlation between AIF and IDIF was highest for T775C ($r_{T40,VT}=0.80$, $r_{T775C,VT}=0.93$, $r_{T40,BPnd}=0.50$, $r_{T775C,BPnd}=0.53$, $p<0.001$ for all, $cAIC_{2TC,T40}$=-269.91, $cAIC_{2TC,T775C}$=-334.66). ***Conclusion:*** Considering the high correlation, the results indicate that IDIFs have a high potential in image quantification for [^{18}F]-DED. Even though, the IDIF underestimates the activity concentration. According to the modelling results, the T775C is better suited due to the high signal matching. Further investigations will include the evaluation of more IDIF approaches and of population-based or image-derived metabolite information.

OP-774

Parametric analysis of dynamic long axial field-of-view ^{18}F-FDG PET/CT studies

C. Smith, *G. J. C. Zwezerijnen, M. E. den Hollander, H. N. J. M. Greuter, N. R. Gerards, J. Zijlstra, C. Menke-van der Houven van Oordt, I. Bahce, M. Yaqub, R. Boellaard;*
Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: Large-axial field of view (LAFOV) PET/CT systems improve whole-body dynamic ^{18}F-FDG imaging, opening new possibilities for quantitative assessment of tracer kinetics. While a non-linear regression (NLR) remains the gold standard for obtaining K_i estimates, it is computationally intensive and sensitive to noise in case of parametric analysis, limiting routine use. Parametric analysis such as Patlak and Generalised Patlak (gPatlak) can be used as alternative. Additionally, parametric images can be obtained from the irreversible (BFM-I) and reversible (BFM-R) basis function method, providing parametric K_i and K_1. This study aims to compare the performance of these parametric methods against NLR in healthy organs and tumours using LAFOV PET/CT. ***Materials and Methods:*** Thirteen patients with malignancies underwent 70-minute dynamic ^{18}F-FDG PET/CT scans on a LAFOV PET/CT system after receiving an intravenous bolus injection of 3.0 MBq/kg. An image-derived input function (IDIF) of the ascending aorta was used. K_i from NLR was compared to those obtained by Patlak (t* = 30 min), gPatlak (t* = 10 min), BFM-I (t* = 0 min), and BFM-R (t* = 0 min). Additionally, we compared K_1 from the NLR to those obtained by BFM-I and BFM-R. K_i and K_1 values were extracted from the brain, liver, spleen, lung, kidney, upper leg muscle, and up to three tumour lesions per patient. ***Results:*** The regional K_i obtained by Patlak strongly correlated with the NLR across all organs (R= 0.96), outperforming gPatlak (R= 0.86). K_i from BFM-I demonstrated the strongest correlation (R= 0.97) and best regression fit with NLR-derived K_i. The K_i's of the liver, brain, and tumour lesions obtained by BFM-R also provided a good agreement for most data points but exhibited higher uncertainty levels than BFM-I. K_1 obtained by BFM-I and BFM-R showed weaker correlations compared to K_i. ***Conclusion:*** LAFOV PET/CT systems enabled whole-body dynamic ^{18}F-FDG PET imaging, offering new possibilities for quantitative assessment of metabolic activity. BFM-R and gPatlak account for reversible kinetics but at the cost of increased uncertainty levels. BFM-I is a strong alternative to Patlak, offering both K_i and K_1 for all organs, but it requires a full dynamic PET scan.

OP-775

Assessment of IDIF Quantification in PET Using 3D Printed Vessel Phantoms

Y. Beqqali[1,2], *A. Zounek*[1], *S. Raju*[1,2], *T. Schmidt*[1], *N. Albert*[1], *S. Ziegler*[1,3], *L. Kaiser*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Physics, Technical University of Munich, Munich, GERMANY,* [3]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY.*

Aim/Introduction: Quantitative pharmacokinetic modelling in dynamic PET relies on invasive blood sampling or a precise image-derived input function (IDIF). IDIFs are extracted with short early frames to capture the vascular peak, followed by longer frames as tissue uptake progresses. In small vessels, IDIF accuracy deteriorates because of partial volume effects (PVEs), noise, and segmentation uncertainty. We examined how vessel diameter, signal-to-background ratio (SBR), and frame duration jointly affect IDIF accuracy and assessed partial volume correction (PVC) strategies in a controlled phantom study. ***Materials and Methods:*** Six phantoms were 3D printed with [^{18}F]FDG activity using a masked-stereolithography (MSLA) printer with different diameter sizes (3, 4, 5, 6, 7 and 8 mm). The phantoms were placed in a water-filled container and imaged on a PET/CT with 5 mm FWHM point-spread function (PSF), then [^{18}F]FDG was added to the background water of the container to obtain five SBRs: ∞, 10, 7.5, 5, and 2.5. Different static frame durations were reconstructed. Three segmentation approaches were compared with and without PVC: true volume (TV) of the 3D models, region growing threshold (RG), and four hottest voxels per plane (VPP). The geometric transfer matrix (GTM) PVC algorithm provided in the PETPVC toolbox was used [1]. Image-based ground truth activity concentrations were determined using a large 3D printed reference volume. ***Results:*** Without PVC, activity was generally underestimated by 10-50%. TV+PETPVC approached 100% of the true activity for diameters ≥6 mm when SBR ≥7.5. RG+PETPVC achieved comparable accuracy only in the 8 mm vessel. VPP+PETPVC showed substantial overestimation (>300%). In early (10-30 s) frames with high SBR, TV+PETPVC slightly over-recovered for ≥6 mm vessels (107-116%) while the values for 3 mm fluctuated from 10% to 80%. In late (≥600 s) frames under different SBRs, ≥6 mm vessels approached 100%, while 3 mm vessel activity ranged from 50% to 80%. The increase in signal from PVC application was insufficient for small diameters <6 mm, with a recovery to only 50-80% for scans with background activity. ***Conclusion:*** PVC-based IDIF quantification proved reliable when the lumen exceeded the scanner PSF (≥ 6 mm, SBR ≥ 7, frame ≥ 600 s). Activity-embedded 3D printed vessels offer a geometry-accurate, reproducible ground truth, enabling the control of diameter variation, contrast, and frame length and to quantify PVC performance more precisely than with patient data or conventional phantoms. ***References:*** [1] Thomas BA. PETPVC: a toolbox for performing partial volume correction techniques in PET. Phys-Med-Biol. 2016.

Differential Binding Kinetics of [^{18}F]F-PSMA-1007 and [^{68}Ga]Ga-PSMA-11: Real-Time Analysis with Potential Impact on PSMA-PET Imaging Protocols

E. Dighero[1], *M. Riondato*[2], *P. Fossa*[3,4], *P. Pelucchi*[4], *B. Casini*[3], *P. D'Ursi*[4], *M. Ghelardoni*[2], *S. Losacco*[2], *L. Sofia*[2], *F. Vitale*[2], *S. Carta*[2], *S. Chiesa*[2], *C. Marini*[5], *G. Sambuceti*[6], *M. Bauckneht*[6];
[1]*Department of Experimental Medicine (DIMES), University of Genoa, Genoa, ITALY,* [2]*Nucelar Medicine Unit, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY,* [3]*Department of Pharmacy, Section of Medicinal Chemistry, School of Medical and Pharmaceutical Sciences, University of Genova, Genoa, ITALY,* [4]*Institute for Biomedical Technologies, National Research Council, Segrate, ITALY,* [5]*Institute of Molecular Biomimaging and Physiology, National Research Council, Milan, ITALY,* [6]*Department of Health Sciences, University of Genoa, Genoa, ITALY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) ligands are widely used for prostate cancer Positron Emission Tomography (PET) imaging. Despite targeting the same receptor, [^{18}F]F-PSMA-1007 and [^{68}Ga]Ga-PSMA-11 exhibit different biodistribution profiles. Clinical studies evaluating delayed imaging protocols with PSMA-targeted tracers have yielded inconclusive results regarding their impact on lesion detectability and image contrast. Furthermore, no direct head-to-head comparisons between [^{18}F]F-PSMA-1007 and [^{68}Ga]Ga-PSMA-11 in delayed imaging settings have been reported. We thus aimed to investigate the binding kinetics of these two tracers on PSMA-expressing cells using real-time interaction analysis. ***Materials and Methods:*** PC3-PIP (PSMA-positive) and PC3 (negative control) prostate cancer cells were seeded on Petri dishes ($3x10^5$ cells per sample) and analysed using a real-time kinetic system based on a rotating Petri dish principle with a stationary β-detector (LigandTracer, LT). After baseline measurement in medium, radioligands were added at increasing concentrations, followed by a dissociation phase in ligand-free medium. The association rate constants (k_{on}) and dissociation rate constants (k_{off}) were determined by fitting with the dedicated software TraceDrawer. To further investigate the reversibility of [^{18}F]F-PSMA-1007 binding, LT competition binding experiments were performed using different concentrations (100 nM to 200 µM) of the PSMA inhibitor 2-(phosphonomethyl) pentanedioic acid (2-PMPA), added with 1 nM [^{18}F]F-PSMA-1007. A separate kinetic uptake experiment was conducted using a gamma counter: $3x10^5$ PC3-PIP and PC3 cells cultured in 24-well plates were incubated with 500 µL 1 nM [^{18}F]F-PSMA-1007, the radioactivity in medium and cells was measured at 5-minute intervals for up to 120 minutes to track time-dependent uptake. ***Results:*** [^{68}Ga]Ga-PSMA-11 exhibited reversible binding, with $k_{on}=1.1\times10^6$ $M^{-1}s^{-1}$ and $k_{off}=2.5\times10^{-4}$ s^{-1}, corresponding to an equilibrium dissociation constant $K_D=2.3\times10^{-10}$ M. In contrast, [^{18}F]F-PSMA-1007 showed no detectable dissociation, suggesting irreversible or strongly retained binding ($k_{on}=3.9\times10^5$ $M^{-1}s^{-1}$, k_{off} fixed at 0). The presence of 2-PMPA reduced the rate of [^{18}F]F-PSMA-1007 uptake but did not result in a signal decrease, even at 200 µM. Gamma counter data confirmed time-dependent uptake, with over 50% of the initial activity linked to the cells at 120 minutes. ***Conclusion:*** [^{18}F]F-PSMA-1007 displays a markedly different binding profile compared to [^{68}Ga]Ga-PSMA-11, with apparent irreversible or highly retained association to PSMA-expressing cells. From a clinical perspective, these findings suggest that [^{18}F]F-PSMA-1007 could enable more stable and prolonged tumor retention in delayed imaging protocols. By contrast, delayed imaging with [^{68}Ga]Ga-PSMA-11 may be less advantageous due to its reversible binding kinetics, which could result in reduced tumor retention and lower lesion contrast over time.

OP-777

Explainable AI Enhances Lung Cancer Diagnosis Using Metabolic and Perfusion Features from Dynamic^{18}F-FDG PET/CT

T. Sun[1], *Z. Yao*[1], *Y. Wang*[2], *Y. Wu*[3], *M. Wang*[3], *Y. Liang*[2];
[1]*Chinese Academy of Sciences, Shenzhen, CHINA,* [2]*Shenzhen Cancer Hospital, Shenzhen, CHINA,* [3]*Henan Provincial People's Hospital, Zhengzhou, CHINA.*

Aim/Introduction: Dynamic ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET/CT imaging offers valuable information beyond static imaging in the evaluation of lung lesions. This study aimed to determine whether dynamic features—specifically metabolic and blood flow components derived from time activity curves (TACs)—can improve differentiation between benign and malignant pulmonary lesions. ***Materials and Methods:*** Dynamic ^{18}F-FDG PET/CT scans were obtained from 187 patients (mean age: 60.41 ± 11.01 years; 117 males). TACs at the primary lesion site were extracted and decomposed using kinetic modeling to separate metabolic and blood flow signals. From these components, features such as area under the curve (AUC), time-to-peak, and slope metrics were computed. A bagging classifier built on decision trees was

trained on these features to differentiate benign from malignant lesions. Model performance was evaluated using cross-validation and receiver operating characteristic (ROC) analysis. External testing was conducted on an independent dataset comprising 42 additional dynamic scans. Feature importance was assessed using SHapley Additive exPlanations (SHAP), and Cohen's effect size were used to compare the model's diagnostic performance against standard PET metrics, including SUVmax and the net influx rate (Ki). ***Results:*** The dynamic feature-based model effectively discriminated between benign and malignant lesions. In cross-validation, the model achieved an AUC of 0.89, sensitivity of 0.80, and specificity of 0.88, outperforming SUVmax (AUC = 0.79, $p < 0.001$) and Ki (AUC = 0.76, $p < 0.001$). On the independent test dataset, the model maintained high performance with an AUC of 0.86, compared to 0.72 (SUVmax) and 0.71 (Ki). SHAP analysis revealed that top contributing features included the slope and peak value of the metabolic TAC and the AUC and peak time of the blood flow TAC. The model's Cohen's effect size (1.71) was notably higher than that of SUVmax (0.96) and Ki (0.81), indicating superior discriminative power ($p < 0.001$). ***Conclusion:*** An explainable machine learning model leveraging dynamic FDG PET/CT metabolic and blood flow features provides a more accurate and interpretable approach for distinguishing benign from malignant lung lesions than conventional metrics such as SUVmax or Ki.

Aim/Introduction: Theranostics is an evolving field in oncology and nuclear medicine therapy. Very limited literature exist with radioligand therapy in primary brain tumors. Large neutral amino acid transporter 1 (LAT1) is overexpressed in glioma cells. LAT1 transports phenylalanine and mediates o-(2-[^{18}F]-fluoroethyl)-l-tyrosine ([^{18}F]FET) uptake in gliomas, including GBM. 4-iodo-l-phenylalanine (IPA) is a derivative of the naturally occurring essential amino acid l-phenylalanine. Iodine-131 [^{131}I] in [^{131}I]IPA is cytotoxic to the cells it penetrates and combines preferential radioactive effects and sustained tumor accumulation. We present results from a study to evaluate safety, tolerability, and preliminary efficacy of (^{131}I-IPA, administered as sequential injections in patients with recurrent GBM concomitantly to second line external radiation therapy. ***Materials and Methods:*** 8 patients were administered intravenous ^{131}I-IPA with with various doses before and after XRT. Radiotherapy treatment was applied with 30 Gy in 5 fractions for low volumes and for tumors > 3 to ≤ 5 cm 36 Gy in 18 fractions. Inclusion criteria comprised patients with GBM with current evidence for first or second recurrence and history of standard radiochemotherapy,interval since end of first line XRT ≥6 months and [^{18}F]FET PET indicating pathologically increased amino acid uptake. Surgery for relapsed tumor was allowed, no other second line treatment. The primary outcomes were safety and tolerability; secondary endpoints comprised progression-free survival and overall survival. ***Results:*** Included patients represent a younger cohort (mean age 55.7 years). 4 patients had more than one relapse before reirradiation. The time between first relapse and start of IPA/XRT ranged from 4.4 to 56.8 weeks. 5 patients with MGMT unmethylated tumors were included. No serious adverse event occurred, 3 patients experienced an adverse event (1 leucopenia grade 2; 1 lymphopenia grade 3; 1 thrombocytopenia grade 3; 1 fatigue grade 2). mPFS from relapse to next progression (PFS2) was 3.8 months (2.8 - 6.4 months). mOS from first relapse (OS2) was 12.4 months and mOS from initial diagnosis (OS1) was 32.2 months. ***Conclusion:*** These preliminary results with radioligand therapy in relapsed GBM showed a favorable safety and tolerability profile with no relevant systemic toxicity and confirmed the first preliminary efficacy results of the IPAX 1 study despite the poor prognostic parameters with MGMT unmethylated tumors and multiple relapses before start of experimental radioligand therapy. Preliminary results support feasibility of higher therapeutic doses in subsequent trials. This is an investigator-initiated trial, with support provided by Telix Pharmaceuticals.

Aim/Introduction: Radioligand therapies (RLT) are becoming more popular in cancer treatment. One recently highlighted target is the fibroblasts activating protein (FAP). Targeting fibroblasts in the tumor microenviroment FAP inhibitors have shown promising results in PET diagnostics of different tumor entities, leading to use it for RLT. The aim of this study was to determine tolerance and toxicity of [177Lu]Lu-DOTAGA-Glu-(FAPi)2 with increasing activities. ***Materials and Methods:*** This retrospective study includes patients examined between August 2020-April 2025 with: advanced cancer disease, interdisciplinary consensus for RLT and sufficient FAPi-Uptake in PET/CT. Medical records were searched for acute side effects and changes in blood values in all available follow-up data, especially Hemoglobin, Leucocytes, Platelets, Bilirubin, Creatinine. ***Results:*** In 27 patients admitted for FAPi-Therapy we performed a [177Lu]Lu-FAPi-scout examination in 22 patients (350-1048 MBq), 5 Patients were directly treated. Cancer diagnoses were: ten prostate-cancers, six thyroid-cancers, five solitary-fibrous-tumors and one pheochromocytoma, Ewing-Sarcoma, breast-cancer, basal-cell-cancer, pleura-mesothelioma and pancreas-cancer, respectively. A total of 19 patients received at least 1 cycle of RLT - 5 patients one cycle, 5 two, 3 three, 1 four, 1 five and 4 six cycles. Overtime activity was increased (33 cycles with about 7.4, 17 with 9.0, 8 with 11.1 GBq). Cumulative activities of all 27 patients ranged between 350 and 57,375 MBq (median 14,971

MBq). Average follow-up after first [177Lu]Lu-FAPi-administration was 96 days (3-349). Acute adverse events were: aggravation of pain in 2, urinary tract infection in 1, mild gastrointestinal disorders in 2 and aggravation of dyspnea in 1 patients. New reported adverse events during the therapy course were: respiratory infection in 2, headache and aphasia in 1 (brain metastasis), nausea in 2, weight loss in 1, pleural effusion in 1, mild alopecia in 3, aggravation of tumor pain in 6, mild gastrointestinal disorders in 2, cough in 2, dyspnea in 2 and cardiac decompensation in 1 patients. One patient experienced paresthesia, rash, weight loss, exsiccosis and dizziness associated with concomitant checkpoint inhibitor therapy. Another patient developed a heart attack 1 month after his 4th therapy cycle. Worsening in lab parameters was seen for Hemoglobin in 4 (one grade 3), leucocytes in 2 (G1), platelets in 3 (G1/2) and creatinine in 1 (G1) patients. ***Conclusion:*** FAPi-RLT was overall well tolerated with no critical hematotoxicity despite one anemia requiring transfusion. Reported AEs were partially tumor-associated, related to previous medical conditions or concomitant treatments. Nevertheless longer follow-up-data after last treatment-cycles are missing.

OP-780

SANTANA-225: A multicentre, open-label, Phase I/II study investigating the safety, tolerability, and preliminary efficacy of 225Ac-SSO110 in participants with extensive stage small cell lung cancer (ES-SCLC) or Merkel cell carcinoma (MCC) receiving Standard of Care (SoC)

E. Zan[1], *J. Fleck*[2], *G. Gericke*[2], *K. Herrmann*[3];
[1]*Cleveland Clinic, Cleveland, OH, UNITED STATES OF AMERICA,* [2]*Ariceum International AG, Basel, SWITZERLAND,* [3]*Universitätsklinikum Essen, Essen, GERMANY.*

Aim/Introduction: ES-SCLC and MCC are neuroendocrine carcinomas with a dismal prognosis. Immune checkpoint inhibition (CPI) has resulted in clinical benefit, yet the need for improved treatment options remains. Somatostatin receptor 2 (SSTR2) is expressed on the majority of SCLC and MCC lesions and SSTR2 targeted radioligand therapy has proven safe and effective in other neuroendocrine tumors. Preliminary data from an ongoing study with ^{177}Lu-SSO110 added to CPI maintenance in ES-SCLC suggests incremental efficacy, non-clinical data demonstrates long-term tumor control and survival of all animals treated with a single, translatable dose of ^{225}Ac-SSO110. We therefore hypothesise that adding ^{225}Ac-SSO110 to SoC will result in clinically relevant efficacy benefits. ***Materials and Methods:*** The main objective of this study is to assess the safety and tolerability of ^{225}Ac-SSO110 and the recommended phase 2 dose (RP2D) in combination with CPI in 1st line maintenance therapy for ES-SCLC and 1st line CPI therapy for MCC, respectively. The secondary objective is to assess the preliminary anti-tumour activity. Exploratory objectives include the assessment of the level of concordance of lesions visible on ^{68}Ga-satoreotide trizoxetan (^{68}Ga-SSO120) PET/CT versus lesions visible on contrast-enhanced CT and/or FDG PET. Inclusion criteria include histologically or cytologically confirmed ES-SCLC or MCC, adequate organ and bone marrow function, a life expectancy >6 months, and ≥1 positive lesion on ^{68}Ga-SSO120 PET/CT. Participants will be treated with 4 cycles of ^{225}Ac-SSO110, which may be extended to 7 in case of clinical benefit. The study will follow a BOIN design to determine the RP2D with a target dose-limiting toxicity (DLT) rate of 0.30. The ^{225}Ac-SSO110 starting dose is 2.4MBq which can be escalated up to 8.4MBq. ***Results:*** Trial design and preliminary results will be presented at the meeting. ***Conclusion:*** This study will support the selection of the RP2D and assess preliminary safety and efficacy of ^{225}Ac-SSO110 added to CPI in participants with ES-SCLC or MCC.

OP-781

Clinicopathological Features Predict Outcomes in Patients with End-Stage Metastatic Cancers Treated with ^{177}Lu-LNC1004

H. Fu[1], *J. Huang*[1], *W. Guo*[1], *J. Zhang*[2], *X. Chen*[2], *H. Chen*[1];
[1]*The First Affiliated Hospital of Xiamen University, Xiamen, CHINA,* [2]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: FAP-targeted radioligand therapy (RLT) is a promising anti-tumor treatment with low toxicity in patients with end-stage metastatic tumors who have not responded to standard treatments. ^{177}Lu-LNC1004 RLT demonstrates promising anti-tumor efficacy with an acceptable safety profile in patients with various end-stage metastatic tumors who have progressed after exhausting standard treatments. In this study, we evaluated the survivals and identified clinicopathological features predicting therapeutic response and outcome in patients with end-stage metastatic cancers receiving ^{177}Lu-LNC1004. ***Materials and Methods:*** Twenty-eight patients with end-stage metastatic tumors treated with a median of 2 cycles of ^{177}Lu-LNC1004 were included. Data were analyzed according to PFS and OS, as well as the RECIST criteria response patterns regarding prior therapies, laboratory biomarkers, metastatic extent, and other clinical pathological characteristics in univariate and multivariate Cox proportional hazards models. ***Results:*** The ^{177}Lu-LNC1004 was given six weekly with a median administered activity of 3.1GBq/cycle up to four cycles. Using the RECIST, disease control was confirmed in 13 patients [13/28, 46%], with 4 and 9 demonstrating partial response and stable disease, respectively. Evaluable patients with SUVmax ≤ 15 in targeted lesions had better DCR than that of patients with SUVmax > 15 (P=0.022). Multivariate analyses revealed that the mean SUVmax of RECIST-targeted lesions was independently associated with better DCR (P=0.021). The median follow-up period was 18.1 months. Among the 28 patients, 16 (57%) were followed for more than 6 months after initiating RLT. The median PFS was 4.0 (95% confidence interval [CI]: 0.8-7.2) months. During the follow-up period, 19 of 28 (68%) patients died and the median OS was 6.3 (95% CI: 0.8-11.7) months. Disease control was associated with improved PFS and OS (P<0.001). PFS and OS were significantly associated with age, baseline ECOG performance status, lines of systemic therapy before ^{177}Lu-LNC1004, baseline leukocyte counts, and received cycles of ^{177}Lu-LNC1004 RLT. Multivariate analysis revealed ≤2 lines of previous systemic therapy, ≤3 organs of tumor involvement, baseline hemoglobin >117 g/L, and baseline leukocyte count ≤10×10^9/L as independent prognostic factors of superior PFS and OS. ***Conclusion:*** FAP-targeted radioligand therapy with ^{177}Lu-LNC1004 was a promising anti-tumor efficacy with an acceptable toxicity profile in patients with various end-stage metastatic tumors. The present data indicate that administering ^{177}Lu-LNC1004 as an earlier line of therapy, targeting patients with better conditions, or ^{177}Lu-LNC1004 performed in combination with immunotherapy may be the strategies to improve therapeutic efficacy and survival in future studies.

OP-782

Deep Learning Model for Automatic Tumour Segmentation and Margin Status Prediction in Micro-PET-CT Images of Breast Lumpectomy Specimens

L. Maris[1,2], *M. Göker*[3], *K. De Man*[4], *B. Van den Broeck*[4], *S. Van Hoecke*[5], *K. Van de Vijver*[6,7], *C. Vanhove*[1,8], *V. Keereman*[1,2];
[1]*Department of Electronics and Information Systems, MEDISIP, Ghent University, Ghent, BELGIUM,* [2]*XEOS Medical, Ghent, BELGIUM,* [3]*Department of Gynaecology, Ghent University Hospital, Ghent, BELGIUM,* [4]*Department of Medical Imaging, Nuclear Medicine, Ghent University Hospital, Ghent, BELGIUM,* [5]*Internet Technology and Data Science Lab (IDLab), Ghent University-Imec, Ghent, BELGIUM,* [6]*Department of Pathology, Ghent University Hospital, Ghent, BELGIUM,* [7]*Department of Diagnostic Sciences and CRIG, Ghent University, Ghent, BELGIUM,* [8]*CORE ARTH INFINITY, Ghent University, Ghent, BELGIUM.*

Aim/Introduction: Complete tumour removal is crucial in curative breast cancer surgery to prevent local recurrence. Recently, high-resolution (micro-)PET-CT imaging with ^{18}F-FDG emerged as a promising technique for fast intraoperative margin assessment (IMA) of lumpectomy specimens. However, interpreting micro-PET-CT specimen images can be challenging and time-consuming in some cases. To address this, we propose a deep learning (DL) model that automatically segments breast tumours in micro-PET-CT images of lumpectomy specimens and predicts the margin status. ***Materials and Methods:*** We trained and evaluated a 2D Residual U-Net (ResU-Net) to delineate invasive carcinoma of no special type (NST) in micro-PET-CT images. We collected micro-PET-CT images from 53 lamellas of lumpectomy specimens from 19 patients, along with corresponding histopathology whole-slide images (WSIs). An in-house developed co-registration algorithm was used to align the micro-PET-CT images with the WSIs. An experienced pathologist annotated the WSIs to obtain ground truth binary tumour segmentations. To train and test the ResU-Net for tumour segmentation, five-fold group cross-validation was performed on this annotated data set. Subsequently, an ensemble model was constructed and applied to a previously unseen data set comprising micro-PET-CT images of 31 NST lumpectomy specimens. The predicted margin statuses were compared with the true margin statuses determined through histopathological examination. ***Results:*** Five-fold cross-validation on the first data set with true tumour segmentation labels yielded a dice similarity coefficient (DSC) of 0.73±0.20 and a precision-recall area under the curve (PR-AUC) of 0.83±0.14 for segmentation. In comparison, conventional intensity thresholding performed slightly worse with a DSC of 0.71±0.22 and PR-AUC of 0.77±0.20. For the second data set, margin status prediction using the ResU-Net achieved a sensitivity of 89%, specificity of 91%, and F1-score of 84%. ResU-Net outperformed conventional intensity thresholding (sensitivity: 100%, specificity: 59%, F1-score: 67%), while reaching a similar performance to 7 physicians who manually interpreted the same image set (sensitivity: 90%±4%, specificity: 86%±7%, F1-score: 81%±4%). ***Conclusion:*** We introduced a DL model for segmenting NST breast tumours and predicting the margin status using micro-PET-CT images of lumpectomy specimens. The model demonstrated comparable performance to 7 physicians and outperformed conventional intensity thresholding in margin status prediction. Although additional data are required to enhance and (clinically) validate the model, this work represents an important step toward developing a decision-support system to assist physicians in interpreting micro-PET-CT images of lumpectomy specimens. Ultimately, it may facilitate the integration of micro-PET-CT imaging as IMA technique in clinical practice.

OP-783

Unlocking the predictive potential of preoperative SPECT/CT roadmaps for signal intensities during cervical cancer sentinel node surgery

G. Pisano[1,2], *N. van Ruremonde*[2], *F. H. P. van Velden*[3], *P. Dibbets-Schneider*[3], *J. J. Beltman*[4], *L. S. Nooij*[4], *M. N. van Oosterom*[2], *F. W. B. van Leeuwen*[2], *D. D. D. Rietbergen*[3,2];
[1]*Nuclear Medicine Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY,* [2]*Interventional Molecular Imaging Laboratory, Leiden University Medical Centre, Leiden, NETHERLANDS,* [3]*Section of Nuclear Medicine, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS,* [4]*Department of Gynecology, Leiden University Medical Center, Leiden, NETHERLANDS.*

Aim/Introduction: Molecular image-guided surgery offers the potential to enhance surgical performance by enabling preoperative imaging and supporting intraoperative target localization. During sentinel node (SN) surgeries, preoperative images as SPECT/CT are currently used for 3D intervention planning, a surgical 'roadmap'. In addition to positional information, these scans provide valuable insights about tracer avidity of SNs. This information could be used to further optimize surgical navigation, such as predicting feasibility and quality of intraoperative radioguidance. Therefore, the aim of this study was to correlate tracer uptake in preoperative images with radio- and fluorescence-guidance during cervical cancer SN surgery. ***Materials and Methods:*** 41 patients undergoing SN procedure, radical hysterectomy and pelvic lymphadenectomy for cervical cancer were included. One day before surgery, they received four peri-cervical injections of hybrid tracer indocyanine green (ICG)-^{99m}Tc-nanocolloid (4x25MBq). Preoperative imaging was performed (planar lymphoscintigraphy and SPECT/CT). Intraoperative gamma-tracing (numerical values) and fluorescence imaging (categorical values, i.e. positive or negative) were performed and checked ex-vivo. Pre-operative imaging metrics of SNs were extracted using custom software workflows, including total, mean, median counts; total counts as ratio of injection site; area (L-ANT), volume (SPECT/CT); kurtosis and skewness. For statistical analysis, Pearson's (r) and Spearman's (rho) correlation coefficients were used. ***Results:*** A total of 63 SNs were analyzed. During surgery, 49 SNs were identified with radioguidance (49/63:77.8%) and 25 with fluorescence guidance (25/59:42.4%, 4 not reported), with 64.4% concordance. The median of gamma probe counts was 8370 in-vivo and 8480 ex-vivo. The mean signal intensity on planar L-ANT imaging correlated with in-vivo (Pearson's r=0.419, p=0.03) and ex-vivo (r=0.572, p<0.001) probe counts. The results for quantified SPECT/CT uptakes were similar (in-vivo r=0.409, p=0.004; ex-vivo r=0.519, p<0.001). Subgroup analysis revealed significantly stronger correlations for patients with BMI<25 (planar L-ANT: in-vivo r=0.740, p<0.001 and ex-vivo r=0.585, p<0.001; SPECT/CT: in-vivo r=0.596, p<0.001 and ex-vivo r=0.561, p=0.002), while almost no significant correlation for patients with BMI≥25 (SPECT/CT: in-vivo r=-0.012, p=0.959 and ex-vivo r=0.351, p=0.199). No significant correlation could be found between preoperative imaging and fluorescence findings (SPECT/CT: in-vivo rho=0.077, p=0.565 and ex-vivo rho=0.099, p=0.495). ***Conclusion:*** During cervical cancer SN biopsy, the signal intensity on preoperative scintigraphy and SPECT/CT proved to be directly correlated with intraoperative radioguidance, particularly in patients with BMI<25. Indicating that preoperative imaging can not only provide positional information to improve intraoperative detection rate, but is also predictive for the quality of radioguided surgery, unlocking further potential of nuclear medicine in surgical decision-making.

OP-784

Integrated Multidisciplinary Workflow for ROLL of PET/CTPositive Lesions: Technical Feasibility and Clinical Impact

M. Zapardiel*, L. León Ramírez, C. Wakfie Corieh, C. González Roiz, J. Armijo Astrain, M. Leyva Vásquez Caicedo, S. Ochagavia Cámara, C. Sánchez del Pueblo, M. Vaillant López, A. Berardinelli Isea, M. Romero Porras, M. Cornide Carrallo, M. Cabrera Martin; H. U. Clínico San Carlos, Madrid, SPAIN.*

Aim/Introduction: This study presents our initial experience with a structured, multidisciplinary protocol for radioguided occult lesion localization (ROLL) of hypermetabolic lesions identified on PET/CT. The aim was to evaluate the technical feasibility, safety, and diagnostic utility of this approach. ***Materials and Methods:*** Between May 2024 to March 2025, twenty ROLL procedures were performed in sixteen patients (10 men, 6 women; mean age 57 years) with PET/CT-positive lesions. Lesion selection was conducted during multidisciplinary tumor board meetings based on metabolic activity and surgical accessibility. Through close collaboration with radiologists, the most appropriate method—ultrasound guidance, in our current experience- was selected to guide the intralesional injection of 99mTcMAA (55-111 MBq), which was always performed within 24 hours prior to surgery. Immediately after injection, correct radiotracer placement was confirmed using SPECT/CT of the region, we confirm correct

radiotracer placement doing a SPECT/CT of the region and nd the area of maximal uptake was marked on the skin to assist the surgical team. During the procedure, a nuclear medicine physician guided lesion localization using an intraoperative gamma-probe. Histopathological results were reviewed during follow-up multidisciplinary case discussions to refine and adapt the workflow. ***Results:*** Lesions were most commonly located in the cervical region (60%), followed by axillary (15%), inguinal (15%), high paratracheal (5%), and abdominal (5%) regions. Radiotracer placement was accurately confirmed in 17 of 20 cases (85%). Intraoperative localization was successful in all procedures led by a nuclear medicine physician (17/17), and no complications were reported. Histopathological analysis confirmed malignancy in 11 cases (five lymphomas, six metastases from known primaries). Among the benign results, five cases were negative for malignancy, two cases were consistent with toxoplasmosis, one with a sclerotic nodule, and one with reactive follicular hyperplasia. From this, only three of them required further pathological evaluation due to inconclusive or discordant findings. ***Conclusion:*** The implementation of a structured, multidisciplinary ROLL workflow has proven to be a safe and effective strategy for the surgical management of PET/CTpositive lesions. High rates of accurate lesion targeting and intraoperative localisation highlight the value of including a nuclear medicine physician as part of the surgical team. This integrated approach enhances surgical precision in PET/CT-positive lesions and supports more personalized clinical decision-making.

OP-785

Radioguided Occult Lesion Localisation (ROLL) for Intraoperative Detection of Parathyroid Adenomas: A Preliminary Single-Centre Experience

L. León Ramírez[1], *C. González Roiz*[2], *T. Diaz Vico*[3], *I. Grao Torrente*[3], *A. García Muñoz Nájar*[3], *A. Hermosín Peña*[3], *M. Durán Poveda*[3];
[1]*Hospital clínico san carlos, Madrid, SPAIN,* [2]*Hospital Puerta del Sur, Madrid, SPAIN,* [3]*Hospital Universitario Rey Juan Carlos, Madrid, SPAIN.*

Aim/Introduction: Precise intraoperative localisation of parathyroid adenomas is essential in the surgical management of primary hyperparathyroidism, particularly in cases where conventional imaging is inconclusive or discordant. Radioguided Occult Lesion Localisation (ROLL) has emerged as a valuable adjunct in enhancing surgical accuracy under these challenging circumstances.To evaluate the feasibility, safety, and histopathological concordance of ROLL-guided parathyroidectomy in patients with primary hyperparathyroidism and difficult preoperative localisation. ***Materials and Methods:*** We retrospectively reviewed 24 patients (19 women, 5 men; mean age 60.1 ± 13.3 years) with primary hyperparathyroidism who underwent ROLL-assisted parathyroid surgery between August 2017 and April 2024 at our centre. All patients were selected based on inconclusive or discordant imaging findings. Preoperative localisation was achieved through ultrasound-guided injection of technetium-99m macroaggregated albumin (99mTc-MAA). Tracer uptake was confirmed by SPECT/CT, and intraoperative localisation was facilitated using a handheld gamma probe. A nuclear medicine physician with expertise in radioguided surgery was present in the operating room and actively contributed to intraoperative navigation. Surgical and histopathological outcomes were analysed, along with postoperative biochemical results. Concordance among ultrasound, SPECT, MRI, and choline PET imaging was also assessed. ***Results:*** ROLL was successfully performed in all 24 cases (100%). The most common surgical approach was focused parathyroidectomy. Histopathological analysis confirmed parathyroid adenoma or hyperplasia in 21 out of 24 patients (87.5%). Imaging concordance was observed in 12 cases (35%), while 23 cases (65%) showed discordant or incomplete localisation. No complications related to the ROLL procedure were reported (0%). Most patients (over 90%) demonstrated a significant postoperative decrease in serum calcium and parathyroid hormone levels, consistent with effective gland removal. ***Conclusion:*** ROLL is a safe, reliable, and effective technique for the intraoperative localisation of parathyroid adenomas, especially in patients with non-localising or discordant preoperative imaging. The dedicated presence of a nuclear medicine physician during surgery enhances operative precision and contributes to optimal outcomes in the management of primary hyperparathyroidism.

Accuracy of PSMA-PET/CT, mpMRI and ex vivo specimen PET/CT for molecular guidance of nerve sparing

P. Fragoso Costa[1], *T. Kahl*[2], *W. Fendler*[1], *H. Reis*[3], *J. Köllermann*[3], *C. Kesch*[2], *L. Püllen*[2], *U. Krafft*[2], *J. Kleesiek*[4], *D. Kersting*[1], *M. Ingenwerth*[5], *B. Hadaschik*[2], *K. Herrmann*[1], *F. Barbato*[1], *C. Darr*[2];
[1]*Clinic for Nuclear Medicine, University Hospital Essen, University Duisburg-Essen, Essen, GERMANY,* [2]*Department of Urology, University Hospital Essen, University Duisburg-Essen, Essen, GERMANY,* [3]*Institute of Pathology, University Hospital Frankfurt, Frankfurt, GERMANY,* [4]*Institute of Artificial Intelligence in Medicine, University Hospital Essen, University Duisburg-Essen, Essen, GERMANY,* [5]*Institute of Pathology, University Hospital Essen, University Duisburg-Essen, Essen, GERMANY.*

Aim/Introduction: Accurate assessment of extraprostatic extension (EPE) has a major impact on RP extent and nerve sparing (NS). We evaluate the accuracy of a novel specimen PET/CT (sPET/CT) scanner for intraoperative real-time whole gland assessment. ***Materials and Methods:*** 28 patients (pts) undergoing RP with high-risk PC and experimental sPET/CT were included in this analysis; preoperative mpMRI imaging was available in 23 pts (82.1%). In 24 pts. (85.7%), conventional clinical PET/CT was performed immediately preoperatively. 4 pts received an intraoperative tracer injection. In terms of used tracer, 9 pts were injected with ^{68}Ga-PSMA-11 while 19 pts received ^{18}F-PSMA-1007. Lesions were segmented using an iterative thresholding method, comparing with histopathological EPE and positive surgical margins (PSM). Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were determined for predicting EPE. ***Results:*** Intraoperative tracer uptake was visible in sPET/CT in 27 patients (96.4%). Sensitivity for EPE of PSMA-PET/CT, mpMRI and sPET/CT was 0.36, 0.9 and 0.88, specificity was 0.92, 0.77 and 1, respectively. PPV was 0.83, 0.75 and 1, NPV was 0.57, 0.91 and 0.85, respectively. Unilateral NS RP was performed in 13 pts; after sPET/CT, NS could have been performed on the opposite side in 69%. No NS was performed in 14 pts; according to sPET/CT, unilateral NS could have been performed in 42.9%. In 10 pts PSM were detected in histopathology, 9 showed a corresponding tracer signal in sPET/CT. ***Conclusion:*** Intraoperative PET/CT correlates well with histopathology. Sensitivity, specificity, PPV and NPV are encouraging and suggest further investigation of this molecular-guided RP approach.

First-in-Human Phase I/IIa Study of [^{99m}Tc]Tc-cAbVCAM1-5: Safety, Dosimetry, and Biodistribution in Healthy Volunteers and Asymptomatic Patients Prior to Carotid Endarterectomy

L. Djaileb[1], *J. Leenhardt*[2], *R. Spear*[3], *N. De Leiris*[2], *G. Reboulet*[2], *M. Faure*[3], *A. Paris*[3], *L. Dumas*[2], *C. Ghezzi*[2], *G. Vanzetto*[2], *D. Fagret*[2], *G. Barone-Rochette*[2], *A. Broisat*[2];
[1]*University Grenoble Alpes,LRB, Grenoble, FRANCE,* [2]*University Grenoble Alpes, LRB, Grenoble, FRANCE,* [3]*University Grenoble Alpes, Grenoble, FRANCE.*

Aim/Introduction: Vascular Cell Adhesion Molecule 1 (VCAM-1) has emerged as a promising target for molecular imaging of vulnerable atherosclerotic plaques due to its overexpression on activated endothelial cells in inflamed vascular regions. To assess safety, dosimetry, and biodistribution of the novel radiopharmaceutical [^{99m}Tc]Tc-cAbVCAM1-5 in Healthy Volunteers and Asymptomatic Patients Prior to Carotid Endarterectomy. ***Materials and Methods:*** This study is a phase I/IIa, prospective, monocentric, non-controlled, non-randomized, open-label interventional study (NCT04483167). Inclusion criteria were healthy volunteers (18-55 years) and patients (18-80 years) with asymptomatic carotid stenosis indicated for surgery. Healthy volunteers underwent a dose-escalation protocol (1+3+3 design) with injected activities of 370, 550, and 750 MBq and nanobody doses below 100 µg of [^{99m}Tc]Tc-cAbVCAM1-5. Dosimetry was calculated using OLINDA V1 software, and multiple blood, urine, and imaging acquisitions were performed up to 24 hours post-injection. Patients followed the same protocol for up to 6 hours before undergoing surgery at the 24-hour. VCAM-1 expression on SPECT imaging and histopathology was classified using a 0-3 uptake scale (denoting absence, low, moderate, and high expression).The primary objective was to safety, dosimetry, and biodistribution in Healthy Volunteers and Asymptomatic Patients Prior to Carotid Endarterectomy. Secondary objectives included correlation between imaging and histological VCAM-1 expression. ***Results:*** Seven healthy volunteers (mean±SD; 41.3±7.6 years) and 6 patients (73.6±9.0) were included. No serious or severe adverse events, nor significant biological changes, were observed after administration of [^{99m}Tc]Tc-cAbVCAM1-5. Biodistribution was consistent with preclinical data, showing predominant renal uptake, moderate splenic, and low bone marrow uptake, with no myocardial or vascular signal. Blood clearance was rapid, with less than 10% of injected activity remaining at 1 hour (half-lives: 30.5 min early, 100 min late phase). Renal radiation dose was highest (0.202 mGy/MBq), with mean (±SD) effective doses of 0.0065±0.8 mSv/MBq. SPECT did not detect significant uptake in patient before surgery (score 0 to 1). Histopathology and SPECT were concordant in 5/6 (83%) with low VCAM-1 expression in 5/6 (83%). One patient had a moderate VCAM-1 expression with no uptake on SPECT. ***Conclusion:*** [^{99m}Tc]Tc-cAbVCAM1-5 demonstrated a favorable safety profile, acceptable dosimetry primarily related to renal uptake, and a biodistribution pattern similar to that observed in animal models. Imaging findings were in accordance with histopathological assessment of VCAM-1 expression. Further studies are warranted to assess the diagnostic performance in patients with symptomatic plaques.

OP-788

Carotid Calcified Inflammatory Plaques and Cardiocerebrovascular Events: A ^{68}Ga-DOTA-TOC PET/CT study in an oncological setting

X. Shao[1,2], *C. Bregenz*[2], *J. Wang*[2], *Y. Chen*[2], *A. Rominger*[2], *K. Shi*[2], *F. Caobelli*[2];
[1]*the Third Affiliated Hospital of Soochow University, Changzhou, CHINA,* [2]*Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Overexpression of somatostatin receptors (SSTR2) in activated M1-macrophages has emerged as a potential marker of plaque vulnerability. The PET-based evaluation of plaque vulnerability in coronary arteries has proven useful in the assessment of cardiovascular risk. Same value may pertain also to vulnerable carotid plaque for the prediction of the risk of cerebrovascular events. We therefore aimed to investigate, whether SSTR2-overexpressing carotid calcified plaques may be predictive of major cerebrovascular events. ***Materials and Methods:*** In this retrospective study, 363 oncological patients undergoing ^{68}Ga-DOTA-TOC PET/CT imaging for oncologic reasons were included. Plaque calcifications and ^{68}Ga-DOTA-TOC uptake in the carotid arteries were evaluated visually and semi-quantitatively. During a median follow-up of 54 months, data on cardio- and cerebrovascular events (myocardial infarction, hospitalization for myocardial ischemia, coronary artery revascularization, stroke) and all-cause death were collected. The incidence of major adverse events between groups with and without ^{68}Ga-DOTA-TOC uptake was compared using the chi-square test and Fisher's exact test. ***Results:*** 128 patients (35.3%) showed carotid artery calcification of any degree in at least one side, with a mean calcification volume of 51.6±147.6 cm^3. A total of 71 focal ^{68}Ga-DOTA-TOC uptake (41 left, 30 right) were seen in 48 patients (13.2%) with SUVmax 1.76 ± 0.35 and TBR 2.23 ± 0.98, respectively. In those patients with a detectable ^{68}Ga-DOTA-TOC uptake, stroke occurred more frequently (8.3% vs. 2.5%, P = 0.036). The incidence of MACE was significantly higher in patients with increased ^{68}Ga-DOTA-TOC uptake compared to those without uptake (8.3% vs. 2.2%, P = 0.021). Patients with concurrent carotid artery calcification and increased ^{68}Ga-DOTA-TOC uptake exhibited the highest incidence of stroke and MACE (11.4 % and 11.4 %). ***Conclusion:*** In an oncological setting, SSTR2-overexpressing carotid calcified plaques in ^{68}Ga-DOTA-TOC PET/CT can predict higher risk of developing cardio- and cerebrovascular events. ***References:*** 1. OP-789

Increase of 18F-rhPSMA-7 uptake in atherosclerotic plaques is associated with higher cardiovascular risk in patients with prostatic cancer.

S. Notohamiprodjo[1], *B. Haller*[2], *I. Rauscher*[1], *M. Eiber*[1], *W. Weber*[1], *M. Krönke*[3];
[1]*Technical University of Munich, TUM School of Medicine and Health, TUM University Hospital, Department of Nuclear Medicine, Munich, GERMANY,* [2]*Technical University of Munich, TUM School of Medicine and Health, TUM University Hospital, Department of Biostatistics and Clinical Epidemiology, Munich, GERMANY,* [3]*Die Radiologie, Munich, GERMANY.*

Aim/Introduction: PSMA expression during neovascularisation is believed to be the cause of PSMA-radioligand uptake in several benign processes. Neovascularization also occurs during the development of vulnerable atherosclerotic plaques and may explain PSMA-radioligand uptake in vascular walls, though its significance remains unclear. We therefore investigated whether PSMA-radioligand uptake in vascular structures correlates with elevated cardiovascular risk (CVR). ***Materials and Methods:*** We analysed 110 ^{18}F-rhPSMA7-PET/CT scans acquired for staging or restating of prostate cancer. All scans were acquired without intravenous CT contrast agents. SUVmax was measured in the thoracic aorta, common iliac arteries, common carotid arteries and mediastinal blood pool (MBP). As a marker of CVR the Agatston calcium score was measured. Depending on the result for Agatston score, patients were assigned to five CVR risk groups. The correlation of SUVs with the risk groups was analysed. Furthermore, intraindividual differences in SUVs between calcified and non-calcified vessel segments were measured. The impact of injected tracer dose, kidney function (serum creatinine, eGFR)on SUVmax values was also determined. ***Results:*** A positive correlation was found between CVR and PSMA-radioligand uptake by arterial walls (r=0.29, p<0.01) . In the intra-individual comparison, vascular segments with calcified plaques showed significantly higher SUVmax values than vascular segments without calcified plaques

(mean ΔSUV 0.42, p<0.01). PSMA uptake of calcified segments correlated with increasing CVR (r=0.5, p<0.01), while PSMA uptake of non-calcified segment correlated slightly with increasing CVR (r=0.27, p<0.01). The ratio of PSMA activity in the arterial vessel wall to blood pool activity was 48%:52%. No significant impact on PSMA-radioligand uptake was shown for injected tracer dose (r=0.13, p=0.19), serum creatinine (r=-0.02, p=0.84) or eGFR (r=-0.11, p=0.29). ***Conclusion:*** We observed a statistical association between markers of elevated CVR and PSMA-radioligand uptake by arterial walls. However, the differences between risk groups are small in absolute terms which may limit the clinically utility of PSMA-radioligand uptake as a marker for CVR.

OP-790

[^{68}Ga]FAPI PET molecular imaging in atherosclerosis compared with [^{18}F]FDG

R. Calabretta, *E. Atli, B. Geist, D. Muin, E. Kretschmer-Chott, C. Spielvogel, S. Schmitl, X. Li, P. Binder, M. Hacker;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Adult cancer survivors have a growing risk of atherosclerotic cardiovascular diseases (CVD), not related to traditional CVD risk factors. Detection of arterial inflammation with imaging is an attractive approach to identify patients at highest risk of plaque rupture, and 2-deoxy-2-[^{18}F]fluoro-D-glucose ([^{18}F]FDG) positron-emission tomography, in combination with computer tomography (PET/CT) or magnetic resonance (PET/MR), is a validated diagnostic tool for atherosclerotic inflammation functional imaging. [^{68}Ga]-labeled fibroblast activation protein inhibitor ([^{68}Ga]FAPI) PET tracer is used in oncology, recently also in CV medicine. ***Materials and Methods:*** Twenty patients with known urothelial carcinoma underwent [^{68}Ga]FAPI PET/MR and [^{18}F]FDG PET/CT imaging have been retrospectively analyzed. We performed a whole-segment analysis by deriving target-to-background ratio (TBR) values at both scans and subsequently assessed the corresponding segments between each other's. 374 PET active arterial lesions have been identified. Additionally, we researched the effects on arterial wall uptake of CVD risk factors, such as arterial hypertension, type 2 diabetes mellitus (T2DM), dyslipidemia, and of a CV-specific therapy with aspirin (100 mg/day). ***Results:*** In the per-lesions analysis, [^{68}Ga]FAPI identified more lesions and showed a 19% higher uptake than [^{18}F]FDG (TBR_{FAPI}:1.7±0.5 vs. TBR_{FDG}:1.4±0.2;P<0.001). In the patient-based analysis, TBR_{FAPI} was also by 19% significantly higher than TBR_{FDG} (TBR_{FAPI}:1.7 ±0.4 vs. TBR_{FDG}:1.4±0.2; P=0.018). Regarding CVD risk factors, the presence of arterial hypertension (P<0.001) or dyslipidemia (P<0.001) alters significantly arterial [^{68}Ga]FAPI-expression compared to [^{18}F]FDG-activity. The difference between TBR_{FAPI} and TBR_{FDG} in patients with T2DM was even higher (TBR_{FAPI}:2.0±0.6 vs. TBR_{FDG}:1.3±0.2; difference 34%;p<0.001). Interestingly, TBR_{FAPI} was 25% higher compared to those without T2DM (TBR_{FAPI}:2.0±0.6 vs. 1.6±0.5,P<0.001), while no significant differences in [^{68}Ga]FAPI-expression were found between subjects suffering from arterial hypertension or dyslipidemia (4%,P=0.4 and 4%,P=0.3, respectively). Considering the aspirin therapy, patients not treated with aspirin showed a 24% higher arterial [^{68}Ga]FAPI-expression than [^{18}F]FDG (TBR_{FAPI}:1.8±0.6 vs. TBR_{FDG}:1.3±0.2;P<0.001), whereas the difference between TBR_{FAPI} and TBR_{FDG} was lower but still significant in patients with aspirin (8% difference,P=0.02). Interestingly, aspirin intake significantly reduces arterial [^{68}Ga]FAPI-expression compared to patients not assuming this drug (1.6±0.3 vs. 1.8±0.6,p=0.02), suggesting that aspirin treatment counteracts the effectivity of accumulating [^{68}Ga]FAPI within the arterial wall. ***Conclusion:*** [^{68}Ga]FAPI-PET identified more lesions and showed higher uptake than [^{18}F]FDG, independently from the presence of CVD risk factors or CV-specific therapy. Our results suggest that [^{68}Ga]FAPI could be a novel and valid marker for PET molecular imaging in atherosclerosis, as well as in cancer patients, particularly in those suffering from T2DM.

OP-791

Impact of Hemoglobin Concentration on Quantitative Cardiac Perfusion Measurements

P. Svanström, *T. Kero, J. Sigfridsson, K. M. Eggers, N. Johnston, A. Brandt, H. J. Harms, M. Lubberink, J. Sörensen;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Anemia is a prognostic factor in chronic coronary syndromes. It remains unclear if hemoglobin concentration (Hb) affects quantitative cardiac perfusion measurements from PET in subjects with suspected angina and whether there are sex differences. This study had 3 aims: 1) Does Hb affect cardiac output? 2) Does Hb alter resting-MBF beyond the effects of sex and cardiac output? 3) Is low Hb associated with a higher risk of abnormal stress PET or MFR? ***Materials and Methods:*** This retrospective study included patients with suspected angina who underwent cardiac ^{15}O-water PET and had Hb measurements available. PET measurements included resting cardiac output quantified using the indicator dilution technique, stroke volume (cardiac output/heart rate), myocardial blood flow (MBF) at rest and stress, and myocardial flow reserve (MFR). Multivariate models were used to address the 3 research aims. ***Results:*** We included 675 consecutive patients (45% female, age 66±11 years, Hb 139±14 g/L, 13% anemic). Hb was inversely associated with resting cardiac output in women (P=0.0002), but not in men (P=0.54). Hb was a strong determinant of resting-MBF, second only to heart rate. Heart rate, Hb, stroke volume, sex and systolic blood pressure explained two-thirds of the variation in resting-MBF (adjusted R^2=0.66). Hb was not associated with stress-MBF in men (P=0.17) or in women (P=0.47). Low Hb was associated with reduced MFR in men (P=0.005), and showed a borderline association in women (P=0.06). ***Conclusion:*** Hemoglobin concentration was associated with cardiac perfusion measurements through several mechanisms, some of which may be sex-dependent. Hb was associated with MFR, mainly because MFR integrates complex regulation of resting-MBF, including the effects of anemia. In contrast, Hb had no significant impact on stress-MBF, suggesting that stress-MBF may be a more robust indicator of maximal coronary capacity.

OP-792

Model-Free Perfusion Quantification for Dynamic Total-body ^{18}F-FDG PET Reveals Remote Blood Flow Alterations in Coronary Artery Disease

T. Sun[1], *Y. Wu*[2], *M. Wang*[2];
[1]*Chinese Academy of Sciences, Shenzhen Insitute of Advanced Technology, Shenzhen, CHINA,* [2]*Henan Provincial People's Hospital, Zhengzhou, CHINA.*

Aim/Introduction: Coronary artery disease (CAD) is increasingly linked to altered systemic perfusion beyond the myocardium. While ^{15}O-water PET is considered the gold standard for non-invasive perfusion imaging, its limited availability restricts broader use. The emergence of long axial field-of-view PET/CT systems provides a unique opportunity to utilize ^{18}F-FDG for dynamic, whole-body perfusion quantification. This study aims to develop a model-free deconvolution framework for extracting perfusion metrics from dynamic ^{18}F-FDG PET and to evaluate its sensitivity in detecting CAD-related abnormalities across multiple organs. ***Materials and Methods:*** Dynamic total-body ^{18}F-FDG PET scans were acquired with ultra-high temporal resolution (i.e., 2-second frames during the first minute, 50 frames over 20 minutes). A model-free deconvolution approach was applied to compute voxel-wise perfusion parameters, including blood flow (BF), blood volume (BV), time-to-peak (TTP), and mean transit time (MTT). These were compared between 8 patients with severe CAD and 8 age-matched healthy controls. For comparison, conventional compartmental modeling was also performed to estimate K1 values. Statistical significance was assessed using Mann-Whitney U with a threshold of $p < 0.05$. ***Results:*** CAD patients exhibited

significantly reduced BF in the spleen, kidney, spine, and pelvis ($p < 0.05$), along with decreased BV in the kidney and pelvis. TTP was delayed in the liver, kidney, and pelvis, while MTT was reduced in the liver, kidney, pelvis, and skeletal muscle. Conventional kinetic modeling (K1) revealed group differences primarily in the lung, liver, kidney, and spine, though with lower sensitivity. No significant perfusion abnormalities were found in the brain between groups. These results demonstrate that model-free metrics may better capture peripheral perfusion impairments associated with CAD than traditional model-based parameters. ***Conclusion:*** Model-free analysis of dynamic ^{18}F-FDG PET enables sensitive and non-invasive quantification of whole-body perfusion, revealing systemic hypoperfusion patterns in CAD patients that are not evident with conventional kinetic models. This approach provides a promising tool for studying heart-body interactions and for the early detection of CAD-related organ dysfunction.

OP-793

Respiratory Motion and Attenuation Corrections Improve Prognostic Value of Myocardial Perfusion Imaging in Patients With Ischemia and Nonobstructive Coronary Arteries

***C. Chen**, C. Ko;*
National Taiwan University Hospital, Taipei, TAIWAN.

Aim/Introduction: Patients with ischemia and nonobstructive coronary arteries (INOCA) often exhibit subtle perfusion abnormalities on myocardial perfusion imaging (MPI), owing to coronary microvascular dysfunction or vasospasm. These abnormalities are particularly susceptible to respiratory motion and photon attenuation, potentially limiting the prognostic value of MPI. This study evaluated whether respiratory motion and attenuation corrections improve the prognostic performance of MPI in patients with INOCA. ***Materials and Methods:*** This retrospective study included 3,166 patients who underwent MPI with cadmium-zinc-telluride (CZT) single-photon emission computed tomography (SPECT). All patients had no significant coronary artery stenosis (< 50%), confirmed by invasive coronary angiography or computed tomography coronary angiography within 6 months before or 2 years after MPI. Respiratory motion correction was performed using a previously validated data-driven gating algorithm. Attenuation correction was applied using a self-developed deep learning model that generated attenuation maps from multi-energy window SPECT images. Patients were followed for a median of 5 years for the occurrence of major adverse cardiovascular events (MACE), including nonfatal stroke, nonfatal myocardial infarction, and all-cause mortality. Cox proportional hazards models were fit to assess the prognostic value of stress total perfusion deficit (STPD), adjusted for age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and smoking status. Model comparisons were conducted using non-nested partial likelihood ratio tests. ***Results:*** Uncorrected STPD was a significant predictor of MACE (adjusted hazard ratio [aHR]: 3.09; $p = 0.026$). Prognostic performance improved with motion correction (aHR: 3.41; $p = 0.014$), attenuation correction (aHR: 9.06; $p < 0.001$), and combined correction (aHR: 7.46; $p < 0.001$). Among these, the combined correction model demonstrated statistically significant improvement over the uncorrected model ($z = 2.048$; $p = 0.020$). ***Conclusion:*** Respiratory motion and attenuation corrections significantly enhance the prognostic performance of CZT SPECT MPI in patients with INOCA. These corrections may improve risk stratification and support clinical decision-making in this challenging population.

OP-794

Stenosis degree and plaque burden differ between the major epicardial coronary arteries supplying ischemic myocardial territories

***T. Kero**[1], J. Knuuti[2], S. Bär[2], J. J. Bax[3], A. Saraste[2], T. Maaniitty[2];*
[1]Uppsala University, Department of Surgical Sciences/Nuclear Medicine & PET, Uppsala, SWEDEN, [2]University of Turku, Turku, FINLAND, [3]Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: There is limited knowledge whether coronary artery luminal narrowing, plaque burden and composition differ between major epicardial coronary arteries supplying ischemic myocardial territories. ***Materials and Methods:*** We evaluated 837 symptomatic patients who underwent both coronary computed tomography angiography (CTA) and ^{15}O-water positron emission tomography (PET) myocardial perfusion imaging for suspected obstructive CAD. Coronary CTA scans were analyzed using Artificial Intelligence-Guided Quantitative Computed Tomography (AI-QCT), with measurements of stenosis degree and parameters of atherosclerotic plaque burden. Presence of myocardial ischemia was defined based on regional PET perfusion in major coronary artery territories (left anterior descending [LAD], left circumflex [LCX], right coronary artery [RCA]). ***Results:*** Among the epicardial coronary arteries supplying ischemic territories the degree of stenosis and absolute and normalized plaque volumes and their components were higher in the LAD as compared to the other main coronary arteries, ($p<0.001$ for all). Many vessels supplying ischemic regions had relatively low stenosis degree and plaque burden, especially in the LCx and RCA vessels. In multivariable logistic regression analyses diameter stenosis ($p=0.001$-0.015), percent atheroma volume ($p<0.001$) and percent non-calcified plaque volume ($p=0.001$-0.017) were associated with myocardial ischemia in all three main coronary arteries whereas percent calcified plaque volume was associated with ischemia only in the RCA ($p=0.001$). ***Conclusion:*** Among the epicardial coronary arteries supplying ischemic myocardial territories, the degree of stenosis and the atherosclerotic burden is significantly higher in the LAD as compared to the LCX and RCA. Many vessels supplying ischemic regions had relatively low stenosis degree and plaque burden. In all the three main coronary arteries both luminal narrowing and plaque burden are independent predictors of ischemia, where the plaque burden is mainly driven by non-calcified plaque.

OP-795

Impact of quantitative CCTA-derived atherosclerotic plaque features on myocardial blood flow assessed by dynamic CZT-SPECT in NOCAD patients

***K. Zavadovsky**, A. Maltseva, R. Dorzhieva, K. Kopeva, A. Dasheeva, A. Mochula, E. Grakova;*
Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Nowadays, studies have demonstrated that patients with non-obstructive coronary artery disease (NOCAD) have an increased risk of myocardial infarction and all-cause mortality, particularly due to coronary microvascular dysfunction. Moreover, atherosclerotic plaque features can affect myocardial blood flow (MBF), but currently, data on this are lacking. Therefore, the aim of this study was to assess the impact of quantitative CCTA-derived atherosclerotic plaque features on myocardial perfusion and MBF in NOCAD patients. ***Materials and Methods:*** Based on CCTA results, a total of 49 NOCAD patients (stenosis <50%; 29 men; mean age 57.4±9.0 years) were included in the study. In addition to stenosis severity estimation, plaque volume (mm3) and burden (%): both generally by coronary bed and separately by structural

components (non-calcified, soft-tissue, fibrous, calcified), were measured. All patients underwent dynamic CZT-SPECT with the assessment of stress and rest MBF and myocardial flow reserve (MFR) [1,2]. ***Results:*** Based on the MFR values, patients were divided into two groups: group 1 enrolled patients with reduced MFR <2.0 (n=20), and group 2 enrolled those with normal MFR ≥2.0 (n=29). All NOCAD patients did not have severe myocardial perfusion abnormalities based on standard myocardial perfusion imaging indeces. Analysis of CCTA data demonstrated that NOCAD patients were characterized by small volumes and burdens of atherosclerotic plaques. Stress MBF significantly correlated with total plaque volume (ρ=-0.40) and burden (ρ=-0.37), as well as non-calcified plaque volume (ρ=-0.34) and burden (ρ=-0.31). Rest MBF significantly correlated with total plaque volume (ρ=-0.50) and burden (ρ=-0.43), and non-calcified plaque volume (ρ=-0.47) and burden (ρ=-0.43). Meanwhile, MFR and standard indeces of myocardial perfusion impairment did not show significant associations with quantitative CCTA parameters. According to multivariate logistic regression analysis, only total plaque volume (OR 1.01; CI 1.00-1.02; p=0.009) was an independent predictor of reduced stress MBF less than 1.5 ml/min/g. ***Conclusion:*** Atherosclerotic plaque features derived from quantitative CCTA data were associated with impaired MBF obtained by dynamic CZT-SPECT. Total plaque volume is an independent predictor of reduced stress MBF. ***References:*** 1.Mochula A, et al. OP-796

Anti-CD8α PET uptake patterns before and during Immune Checkpoint Inhibitor therapy related to irAEs

E. Peeters[1], *E. A. J. van Genugten*[1], *M. R. Ferris*[2], *K. A. Margolin*[3], *C. M. L. van Herpen*[1], *S. Heskamp*[1], *H. Westdorp*[1], *E. H. J. G. Aarntzen*[1,4];
[1]*Radboudumc, Nijmegen, NETHERLANDS,* [2]*ImaginAb, Inglewood, CA, UNITED STATES OF AMERICA,* [3]*Saint John's Cancer Institute, Santa Monica, CA, UNITED STATES OF AMERICA,* [4]*University medical center Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Immune Checkpoint Inhibitors (ICI) have shown durable responses in patients with solid tumours but can cause serious immune related adverse events (irAEs) with great impact on quality of life. CD8+ lymphocytes are considered as key effectors cells, infiltrating tissues affected by irAEs. Anti-CD8α PET enables visualisation of CD8+ lymphocytes in vivo. This analysis investigates changes in PET-derived CD8+ lymphocyte distribution and uptake in non-tumour tissue upon ICI treatment, including associations with irAEs. ***Materials and Methods:*** Metastatic cancer patients (n=48) enrolled in two prospective multi-center studies underwent PET/CT 24 hours p.i. of a ^{89}Zr-labeled minibody targeting CD8α (1.5 mg protein dose) at baseline and 4-6 weeks after first dose of ICI (anti-PD-1 n = 22, anti-PD-1 and anti CTLA-4 n = 26). Organs of interest were automatically segmented using CT-based segmentation software, known tumour lesions were excluded. Mean standardized uptake values (SUVmean) at baseline and on-treatment were computed. Clinical characteristics including irAEs grade ≥2, were correlated to (changes in) CD8+ lymphocyte distributions. Analyses for expanded cohort (n=98 total) are ongoing and will be presented. ***Results:*** Baseline CD8+ lymphocyte distributions showed large inter-patient variation, depending on age and tumour-type; e.g. SUVmean in morphological normal lymph nodes was lower with increasing age. In contrast to decreasing SUVmean in most organs on the on treatment scan upon anti-PD-1 or combined anti-CTLA-4 and anti-PD-1 treatment, SUVmean values of kidney, blood pool and spleen increased upon combination of anti-PD-1 treatment with chemotherapy or TKIs. For 19/48 patients, at least 1 suspected irAE grade ≥2 was reported during the study. None of the patients with documented irAE involvement showed a decrease in SUVmean in affected organs, although not all showed a strong increase. Interestingly, patients with irAEs had increased liver uptake upon treatment, regardless of direct liver involvement. Automated organ segmentation was affected by respiratory motion and spill-over from high splenic or liver activity, requiring standard correction. ***Conclusion:*** Baseline in vivo distributions of CD8+ lymphocytes in non-tumour tissue as measured by SUVmean in part depend on age and tumour-type. Change upon treatment differed between treatment regimens, which should be considered with anti-CD8α PET interpretation. Quantification of anti-CD8α PET requires adaptations of automated methods, to avoid spill over from organs with high activity. Preliminary analysis suggests that anti-CD8α PET allows non-invasive evaluation of both organ specific and systemic changes in CD8+ lymphocytes distribution related to the development of clinically relevant immune toxicities.

OP-797

Unveiling the diagnostic potential of ^{18}F-FDG PET/CT in evaluation of post-transplant disorders.

B. Mittal*, K. Preet, P. Singh, N. Agrawal, R. Kumar, H. Singh;*
Postgraduate Institute of Medical Education & Research, Chandigarh, INDIA.

Aim/Introduction: Transplant recipients incur a lifelong risk of complications due to continuous immunosuppressive therapy, essential for the prevention of graft rejection. However, this compromises the immune system. Thus, increasing vulnerability to infections and malignancies. Reducing immunosuppression can help treat these issues, but it risks graft rejection. Routine diagnostic methods may be insufficient, and advanced imaging techniques like ^{18}F-FDG PET/CT, which detects metabolic activity in inflammatory and cancerous cells, may offer improved diagnosis and monitoring. In this study, we aimed to evaluate the diagnostic potential of PET/CT in the evaluating post-transplant disorders. ***Materials and Methods:*** This was a retrospective study including patients with a history of renal transplant who underwent ^{18}F-FDG PET/CT scan during 2012-2024. PET/CT images were evaluated by experienced Nuclear Medicine physicians and diagnostic efficiency of PET/CT was evaluated in terms of sensitivity (Sn), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) & accuracy (Ac). Also, the diagnostic yield of PET/CT was evaluated. HPE/ clinical course was taken as the gold standard. ***Results:*** The study included 116 post-renal transplant patients (92 males, median age 45 years, range: 11-72 years) who underwent ^{18}F-FDG PET/CT scan for evaluation of suspected post-transplant disorders. The median time from the transplant to the development of post-transplant lymphoproliferative disorder (PTLD) was 7 years (range: 1-16 years). Fever was the most common clinical presentation seen in 30 (25.8%) patients, followed by pain in the abdomen seen in 27 patients (23.2%). Other presenting complaints include loss of weight, loss of appetite, diarrhoea etc. The detailed clinical

presentation is given in table 1. PET/CT scan revealed PTLD in 33 (28.4%) patients, infective/ inflammatory aetiology in 42 (36.2%) patients, 11 (9.5%) patients had features suggestive of neoplastic pathologies other than PTLD, while 18F FDG PET/CT was normal in 30 (25.8%) patients. The detailed HPR /clinical follow-up details (gold standard) are given in table 1. Overall PET/CT demonstrated a Sn, Sp, PPV, NPV, Ac of 96.4%, 94.3%, 84.4%, 98.8% & 94.8 % respectively for diagnosis of PTLD while 69.4%, 80%, 60.9%, 85.3% & 76.7% respectively for detection of infection/ inflammation with an overall yield of 74% for evaluation of post-transplant disorders. ***Conclusion:*** 18F-FDG-PET/CT is a valuable diagnostic tool for evaluation of post-renal transplant patients. Due to their lifelong immunosuppression, these patients are at increased risk of malignancy & infection. PET/CT has shown high diagnostic accuracy as well as diagnostic yield for evaluation of post-renal transplant disorders.

An Example of Higher Accuracy of [68Ga]Ga-FAPI-46 PET/CT in Staging Lymph Nodes Metastases Compared to [18F]F-FDG PET/CT in a Head and Neck Cancer Patient

E. Fortunati[1], *I. Brusa*[1], *G. Cuzzani*[2], *A. Farolfi*[1], *E. Tabacchi*[1], *L. Calderoni*[1], *D. Dall'Olio*[3], *M. Assenza*[4], *C. Nanni*[1], *P. Castellucci*[1], *R. Mei*[1], *M. Fermi*[5], *G. Siepe*[6], *S. Fanti*[1,2];
[1]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [3]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY,* [4]*Professional Development and Implementation of Research in Health Professional Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Department of Otorhinolaryngology-Head and Neck Surgery, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [6]*Radiation Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: A 63y.o. male patient showing squamous cell carcinoma HPV+ of the left amigdaloglossus sulcus. He was an ex-smoker without relevant and known diseases. ceCT described the primary lesion and multiple enlarged left laterocervical lymph-nodes. ***Materials and Methods:*** The patient performed a [18F] F-FDG PET/CT and a subsequent [68Ga]Ga-FAPI-46 PET/CT (6days later) within an ongoing prospective monocentric investigational trial (EudraCT number: 2020-005549-17). [68Ga]Ga-FAPI PET/CT was performed with a 60' dynamic acquisition on LAFOV scanner (uExplorer, United Imaging). The static image was reconstructed with last 5' list mode acquisition. VOIs were manually drawn on suspect lesions. The lesions and references tissues time-to-activity curves (TACs), were fitted using two different graphical models, i.e. Patlak (for irreversible model) and Relative Equilibrium (RE) (for reversible model). Mean absoluted scaled error (MASE) and Akaike Information Criterion (AIC) were utilized to perform model selection for each VOI. ***Results:*** [18F]F-FDG PET/CT and [68Ga]Ga-FAPI-46 PET/CT detected significant uptake (SUVmax=23.1 and 19.5) in the amigdaloglossus lesion. FDG uptake was enhanced in some left laterocervical lymph-nodes at level II (SUVmax=4.8), III and IV (SUVmax=7.2), suspicious for metastases. [68Ga]Ga-FAPI-46 PET/CT was positive only on II level FDG positive nodes, with a very faint uptake in the remaining ones. A subsequent ultrasound-guided-fine-needle-aspiration on lymph nodes of the II, III and IV laterocervical levels showed metastases from SCC only on II level. The reversible RE model was the most appropriate to describe [68Ga]Ga-FAPI-46 pharmacokinetics, and the estimated-distribution volume (DV) resulted higher for primary lesion (meanDV=6.2) and metastatic lymph node of the II laterocervical level (meanDV=4.2) compared to benign lymph nodes of the III and IV levels (meanDV=0.7 and 0.8, respectively). After combined chemotherapy and radiotherapy a further [18F]F-FDG PET/CT was negative in the primary and lymph nodal lesions. ***Conclusion:*** Lymph nodal status in head and neck(H&N) tumours is critical for treatment planning. [68Ga]Ga-FAPI-46 PET/CT has shown higher accuracy in identifying metastatic lymph nodes compared to [18F]F-FDG PET/CT. [68Ga]Ga-FAPI-46 PET/CT could reduce the incidence of false positives, which can lead to unnecessary biopsies and treatments. This case underscores the potential advantages of incorporating [68Ga]Ga-FAPI-46 PET/CT into clinical practice for enhanced accuracy in the staging of lymph nodal metastases in H&N cancers. Dynamic acquisition confirmed the stability of radiopharmaceutical accumulation during the 60 minutes in correspondence of the described lesions. In particular, stability was observed in correspondence of the non-metastatic lymph nodes, which did not show peaks of accumulation.

OP-799

Seeing beyond ^{68}Ga DOTANOC and ^{18}F FDG PET/CT : ^{68}Ga FAPI only uptake in a rare metastatic well differentiated grade I pancreatic neuroendocrine tumor

C. Singareddy, *A. Baa, S. Kankara, M. Bukelo;*
St.Johns's Medical college Hospital, Bengaluru, INDIA.

Aim/Introduction: Nuclear medicine imaging has been increasingly employed in recent years in staging of neuroendocrine tumors (NETs) and guiding management. Somatostatin receptor (SSTR) agonists like Gallium-68 (^{68}Ga) DOTANOC target SSTR expressed by well-differentiated NET. The tracer uptake is higher in well-differentiated NETs compared to poorly-differentiated NETs, and correlates strongly with $SSTR_{2A}$ receptor expression. Fluorine-18 (^{18}F) deoxy-glucose (FDG) PET avidity, on the other hand, reflects increased tumour metabolic activity and is more likely to be positive with increasing histological grade. We present a rare case of Grade I metastatic pancreatic NET with no significant tracer avidity on SSTR/FDG PET-CT; however, showing intense positive lesions on ^{68}Ga FAPI PET-CT. ***Materials and Methods:*** A 35-year-old woman presented to our hospital with complaints of abdominal pain, easy fatiguability, diarrhoea, loss of weight and loss of appetite, 6 months ago. USG and CT abdomen showed multiple space occupying lesions in liver. Liver core biopsy shows foci of metastatic tumour with immunoprofile features consistent with a neuroendocrine tumour with a Ki67 proliferative index of 1-2%. (The neoplastic cells are positive for CK, Synaptophysin (3+, >90%), Chromogranin (2+, >90%) and CD56 (1+,>90%) and negative for LCA and CD99). ***Results:*** ^{68}Ga DOTANOC PET-CT done for initial staging showed no significant SSTR expression in liver lesions or elsewhere in the body. ^{18}F FDG PET-CT was done to rule out poorly differentiated transformation, which also showed no significant FDG avid lesions. Patient was started on injection octreotide LAR 30mg monthly once, but showed no signs of clinical improvement with persistent diarrhea (~ 4-5 episodes/day). ^{177}Lu DOTATATE therapy was not considered in view of absence of tracer avidity on ^{68}Ga DOTANOC PET-CT. After a multidisciplinary tumour board discussion, ^{68}Ga FAPI PET-CT was suggested in theranostic point of view. ^{68}Ga FAPI-04 PET CT showed intense tracer avid enhancing soft tissue density lesion in uncinate process of pancreas measuring 2.7 x 2.2 cm with SUVmax 14.5, along with few subcentimetric mild tracer avid periportal lymph nodes and multiple hypoenhancing lesions in both lobes of liver, largest measuring 4.0 x 3.8 cm with SUVmax 17.8 in segment IV. The patient is now being planned for ^{177}Lu FAPI therapy. ***Conclusion:*** Literature search revealed few NET cases showing FAP expression with discordant SSTR/FDG PET-CT findings. To the best of our knowledge, this is the first NET case negative on both SSTR and FDG PET-CT, but illuminating on ^{68}Ga FAPI PET-CT.

Lack of FES Avidity in FDG-Positive ER-Positive Breast Cancer: A Case Indicating Non-Functional Estrogen Receptors in a Treatment-Naive Patient

A. Mahalik, *N. Kundu, A. Roy, K. Jain, M. Tripathi, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: 18F-FES PET/CT is a molecular imaging modality that non-invasively assesses estrogen receptor (ER) expression in vivo. While ER positivity on histopathology typically corresponds with FES avidity, discordance may reflect tumor heterogeneity or receptor downregulation. This case challenges the assumption of consistent ER expression throughout the disease burden, even at baseline. ***Materials and Methods:*** A 57-year-old female diagnosed with ER-positive invasive ductal carcinoma of the right breast underwent staging workup. Baseline ^{18}F-FDG PET/CT revealed intense metabolic activity in the right breast primary lesion and right axillary lymph nodes. However, corresponding 18F-FES PET/CT performed within a short interval did not demonstrate any significant tracer uptake in these sites, despite confirmed ER positivity on biopsy, suggesting a discrepancy between receptor expression and receptor functionality. ***Results:*** The absence of FES uptake in known FDG-avid, biopsy-confirmed ER-positive primary and nodal lesions raises critical questions about receptor functionality. This suggests either non-functional or inaccessible estrogen receptors despite positive immunohistochemistry. Possible contributing factors include receptor internalization, post-translational modifications, or alterations in receptor co-factor expression. Such cases underline the importance of functional imaging to complement static receptor expression data and help refine therapeutic decisions, especially when endocrine therapy is considered. ***Conclusion:*** This case demonstrates clinically significant discordance between FDG and FES PET/CT in ER-positive breast cancer, highlighting the gap between receptor presence and functional activity. The absence of FES uptake in both the breast and axillary nodes, despite FDG avidity and biopsy-confirmed ER positivity, underscores the potential for non-functional ER expression. Receptor functionality assessment through molecular imaging may better predict endocrine responsiveness than histology alone.

OP-801

Detection of Insulinoma Using 68Ga-NODAGA-Exendin-4 PET/CT: A Report of Two Cases

A. Guercio[1], *T. Graziani*[1], *M. Scarlattei*[1], *S. Migliari*[1], *C. Cidda*[1], *G. Baldari*[1], *V. Cervati*[1], *A. Gagliardi*[1], *A. Dei Cas*[2], *R. Bonadonna*[3], *L. Ruffini*[1];
[1]*Nuclear Medicine Division, University Hospital of Parma, Parma, ITALY,* [2]*Laboratory of Endocrinology, Diabetes and Metabolic Diseases, Department of Medicine and Surgery, University of Parma, Parma, ITALY,* [3]*Endocrinology Division, Diabetes and Metabolic Diseases, Department of Medicine and Surgery, University of Verona, Verona, ITALY.*

Aim/Introduction: Insulinomas are rare pancreatic neuroendocrine tumors that inappropriately secrete insulin, causing recurrent hypoglycemia. Diagnosis relies on biochemical confirmation and accurate lesion localisation via contrast-enhanced CT, MRI, and endoscopic ultrasound [1]. Recently, 68Ga-NODAGA-Exendin-4 PET/CT has emerged as a promising molecular imaging technique for insulinoma detection, targeting glucagon-like peptide-1 receptor (GLP-1R), overexpressed in these tumors [2]. The synthesis of 68Ga-NODAGA-Exendin-4 has been validated at our center [3], supporting its clinical use. This report illustrates the diagnostic value of 68Ga-NODAGA-Exendin-4 PET/CT in two insulinoma patients. ***Materials and Methods:*** The radiotracer was synthesized in-house using an automated module and a GMP-certified 68Ge/68Ga generator. Whole-body PET/CT images were acquired 60 minutes after i.v. tracer injection (from skull basis to pelvis). Tracer uptake was quantitatively assessed using SUVmetrics across defined pancreatic volumes of interest and in splenic tissue as background, being the spleen a non-binding site for 68Ga-NODAGA-Exendin-4 [4]. Tumor-to-background ratio (TBR) was also calculated. ***Results:*** Case 1: A 77-year-old man presented with symptomatic hypoglycemia and a nodular lesion in the pancreatic head detected on CT. Initial imaging with 68Ga-DOTATOC PET/CT showed small focal uptake in the pancreatic head. 68Ga-NODAGA-Exendin-4 PET/CT revealed a lesion highly expressing GLP-1R in the same area (SUVmax 27.70; SUVmean 20.07; TBRmean 32.37). Histopathology confirmed a well-differentiated G1 insulinoma. 68Ga-NODAGA-Exendin-4 radiosynthesis: 56.9% radiochemical yield (RCY%), 97.6% and 100.0% radiochemical purity (RCP%) by HPLC and TLC, respectively. Mean peptide amount was 3.77 µg in a 150 MBq dose. Case 2: an 88-year-old diabetic patient with hypoglycemia showed a CT-positive vascularized lesion (13 mm) in the pancreatic tail. 68Ga-NODAGA-Exendin-4 PET/CT confirmed high uptake in the lesion (SUVmax 17.47; SUVmean 14.31; TBRmean 14.17). Unfortunately, further diagnostic or therapeutic interventions were not possible, as the patient passed away shortly after the scan due to cardiovascular complications. Radiosynthesis: RCY% 52.0%, RCP% 97.6% (HPLC), 100.0% (TLC). The injected dose (100 MBq) contained 1.55 µg of peptide. ***Conclusion:*** PET/CT with 68Ga-NODAGA-Exendin-4 demonstrated high sensitivity in detecting insulinomas in both cases, due to its capacity to specifically target GLP-1R. Its ability to provide precise localization, even in challenging anatomical contexts, supports its use as a valuable diagnostic tool. ***References:*** 1) Christ E, et al. OP-802

A Weighty Problem: GLP-1 Agonists and the Altered Images of FDG PET-CT

P. Strouhal, *A. Meadows, A. McGovern;*
Alliance Medical Ltd, Warwick, UNITED KINGDOM.

Aim/Introduction: GLP-1 receptor agonists - such as Semaglutide - are increasingly prescribed for type 2 diabetes and obesity, with reported 700% increased use in USA. These agents affect glucose metabolism, gastric motility and sympathetic tone, raising concerns about altered ^{18}F-FDG biodistribution on PET-CT. Case reports describe increased uptake in skeletal muscle, myocardium, and brown adipose tissue (BAT), mimicking malignancy or inflammation. Our case series highlights implications for scan interpretation and patient preparation. ***Materials and Methods:*** Retrospective review of oncological FDG PET-CT scans from patients on GLP-1 agonists. Scan findings compared with expected physiological uptake and evaluated alongside current literature. Attention focused on interpretative difficulties likely to influence clinical decisions. ***Results:*** Several cases showed atypical tracer uptake in sites of possible pathology, underscoring diagnostic pitfalls (pics included). These observations aligned with published data and reinforced the need for clinical context and medication history during interpretation. ***Conclusion:*** GLP-1 receptor agonists pose an increasing challenge in FDG PET-CT scanning. Current UK guidelines (EANM/BNMS) do not address this yet, though Australian guidance recommends continuing treatment, fasting from midnight, scheduling morning scans, and ensuring good glucose control. A consensus view needs adopting in UK practice to reduce false positives and improve diagnostic confidence. Awareness among imaging teams is essential, and national guidance should be developed to standardise approaches amid growing GLP-1 agonist use. ***References:*** 1. The BMJ. Semaglutide:

OP-803

Efficacy of short acting and ultra-short acting insulin in improving image quality of ^{18}F-FDG PET in diabetic cancer patients.

S. Saeed[1], *M. Nadeem*[2], *S. Hanan*[3], *M. Younis*[4], *S. Saeed*[5]; *[1]Punjab Institute of Cardiology, Lahore, PAKISTAN, [2]Al Nasar Lab & Diagnostic Center, Lahore, PAKISTAN, [3]NUR International University, Lahore, PAKISTAN, [4]Doctors Hospital and Medical Center, Lahore, PAKISTAN, [5]Fatima Memorial College of Medicine and Dentistry, Lahore, PAKISTAN.*

Aim/Introduction: Aims: To evaluate and compare the effectiveness of Ultra-short versus Short acting insulin on normalization of blood glucose levels in diabetic patients presenting for ^{18}F-FDG PET-CT, their effects on image quality and SUV_{mean} values. Introduction: Diabetes and cancer are two heterogeneous, multifactorial, severe, and chronic diseases. Diabetes increases the risk of various cancers, including pancreatic, liver, breast, and colorectal cancer. ^{18}F-FDG PET imaging is a noninvasive diagnostic tool that can be used to acquire quantitative parameters concerning the metabolic activity of target tissues. ***Materials and Methods:*** A triple arm prospective interventional study was conducted, constituting of 45 subjects equally divided into three groups of 15 subjects in each. Group A included diabetics injected with ultra short acting insulin, Group B included diabetics injected with regular/short acting insulin when patients showed high blood glucose levels > 180 mg/dL (10 mmol/L) and Group C included non-diabetics.^{18}F-FDG was injected as blood glucose levels lowered down to acceptable range (cutoff 180 mg/dL), and images were acquired. Blood glucose levels normalization after insulin administration, visual scoring and SUV_{mean} of anterior liver and thigh muscles were assessed to compare the effectiveness of ultra-short versus short acting insulin. ***Results:*** The basal blood glucose level in group A and B was not significantly different (236.1 ± 25.4, 242.2 ± 26.7, P= 0.52). However, after insulin administration the blood glucose levels of group A patients were lowered down to acceptable range earlier than group B (27.00 ± 11.6 min vs. 51.00 ± 7.6 min, P= 0.0000). Nevertheless, the image quality was not significantly different between group A-B, A-C, B-C (Mann-Whitney U test, P = 0.84, 0.52, 0.36 respectively). No significant differences were seen in between group A-B, A-C and B-C SUV_{mean} in the liver (P = 0.11, 0.75, 0.07 respectively), and anterior thigh muscle (P =0.18, 0.07, 0.46 respectively), between groups. ***Conclusion:*** Intravenous ultra-short acting insulin can successfully be used to lower down blood glucose levels to acceptable range in shorter time and with comparable effects on ^{18}F-FDG bio-distribution in terms of image quality and mean standardized uptake value (SUV_{mean}) as compared to short acting insulin in most cancer patients undergoing an ^{18}F-FDG PET examination with least chances of being hypoglycemic.

OP-804

Multimodality Imaging in the Assessment of Liver-Directed Therapy Response in Prostate Cancer: A Case Demonstrating False Positive PSMA Uptake

Y. Eryilmaz, *O. Kodaz, G. Kaya, B. Volkan Salancı, M. Tuncel; Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Ga-68 PSMA PET/CT is highly sensitive for detecting prostate cancer (PCa) metastases, but post-treatment interpretation can be challenging due to potential false positives. This case demonstrates how FDG PET/CT and liver-dedicated MRI can clarify equivocal PSMA findings following microwave ablation (MWA) of liver metastasis, highlighting a diagnostic pitfall in PSMA PET/CT. ***Materials and Methods:*** A 63-year-old male with high-risk PCa and a biopsy-proven liver metastasis underwent MWA of the metastatic lesion in the liver. Six months post-ablation, he presented with rising PSA levels. PSMA PET/CT was performed for restaging. Due to equivocal PSMA PET/CT findings, FDG PET/CT and liver-MRI were performed for further evaluation. Follow-up included all three imaging modalities. ***Results:*** Ga-68 PSMA PET/CT initially demonstrated faint uptake in a new lesion located in segment-IV (near the porta hepatis) and persistent uptake in the previously ablated segment-VI site, raising suspicion of recurrent or residual disease. Due to the low PSMA avidity of the segment-IV lesion, FDG PET/CT was performed. It revealed intense FDG uptake (SUVmax 9.5) in the segment-IV lesion, suggesting viable tumor with possible neuroendocrine differentiation. No FDG uptake was noted in the previously treated segment-VI lesion. Liver-MRI confirmed the presence of a new lesion in segment-IV and complete ablation of the segment-VI metastasis. The segment-IV lesion was subsequently treated with MWA, and androgen receptor pathway inhibitor therapy was added to the systemic treatment. Follow-up imaging with PSMA PET/CT, FDG PET/CT, and liver-MRI was performed to assess treatment response. MRI and FDG PET/CT showed no sign of residual tumor in the liver. PSMA PET/CT showed no increased uptake in segment-IV; however, it demonstrated persistent uptake in the previously ablated segment-VI lesion, with no corresponding FDG uptake or suspicious MRI findings. PSA levels gradually declined, with no biochemical recurrence observed over the last eleven months, supporting the interpretation of persistent PSMA uptake as a post-ablation effect rather than active disease. ***Conclusion:*** This case demonstrates the potential for false-positive PSMA uptake at prior ablation sites due to post-treatment histopathological changes such as neovascularization. MRI is the preferred modality for evaluating liver-directed therapy response, while FDG PET/CT provides valuable insight into tumor heterogeneity. The combined use of PSMA PET/CT, FDG PET/CT, and liver-MRI enhances diagnostic clarity and supports more accurate clinical decisions in challenging prostate cancer cases. To our knowledge, this is the first case reporting PSMA uptake secondary to post-ablation changes in liver metastases from prostate cancer.

Head-to-head comparison of bone scintigraphy metastasis detection provided by a high-speed whole-body 360° CZT-SPECT and a currently recommended Anger camera protocol

A. Bahloul, *M. Perrin, A. Verger, S. Ouguirti, V. Roch, P. Marie, L. Imbert;*
CHU de Nancy, Vandoeuvre Les Nancy, FRANCE.

Aim/Introduction: Bone scintigraphy recording time may be dramatically decreased with whole-body high-speed 360° CZT-SPECT (Fast-CZT), as compared with the Anger camera bone scintigraphy protocols recommended for cancer patients (Reco-Anger). However, it remains unknown how Fast-CZT results compare with Reco-Anger ones. The OSS prospective study aimed to provide a head-to-head comparison of bone scintigraphy results provided by Fast-CZT and Reco-Anger in the same cancer patients. ***Materials and Methods:*** We selected 133 patients with history of cancer (breast: 76, prostate: 47, other: 10) who were referred to bone scintigraphy for the detection or survey of bone metastasis. Three to 4 hours after 569 ± 41 MBq [^{99m}Tc]Tc-HDP injection, they underwent consecutively and in a random order (i) an 18 min single whole-body Fast-CZT SPECT recording preceded by a whole-body low-dose CT, and (ii) a 30 to 60 min Reco-Anger protocol with whole-body planar followed by one to three SPECT/CT recordings. Fast-CZT and Reco-Anger images were analyzed separately at least one month apart through a consensus of three blinded experienced observers and assigned a grading known to impact further medical management -i.e., no bone metastasis, oligometastases (≤ 5), or polymetastases (> 5). ***Results:*** There were 81 women and 52 men with mean age of 67 ± 10 years, and mean body mass index of 27.3 ± 5.7 kg.m^{-2}. Inter-observer agreements in the 3-group classification were high for both Reco-Anger (87.0%) and Fast-CZT (88.5%) analyses. Per-patient rates were not significantly different between Reco-Anger and Fast-CZT for the detection of one or more bone metastases (37.6% (50/133) vs. 33.8% (45/133), p=0.23) or a polymetastatic stage (18.0% (24/133) vs. 16.5% (22/133), p=0.50). Furthermore, there was strong agreement between the 3-group classification achieved by the two cameras, given a Cohen's kappa score of 0.813 ± 0.045 and a global agreement rate of 90.2%. The classifications by camera were different in only 13 cases (9.8%), with a higher metastasis grading from the Reco-Anger in 10 cases and from Fast-CZT in 3. ***Conclusion:*** The detection of bone metastasis by whole-body high-speed bone 360° CZT-SPECT compares well with that provided by a recommended Anger camera protocol with (i) a global agreement rate that is in the range of the interobserver agreements observed for the analyses of Fast-CZT or Reco-Anger but (ii) a dramatic decrease in recording time, a property that is beneficial for patient comfort and throughput.

EPS-265

Potential of 68Ga-FAPI-46 PET/CT in patients with primary bone and soft tissue sarcoma: head-to-head comparison with ^{18}F-FDG PET/CT

E. Davydova[1], *M. Komarova*[1], *A. Chaban*[2], *A. Pronin*[1], *A. Martinovich*[1], *O. Ryzhova*[1], *I. Amosova*[1];
[1]*N.N Blokhin National Medical Research Center of Oncology of the Russian Ministry of Health, Moscow, RUSSIAN FEDERATION,* [2]*Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: to evaluate the role of 68Ga-FAPI PET/CT in patients with primary bone and soft tissue sarcoma, compared with ^{18}F-FDG PET/CT. ***Materials and Methods:*** the study included 24 patients (13 females and 11 males; median age, 44 years) with 15 subtypes of primary bone and soft tissue sarcoma. All individuals underwent both ^{18}F-FDG and 68Ga-FAPI PET/CT examination within 1 week for assessment of primary tumor or distant metastasis. Positive lesions on PET/CT were histologically verified or confirmed with 3-month follow-up. Wilcoxon matched-pairs signed-rank test was used to compare the semiquantitative values (SUVmax and TBR) of ^{18}F-FDG and 68Ga-FAPI PET/CT in tumor lesions. ***Results:*** 119 tumor lesions (primary tumor, lymph nodes, bone, lung and other distance metastasis) were identified. 68Ga-FAPI PET/CT demonstrated significantly higher values of SUVmax and TBR than ^{18}F-FDG in liposarcoma, malignant solitary fibrous tumor, desmoid fibromatosis and fibrosarcoma: 36,67 [9,26-48,64] vs 4,28 [2,56-9,34] and 24,16 [7,43-25,47] vs 1,6[0,96-4,66] respectively, p =0,0039. However in some subtypes there was favorable uptake of ^{18}F-FDG over 68Ga-FAPI (synovial sarcoma, pleomorphic sarcoma, leiomyosarcoma, intimal sarcoma): SUVmax were 8,66 [7,17-14,4] vs 4,91 [3,5-7,34], p =0,0317; TBR were 7,65 [4,15-13,87] vs 2,5 [1,87-`2,87], p=0,0159. There was no significant difference between SUVmax and TBR in other subtypes of bone and soft tissue sarcoma. The total sensitivity specificity and accuracy in the detection of all tumor lesions using 68Ga-FAPI were 66%, 73,68% and 67,23 % resp. and ^{18}F-FDG were 76,6%, 29,17 % and 66,95% resp. ***Conclusion:*** 68Ga-FAPI PET/CT outperforms ^{18}F-FDG in identifying lesions of liposarcoma, malignant solitary fibrous tumor, desmoid fibromatosis and fibrosarcoma. In other subtypes of sarcomas, the 68Ga- FAPI PET/CT has the same or less performance compared with 18F-FDG.

EPS-266

Baseline Bone Marrow Scintigraphy as Predictive Marker of Outcomes in mCRPC Patients Treated with Radium-223 Dichloride

Q. Shagera, *O. Gheysens, E. Jonard, E. Seront, B. Tombal, F. Jamar; Cliniques univérsitaires Saint-Luc, UClouvain, Brussels, BELGIUM.*

Aim/Introduction: We aimed to assess the value of baseline Bone Marrow Scintigraphy (BMS) in predicting overall survival (OS) in patients with mCRPC treated with Ra-223 dichloride. ***Materials and Methods:*** Among 82 patients treated with radium-223 (Ra-223) between 2014 and 2024, 28 underwent BMS on the same day as the first Ra-223 dose, were included. Whole body planar imaging was conducted 30-60 minutes after injection of ~ 7.5 mCi of (Tc-99m)-labeled nanocolloids using a dual-head gamma camera. Visual image analysis was performed and defined as follows: a score of 0 indicated normal biodistribution, score 1 denoted mild expansion (discrete uptake outside regions of normal distribution), and score 2 represented moderate to extensive medullary expansion exemplified by uptake at the distal half of femoral and/or humeral diaphyses or more distally. Patients were subsequently dichotomized as those with scores of 0+1 versus 2. A t-test comparing the mean was conducted to assess the relationship between BMS status and baseline hemoglobin (Hb) levels. Cox proportional hazards regression and Kaplan-Meier survival analysis were performed to evaluate the relationship between BMS status and the clinical variables and patient outcomes. ***Results:*** A total of 130 doses of Ra-223 were administered, with a median of 6 cycles (IQR 3-6). Baseline BMS status was significantly associated with baseline Hb levels: patients with normal BMS had a significantly higher mean Hb (13.2±1.2 g/dL) compared to those with bone marrow (BM) expansion (10.8 ± 1.7 g/dL, p<0.001). The median number of Ra-223 cycles in patients with BM expansion was lower than in those with normal BMS (3 vs. 6, p=0.08). Medullary expansion status was significantly associated with the number of prior systemic therapies (p=0.032)

and salvage or metastatic targeted radiotherapy (p=0.01). Median OS was 18 months, with 16/28 (57%) patients dead. BMS status, hemoglobin, number of prior systemic therapies, and number of Ra-223 cycles were significantly associated with OS (hazard ratios and p-values: 3.3, p=0.02; 0.75, p=0.042; 1.6, p=0.019; 0.6, p=0.002; respectively). Patients with normal BMS had a median OS of 33 months compared to 8 months in those with BM expansion (log-rank 5.5, p=0.019). ***Conclusion:*** The study findings demonstrate the association between BMS status and patient OS. Patients with BM expansion have worse outcomes compared to those with normal BMS. The study findings also showed a correlation between the BM expansion status and baseline clinical factors in mCRPC patients treated with Ra-223.

EPS-267

Unspecific Bone Uptake on PSMA PET/CT in Prostate Cancer: Distinguishing Early Metastases from Benign Findings

N. Vasconcelos, *D. Barbosa, D. Silva, R. Marão, J. Teixeira, I. Lucena Sampaio;*
Instituto Português de Oncologia, Porto, PORTUGAL.

Aim/Introduction: Detection of focal unspecific bone uptake (UBU) on prostate-specific membrane antigen (PSMA) PET/CT scans of prostate cancer (PCa) patients poses a diagnostic challenge. These findings may represent early metastatic disease or benign processes. Their correct interpretation is critical to guide management. This study aimed to characterize UBUs detected on PSMA PET/CT and to evaluate clinical and imaging predictors of malignancy. ***Materials and Methods:*** Retrospective analysis of [^{68}Ga]Ga-PSMA-11 PET/CT scans (January 2017-December 2024) in patients with histologically confirmed PCa presenting with UBUs, in the absence of other bone metastases (n = 107). Assessed clinical variables included age, Prostate Specific Antigen (PSA) levels, ISUP (International Society of Urological Pathology) grade, PET/CT indication, and nodal status (N1 and M1a). Imaging variables included maximum standardized uptake value (SUVmax), lesion location, and CT morphological correlation. Lesion outcomes were determined by clinical follow-up, PSA kinetics, subsequent imaging, or histological confirmation when available. Univariate logistic regression was initially performed to identify variables associated with malignancy, followed by multivariate logistic regression to determine independent predictors among the significant factors. ***Results:*** Among the 107 UBUs analysed, the most frequently involved anatomical sites were the ribs (48.6%) and pelvic bones (32.7%). Based on follow-up, 63 lesions (58.9%) were classified as benign, 17 (15.9%) as malignant, and 27 (25.2%) remained indeterminate. Among the 80 UBUs with definitive outcome, SUVmax (p = 0.004), presence of regional (N1) and distant (M1a) lymph node metastasis (p = 0.005 and p=0.029, respectively) were significantly associated with malignancy in univariate analysis. Multivariate logistic regression identified both SUVmax (Odds Ratio [OR] 1.63, 95% confidence interval [95% CI] 1.08-2.46, p = 0.020) and N1 positivity (OR 7.03, 95% CI 1.87-26.52, p = 0.004) as independent predictors of malignancy. The model demonstrated good discriminative ability (Area Under the curve [AUC] 0.76). The optimal SUVmax cutoff to predict malignancy was 3.54, yielding 64.7% sensitivity and 79.4% specificity. ***Conclusion:*** In this review, 15.9% of UBUs were confirmed as metastatic. SUVmax (cutoff value of 3.54) and N1 status were independent predictors of malignancy, emphasizing the value of integrating semi-quantitative metrics and nodal assessment to improve diagnostic accuracy in indeterminate bone lesions.

EPS-268

Targeting SSTR2 in Monitoring Skeletal Stem Cells and Osteosarcoma via [^{18}F]-Octreotide PET-CT

Z. Li, *X. Su;*
First Affiliated Hospital of Zhejiang University, School of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Skeletal stem cells (SSCs) serve as progenitors of osteogenic cells and regulate skeletal development, injury repair, and pathological processes including neoplasia such as osteosarcoma[1,2]. While conventional skeletal imaging modalities assess structural morphology, they fail to capture cellular-level alterations critical for SSC-related disorders such as osteosarcoma. Given the reported expression of somatostatin receptor 2 (SSTR2) in SSCs[3], we aimed to investigate SSC dynamics and associated malignancies, using ^{18}F-labeled Octreotide. ***Materials and Methods:*** Publicly available single-cell RNA sequencing (scRNA-seq) datasets (GSE205945) were analyzed to evaluate colocalization of SSTR2 with established SSC markers. Retrospective analysis included 6 patients undergoing [^{18}F]-octreotide PET-CT: three pediatric cases (<10 years) with suspected neuroendocrine neoplasms (NENs) yielding negative diagnoses, and three adults (>30 years) with surgically treated NENs in complete remission. One biopsy-confirmed osteosarcoma patient underwent prospective [^{18}F]-octreotide PET-CT. Immunohistochemistry (IHC) validated SSTR2 expression in tumor specimens. ***Results:*** scRNA-seq revealed SSTR2 predominance in SSC subsets co-expressing Itgav and CD200, with upregulated SSTR2 during SSC expansion in fracture repair. Pediatric patients exhibited distinct [^{18}F]-octreotide uptake in metaphyseal regions (mean SUVmax 4.0±1.1), correlating with SSC-rich zones, while adults showed background-level skeletal signals (SUVmax 0.1±0.0). Osteosarcoma lesions demonstrated elevated tracer uptake (SUVmax 7.2), supported by scRNA-seq showing SSTR2 co-expression with SSC markers in malignant cells. IHC confirmed ubiquitous SSTR2 expression in osteosarcoma. ***Conclusion:*** [^{18}F]-octreotide PET-CT enables non-invasive SSC monitoring and shows diagnostic potential for osteosarcoma by targeting SSTR2. ***References:*** [1]Yuan G, Lin X, Liu Y, Greenblatt M B, Xu R. Use of ^{18}F-FDG PET-CT in pediatric Rhabdomyosarcoma:can progression be predicted?

S. Iaria[1], *C. Caldarella*[2], *L. Leccisotti*[1,2];
[1]*Università Cattolica del Sacro Cuore, Rome, ITALY,* [2]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY.*

Aim/Introduction: Rhabdomyosarcoma is a rare, aggressive mesenchymal malignancy that originates from skeletal muscle cells. It may also occur in the pediatric age. Metastases usually arise in lung (parenchyma and pleura), bones and lymph nodes, and may be present at diagnosis or occur during post-treatment follow-up. Nuclear medicine imaging, especially using ^{18}F-FDG PET-CT, is helpful in these patients' management for staging and therapy evaluation, and may aid in prognosis stratification. Aim of this study is to evaluate whether semi-quantitative parameters expression of ^{18}F-FDG uptake in the primary lesion may predict progression in pediatric patients with rhabdomyosarcoma. ***Materials and Methods:*** In this monocentric retrospective study, we collected data about ^{18}F-FDG PET-CT scans performed from

2011 to January 2024 in patients with rhabdomyosarcoma who were < 18 years old at the time of diagnosis. Particularly, scans were included only when the primary lesion was evident and with increased ^{18}F-FDG uptake (patients excluded in case primary lesion was surgically removed). Information on possible previous therapy (chemo- or radiotherapy), tumor histology and patients' death or loss to follow-up was also collected. SUVmax, SUVmean, SUVpeak, MTV and TLG of the primary lesion were obtained by a semi-automatic 40% threshold contouring. Disease progression (either appearance of new lesions or increase in uptake of already known ones) was noticed. ***Results:*** 28 pediatric patients (age range 2-17) were included in the study: 11 of them had signs of progressive disease (PD), and 17 had no evidence of progressive disease (NPD). Patients with PD were slightly older than ones with NPD (median 16 y.o., IQR 15-17 vs median 11 y.o., IQR 8-14). Moreover, although SUVmax, SUVmean and SUVpeak did not differ significantly between these two cohorts of patients, MTV was higher in PD than in NPD (median 35 cm^3; IQR 21.46-85.57 vs median 12 cm^3; IQR 2.71-17.43; p=0.001); TLG was also higher in in PD than in NPD patients (median 137.84 SUV x cm^3; IQR 57.12-421.29 vs median 33.52 SUV x cm^3; IQR 15.17-82.8; p=0.006). ***Conclusion:*** Higher MTV and TLG are associated to a higher risk of disease progression in pediatric patients with rhabdomyosarcoma, therefore inferring an invaluable role of PET-CT in the management of this serious condition and confirming the superior role of volume-based parameters for prognosis prediction.

EPS-270

Diagnostic Potential of ^{68}Ga-FAPI-46 PET/CT in the Evaluation of Metastatic Soft Tissue Sarcomas: A Comparative Analysis with ^{18}F-FDG PET/CT

S. Shamim*, Y. Khandelwal, B. Jain, S. Rastogi;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Fibroblast activation protein (FAP), a serine protease, is highly expressed on cancer-associated fibroblasts (CAFs) and certain tumor cells, including those of soft tissue sarcomas (STS). While ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET/CT remains the conventional imaging modality for staging, restaging, therapy assessment, and prognostication in metastatic STS, its diagnostic sensitivity is limited in specific histologic subtypes, particularly low-grade tumors. This study prospectively assesses the diagnostic performance of ^{68}Ga-labeled FAP inhibitor (^{68}Ga-FAPI-46) PET/CT in metastatic STS and benchmarks it against ^{18}F-FDG PET/CT. ***Materials and Methods:*** In this prospective investigation conducted at a tertiary care center, 25 patients (11 females, 14 males; median age 35 years, range 16-68) with histologically confirmed metastatic STS underwent both ^{18}F-FDG and ^{68}Ga-FAPI-46 PET/CT imaging within a one-week interval, using Siemens Biograph mCT 64 or GE Discovery 710 PET/CT systems. Imaging datasets were evaluated both qualitatively and semi-quantitatively. Parameters analyzed included lesion count, maximum standardized uptake value (SUVmax), and tumor-to-background ratio (TBR). Comparative analysis employed the Wilcoxon matched-pairs signed-rank test for SUVmax and TBR, and the McNemar test for lesion detection rates. ***Results:*** Eight distinct histologic STS subtypes were represented among the cohort. ^{68}Ga-FAPI-46 PET/CT identified a greater total number of metastatic lesions compared to ^{18}F-FDG PET/CT (167 vs. 132 lesions). Mean ± SD SUVmax was 5.4 ± 2.1 for ^{18}F-FDG and 4.7 ± 2.3 for ^{68}Ga-FAPI-46. Notable inter-tracer discrepancies were observed, particularly in liposarcoma, leiomyosarcoma, and undifferentiated pleomorphic sarcoma, where ^{68}Ga-FAPI-46 demonstrated superior lesion conspicuity. ***Conclusion:*** ^{68}Ga-FAPI-46 PET/CT exhibits comparable, and in certain histological subtypes superior, diagnostic efficacy to ^{18}F-FDG PET/CT in the detection of metastatic STS. Its higher lesion detection rate and favorable uptake in select sarcoma subtypes underscore its potential as an alternative imaging biomarker. Validation through larger-scale, multicenter studies is warranted to define its definitive clinical utility ***References:*** Gu B, Liu X, Wang S, Xu X, Liu X, Hu S, Yan W, Luo Z, Song S. Head-to-head evaluation of [18F]FDG and [68 Ga]Ga-DOTA-FAPI-04 PET/CT in recurrent soft tissue sarcoma. Eur J Nucl Med Mol Imaging. 2022 Jul;49(8):2889-2901. doi: 10.1007/s00259-022-05700-4. EPS-271

^{68}Ga-FAPI-PET/CT leads to changes in clinical management of patients with malignant and benign peripheral nerve sheath tumors

A. Spektor*[1], A. Waldschütz[1], M. Fried[2,3], D. Kalasauskas[4,5], M. Schreckenberger[1], M. Röhrich[1];*
[1]Department of Nuclear Medicine, University Center Mainz, Mainz, GERMANY, [2]University Center for Oncology, University Medical Center Mainz, Mainz, GERMANY, [3]Clinic and Polyclinic for Internal Medicine III, University Center Mainz, Mainz, GERMANY, [4]Department of Neurosurgery, University Center Mainz, Mainz, GERMANY, [5]Department of Neurosurgery, University Hospital LMU Munich, Munich, GERMANY.

Aim/Introduction: Malignant peripheral nerve sheath tumors (MPNST) are aggressive soft tissue sarcomas, which can occur sporadically, post radiation or in association with Neurofibromatosis type 1 (NF1). As MPNST and benign PNST (BPNST; neurofibroma and schwannoma) present a similar clinical and radiological picture, differentiation between MPNST and BPNST is challenging in early state. Thus, MPNST are associated with a poor prognosis due to delayed diagnosis, high metastasis rate and difficult resection being a main cause for mortality in patients with NF1. Diagnostic modalities of choice such as magnetic resonance imaging (MRI) as well as ^{18}F-Fluorodeoxyglucose positron emission tomography with computed tomography (^{18}F-FDG-PET/CT) show high sensitivity for the detection of MPNST but moderate specificity. PET/CT with ^{68}Gallium-labeled fibroblast activation protein inhibitor (^{68}Ga-FAPI) showed a specific uptake in sarcomas and enabled differentiation of benign and malignant lesions in other entities. The aim of our study is to analyze the ^{68}Ga-FAPI uptake in MPNST and BPNST with regard to their discriminability and subsequently to clinical consequences. ***Materials and Methods:*** Patients with suspected PNST after inconclusive prior MRI were examined by ^{68}Ga-FAPI-46-PET/CT. Subsequently, the clinical course of each patient was monitored and MRI findings as well as tumor board decisions prior and after FAPI-PET/CT were compared. PET evaluation (SUVmax/mean/peak, TBRmax/mean/peak) was performed in PMOD 4.401 with VOIs (isocontour 50%). ***Results:*** To date, 4 patients with histologically confirmed (hc) MPNST, 5 patients with hc BPNST (4 schwannoma, 1 neurofibroma), 1 patient with suspected non-hc MPNST and 3 patients with non-hc BPNST have undergone FAPI-PET/CT examination. Hc MPNST showed significantly higher SUVmax/mean/peak (14.35 ± 3.91/ 7.79 ± 2.18/ 13.67 ± 3.67 versus (vs.) 2.84 ± 1.15/ 1.58 ± 0,69/ 2.71 ± 1.09; p < 0.0001) and higher TBRmax/mean/peak (6.44 ± 1.66/ 5.99 ± 2.04 / 6.53 ± 1.63 vs. 1.17 ± 0.26/ 1.14 ± 0.17/ 1.19 ± 0.25; p < 0.0001) than hc BPNST. FAPI-PET/CT led to changes in clinical course in 6 (2 upstagings, 2 waiver of surgery/biopsy, 1 intensification of therapy, 1 FAPI-hotspot biopsy) of 9 patients with hc PNST, in all 3 (waiver of surgery/biopsy) non-hc BPNST and 1 (upstaging) non-hc MPNST patients. ***Conclusion:*** MPNST and BPNST can be specificly differentiated by FAPI-uptake leading to drastic changes in clinical course by upstaging or prevention of surgery/ biopsy. ^{68}Ga-FAPI-PET/CT might be thus a promising modality for targeted diagnosis and clinical management of patients with MPNST and BPNST.

Meyer, Florence, ITALY, [5]Oncology Unit, IRCSS Istituto Giannina Gaslini, Genoa, ITALY, [6]Pediatric Hematology and Oncology Unit, ARNAS "Civico, Di Cristina and Benfratelli" Hospitals, Palermo, ITALY, [7]Nuclear Medicine, University of Brescia and Spedali Civili di Brescia, Brescia, ITALY, [8]Department of Radiological Sciences, Oncology and Anatomical Pathology, Sapienza, Rome, ITALY, [9]Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', University of Florence, Florence, ITALY, [10]Nuclear Medicine Department, Salus Alliance Medical, Genoa, ITALY.

Aim/Introduction: Radiomic descriptors from the tumour core and from the 0.5cm peritumoral ring may be complementary. We assessed whether combining both regions and both modalities (PET and CT) improves noninvasive discrimination of osteosarcoma (OS), Ewing sarcoma (EWS) and rhabdomyosarcoma (RMS) compared with models based on either region alone. ***Materials and Methods:*** Eightyeight children/young adults underwent baseline [^{18}F]FDG PET/CT at three Italian centers. These subjects were affected by Ewing's Sarcoma (ES, N=46, 52%), osteogenic sarcoma (OS, N=29, 33%) or Rhabdomyosarcoma (RMS, N=13, 15%). Tumourcore and concentric 0.5cm ring volumes were segmented; 389 radiomic features were extracted from each PET or CT volume with LIFEx v 7.7, yielding four prefixed sets (CORE_PET_, CORE_CT_, RING_PET_, RING_CT). Kruskal-Wallis with Benjamini-Hochberg FDR correction ($\alpha = 0.05$) selected informative variables were obtained. Ten RandomForest classifiers (200 trees, fivefold stratified crossvalidation) were compared. Balanced accuracy was the primary metric. ***Results:*** Core PET radiomics yielded a fair balanced accuracy (0.64), which did not improve by adding the ring data (0. 63). Core CT also had sufficient accuracy (0.62); yet, it was not improved by adding the ring data (0.62). The mixed CORE PET/CT model had an accuracy of 0.63, whit a minimal impact from adding the ring information (CORE+RING PET/CT model: 0.67). However, this last model achieved higher recall for EWS (0.74) and RMS (0.73), while recall for OS was lower (0.52). ***Conclusion:*** Our preliminary data show that analyzing the textural pattern of PET and CT in sarcomas can convey valuable information for developing non-invasive histological diagnosis models. Moreover, data from the tumor core and the margin appear to be synergic, indicating that the mechanisms of tumor growth might be necessary in stratifying these tumors.

Diagnostic Utility of Bone Scintigraphy in Pediatric Acute Osteomyelitis

K. Guichay Duran*, M. Tagliatori Nogueira, C. Galindo Fernández, D. Rodriguez Oviedo, J. Sanchez Calderón, M. Castillejos Rodriguez, A. Herrero Muñoz, C. Paniagua Correa, A. Ortega Valle, M. Álvarez Moreno, M. García Alonso, M. De la Rubia Marcos; Department of Nuclear Medicine, Getafe University Hospital, Madrid, SPAIN.*

Aim/Introduction: To evaluate the diagnostic performance of bone scintigraphy in pediatric patients with clinical suspicion of acute osteomyelitis (AO). ***Materials and Methods:*** We conducted a retrospective, descriptive observational study involving patients under 15 years old who were admitted to our institution with suspected AO between 2019 and 2024. All patients underwent three-phase bone scintigraphy as part of the initial diagnostic assessment. ***Results:*** A total of 30 patients were included (66.7% male), with a mean age of 3 years. The most frequent presenting symptoms were functional impairment (86.7%), localized pain (83.3%), fever (80%), and signs of localized inflammation (33.3%). Laboratory results showed leukocytosis (>12,000/µl) in 66.7% of cases, elevated erythrocyte sedimentation rate (ESR >20 mm/h) in 80%, and increased C-reactive protein (CRP >20 mg/L) in 70%. Blood cultures were positive in 36.7% of patients, with Staphylococcus aureus being the most commonly isolated pathogen (90%) Bone scintigraphy was performed on average 6.6 days after symptoms onset and yielded positive findings in all cases (100%), confirming the clinical diagnosis. Additionally, the scan revealed contiguous bone involvement in 6 patients (20%) and multifocal osteomyelitis in 2 cases. The most frequently involved sites were the tibia (43.3%), femur (16.7%), and calcaneus (13.3%). All patients received intravenous antibiotic therapy for an average duration of 7 days. Surgical drainage was required in 2 cases due to associated complications. Clinical outcomes were favorable in all patients. ***Conclusion:*** Acute osteomyelitis in children requires a high index of suspicion, as early diagnosis and prompt treatment are essential for a favorable outcome and prognosis. Bone scintigraphy has proven to be a highly sensitive diagnostic tool for AO, with low radiation exposure. Furthermore, it offers the advantage of whole-body imaging, facilitating the detection of multifocal involvement.

EPS-274

Quantitative Bone SPECT/CT in Hand and Wrist Osteoarthritis Imaging and Management

M. Soltanolkotabi*, G. Safazadeh, G. J. Stoddard, M. K. Mills, A. Wang, S. Minoshima;*
University of Utah, Salt Lake City, UT, UNITED STATES OF AMERICA.

Aim/Introduction: Hand and wrist osteoarthritis (OA) is highly prevalent and frequently underdiagnosed in its early stages due to limited radiographic findings. Pain is often the primary clinical complaint, yet traditional imaging correlates poorly with symptom severity. This study aimed to evaluate the reliability and reproducibility of quantitative single-photon emission computed tomography/computed tomography (SPECT/CT) uptake values and to investigate their association with pain and functional outcomes in patients with early, radiographically occult hand/wrist OA, particularly in the context of treatment planning for intra-articular steroid injections. ***Materials and Methods:*** In this prospective single-center pilot study, eight adult patients with wrist/hand pain ≥6 weeks and pain scores ≥4 were enrolled. All had radiographically occult OA and were candidates for intra-articular steroid injections. Twenty at-risk joints per patient were selected, totaling 160 joints. Prior to intervention, we recorded SUVmax and SUVmean from SPECT/CT scans, pain scores (numeric rating scale 0-10), QuickDASH, SF-12, grip strength, and three-point pinch. Two MSK radiologists independently measured SUVs, with repeat measurement at 6 months for intra-rater assessment. Intraclass correlation coefficients (ICC) assessed measurement reliability. Associations between SUV and clinical outcomes were analyzed using random-effects models at the joint level and Spearman correlation at the patient level. ***Results:*** Among 160 joints analyzed (thumb/index: 80; 3rd-5th digits: 80), 46 were painful, and 19 underwent injection. Inter-rater reliability was excellent (ICC SUVmean = 0.95; SUVmax = 0.98), as was intra-rater reliability for SUVmax (ICC = 0.99). Across all joints, pain intensity was positively associated with SUVmax (β=0.27, 95%CI: 0.17-0.37, p<0.001). Among the most painful joints, a stronger correlation was observed (Spearman's ρ=0.73, p=0.04). Notably, a linear relationship between SUVmax and pain emerged at thresholds of pain ≥5 and SUVmax ≥2.5, suggesting potential clinical cutoffs for injection decisions. While QuickDASH scores did not significantly correlate with SUVmax, there was a borderline significant inverse correlation with the SF-12 physical component (ρ=–0.70, p=0.058). In the subset of injected joints, pain significantly decreased post-intervention (median pain score reduced from 5 [IQR: 5-8] to 1.5 [IQR: 0-7], p<0.001). ***Conclusion:*** Quantitative SPECT/CT demonstrates high inter- and intra-rater reliability and a robust association between SUVmax and joint pain in early hand/wrist OA. The identification of linearity thresholds (pain ≥5, SUVmax

≥2.5) supports the potential use of SUV as a biomarker to guide intra-articular injection decisions. Further studies are warranted to validate these thresholds and evaluate longitudinal and functional outcomes.

EPS-275

Contribution of ^{99m}Tc-SPECT/CT to Magnetic Resonance Imaging Inpainful Foot Pathologypainful Foot Pathology

C. Gonzalez Roiz[1], *L. León-Ramírez*[2], *P. Recarte Ortega*[1], *G. Orlandini*[1], *M. Ollarves Carrero*[1], *M. Alvarez*[1], *L. Garcia Cañamaque*[1];
[1]*Hospital Puerta del Sur, Móstoles, Madrid, SPAIN,* [2]*Hospital Clínico San Carlos, Madrid, SPAIN.*

Aim/Introduction: To evaluate the role of single-photon emission computed tomography combined with computed tomography (SPECT/CT) in bone pathology of the foot and ankle, and its complementary value to magnetic resonance imaging (MRI) findings. ***Materials and Methods:*** A prospective study was conducted between 2024 and 2025 including 54 patients (31 women, 23 men; mean age: 55 years) with foot and/or ankle pain. All underwent SPECT/CT following the administration of 800 MBq of ^{99m}Tc. In patients with available MRI, concordance between imaging techniques was assessed. The ability of SPECT/CT to detect osseous, tendinous and/or articular abnormalities was evaluated. ***Results:*** Of the total cohort, 42.6% (23/54) had a history of previous surgery. SPECT/CT was diagnostic in 82% of these cases, with reduced specificity observed depending on the time elapsed since surgery. MRI was available in 8 of the 23 postoperative patients, demonstrating full concordance with SPECT/CT (100%). In two cases where MRI yielded inconclusive findings, SPECT/CT provided a definitive diagnosis. Additionally, it contributed further diagnostic information in 75% of these cases. Among patients without previous surgery (57.4%), SPECT/CT revealed clinically relevant additional findings in 53% (8/15), particularly in cases of degenerative joint disease, enabling targeted intra-articular interventions. ***Conclusion:*** While MRI remains fundamental in the evaluation of chronic foot pain, SPECT/CT should be considered within the diagnostic algorithm—not only in patients with orthopaedic hardware limiting MRI, but also for its added functional value, ability to refine diagnosis, and support in guiding treatment decisions in complex or refractory cases. ***References:*** 1. Clinical Decision-Making Using [^{18}F]NaF PET/CT Imaging in Non-Unions

N. D. van Rijsewijk*, M. Wouthuyzen-Bakker, J. H. van Snick, J. van Sluis, K. ten Duis, A. W. J. M. Glaudemans, F. F. A. IJpma;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Non-unions remain a major challenge in (trauma) fracture care, with limited tools to assess biological healing potential. This study evaluated [^{18}F]NaF PET/CT imaging as a decision-making tool in the management of long-bone non-unions. ***Materials and Methods:*** From June 2019 to December 2024, a prospective study was conducted at a level 1 trauma center, including 13 patients (15 non-unions) eligible for revision surgery after failed initial fracture treatment. All patients underwent [^{18}F]NaF PET/CT scans, including a dynamic scan for the first 10 minutes and a static scan after one hour, to assess bone healing capacity. Imaging results were analyzed qualitatively and quantitatively and compared to clinical outcomes after an extended observation period. ***Results:*** Increased [^{18}F]NaF uptake, suggestive of healing potential, was observed in all non-unions (15/15). Based on the PET/CT results, an extended observation period was recommended. However, two patients opted for surgery. Of the 13 non-unions managed with an extended observation period, 9 (69%) showed spontaneous fracture healing over time. Revision surgery was required in four cases, of which 3 (75%) needed additional stabilization of the fracture. Finally, [^{18}F]NaF PET/CT helped to avoid surgery in 60% (9/15) of cases. Visual uptake pattern analysis (whole-bone uptake) was significantly associated with surgical need (χ^2 = 5.31, p = 0.021), while quantitative imaging added no clinical value. ***Conclusion:*** [^{18}F]NaF PET/CT imaging showed healing potential in all non-unions and supported an extended observation period. Whole-bone uptake may suggest a need for additional fracture stabilization. In total, 60% of surgeries for non-unions were avoided.

EPS-277

Beyond the Bone Scan: FDG PET/CT as a Decisive Tool in Differentiating PJI from Aseptic Loosening

J. Choudhary*, A. Mahalik, N. Kundu, S. Singh, V. Singh, J. Krishna P., K. Jain, S. Shamim, R. Kumar;*
All india institute of medical sciences., New Delhi, INDIA.

Aim/Introduction: Differentiating prosthetic joint infection (PJI) from aseptic loosening remains a diagnostic challenge, especially when the 3-phase bone scan yields equivocal results. FDG PET/CT has emerged as a promising modality, offering functional insights beyond conventional imaging. This study evaluates the role of FDG PET/CT in distinguishing infective vs non-infective etiologies in such ambiguous cases. ***Materials and Methods:*** This retrospective analysis included 16 patients with painful prostheses and equivocal findings on 3-phase bone scan. FDG PET/CT was performed to evaluate the metabolic activity at the prosthetic site. Demographic data, ESR/CRP levels, and clinical features like pus discharge were recorded. SUVmax and SUVpeak were measured at the prosthetic site. Final diagnosis was confirmed using clinical, microbiological, surgical, or histopathological correlation. ***Results:*** A total of 16 patients were included (female: 9, male: 7; mean age: 48.1 years). FDG PET/CT demonstrated significantly higher SUVmax and SUVpeak values in infective cases (mean SUVmax: 18.98; SUVpeak: 11.47) compared to aseptic loosening (mean SUVmax: 13.17; SUVpeak: 7.66). ROC analysis indicated SUVmax > 16.88 as an optimal cut-off for infection, with a sensitivity of 83.3% and specificity of 70.0%. The AUC for SUVmax was 0.68. ***Conclusion:*** FDG PET/CT is a valuable tool in differentiating prosthetic joint infection from aseptic loosening in cases where 3-phase bone scan is inconclusive. With an AUC of 0.68, FDG PET/CT demonstrates moderate accuracy, and combining it with clinical and laboratory parameters may enhance diagnostic precision.

EPS-278

Integrating Whole-Body Bone SPECT and AI-Synthetic CT in the Evaluation of Non-Oncologic Disorders

M. Einieh[1], *S. Barna*[2,3], *Á. Budai*[2], *G. Ország*[2], *C. Csikos*[3], *I. Garai*[2,3];
[1]*University of Debrecen, Faculty of Medicine, Debrecen, HUNGARY,* [2]*Scanomed Ltd., Debrecen, HUNGARY,* [3]*University of Debrecen, Faculty of Medicine, Medical Imaging Department, Division of Nuclear Medicine, Debrecen, HUNGARY.*

Aim/Introduction: Multiphase regional bone SPECT/CT is an established method for assessing inflammatory, degenerative, and postoperative changes in non-oncological bone conditions.

However, in some cases, patients' symptoms do not correlate with regional findings. This study evaluates the added diagnostic value of whole-body SPECT with AI-generated synthetic CT for detecting clinically relevant abnormalities beyond the primary region of interest. ***Materials and Methods:*** A total of 135 patients (mean age: 63.9 ± 14.3 years; female-to-male ratio 2:1) underwent multiphase SPECT/CT for non-oncological indications, including orthopedic (n=71), rheumatologic (n=31), neurosurgical (n=8), and other (n=11) conditions. All patients received BMI-adjusted 500-600 MBq [Tc-99m]-MDP. Early- and late-phase regional SPECT/CT was followed by whole-body SPECT to assess uptake outside the initial region. When extra-regional uptake was observed, AI-generated synthetic CT aided anatomical localization. 8 patients were excluded due to loss of clinical follow-up, and 13 were excluded from the whole bone SPECT evaluation due to having only planar bone scans. Diagnostic performance (sensitivity, specificity) and correlation analyses (chi-square, Pearson's regression) were conducted. ***Results:*** Regional SPECT/CT showed strong diagnostic value. Orthopedic indications had a sensitivity of 92% and a specificity of 95% (hip: 96%/78%, knee: 80%/89%). Rheumatologic cases showed 100% sensitivity and 67% specificity. Neurosurgical and other groups showed no false negatives, while the latter experienced two false positives. Whole-body SPECT detected pathological uptake beyond the primary region in 69 of 122 cases (56%), significantly correlating with clinical true positives ($\chi^2 = 3.39$, $p = 0.066$). Vertebral accumulations (41), rib hot spots (13), and joint uptakes (33) were common. Among 27 patients with true positive results for metal implant loosening, 13 had incidental dental uptake ($\chi^2 = 3.43$, $p = 0.064$). We found no significant correlation ($r = -0.110$, $p = 0.386$) between the time since surgery and positive findings. ***Conclusion:*** Multiphase regional SPECT/CT offers high diagnostic reliability for non-oncological bone and joint symptoms. Whole-body SPECT with AI-synthetic CT enhances detection of clinically relevant findings beyond the region of interest, supporting its inclusion in complex cases to guide more comprehensive care.

EPS-279

Composite 3-phase bone scan and FDG-PET in suspected infections post open reduction and hardware fixation of fractures

I. El Bez*, R. Tulbah, S. Alhazza, R. Alsalah, K. Ibrahim, F. Algmlas, M. Alharbi;*
AAML, Riyad, SAUDI ARABIA.

Aim/Introduction: Management of infection post open reduction and internal fixation of fractures is a real dilemma: In fact, infection in the presence of hardware mandates revision/removal of HDR; conversely early removal of HRD, in the presence of non-union, complicates management of both infection and fractures. we evaluated the role of composite triphasic bone scan and FDG-PET in suspected infections post open reduction and hardware fixation of fractures. ***Materials and Methods:*** This is a retrospective study from 2018-2025, including all patients suspects infection post open reduction or internal fixation of fractures, having undergone PET-CT and bone scans scans. Fifty patients were included. A planar three phase bone scan was performed first, if it was positive, a PET-CT was performed on the same day or one day after. If the bone scan is negative (flow and blood pool negative), PET-CT was not performed. The PET-CT fusion images were reviewed interactively on a dedicated workstation Findings on composite PET and bone scan were correlated. ***Results:*** A total of 50 patients were evaluated. The composite PET and BS were matching, both two positive in 45 cases: the bone scan showed hyperemia and increased blood pool and delayed uptake, matching with FDG avid soft tissue inflammation en PET-CT.), PET was helpful in localizing the findings on BS In case of the bone scan was negative, normal flow and blood pool ; PET-CT was not performed. The composite PET and BS were mismatching, discordant in 5 cases: the bone scan showed hyperemia and increased blood pool and delayed uptake, mismatching with negative PET-CT. Bone scan was positive due to dislocation/subluxation and ulcers. Our study is limited by number of cultures obtained, and limited follow up. ***Conclusion:*** The composite bone scan and FDG-PET appear to be highly complementary. The composite dual modality imaging improves for same day diagnostic work-up. Potentially improves accuracy of detection and localization of infected foci.

EPS-280

Assessment of Noise Reduction Deep Learning Reconstruction Algorithm for Bone Scan: A pilot study

J. Hagerman[1]*, I. Ceric Andelius*[2]*;*
[1]*Clinical Physiology, Department of Clinical Sciences Lund, Lund University, Skåne University Hospital, Lund, SWEDEN,* [2]*Radiation Physics, Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, SWEDEN.*

Aim/Introduction: A vendor-specific deep learning (DL) reconstruction algorithm, designed for a ring-configured cadmium-zinc-telluride gamma camera, was recently marketed for its noise reduction quality in single-photon emission computed tomography (SPECT) bone scans [1]. The frequency of the DL-algorithm can be varied, with minimum set to apply after 10 updates and maximum corresponding to the total number of updates. We aimed to assess signal characteristics with coefficient-of-variation (CV) and signal-to-noise ratio (SNR) in SPECT bone scan images reconstructed with ordered subset expectation maximization (OS-EM), block sequential regularized expectation maximization (BSREM), and DL-BSREM with three different frequency updates. ***Materials and Methods:*** SPECT bone scans from seven patients with prostate cancer referred for assessment of bone metastasis were evaluated. Images were reconstructed with BSREM factory protocol, with/without DL (frequency set: 10 (DL10), 30 (DL30), and 60 (DL60) updates), and with OS-EM, for acquisition time 4-, 3-, and 2-min. Images were corrected for collimator detector response, attenuation, and scatter. All patients had at least one focal area of increased uptake (lesion). Volume-of-interest (VOI) was drawn manually on 1-3 lesions per patient (n=14, six metastatic/two patients, eight degenerative/five patients), and on a uniform sacral area without pathology (n=7). VOI was drawn in OS-EM (4-min) and duplicated in the same position across all datasets, and average counts per voxel and deviation were extracted. Results are reported as median (range) at lesion level, combining metastatic and degenerative. ***Results:*** The lesion-to-sacrum uptake was 4.7(1.3-10.1) and 2.0(1.3-2.7) for metastatic and degenerative lesions. For a sacral region, CV ranged from 15.2% $(11.2\text{-}18.0\%)_{(BSREM)}$ to 18.2% $(14.1\text{-}31.3\%)_{(DL10)}$ for 4-min acquisition. Corresponding results for 3- and 2-min acquisitions were 15.3% $(7.7\text{-}21.7\%)_{(BSREM)}$ to 20.3% $(13.1\text{-}46.2\%)_{(DL10)}$, and 19.7% $(13.4\text{-}28.2\%)_{(BSREM)}$ to 29.8% $(13.2\text{-}34.9\%)_{(DL10)}$. The CV results for lesions were 14.4% $(9.0\text{-}36.0\%)_{(BSREM)}$ to 18.4% $(10.8\text{-}34.8\%)_{(CDL30)}$, 17.1% $(7.3\text{-}37.4\%)_{(BSREM)}$ to 23.1% $(4.9\text{-}43.5\%)_{(DL10)}$, and 17.1% $(9.7\text{-}35.6\%)_{(BSREM)}$ to 23.9% $(8.5\text{-}37.1\%)_{(CDL10)}$ for 4-, 3- and 2-min acquisition. SNR varied, for sacrum, between 5.5 $(3.2\text{-}7.1)_{(DL10)}$ and 6.6 $(5.6\text{-}9.0)_{(BSREM)}$, 4.9 $(2.2\text{-}7.7)_{(DL10)}$ and 6.5 $(4.6\text{-}12.9)_{(BSREM)}$, and 3.4 $(2.9\text{-}7.6)_{(CDL10)}$ and 5.1 $(3.5\text{-}7.4)_{(BSREM)}$ for 4-, 3- and 2-min acquisition. Corresponding values for lesions were 5.5 $(2.9\text{-}9.3)_{(DL30)}$ and 7.0 $(2.8\text{-}11.1)_{(BSREM)}$, 4.5 $(2.3\text{-}20.6)_{(DL10)}$ and 6.7 $(2.7\text{-}13.7)_{(BSREM)}$, and 4.2 $(2.7\text{-}11.8)_{(DL10)}$ and 5.9 $(2.8\text{-}10.4)_{(BSREM)}$ for 4-, 3- and 2-min acquisition. ***Conclusion:*** Despite the smal sample size, results indicate that BSREM without DL outperforms reconstructions with DL and OS-EM, in terms of CV and SNR. ***References:*** Ziv O, et al. Clarify DL-Deep learning image reconstruction for bone SPECT scans. GE HealthCare;2024. White paper.

EPS-281

Using Limphoscintigraphy to Assess Lymphatic Insufficiency after Total Knee Arthroplasty. A Pilot Study in Ukraine

P. Korol[1], *O. Shcherbina*[1], *M. Tkachenko*[2], *M. Kostylev*[3];
[1]Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE, [2]Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE, [3]Shalimov National Scientific Center of Surgery and Transplantation, Kyiv, UKRAINE.

Aim/Introduction: Extremity swelling is a common complication of total knee arthroplasty (TKA). In long-term follow-up, persistent or progressive swelling may indicate lymphatic insufficiency. Lymphoscintigraphy offers an objective and reliable approach to diagnosis and characterization of disease severity. The aim of this study is to detect abnormalities or insufficiencies of lymphatic drainage using lymphoscintigraphy in patients complaining of discomfort and swelling after TKA during a 6-month follow-up. ***Materials and Methods:*** We evaluated 140 patients (87 women and 53 men, mean age 55 years) who underwent TKA at the Kyiv City Center for Endoprosthetics between 2014 and 2024 and had unilateral limb edema at long-term evaluation. Other causes of limb edema (venous insufficiency, infectious diseases, etc.) were excluded. Dynamic scanning began immediately after injection of 1.5 mCi of Teknetium-99m-labeled nanocolloid into the first interdigital space of both feet, followed by scanning of the patients' lower limbs, pelvis, and abdomen at 15 minutes, 2 hours, and 6 hours. The scans were analyzed and assessed for: visualization and dilation of the main lymphatic vessels, regional and deep lymph nodes, collateral vessels, and dermal return flow. All images were scored on a scale of 0 to 12 according to the criteria of our Department of Nuclear Medicine grading system. ***Results:*** In lymphoscintigraphic evaluation of 140 patients, we show: radiopharmaceutical passage into the main lymphatics in 121 (86.4%), collateral vessels in 87 (62.1%), deep lymphatic drainage (popliteal lymph nodes) in 61 (43.5%), dilation of the main lymphatics in 46 (32.9%), skin backflow in 53 (37.8%), adequate uptake of the radiopharmaceutical by regional lymph nodes in 116 (82.8%) extremities. The average lyphoscintigraphic score was 9/12. Based on the results of the study analysis, we show abnormalities or insufficiency of lymphatic drainage in patients who complained of discomfort and unexplained swelling after TKA. ***Conclusion:*** Unexplained pain, swelling, and discomfort are unpleasant findings after TKA, and identifying the underlying causes is critical for clinical management. Lymphoscintigraphy with lymphatic mapping may play a key role in determining the etiology of limb swelling and predicting the success of conventional treatments. The addition of quantitative lymphatic flow and nodal accumulation may be a more sensitive approach to the diagnosis of lymphatic insufficiency. We will continue to study with a larger patient population to establish clinical guidelines for performing lymphoscintigraphy in patients undergoing TKA.

EPS-282

Association of Renal "Hot Spots" on Bone Scan and Serum Ferritin Levels. A Pilot Study in Ukraine

P. Korol[1], *M. Kostylev*[2], *O. Shcherbina*[1], *M. Tkachenko*[3];
[1]Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE, [2]Shalimov National Scientific Center of Surgery and Transplantation, Kyiv, UKRAINE, [3]Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE.

Aim/Introduction: In our Department of Nuclear Medicine, we have noted high serum ferritin levels in patients with inflammatory, autoimmune and malignant diseases, who had high renal uptake on bone scan. The aim of the study was to evaluate and investigate this association. ***Materials and Methods:*** We retrospectively analyzed data from patients who underwent 99m-Tc-MDP bone scan and serum ferritin measurement for 2 weeks. Serum ferritin was measured to check for anemia. The ratio of the radiopharmaceutical uptake in the kidneys and vertebral bone average amount per pixel was calculated as the K/V ratio, and its correlation with the blood levels of ferritin, iron, creatinine, C-reactive protein, hemoglobin, and white and red blood cell counts was analyzed using the rank correlation coefficient. Renal uptake of 99m-Tc-MDP was also visually assessed in comparison with the uptake of the tracer in the ribs and lumbar spine on bone scintigraphy. ***Results:*** A total of 48 patients with high renal uptake, 26 with suspected joint osteoarthrosis, 6 with amyloidosis, and 16 with malignancies were included. The mean interval between bone scintigraphy and blood sampling for ferritin measurement was 6.4±3.7 days. A significant correlation was found between the K/V ratio and ferritin level ($r=0.58$, $p<0.005$), red blood cell count ($r=0.63$, $p=0.003$) and hemoglobin level ($r=0.51$, $p=0.001$). However, there was no correlation with the following parameters thought to be associated with nephritis and iron and bone metabolism: creatinine ($r=0.21$, $p=0.35$), C-reactive protein ($r=-0.17$, $p=0.72$), white blood cell count ($r=-0.23$, $p=0.54$), iron ($r=0.41$, $p=0.32$). A significant correlation was also found between the K/V ratio and the visual assessment score ($r = 0.79$, $p < 0.001$). ***Conclusion:*** There was a significant correlation between serum ferritin levels and the increase in renal 99m-Tc-MDP accumulation on bone scintigraphy. The mechanism of this phenomenon is being investigated in our department. It is suggested that this mechanism is related to changes in the number of red blood cells caused by their destruction, but without any relationship with iron deficiency.

EPS-283

Clinical Role of Tc-99m-MDP Bone Scintigraphy in Patients with Alkaptonuria. A Pilot Study in Ukraine

P. Korol[1], *M. Tkachenko*[2], *M. Kostylev*[3], *O. Shcherbina*[1];
[1]Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE, [2]Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE, [3]Shalimov National Scientific Center of Surgery and Transplantation, Kyiv, UKRAINE.

Aim/Introduction: The clinical value of Tc-99m bone scan as a diagnostic tool for monitoring response in ochronotic lesions remains controversial to date, mainly due to the lack of evidence. Using a retrospective study, we analyze the potential of bone scintigraphy as a monitoring tool in alkaptonuria. ***Materials and Methods:*** Our Department of Nuclear Medicine of the National University of Health of Ukraine provides medical care to the largest national cohort of patients diagnosed with alkaptonuria. We included a total of 47 patients in our study and analyzed changes in tracer distribution patterns in long-term bone scans. The study cohort included 28 women and 19 men, age at initial isotope scan: 25-72 years, median 57 years. Time difference between bone scans: minimum 6 months, maximum 28 months). In this group, 45 patients received Orfadin treatment at the time of the follow-up bone scan (duration of nitosinone treatment: minimum 6 months, maximum 28 months, daily dose 4-10 mg/dl). We investigated the distribution patterns of early angiographic, blood pool and delayed-phase SPECT bone scans, as well as changes in dynamic follow-up. ***Results:*** The most common findings were spinal ochronosis, affected large joints (hip, shoulder). In most cases, the results improved at follow-up in 89% (40 of 45 patients) or were constant in 24% (11 of 45 patients) with Orfadin treatment. At the same time, progress was observed in large joints that were not yet affected or slightly affected in 51% (23 of 45 patients). ***Conclusion:*** Tc-99m bone scintigraphy is likely to be an important tool for monitoring ochronotic or degenerative changes in the course of alkaptonuria. Accordingly, Tc-99m bone scanning may play a key role in the dynamic monitoring of Orfadin therapy.

EPS-284

Acute Multifocal Osteomyelitis with Visceral Extension: Contribution of 18FDG PET/CT in Diagnosis, Assessment of Extent, and Therapeutic Follow-up

Z. Missaoui, *A. Ezzine, M. Ben Fredj, H. Boudrigua, R. Mehri, G. Baazoug, K. Chatti;*
Department of Nuclear Medicine, Sahloul University Hospital Center, Sousse, TUNISIA.

Aim/Introduction: Acute multifocal osteomyelitis in children is a serious condition that may rapidly progress to septicemia if not promptly treated. ^{18}F-FDG PET/CT has emerged as a valuable imaging modality for detecting infectious foci, particularly when conventional imaging is inconclusive. We report a rare case of acute multifocal osteomyelitis with visceral involvement following scorpion envenomation, in which ^{18}F-FDG PET/CT played a key role in diagnosis, assessment of disease extent, and monitoring of treatment response. ***Materials and Methods:*** A whole-body FDG PET/CT scan, including the extremities, was performed 60 minutes after administration of 62.9 MBq of 18F-FDG, in accordance with pediatric dosing guidelines from the European Association of Nuclear Medicine. ***Results:*** A 3-year-old child with a history of untreated congenital heart disease was admitted following a scorpion sting on the left index finger. A few days after receiving specific treatment for severe scorpion envenomation (stage III), the patient developed febrile polyarthritis, with persistent fever and functional impairment of the lower limbs . Laboratory tests showed elevated CRP (257 mg/L), while ultrasound examinations of the hips, knees, and ankles, also echocardiography were unremarkable. Blood cultures, performed after the initiation of empirical antibiotic therapy, were negative. Given the persistence of fever despite 13 days of antibiotics, an ^{18}F-FDG PET/CT was performed, revealing multiple hypermetabolic lesions including extensive soft tissue infiltration in both thighs, adjacent osteomedullary involvement, and bone lesions in the right clavicle and feet. Additional findings included bilateral hypermetabolic pulmonary nodules suggestive of septic emboli and supradiaphragmatic and subdiaphragmatic hypermetabolic lymphadenopathies. Following these findings, The patient underwent surgical drainage and bone trephination. Bacteriological analysis of the pus (on day 23 of antibiotics) and PCR testing for Mycobacterium tuberculosis in sputum and pus were negative. The final diagnosis was acute multifocal osteomyelitis with hematogenous dissemination, involving bone, lungs, and lymph nodes. The patient received six weeks of intravenous antibiotics followed by oral therapy, with clinical and biological improvement. A follow-up ^{18}F-FDG PET/CT performed after seven weeks of treatment showed marked metabolic improvement, with near-complete resolution of pulmonary and lymph node lesions and significant improvement of bone lesions. ***Conclusion:*** ^{18}F-FDG PET/CT is a valuable diagnostic tool in pediatric osteomyelitis, enabling early detection of infectious sites, especially when multiple lesions are present or conventional imaging is inconclusive. It also provides valuable guidance for surgical intervention and allows assessment of therapeutic response during follow-up.

EPS-284a

Role of Early Blood Pool FASpect/CT in Osteomyelitis

A. Khawar[1], *M. Sahar*[1], *M. A. Saeed*[2];
[1]*Pakistan Institute of Engineering and Applied Sciences, Islamabad, PAKISTAN,* [2]*Atomic Energy Cancer Hospital, Nuclear Medicine Oncology and Radiotherapy Institute, Islamabad, PAKISTAN.*

Aim/Introduction: Fewer angle SPECT/CT (FASpect/CT) using iterative reconstruction in less time with images comparable to normal SPECT/CT has geared the interest in evaluation of early blood pool FASpecT/CT in various skeletal disorders like osteomyelitis, tendinopathies etc. The current study aims to evaluate the role of early blood pool Tc-99m MDP FASpecT/CT in diagnosing osteomyelitis. ***Materials and Methods:*** It is a prospective single arm study conducted at the Nuclear Medicine Department of AECH-NORI Hospital, Islamabad, over seven months. The study enrolled 23 subjects suspected of having osteomyelitis on the basis of history, clinical features, laboratory investigations and relevant radiological findings. All subjects underwent three acquisitions post Tc-99m MDP injection i.e., three-phase bone scintigraphy (TPBS), Early Blood pool FASpecT/CT, and delayed-phase SPECT/CT (d-SPECT). The final diagnoses was established through histopathology reports following surgery or clinical follow-up for over 3-5 months. The three diagnostic criteria (I) TPBS alone, (II) combined planar blood pool with d-SPECT/CT, and (III) Blood pool FASpecT/CT alone were compared qualitatively. Statistical McNemar test and Cohen Kappa test were applied to analyze the results statistically. ***Results:*** OM was diagnosed in 17 out of 23 patients. Tc-99m MDP blood pool FASpecT/CT was found to have advantage of delineating bone and soft tissue involvement at same time as compared to only soft tissue by planar blood pool and only bone at d-SPECT/CT. The specificity for Criterion I, II and III came out to be 50.00%, 66.67%, and 100% respectively and sensitivity came out to be same for all three criteria i.e 94.12%. The Kappa analysis also revealed that criteria 3 had better and statistically significant agreement with the gold standard. ***Conclusion:*** Tc-99m MDP blood pool FASpecT/CT was found to have higher specificity and accuracy than conventional skeletal scintigraphy techniques for diagnosis of osteomyelitis and can be considered for inclusion in imaging protocol for Tc-99m MDP imaging for OM. It is firther proposed that prospective studies with Fast SPECT/CT for blood pool in combination with d-SPECT/CT in osteomyelitis may be conisdered for evaluation. ***References:*** 1. Aim/Introduction: PSMA-targeted radiopharmaceuticals have emerged as a cornerstone in the management of prostate cancer, improving both progression-free and overall survival. Among these, radioligand therapies with β-emitting radionuclides such as ^{177}Lu, have demonstrated favorable safety profiles. However, when α-emitters are used, high uptake in dose-limiting organs, particularly the salivary glands, can lead to significant adverse effects, limiting therapeutic potential. NTA-476 is a novel PSMA-binding peptide, designed to reduce uptake in off-target organs for therapeutic use. This abstract presents results from two investigator-initiated trials evaluating the biodistribution of ^{68}Ga-NTA-476 compared to ^{68}Ga-PSMA-11 and ^{18}F-DCFPyL in men with prostate cancer. ***Materials and Methods:*** At PreMIT, ten men with biochemically recurrent prostate cancer underwent paired PET/CT imaging with ^{18}F-DCFPyL and ^{68}Ga-NTA-476 using a Siemens Vision Quadra system. At Murdoch, a similar design was used to compare ^{68}Ga-NTA-476 with ^{68}Ga-PSMA-11. For NTA-476, imaging included multiple acquisitions up to 6 hours post-injection. Uptake in tumour lesions and normal tissues were quantified, and time-activity curves and radiation dosimetry estimates were derived. ***Results:*** NTA-476 showed tumour uptake comparable to both comparator tracers at delayed timepoints, with substantially lower physiological uptake in kidneys, salivary glands, and lacrimal glands. These properties resulted in increased tumour-to-background uptake ratios over time. Dosimetry modelling suggests that NTA-476 may offer an improved therapeutic index when labelled with therapeutic isotopes. No NTA-476-related adverse events were observed. Lesion detection was highly concordant between NTA-476 and comparator tracers across both studies. ***Conclusion:*** NTA-476 demonstrates a favourable biodistribution profile, characterised by sustained tracer tumour retention and reduced off-target uptake in critical organs. These findings highlight its potential as a theranostic agent and support its clinical development for radiolabelling with therapeutic isotopes such as ^{225}Ac or ^{177}Lu.

Herrmann*[2], *on behalf of Thera4Care IHI Horizon Project;* [1]*Gemelli, Rome, ITALY,* [2]*Essen University, Essen, GERMANY,* [3]*SCKCEN, Brussels, BELGIUM,* [4]*PSI, Zurich, SWITZERLAND,* [5]*GE Healthcare, Budapest, HUNGARY,* [6]*Collaborate, Munich, GERMANY,* [7]*EANM, Vienna, AUSTRIA,* [8]*Curasight, Copenaghen, DENMARK,* [9]*Atley, Goteborg, SWEDEN,* [10]*Jules Bordet, Brussels, BELGIUM,* [11]*Medipass Ergea, Rome, ITALY,* [12]*Oncidium, Brussels, BELGIUM,* [13]*Terthera, Breda, NETHERLANDS,* [14]*GE Healthcare, Uppsala, SWEDEN,* [15]*GE Healthcare, Chicago, IL, UNITED STATES OF AMERICA,* [16]*GE Healthcare, London, UNITED KINGDOM,* [17]*Università Cattolica, Rome, ITALY.*

Aim/Introduction: Thera4Care is the largest EU-funded public-private consortium on Theranostics, funded by EU Innovative Health Initiative, aiming to improve awareness and leadership on Theranostics in next 5 years. Thera4Care brings together 27 partners, as academic centres, healthcare providers, SMEs, and industries, from different 15 countries, with 9 work-packages and >25M budget. With a Public Short Survey, consortium aimed to have a comprehensive overview about Theranostics in 2025, to better address further issues on regulation, production, research and clinics during the project (2024-2029). ***Materials and Methods:*** A questionnaire of 20 questions was prepared for healthcare professionals, addressing the following issues: 1) general information; 2) Authorized Therapeutics; 3) Experimental Therapeutics. An online invitation to the Survey was sent to the consortium, delivered through public and personal channels, and to the corresponding authors of articles focused on Theranostics indexed in 2024. ***Results:*** In a preliminary analysis since January to April 2025, 51 responders from 15 different countries worldwide participated. Most were Nuclear Medicine physician (53%), from Academic hospitals (67%). As for Theranostic facilities, most of responders (>70%) had institutional In-Patient and Out-Patient Services, PET/CT and SPECT/CT, and a Diagnostic Radiopharmacy. A smaller number (<60%) could offer Ciclotron-equipped Radiopharmacy, Phase 1 Authorization, GMP Therapeutic Radiopharmacy and Pre-Clinical Facilities. About Authorized Therapeutics, most commonly used were 131I, 177Lu-DOTATATE, 177Lu-PSMA, 223Ra and 90Y-TARE (>60%). Interestingly, about 50% used other Authorized Therapeutics and

<10% no Authorized Therapeutics. Most responders administered Authorized Therapeutics in a unit of Nuclear Medicine (>90%), thanks to national public reimbursement (>60%). Half responders had access to ready-to-use Experimental Therapeutics (49%) and some had no access to Experimental Therapeutics (35%). At the moment, Experimental Therapeutics were mostly limited to 177Lu compounds (60%), followed by 225Ac in some cases (43%). Most responders had access to new EU CTIS portal for clinical trials authorizations (57%), but some asked to local Ethical Committees (30%). Main funding schemes for Experimental Therapeutics seemed by Companies (60%), over no-profit schemes (40%). ***Conclusion:*** From this preliminary Thera4Care Survey data, the context of Theranostics worldwide seems promising but heterogeneous, due to different national and local issues, especially about access and regulatory. Access to Authorized Therapeutics and spread of Experimental Therapeutics could be allowed thanks to the engagement of proper stakeholders at a national and international level. ***References:*** - IHI JU grant agreement 101172788.

OP-819

Comparative Study of Hematological and Survival Outcomes in Reduced vs. Standard Dose Ac-225-PSMA Radioligand Therapy

A. Luna Mass*, S. Raad, R. Bundschuh, S. Hoberück, M. Miederer, C. Brogsitter;*
Universitätsklinikum Carl Gustav Carus Dresden, Dresden, GERMANY.

Aim/Introduction: This retrospective study aimed to evaluate whether individualized dose reduction, adjusted according to baseline clinical characteristics, impacts overall survival (OS) and hematological side effects of Prostate Specific Membrane Antigen (PSMA)-targeted Ac-225 radioligand therapy (RLT). ***Materials and Methods:*** A retrospective analysis of 33 consecutive patients who underwent Ac-225 based PRLT between 2018 and 2023. While 18 patient received reduced doses of 4-6 MBq Ac-225-PSMA-I&T (mean 4.8 MBq ± 0.2) the other 15 were apllied a standard dose of 6-8 MBq Ac-225-PSMA-I&T (mean 6.8 MBq ± 0.82). Baseline clinical data were systematically collected, including bone marrow reserve parameters, prostate-specific antigen (PSA) levels, and tumor staging in pretherapeutic PSMA-targeted positron emission tomography (PET) according to the PROMISE V2 criteria. Tumor burden was assessed using the software aPROMISE to analyze and compare the semiquantitative metrics between groups, including PET-based total tumor volume (TVTotal), SUVmaxTotal, and SUVmeanTotal. Inflammatory markers, such as LDH and CRP, as well as renal function (GFR), were also evaluated. The Mann-Whitney U test was used for non-parametric variables, while Student's t-test was applied to normally distributed data. A p-value <0.05 was considered statistically significant. ***Results:*** There were no statistically significant differences between the two groups in baseline tumor burden assessed by SUVmaxTotal (p = 0.551), SUVmeanTotal (p = 0.194), and TVTotal (p = 0.268). The reduced-dose group showed significantly lower baseline hemoglobin levels (10.5 vs. 11.4 g/dL, p = 0.048) and higher CRP values (9.85 vs. 8.8 mg/L, p = 0.039), indicating preexisting increased hematological and inflammatory alterations. Although PSA levels were higher (742.0 vs. 150.45 ng/mL, p = 0.082) and glomerular filtration rate was lower (73.5 vs. 87.4 mL/min, p=0,064) in the reduced-dose group, these differences did not reach statistical significance. In particular, there was no significant difference in overall survival between the reduced and standard dose groups (OS 6,43 months ± 4,3 vs. 8,13 months ± 3,36 p = 0.317). ***Conclusion:*** Our findings indicate that individualized dose reduction of Ac-225-PSMA does not negatively impact overall survival when compared to the standard dosing regimen. This pivotal result supports the feasibility of patient-tailored, lower-dose protocols that may preserve therapeutic efficacy while potentially reducing treatment-related adverse effects. It also highlights the need for continued research to optimize therapeutic strategies for patients with advanced prostate cancer.

Promising Efficacy of [^{177}Lu]Lu-PSMA Radioligand Therapy in Hormone Treatment-Naive Metastatic Hormone-Sensitive Prostate Cancer Patients

I. Langrate[1]*, H. Einspieler*[1]*, E. Kretschmer-Chott*[1]*, S. Schmitl*[1]*, L. Nics*[1]*, S. Shariat*[1,2,3]*, M. Hacker*[1]*, G. Kramer*[2]*, S. Rasul*[1]*;*
[1]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Urology, Medical University of Vienna, Vienna, AUSTRIA, [3]Department of Urology, Comprehensive Cancer Center, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Radioligand therapy (RLT) with [^{177}Lu]Lu targeting prostate specific membrane antigen receptors (PSMA) is approved as a third-line treatment for patients with metastatic castration resistant prostate cancer. Here, we aimed to explore whether PSMA-RLT could serve as an effective early-line therapeutic alternative for hormone treatment-naive patients with metastatic hormone-sensitive prostate cancer (mHSPC). ***Materials and Methods:*** This retrospective study included mHSPC patients with no previous history of systemic hormone treatment, who underwent [^{177}Lu]Lu-PSMA RLT therapy between June 2015 and December 2024. Hematological and biochemical parameters were evaluated before, during, and after the RLT. Kaplan-Meier models were used to estimate prostate-specific antigen (PSA) response and progression-free survival (PFS). ***Results:*** Collectively, 25 mHSPC patients with a mean age of 66.9 (range: 55-77) years at the time of the first therapy cycle were eligible for this analysis. Patients received 3 to 6 RLT cycles (9 patients received 3 cycles, 2 received 4 cycles, 6 received 5 cycles, 8 received 6 cycles). One month after the last PSMA-RLT cycle, 76% of patients (19 out of 25) showed any PSA decline (median PSA: 3.15 ng/mL before vs 0.54 ng/mL after, p<0.001). Among the 19 responders, 89.4% (17 out of 19) showed a ≥ 50% PSA decline, and 57% (11 out of 19) experienced a decline of ≥ 80%. The median PFS among men who had ≥ 50% PSA decline 1 month after the last RLT cycle was 78 weeks (range: 40-215.7 weeks) compared to 14 weeks (range: 5 - 38 weeks) in men who did not experience any PSA decline (p<0.001). Median overall survival was not reached. No therapy-related side effects were reported. Hematological and renal parameters remained within normal range before and after treatment. The values of alkaline phosphatase and lactate dehydrogenase dropped after the last RLT from an average of 136.2 to 77.7 U/l (p=0.146) and from an average of 197.0 to 183.3 U/l (p=0.030), respectively. ***Conclusion:*** Systemic PSMA-RLT demonstrates efficacy and good tolerability in hormone treatment-naive mHSPC patients. These findings suggest that PSMA-targeting RLT may be applicable not only in advanced-stage prostate cancer, but also in patients with earlier-stage of the disease. Further prospective studies are warranted.

OP-821

Renal Effect of ^{177}Lu-PSMA Radioligand Therapy: A Prospective Study in Metastatic Castration Resistant Prostate Cancer Patients

R. Mehra*, P. Chauhan, A. H. Nazar;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: ^{177}Lu-PSMA radioligand therapy (RLT) has emerged as a promising treatment for metastatic castration-resistant prostate cancer (mCRPC). However, PSMA expression in proximal tubular cells raises concerns about nephrotoxicity. This study aimed to assess the renal outcomes of ^{177}Lu-PSMA-RLT using measured glomerular filtration rate (mGFR) with 99mTc-DTPA plasma clearance, which provides more accurate assessment compared to estimated GFR methods commonly used in

previous studies [1-4]. ***Materials and Methods:*** This prospective observational study included 36 mCRPC patients who received ^{177}Lu-PSMA-RLT. All patients received a minimum of 3 cycles, with a subset (n=14) completing 6 cycles. Renal function was evaluated at baseline and after 3rd cycle using mGFR via Tc-99m DTPA plasma clearance (Russell's method). For comparative analysis, 50 evaluable treatment periods were assessed. Nephrotoxicity was graded according to CTCAE v5.0 criteria, with clinically significant decline defined at ≥10%, ≥20%, and ≥30% mGFR reduction thresholds. ***Results:*** Baseline mean mGFR was 52.5 ± 14.5 mL/min/1.73m^2. Following therapy, mean mGFR decreased to 47.6 ± 14.1 mL/min/1.73m^2 (p=0.0023), representing a mean percentage decline of 9.3 ± 25.2%. Clinically significant decline thresholds were met in 46%, 34%, and 18% of patients for ≥10%, ≥20%, and ≥30% mGFR reduction, respectively. Grade worsening occurred in 26.0% of patients, improvement in 12.0%, and stability in 62.0%. Notably, patients with pre-existing Grade 2 nephrotoxicity (n=32) demonstrated minimal mean percentage decline (0.9%) compared to those with Grade 1 (20.0%) and Grade 3 (22.4%). ***Conclusion:*** ^{177}Lu-PSMA-RLT is associated with statistically significant renal function decline, with nearly half of the patients experiencing clinically meaningful reductions in mGFR. This study highlights the importance of using measured GFR methods rather than estimated GFR for accurate renal function monitoring in these patients, as the latter substantially underestimates toxicity rates. ***References:*** 1. Aim/Introduction: To assess the prognostic value of post-therapy [^{177}Lu]Lu-PSMA (LuPSMA)-SPECT/CT by visual Response Evaluation Criteria In PSMA-imaging (RECIP) 1.0 during LuPSMA radioligand therapy and to develop an evidence-based clinical protocol to monitor efficacy to LuPSMA. ***Materials and Methods:*** Patients with metastatic castration-resistant prostate cancer who received LuPSMA between April 2019 and November 2023 and underwent at least two LuPSMA cycles were retrospectively included. Pairs of baseline and interim LuPSMA-SPECT/CT (SPECT) and PSMA-PET/CT (PET) after two therapy cycles were analyzed for visual RECIP 1.0. Changes in PSA levels at 12 wk were categorized by PCWG3 and combined with RECIP 1.0 reads to determine progression using a composite classification method PSA + RECIP. The primary outcome was the prognostic value of post-therapeutic SPECT by RECIP 1.0 for overall survival (OS). The clinical protocol was developed based on the prognostic accuracy (C-index) of SPECT versus PET and SPECT+PSA versus PET+PSA. ***Results:*** 105 patients were eligible and included. Progression disease (PD) by SPECT was associated with shorter OS compared to stable disease (SD) (HR=2.5; 1.2-5.3; p=0.015) and to partial response (PR)(HR=6.5; 2.7-15.7; p<0.001). 73/105 (70%) patients received a PET after 2 cycles. 7/73 (10%), 30/73 (41%), 22/73 (30%), and 30/73 (41%) patients had tumor progression by SPECT, PET, SPECT+PSA, and PET+PSA, respectively. The C-index for SPECT was inferior compared to PET (0.54 vs 0.66; p<0.001), while SPECT+PSA did not differ significantly from PET+PSA (0.62 vs 0.66; p=0.07). ***Conclusion:*** Post-therapeutic LuPSMA-SPECT/CT by RECIP 1.0 after two therapy cycles therapy is prognostic for OS. LuPSMA-SPECT/CT identified significantly fewer patients with RECIP-PD, however, LuPSMA-SPECT/CT+PSA achieved similar prognostic accuracy to PSMA-PET/CT+PSA for response evaluation during LuPSMA.

Aim/Introduction: [^{177}Lu]Lu-PSMA radioligand therapy ([^{177}Lu]Lu-PSMA-RLT) is an established treatment for metastatic castration-resistant prostate cancer (mCRPC).IThe pivotal phase 3 VISION study reported adverse effects such as nausea (35.3%), vomiting (18.9%) and fatigue (43.1%)when [^{177}Lu]Lu-PSMA-617 was added to protocol-permitted standard care. This study investigated whether premedication with corticosteroids and antiemetics prior to the administration of [^{177}Lu]Lu-PSMA-617 can reduce the incidence and severity of these side effects in routine clinical practice. ***Materials and Methods:*** We conducted a multicenter retrospective analysis incorporating data from three Swiss institutions - Bern, Baden, and Bellinzona. The study included patients who received a minimum of two cycles of [^{177}Lu]Lu-PSMA-617 therapy, some as part of a Managed Access Program. All participants were premedicated with 8 mg dexamethasone and 8 mg ondansetron approximately 30 minutes prior to the administration of [^{177}Lu] Lu-PSMA-617. Incidence of nausea, vomiting and fatigue were evaluated following each treatment cycle using standardized questionnaires . ***Results:*** An analysis of 195 patient questionnaires (equivalent to 195 treatment cycles) demonstrated lower rates of nausea (7.7%) and vomiting (3.6%) compared to those reported in the VISION trial (35.3% and 18.9%, respectively). While the overall prevalence of fatigue was higher in our cohort (67.2% vs. 43.1% in the VISION trial), only 3% of patients developed fatigue following the initiation of [^{177}Lu]Lu-PSMA-RLT. This indicates that 64.2% of patients were already experiencing fatigue prior to the start of therapy. ***Conclusion:*** Premedication with 8mg dexamethasone and 8mg ondansetron before administration of [^{177}Lu]Lu-PSMA-RLT appears to substantially reduce the incidence of nausea and vomiting compared to historical data from the VISION trial.

OP-824

Influence of bone marrow segmentation approach on absorbed dose estimates in a single time point protocol for ^{177}Lu-PSMA-617

T. Frigerio, *Z. Ells, M. Dahlbom, J. Calais, J. Hoffman, C. Meyer; UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Bone marrow is a dose-limiting organ for 177Lu-PSMA radiopharmaceutical therapy. However, the segmentation required for accurate absorbed dose (AD) estimates for bone marrow represent a clinical challenge. This study evaluates the influence of two bone marrow segmentation approaches on the AD estimate using a single time point dosimetry protocol on patients with late stage mCRPC treated with 177Lu-PSMA-617. ***Materials and Methods:*** This study's cohort consists of 19 patients from the RESIST-PC phase II trial (NCT03042312), with a high tumor burden and bone disease involvement. Patients underwent post-therapy quantitative SPECT/CT imaging 24h after the first cycle of 177Lu-PSMA-617 (7.2 ± 0.7 GBq). Two segmentation algorithms were compared: the first using lumbar vertebrae (LV) as a bone marrow surrogate, the second using the whole skeleton (WS). In the LV method, L1-L5 were contoured manually, while vertebrae with significant disease involvement were excluded. When all LV presented tumor burden, an alternative representative bone (thoracic vertebrae, or humerus) was selected for segmentation. In the WS method, bones were first segmented using a publicly available neural network tool, TotalSegmentator. Bone marrow volumes were segmented using Hounsfield unit thresholding based on voxel distributions in individual bones to separate soft tissue from cortical bone, and excluding lesions using a SPECT SNR cutoff of 5. This fully automated algorithm produces a bone marrow mask for the SPECT/CT field of view. AD calculations were performed using the Hänscheid approach for single time point dosimetry. Finally, we performed a one sample t-test on the absolute value of the normalized dose difference (ADD). ***Results:*** The two methods yielded significant intra-patient differences of AD estimates, with a mean ADD of 60%, or 0.19 ± 0.20 Gy ($p<0.001$). LV AD averaged to 0.27 Gy (avg volume 52 ± 37 ml) and the WS AD averaged to 0.26 Gy (650 ± 190 ml). The disagreement in dose estimate varied in direction and magnitude depending on disease distribution. ***Conclusion:*** Comparison of estimated bone marrow AD indicates a significant difference attributable to the segmentation method. This suggests the LV method may not be an appropriate surrogate for bone marrow estimation, as it is not representative of the dose to the whole skeletal volume. The WS method produces bone marrow masks with consistent methodology while the LV method relies on patient-specific adjustments. Further investigation of a larger patient cohort will further validate these findings and explore the correlation with clinical outcome.

OP-825

Clinical Trial Protocol for RHINO trial: Prospective Single-center Phase I/II study of RHN001-Dx/Tx in men with PSMA-positive prostate cancer post adjuvant androgen deprivation therapy and/or taxane-based chemotherapy.

Aim/Introduction: [^{177}Lu]Lu-PSMA is an effective class of therapy for patients with metastatic castration-resistant prostate cancer (mCRPC) and its role has evolved to include prechemotherapy patients; however, access to it in low and middle-income countries is hampered by a variety of factors, including cost. This justifies the need for a cheaper, easily accessible PSMA targeting therapy with relatively similar efficacy to [^{177}Lu]Lu-PSMA. The theranostic pair ^{188}Re/^{99m}Tc which is completely generator based and may offer a chance to disclose this valuable therapy for countries with low PET infrastructure and/or lacking nuclear infrastructure. Within the RHINO trial we aim to identify the recommended Phase 2 dose (RP2D), and schedule of administration for RHN001-Tx (^{188}Re-PSMA) and assess the safety, including the dosimetry of RHN001-Tx and RHN001-Dx (^{99m}Tc-PSMA) in men with prostate cancer. ***Materials and Methods:*** This single-center, single-arm, phase I/II trial will recruit patients with prostate cancer in three cohorts. Cohort A will assess the dosimetry of diagnostic use of RHN001-Dx in patients with newly diagnosed prostate cancer and low-volume disease. Cohort B will assess the dosimetry of therapeutic use of RHN001-Tx in patients with newly diagnosed prostate cancer and low-volume disease. In Cohort B we aim to assess the overall safety, including the dosimetry of RHN001-Tx in men with PSMA-positive prostate cancer with or without prior therapies. The dose escalation will be done for Cohort C with 3 patients per dose level, each in the range of 50-100 % maximum tolerable dose (MTD; 4-8GBq currently estimated). Up to 4 cycles of RHN001-Tx will be administered intravenously every 4-6 weeks. The maximum tolerated dose will be defined as the highest activity level at which a dose-limiting toxicity. Key eligibility criteria include a diagnosis of mCRPC with progression on androgen-deprivation therapy and/or taxane-based chemotherapy and Eastern Cooperative Oncology Group performance status of no more than 2, and no prior treatment with another radioisotope. Secondary objectives include assessing health-related quality of life using the Functional Assessment of Cancer Therapy- Prostate (FACT-P), Brief Pain Inventory-Short Form (BPI-SF), EQ-5D-5L and XeQOLS xerostomia questionnaire. ***Results:*** No results at this time as trial is currently enrolling. The trial has received ethical and regulatory approval. ***Conclusion:*** Enrolment is ongoing. This Trial is supported by Rhine Pharma GmbH, a Telix Company.

Inflammation Imaging via CD206-Targeted ^{68}Ga-NOTA-UNO in the Mouse Myocardial Infarction Model

D. Zheng, *Y. Lv, Z. Zhou, S. Wei, Z. Lin, Z. Wu, Y. Deng, X. Lv, X. Song, C. Qin, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: After myocardial infarction (MI), cardiac inflammatory-repair response correlates with ventricular remodeling and heart failure progression. Anti-inflammatory therapies demonstrate substantial potential, necessitating novel monitoring strategies. Macrophages, significant both quantitatively and functionally, are crucial for innovative monitoring. CD206, a reparative macrophage marker, is specifically targeted by the UNO peptide. This study aimed to evaluate the utility of a CD206-targeted PET probe, 68Ga-NOTA-UNO, for macrophage imaging in the mouse MI model. ***Materials and Methods:*** ^{68}Ga-NOTA-UNO was synthesized by reacting NOTA-UNO with $^{68}GaCl_3$ at 95°C for 15-minutes at pH 3.5, then purified using a C18 column. PET imaging and biodistribution studies were performed in MI and sham-operated mice at 0.5 h post-injection. Ex-vivo cardiac imaging was conducted to further confirm imaging specificity. Tracer uptake in infarcted and remote myocardium, liver, blood, and muscle was quantified via region-of-interest (ROI) analysis, expressed as percentage injected dose per gram (%ID/g). To map inflammatory activity spatially, ^{18}F-FDG metabolic imaging was performed to delineate infarct regions and compared with the ^{68}Ga-NOTA-UNO uptake region. Flow cytometry was employed to assess the differential expression of CD45 (leukocytes), F4/80 (macrophages), and CD206 among infarcted, remote, and sham-operated myocardium at day 7. Data were analyzed using Student's t-test and one-way ANOVA, with statistical significance as $P < 0.05$. ***Results:*** ^{68}Ga-NOTA-UNO exhibited > 99% radiochemical purity. Tracer uptake was obvious in the infarcted myocardium, but not in the remote myocardium or sham-operated mice. Quantitative analysis revealed higher uptake ratios in infarcted myocardium versus the corresponding area of sham groups, P values for infarcted myocardium, infarct/remote myocardium, infarct/liver, and infarct/blood 0.011, 0.0002, 0.001, 0.000086, respectively. Both ex vivo imaging and the biodistribution experiment indicated higher ^{68}Ga-NOTA-UNO uptake in the infarcted myocardium compared to the remote myocardium and the sham-operated group, whereas the biodistribution experiment showed no significant difference in other organs. The ^{68}Ga-NOTA-UNO uptake region spatially matched ^{18}F-FDG metabolic defects. Flow cytometry confirmed elevated proportions of $CD45^+$ leukocytes, $CD45^+F4/80^+$ macrophages, and CD206 in infarcted myocardium versus remote or sham-operated myocardium. $CD206^+$ macrophages ($CD45^+F4/80^+CD206^+$) constituted a significantly higher proportion of total macrophages ($CD45^+F4/80^+$) in both infarcted and remote myocardium, compared to sham-operated mice ($P < 0.05$), indicating increased reparative macrophage polarization by day 7 post-MI. ***Conclusion:*** This study successfully synthesized the PET probe ^{68}Ga-NOTA-UNO and verified its

feasibility for non-invasive visualization of CD206+ macrophages in MI models. These findings may offer a novel tool for guiding and evaluating anti-inflammatory therapies in cardiovascular disease.

OP-838

Synergistic effects of dapagliflozin and low salt diet evaluated by multi-nuclear ^{18}F-FDG PET-MRI (^{23}Na/^{1}H) in radiation-induced heart failure with preserved ejection fraction (HFpEF)

H. Rida[1], *M. Guetlin*[1,2], *C. Simard*[1], *M. Naveau*[3], *S. Allouche*[4], *L. Coulbault*[1], *P. Dupont*[1], *A. Lebrun*[1], *M. Joubert*[1,2], *A. Manrique*[1,5]; [1]*Cyceron UR4650 PSIR, Université Caen Normandie, Caen, FRANCE,* [2]*Diabetology, CHU de Caen, Caen, FRANCE,* [3]*UAR3408/US50 Cyceron, CNRS, INSERM, Université Caen Normandie, Caen, FRANCE,* [4]*Biochimie, CHU de Caen, Caen, FRANCE,* [5]*Nuclear Medicine, CHU de Caen, Caen, FRANCE.*

Aim/Introduction: Due to the cardiotoxic effects of radiotherapy, breast cancer patients are at increased risk of developing heart failure. Sodium-glucose co-transporter 2 (SGLT2) inhibitors, originally designed as antidiabetic drugs, demonstrated cardiovascular protection. However, the precise mechanisms behind these cardiovascular effects are still not fully understood due to their combined effects on glucose and sodium. ^{18}F-FDG PET and multi-nuclear MRI (^{23}Na/^{1}H) offer the potential to evaluate both tissue sodium content and cardiac glucose metabolism, in a murine model of radiation-induced cardiotoxicity on a normal and moderately low salt diet. ***Materials and Methods:*** Sixty-two Sprague Dawley rats were randomly divided into control (Ctrl, non-irradiated, n=13) and irradiated group (receiving 10 Gy of cardiac irradiation). At 3 months, the irradiated group was further subdivided into three subgroups receiving: placebo (PCB, n=21), dapagliflozin (DAPA, n=13), and dapagliflozin with 30% salt reduction (DAPA DIET, n=15). After 6 weeks of treatment, cardiac glucose metabolism was assessed through dynamic ^{18}F-FDG PET imaging using a 7-T PET-MRI system (Bruker Biospin). Left ventricular glucose metabolism was assessed by the net influx constant Ki. Tissue sodium content in the skin, pectoral muscle, and heart was measured using Na-MRI with a ^{1}H/^{23}Na surface coil. Left ventricular function was evaluated by echocardiography. ***Results:*** ^{18}F-FDG PET showed a significant increase in cardiac glucose metabolism in the PCB while DAPA reduced this metabolism. The influx rate (Ki) was 0.038±0.018 min^{-1} in PCB vs. 0.019±0.01 min-1 in DAPA (p=0.0005) vs. 0.024±0.007min-1 in DAPA DIET (p=0.0250) and vs. 0.021 ±0.01 min-1 in Ctrl (p=0.01). In the skin, the ^{23}Na signal significant increase in PCB (0.35±0.16) vs. DAPA (0.23±0.07, p=0.0295) vs. DAPA DIET (0.18±0.06, p=0.0004) but not vs. Ctrl (0.25±0.08, p=0.1). In the muscle, ^{23}Na MRI signal was increased in PCB (0.3±0.12) vs. DAPA (0.15±0.05, p=0.0007) vs. DAPA DIET (0.12±0.05, p<0.0001) and vs. Ctrl (0,18±0,06, p=0.0053). In the myocardium, the ^{23}Na signal was increased in PCB (0.21±0.13) vs. DAPA DIET (0.1±0.03, p=0.0092) vs. Ctrl (0.1±0.05, p= 0.03) but not vs. DAPA (0.13±0.04, p=ns).After treatment, ejection fractions was preserved in all groups, as expected (Ctrl: 71±7%, PCB: 76±8%, DAPA: 79±8%, DAPA DIET: 72±6%, p=ns). ***Conclusion:*** Cardiac irradiation resulted in increased cardiac glucose metabolism and sodium MRI signals. Dapagliflozin combined with a low-salt diet, reduced both of them while preserved LV systolic function.

OP-839

Longitudinal Multimodal Imaging Elucidates Temporal Metabolic Reprogramming and Mitochondrial-Microvascular Dysfunction in Diet-Induced HFpEF

J. Zhao[1,2,3], *Z. Xiang*[1,2,3], *Q. Wang*[1,2,3], *R. Shen*[1,2,3], *Y. Wen*[1,2,3], *X. Liu*[1,2,3], *P. Wu*[1,2,3], *Z. Wu*[1,2,3], *S. Li*[1,2,3];
[1]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA.*

Aim/Introduction: Heart failure with preserved ejection fraction (HFpEF) involves complex interactions among metabolic dysregulation, mitochondrial dysfunction, and microvascular impairment. However, the temporal progression of these pathological events remains undefined. This study employs serial molecular imaging and metabolomics to map the dynamic evolution of HFpEF in a murine model. ***Materials and Methods:*** Male C57BL/6 mice were randomly assigned to two groups: one group received a high-fat diet (60% of calories from fat) combined with L-NAME (0.5 g/L), while the other group served as the control. Longitudinal evaluations included weekly monitoring of body weight and blood pressure, echocardiograms at weeks 15 and 25, assessments of exercise tolerance, and PET/CT scans at weeks 5, 15, and 25. The PET/CT imaging employed [^{18}F] Flurpiridaz for myocardial perfusion, [^{18}F] FDG for glucose uptake, and TSPO-targeted [^{18}F] DPA-714 for mitochondrial stress. The final analysis at week 36 assessed cardiopulmonary mass, histopathology (including hypertrophy and fibrosis), and untargeted metabolomics. ***Results:*** HFD/L-NAME led to weight gain, hypertension, exercise intolerance, and progressive cardiac hypertrophy. Stress myocardial blood flow (MBF, [^{18}F]Flurpiridaz) decreased by week 15 (8.42 vs 15.87 ml/g/min, p>0.05) and deteriorated by week 25 (p<0.05). The compensatory elevation of LVEF at week 15 (71.70% ± 7.60%) returned to normal by week 25 (59.50% ± 15.03%). FDG uptake increased from week 15 (P<0.05) to week 25 (P<0.01), while TSPO uptake ([^{18}F]DPA-714) surged at week 25 (P<0.001), correlating with terminal heart/lung mass (week 15: r_{heart}=0.38, p<0.05; r_{lung}=0.54, p<0.01; week 25: r_{heart}=0.74, p<0.001; r_{lung}=0.47, p<0.01). Histopathological analysis at week 36 confirmed the presence of hypertrophy, fibrosis, and lipidosis. Metabolomics identified elevated trimethyllysine, which was positively correlated with TSPO at week 25 (r=0.84, p<0.01). Additionally, thiamine monophosphate (TMP) was decreased and showed an inverse correlation with FDG (r=-0.75, p<0.01). These findings are mechanistically linked to mitochondrial dysfunction and glycolytic flux via GLUT1/4. ***Conclusion:*** This study delineates a temporal HFpEF cascade: early microvascular dysfunction (reduced MBF) and metabolic adaptation (increased FDG uptake) precede mitochondrial failure (elevated TSPO expression) and culminate in terminal structural remodeling. TSPO uptake at week 15 predicts later cardiopulmonary hypertrophy, while trimethyllysine and thiamine monophosphate (TMP) imbalances drive mitochondrial-metabolic crosstalk, exacerbating disease progression. Longitudinal multimodal imaging (MBF/FDG uptake/TSPO expression) provides a non-invasive framework for staging HFpEF and targeting metabolic-mitochondrial pathways.

OP-840

In vitro functional assessment of cardiac membrane transporter P-glycoprotein with [^{18}F]MC225 by using µ-engineered heart tissues

W. Liu[1], *M. Dannenberg*[2], *R. Slart*[1], *V. Schwach*[2], *G. Luurtsema*[1];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS.*

Aim/Introduction: P-glycoprotein (P-gp), an efflux transporter with diverse compound effects, and is a vital part of cardiac function. P-gp function at the blood- brain barrier can be measured with PET and the tracer [^{18}F]MC225. To determine if the selective substrate tracer [^{18}F]MC225 also functions in cardiac P-gp, micro-engineered heart tissues (µ-EHTs) utilizing human induced pluripotent stem cell (hiPSC)-derived cardiomyocytes were used. This model offers advantages in potentially reducing animal experiments and allowing direct evaluation on human cells. However, its adoption in nuclear medicine remains very limited. This study aims to evaluate [^{18}F]MC225 as measurement method for cardiac P-gp function using a heart-on-chip model. ***Materials and Methods:*** µ-EHTs were treated with the P-gp inhibitor Tariquidar (200 nM for 30 minutes), while the corresponding control group

was treated with vehicle solution only. In parallel, another set of µ-EHTs was treated with the P-gp inducer Doxorubicin (1 µM for 24 hours), and its control group received the corresponding vehicle. Following treatment, all samples were incubated with [^{18}F] MC225 (1 MBq/mL for 30 minutes). Autoradiographic imaging was performed to assess the distribution of the tracer within the tissue. The expression of P-gp in the µ-EHTs was assessed via immunofluorescent staining. ***Results:*** Immunofluorescent staining showed an increase of P-gp expression after Doxorubicin treatment in µ-EHTs. According to γ-counter measurements, tissues treated with Tariquidar exhibited significantly higher uptake of [^{18}F]MC225 (117.5 ± 33.67%, n = 24; P = 0.035) compared to vehicle control group. In contrast, Doxorubicin-treated tissues showed a significantly reduced uptake (63.97 ± 21.89%, n = 20; P < 0.001) relative to their corresponding untreated controls . Autoradiographic imaging demonstrated a homogeneous uptake of [^{18}F]MC225 within the µ-EHTs and reflected the same trends observed in the γ-counter measurements. ***Conclusion:*** [^{18}F]MC225 effectively demonstrated cardiac P-gp function in µ-EHTs on the heart-on-chip platform. This research sets the stage for future studies using P-gp function to evaluate the efficacy and safety of novel cardiovascular drugs using µ-EHTs.

Spatiotemporal TSPO Dynamics Predict Ventricular Remodeling in Pressure Overload: Early Inflammation to Late Mitochondrial Dysfunction

Z. Xiang[1,2,3], *L. Gao*[4], *X. Liu*[1,2,3], *H. Song*[1,2,3], *Z. Qin*[1,2,3], *P. Wu*[1,2,3], *Z. Wu*[1,2,3], *S. Li*[1,2,3];
[1]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA,* [4]*Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, and the Department of Physiology, School of Basic Medicine, Shanxi Medical University, Taiyuan, CHINA.*

Aim/Introduction: Mitochondrial dysfunction represents a significant mechanism underlying heart disease. The translocator protein (TSPO), located on the outer membrane of mitochondria, exhibits altered expression in various pathological conditions associated with heart disease, making it a potential target for diagnosis and therapy. Research has shown that TSPO-PET effectively identifies early post-infarction myocardial inflammation. Furthermore, TSPO functions as a mitochondrial marker indicative of myocyte dysfunction in heart failure. However, the dynamic pattern of TSPO expression over time and its relationship with prognosis in non-ischemic heart disease remains unclear. ***Materials and Methods:*** Male C57BL/6 mice underwent transverse aortic constriction (TAC) (n=25) and sham surgery (n=25). ^{18}F-DPA-714 TSPO-PET and cardiovascular magnetic resonance imaging (CMR) were conducted at 1, 4 and 8weeks post-surgery. Following imaging, the animals were euthanized (n=5 per time point), and the cell-specificity of abnormal TSPO expression was assessed through immunofluorescence. Differences in TSPO-PET signals between the two groups, as well as the cell-specific origins of TSPO-PET signals during disease progression, were analyzed. Finally, we investigated the correlation between TSPO signals and left ventricular remodeling. ***Results:*** Compared to the sham group, the TAC group exhibited a significant decrease in ejection fraction (EF) at both 4 weeks (61.86 ± 1.32 vs. 55.49 ± 1.87, p<0.01) and 8 weeks (61.86 ± 1.32 vs. 46.16 ± 2.03, p < 0.001). Additionally, the TAC group demonstrated increased accumulation of [18]F-DPA-714 in the heart compared to the sham group at 1 week (SUVmean * Volume: 0.3056 ± 0.0099 vs. 0.1893 ± 0.0035, p<0.05), which localized to activated CD68+ inflammatory cells. Early TSPO-PET signal was predictive of subsequent left ventricular remodeling at 8 weeks (EF: R=-0.5140, p=0.0291). Following a decline at 4 weeks (0.2943 ± 0.1084, p > 0.05), the TSPO-PET signal was concurrently upregulated in cardiomyocytes at 8 weeks (0.4066 ± 0.1022, p < 0.01) despite the absence of inflammatory cell infiltration, indicating mitochondrial impairment. ***Conclusion:*** TSPO-PET captures spatiotemporal shifts from early macrophage-driven inflammation to late cardiomyocyte mitochondrial dysfunction in pressure-overload cardiomyopathy, with early uptake predicting late systolic dysfunction that informs timed interventions to mitigate remodeling.

Assessment of cerebral blood flow in extracorporeal cardiopulmonary resuscitation in a pig model of prolonged cardiac arrest: a [^{15}O]water PET study

R. Berti[1], *J. C. Fostitsch*[1], *B. A. Bretthauer*[2], *S. Brixius*[2], *L. Blum*[3], *C. Scherer*[2], *J. Dinkelaker*[4], *J. Haberstroh*[4], *H. J. Busch*[3], *C. Benk*[2], *G. Trummer*[2], *F. Beyersdorf*[2], *M. Mix*[1], *P. T. Meyer*[1], *J. S. Pooth*[3];
[1]*Department of Nuclear Medicine, Medical Center – University of Freiburg, Faculty of Medicine – University of Freiburg, Freiburg, GERMANY,* [2]*Department of Cardiovascular Surgery, Medical Center – University of Freiburg, Faculty of Medicine – University of Freiburg, Freiburg, GERMANY,* [3]*Department of Emergency Medicine, Medical Center – University of Freiburg, Faculty of Medicine – University of Freiburg, Freiburg, GERMANY,* [4]*Department of Experimental Surgery, Center for Experimental Models and Transgenic Service, Medical Center – University of Freiburg, Faculty of Medicine, Freiburg, GERMANY.*

Aim/Introduction: Neurological recovery after prolonged cardiac arrest (CA) remains a major challenge despite advances in resuscitation. Although extracorporeal cardiopulmonary resuscitation (ECPR) rapidly restores circulation, the time course of reperfusion in the different brain regions still remains unclear. To address this, we developed a porcine model to investigate regional cerebral blood flow (rCBF) dynamics during ECPR following prolonged CA for 20 min, aiming to identify perfusion patterns to guide targeted neuroprotective interventions. ***Materials and Methods:*** Four Landrace hybrid pigs underwent PET/CT imaging using [^{15}O]water PET (780 ± 25 MBq). Two to three baseline scans were acquired before normothermic CA induced by ventricular fibrillation. ECPR was initiated at 20 min of CA with a pulsatile blood flow of 5-6 L/min. PET scans were acquired at 8, 24, 46, and 61 minutes after the start of ECPR. rCBF was quantified using a 1-tissue compartment model and the arterial input function with a fixed brain tissue partition coefficient (p = 0.95 ml/cc, rCBF = k_2 * p). Individual rCBF time curves of several cortical and subcortical brain regions were fitted using a nonlinear exponential saturation function, from which λ was derived to estimate regional perfusion recovery. Regions were ranked by λ, and statistical analysis was performed using the Friedman test. ***Results:*** Baseline whole-brain (WB) CBF was consistent across animals (mean ± std = 49.1 ± 11.3 ml/min/100 ml). Following ECPR, all pigs exhibited a rapid increase in WB CBF consistent with exponential recovery. Perfusion recovery across brain regions revealed a reproducible reperfusion hierarchy across pigs despite individual differences in overall timing. Subcortical areas as mesial temporal lobe, striatum and thalamus exhibited the earliest perfusion recovery, followed by the cerebellum. In contrast, cortical regions showed a more delayed response. Among these, lateral temporal, primary visual, and auditory cortices recovered earlier than frontal, motor and lateral occipital regions, while the primary somatosensory and somatosensory association cortices were the last to show reperfusion. The Friedman test (χ^2 = 39.3, p < 0.001) showed significant variation in perfusion timing across regions. ***Conclusion:*** Cerebral reperfusion during ECPR follows a consistent, hierarchically organized pattern with faster recovery in subcortical regions and delayed hyperperfusion in primary and associative cortical areas. This hierarchical pattern of perfusion highlights a temporally structured recovery sequence, beginning

with basic vital function and evolutionarily older regions, and gradually extending to higher-order sensory and cognitive areas. This porcine model may be useful for further exploration of neuroprotective and perfusion-guided strategies after prolonged CA.

OP-843

Dual-tracer PET/CT Reveals the Spatiotemporal Evolution Patternof Fibro-inflammatory InteractionsAfter Myocardial Infarction: A Longitudinal Rodent Study

Y. Hong, *J. Song, L. Li;*
First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: This study aims to elucidate the spatiotemporal dynamic evolution of myocardial inflammation and fibrosis after myocardial infarction (MI) using non-invasive dual-tracer (^{18}F-FAPI-74 and ^{18}F-FDG) PET/CT imaging. ***Materials and Methods:*** 10-week-old male Sprague-Dawley rats were divided into MI group (model established by ligating LAD), sham surgery, and blank control groups. Serial PET/CT scans using ^{18}F-FAPI-74 (fibrosis), ^{18}F-FDG (inflammation), and ^{18}F-FDG (infarct) were performed from 1 day to 12 weeks post-MI. The MI regions of interest (ROI) were defined by ^{18}F-FDG metabolic defect. The maximum target-to-background ratio (TBRmax) were calculated as the ratio of the maximum standardized uptake value (SUVmax) to the mean left ventricular blood pool uptake (SUVmean), the abnormal tracer uptake area quantified by polar coordinate bull's-eye mapping. Longitudinal correlations were assessed between imaging findings, serum biomarkers (IL-6, hs-CRP, TGF-β1), and histopathology (HE, Masson, and immunofluorescence staining). ***Results:*** 1. Time-dependent bimodal uptake patterns with highly synchronous: The early peak at 1 week post-MI (^{18}F-FAPI TBRmax:10.60 ± 2.11 vs. 2.35±0.46 , $p < 0.0001$ vs. controls; ^{18}F-FDG TBRmax: 9.73 ± 2.60 vs. 2.09±0.33 , $p < 0.05$ vs. controls) , and a weaker late peak at 10 weeks post-MI (^{18}F-FAPI TBRmax: 4.10 ± 1.15 vs. 1.87±0.12 , $p > 0.05$ vs. controls; ^{18}F-FDG TBRmax: 8.43 ± 2.39 vs. 2.06±0.13 , $p < 0.05$ vs. controls). 2. Uniform spatial distribution with hierarchical differentiation: The abnormal uptake area: ^{18}F-FDG (inflammatory response) > ^{18}F-FAPI (active fibrotic) > ^{18}F-FDG (metabolic infarction) (18.92 ± 3.54% vs. 11.50 ± 3.14% vs. 5.36 ± 1.33% , $p < 0.01$ for all comparisons), but the differences gradually decrease over time. 3. Consistency between blood biochemistry and pathology: PET/CT findings correlated with serum biomarkers and histopathology. No pathological activity was detected in remote myocardium. ***Conclusion:*** Dual-tracer ^{18}F-FAPI and ^{18}F-FDG PET/CT enables precise delineation of the spatiotemporal dynamics of inflammation and fibrosis following MI. The bimodal uptake pattern offers critical guidance for identifying therapeutic targets and optimal intervention windows, thereby underscoring the clinical translational potential of molecular imaging-guided stratification in optimizing cardiovascular outcomes.

OP-844

The dynamic process of cardiac fibroblast activation after myocardial infarction

L. Wang[1], *S. Huang*[2], *F. Shan*[1], *X. Ye*[2], *J. Lou*[1], *X. Liu*[1];
[1]*Shanghai Pudong Hospital, Fudan University, Shanghai, CHINA,*
[2]*Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: The novel fluorine-18-labeled fibroblast activation protein inhibitor (^{18}F-FAPI) serves as a PET radiotracer that binds to activated fibroblasts. The aim was to explore the intensity, extent, and time course of fibroblast activation after myocardial infarction (MI). ***Materials and Methods:*** A total of 18 swines with acute MI underwent ^{18}F-FAPI PET/CT and cardiac MRI. The intensity of ^{18}F-FAPI-04 uptake was quantified by the maximum target-to-background ratio (TBRmax). The extent of fibroblast activation was assessed by the percentage of FAPI-avid myocardium in the left ventricle (LV) and late gadolinium enhancement (LGE), respectively. The FAPI amount was calculated as the product of the percentage of FAPI-avid LV myocardium and TBRmax. ***Results:*** During the dynamic progression of MI from the acute to chronic phase, no significant ^{18}F-FAPI-04 uptake was observed in the infarcted area on day 1 after infarction, which was lower than the normal group (TBRmax: 0.96 ± 0.18 vs. 1.71 ± 0.26). By day 4, significant FAPI uptake was observed in the infarcted area. Myocardial FAPI uptake was observed in acute infarct and peri-infarct regions, exceeding the extent of LGE ($P < 0.001$). One week after MI, the entire LV was activated and activation continued until the 10th week; two-fifths of the swines also demonstrated right ventricular involvement, which persisted until the chronic infarct phase. Myocardial FAPI uptake peaked at 1 and 2 weeks post-AMI before declining at 4, 7, and 12 weeks (TBRmax: 6.77 ± 0.91, 7.59 ± 0.29, 4.36 ± 1.07, 3.09 ± 0.37, and 3.46 ± 0.37; $P < 0.001$). Chronic infarcts exhibited increased FAPI uptake at lower intensity compared to acute infarcts (TBRmax: 3.81 ± 0.40 vs. 6.13 ± 1.29; $P < 0.001$). Increased remote myocardial FAPI uptake was associated with left ventricular dilatation and systolic dysfunction. In addition, hepatic ^{18}F-FAPI-04 uptake peaked at 2, 5, and 9 weeks post-AMI (TBRmax: 5.54 ± 1.10, 8.19 ± 0.22, and 6.03 ± 0.25). After entering the chronic phase, the hepatic FAPI uptake remained stable and increased compared to the normal group (TBRmax: 5.36 ± 0.63 vs. 3.25 ± 0.44; $P < 0.001$). ***Conclusion:*** Myocardial fibroblast activation peaks within two weeks of MI, extends beyond the infarct region, and gradually declines over months, providing a theoretical basis for defining the therapeutic window of anti-fibrotic interventions. Persistent fibroblast activation contributes to subsequent LV remodeling. Furthermore, a potential correlation exists between myocardial infarction and the activation of hepatic FAP proteins.

OP-845

Preparation of a Novel P2X7 Targeted Nanobody Molecular Probe [^{18}F]F-1c81 and micro PET Imaging Study of Atherosclerotic Plaque

B. Hu, *T. Mou, M. Yun, Y. Wang, X. Xu, Y. Tian, X. Zhang;*
Department of Nuclear Medicine, Molecular Imaging Lab, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: A novel purinergic receptor P2X7 targeted nanobody-based probe [^{18}F]F-1c81 was developed and evaluated for its potential application in atherosclerotic plaque (AP) micro PET imaging. ***Materials and Methods:*** The nanobody 1c81 was expressed in Escherichia coli and the free amino groups were coupled with 2,5-dioxopyrrolidin-1-yl 1-(cyclooct-4-en-1-yl)-1-oxo-5,8,11,14-tetraoxa-2-nonazine-17-sulfonic acid (TCO-PEG4-NHS) to obtain the labeled precursor TCO-1c81. Al[^{18}F]F-2,2'-(7-(14-(4-(6-methyl-1,2,4,5-tetrazin-3-yl)phenoxy)-2-oxo-6,9,12-trioxa-3-azatetradecyl)-1,4,7-triazonane-1,4-diyl) diacetic acid (Al[^{18}F]F-NOTA-Tz) was synthesized, and then it was coupled with TCO-1c81 via bioorthogonal reaction to synthesize the P2X7 targeted radiotracer Al[^{18}F]F-NOTA-Tz-TCO-1c81 ([^{18}F]F-1c81). The labeling rate of the probe was evaluated, and [^{18}F]F-1c81 PET imaging and pathological correlation studies were conducted in 3 AP model mice (20 weeks on high-fat diet) and 3 normal C57BL/6 mice (20 weeks on normal diet). ***Results:*** The preparation of [^{18}F]F-1c81 was completed within 85~95 min, with a non-decay corrected yield of 21.5 ± 5.6 % (n = 3). The radiochemical purity of [^{18}F]F-1c81 was greater than 98%, and the molar activity was 13.9 MBq/nmol. The micro PET imaging results at 1 hour post injection showed that the mean Standardized Uptake Value (SUVmean) of the probe in the aortic arch of AP model mice was significantly higher than that of control mice (0.52±0.02 vs 0.36±0.03, $P = 0.0034$), indicating that the probe has certain plaque-targeting ability and imaging ability. Immunofluorescence staining showed P2X7 expression by CD68-positive macrophages and other myeloid cells located in the fibrous cap layer and shoulder region

of plaques. ***Conclusion:*** The novel molecular probe [^{18}F]F-1c81 is characterized by a simple and efficient preparation process, exhibits favorable physicochemical properties, and can be utilized for the detection of AP.

^{18}F-FDG PET Radiomics as a Prognostic Tool in Pediatric Ewing Sarcoma

B. Soydas Turan[1], *C. Küçüker*[2], *B. Volkan Salancı*[2], *P. Ozgen Kiratli*[2]; [1]*Kastamonu Training and Research Hospital, Department of Nuclear Medicine, Kastamonu, TÜRKIYE,* [2]*Hacettepe University, Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: This study aimed to assess the prognostic significance of radiomic features obtained from baseline ^{18}F-FDG PET/CT scans in predicting progression-free survival (PFS) in pediatric Ewing sarcoma (ES). ***Materials and Methods:*** Baseline ^{18}F-FDG PET/CT scans from pediatric ES patients, acquired between January 2010 and December 2020, were retrospectively analyzed. LIFEx v.7.7.0 was used to delineate the volume of interest (VOI) for primary tumors using a threshold set at 40% of the SUVmax. These VOIs were used for radiomic feature extraction, including conventional metabolic parameters [SUVmax, SUVmean, SUVpeak, metabolic tumor volume, total lesion glycolysis], shape indices (compacity, compactness, sphericity), histogram-based features (skewness, kurtosis, entropy, uniformity), and textural features [gray-level co-occurrence matrix, gray-level run-length matrix, neighborhood gray-tone difference matrix (NGTDM), gray-level size zone matrix (GLSZM)]. The prognostic significance of each variable for PFS was evaluated using univariate and multivariate Cox regression analyses. Variables with $p<0.05$ in the univariate analysis were included in the multivariate model using backward elimination. For continuous variables, optimal cutoff values were determined using Youden's index. Kaplan-Meier curves were generated to estimate PFS, and differences between groups were assessed using the log-rank test. ***Results:*** PET/CT scans of 41 patients (mean age 10.53±3.72 years; 15 females) were analyzed. At diagnosis, eighteen patients (43.9%) had metastatic disease. During follow-up, nineteen patients (46.3%) had disease relapse or progression, and fourteen patients (34.1%) died. The mean PFS was 86 months. Variables evaluated for their prognostic value in PFS included age, gender, presence of metastasis at diagnosis, and the aforementioned radiomic features. In the univariate analysis, histogram-based kurtosis and some textural features, specifically NGTDM_Busyness, GLSZM_Large Zone Emphasis, GLSZM_Large Zone Low Gray Level Emphasis, GLSZM_Zone Size Variance were significantly associated with PFS ($p<0.05$). Other evaluated parameters did not show a statistically significant association. In the multivariate model, only histogram-based kurtosis and NGTDM_Busyness remained independent prognostic factors (HR=4.03; 95%CI=1.32-12.29; p=0.014 and HR=3.94; 95%CI=1.47-10.55; p=0.006, respectively). Kaplan-Meier analysis showed that patients with high kurtosis (>-0.01) and high NGTDM_Busyness values (>5.22) had significantly shorter mean PFS compared to those with lower values (60 vs. 117 months; p=0.003 and 25 vs. 98 months; p=0.001, respectively). ***Conclusion:*** Specific radiomic features extracted from baseline ^{18}F-FDG PET/CT scans—particularly histogram-based kurtosis and NGTDM_Busyness—are independent prognostic factors for PFS in pediatric ES. These findings suggest that tumor heterogeneity, as reflected by these parameters, may provide valuable prognostic information beyond conventional PET parameters. Further validation in prospective studies is needed.

OP-847

Prognostic Value of Baseline ^{18}F-FDG PET/CT Metabolic Parameters for Pediatric Nasopharyngeal Carcinoma Patients

A. Pala*, O. Kodaz, P. Özgen Kıratlı, B. Volkan Salancı; Hacettepe University Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Nasopharyngeal carcinoma (NPC) is a rare tumor in children. Most cases are diagnosed with locally advanced stage, often affecting the retronasal cavity and regional lymph nodes, while a few patients present with distant metastases at the time of diagnosis. Identifying patients at higher risk of treatment failure is crucial. In this study, the authors searched for which metabolic parameters at baseline 18F-FDG-PET/CT can predict event-free-survival (EFS) and overall-survival (OS). ***Materials and Methods:*** Baseline 18F-FDG-PET/CT images of pediatric patients with histologically confirmed non-keratinized-undifferentiated NPC were evaluated retrospectively. Metabolic tumor volume(MTV) and total lesion glycolysis(TLG) of the primary tumor(P), regional lymph nodes(N), and distant metastases(M) were obtained separately. Tumor segmentation was defined based on the threshold SUVmax values of 2.5, the hepatic reference(HR) SUVmean, and a threshold of 40% of SUVmax. The cumulative values of MTV and TLG across all pathological lesions produced whole-body(WB) MTV and TLG, respectively. Kaplan-Meier curves and the log-rank test were used to compare survival experiences between metabolic PET parameters at cut-off values (ROC curve and Youden Index). ***Results:*** The study group consisted of 23 patients (F/M:6/17, median age:14.91, range:7.57-17.37) referred between May 2014 and July 2023. Of these patients, 20/23 (87%) had locally advanced and 3/23 (13%) had metastatic disease. The median duration of follow-up was 74 months (range:12-132). After completing the treatment, a complete response with no reported events was achieved in 21 patients. While five patients had disease-related events, two patients progressed during initial treatment, and three patients developed relapse after the completion of therapy. Among the five patients with disease-related events, two developed locoregional progression, and four developed distant metastasis. OS was 87%. Patients with WB-$MTV_{2.5}$>105.82 (44 vs 121 months; p=0.009), WB-$MTV_{40\%}$>48.56 (39 vs 121 months; p=0.004), WB-$TLG_{40\%}$>499.23 (32 vs 115 months; p=0.012), P-$MTV_{40\%}$>37.21 and P-MTV_{liver}>96.78 (7 vs 112 months; p<0.001) had lower EFS. Besides, WB-$TLG_{40\%}$>499.23 (50 vs 127 months; p=0.012), P-$MTV_{40\%}$>37.21, and P-MTV_{liver}>96.78 (25 vs 127 months; p<0.001) were significantly associated with lower OS. Although patients with WB-$MTV_{2.5}$>105.82 and WB-$MTV_{40\%}$>48.56 had shorter OS, this did not reach statistical significance. Also, the presence of any lesion with SUVmax>20.6 (45 vs 106 months; p=0.3) corresponded to a lower EFS, which is not statistically significant. ***Conclusion:*** Baseline 18F-FDG-PET/CT metabolic parameters can be prognostic indicators in pediatric NPC patients. Various threshold approaches can be used for tumor segmentation. High WB-MTV&TLG, P-MTV, and overall-SUVmax values are associated with poor OS and EFS.

OP-848

Utility of 18F-fluorodeoxyglucose positron emission tomography in presurgical evaluation of paediatric patients with Drug Resistant Epilepsy - A Concordance Analysis between PET/MRI and EEG

A. Meena, *A. Subramanyam, H. Singh, R. Kumar, B. Mittal; Post Graduate Institute of Medical Education and Research, Chandigarh, Chandigarh, INDIA.*

Aim/Introduction: The aim of our single center ambispective observational cohort study was to evaluate the clinical impact of hybrid ^{18}F FDG PET/CT on the decision workflow of drug-resistant epileptic patients with equivocal and/or discordant electroclinical and MRI data. ***Materials and Methods:*** Drug resistant epileptic paediatric patients with discordant clinical and diagnostic results or MRI negativity were included in this study. Hypometabolic regions (mean ± SD age 10.2 ± 3.1 years) in refractory symptomatic (MRI-positive, n = 121) and cryptogenic (MRI-negative, n = 44) epilepsy were quantitatively identified via statistical parametric mapping (SPM) and qualitatively analyzed via visual examination of PET/MR co-registration images. ***Results:*** We included 165 patients in this study; 100 had temporal lobe epilepsy (TLE), 43 extratemporal epilepsy (ETLE), and 22 had epilepsy of uncertain lobar origin. FDG-PET showed a distinct hypometabolism in 62% and was concordant with ictal EEG in 74% in TLE and in 56% in ETLE ($p < .001$). FDG-PET was useful in presurgical decision-making in 77 patients (47%) and most beneficial in TLE compared to ETLE (58% vs. 44%, $p = .001$). In TLE, seizure-freedom 1 year after surgery did not differ significantly ($p = .48$) between patients with negative MRI and EEG-PET concordance (65%) and those with positive MRI and concordant EEG (68%). In ETLE, half of patients with negative MRI and EEG-PET concordance and three-quarters with positive MRI and concordant EEG were seizure-free post-surgery (n = 5 vs. n = 6, $p = .28$). The visual analysis localised the epileptogenic zone in 82 % while SPM localised the EZ in only 47%. Cohen's kappa for visual Vs. SPM analysis was is 0.30 suggesting fair concordance between the two analysis. There was a significant concordance to detect hypometabolic areas between both SPM and visual analyses ($K = 0.45$; $p < 0.005$), in symptomatic ($K = 0.74$; $p < 0.005$) and in cryptogenic patients ($K = 0.26$; $p < 0.01$). Among the 165 children, visual analysis succeeded detecting hypometabolic area in 62% of the cases (interobserver kappa = 0.31). ***Conclusion:*** FDG-PET is valuable to localize the seizure onset zone when MRI and scalp EEG are not localizing or are discordant. MRI-negative and MRI-positive cases with concordant FDG-PET results (with either EEG or MRI) had a comparable outcome after surgery. These findings confirm the significance of FDG-PET in presurgical epilepsy diagnostics.

OP-849

Extracranial Disease Burden in Paediatric Tuberculous Meningitis Characterised on F-18 FDG PET-CT

B. Berndorfler[1], *J. M. Warwick*[1], *J. A. Seddon*[2,3], *C. Bekker*[3], *R. S. Solomons*[1], *R. Van Toorn*[1], *A. G. G. Doruyter*[1,4]; *[1]Stellenbosch University, Cape Town, SOUTH AFRICA, [2]Imperial College London, London, UNITED KINGDOM, [3]Desmond Tutu TB Centre, Stellenbosch University, Cape Town, SOUTH AFRICA, [4]NuMeRi Node for Infection Imaging, Stellenbosch University, Cape Town, SOUTH AFRICA.*

Aim/Introduction: Tuberculous meningitis (TBM) disproportionately affects children under five years of age. It is believed that TBM occurs through lympho-haematogenous dissemination of bacilli, putting other extrapulmonary organs at risk. However, diagnosing extracranial TB can be challenging due to non-specific symptoms, variable presentation and limited diagnostic tools. To address these challenges, healthcare providers use various imaging studies, biopsy, histopathology and molecular tests. While studies in adults have found extracranial disease in 80-90% of TBM cases, there is a knowledge gap in paediatric TBM, particularly regarding the use of metabolic imaging like FDG PET-CT to characterized extracranial involvement. ***Materials and Methods:*** Fifty-three children with TBM underwent whole-body F-18 FDG PET-CT imaging at Tygerberg Hospital between June 2023 and March 2025. After excluding one child with a revised diagnosis, 52 children meeting standard diagnostic criteria for probable or confirmed TBM were analysed. PET-CT scans were evaluated by a nuclear medicine physician to identify extracranial sites of tuberculosis based on both metabolic and structural imaging findings. Equivocal cases were reviewed jointly with a second nuclear medicine physician experienced in infection and inflammation imaging. ***Results:*** The study included 52 children (n=52) with a median age of 3.5 years (interquartile range 1.9-6.6 years). Extracranial manifestations of TB were identified in 48 (92%) of children. Among these, pulmonary involvement was observed in 39 (75%), nodal involvement in 43 (83%), skeletal involvement in 5 (10%), and soft tissue involvement in 10 (19%). ***Conclusion:*** This study highlights a significant prevalence of extracranial TB in children with TBM, as detected by F-18 FDG PET-CT. Notably, the rates exceed those reported in adult TBM patients. Identifying extracranial disease is crucial, as it can impact treatment duration, inform infection control measures, and potentially prevent complications.

OP-850

Prognostic Value of Quantitative Interim PET in Pediatric High-Grade Non-Hodgkin Lymphomas: Toward More Predictable Outcomes

G. Kaya[1], *O. Kodaz*[2], *B. Volkan Salanci*[2], *B. Aydın*[3], *P. Özgen Kıratlı*[2]; *[1]Republic of Türkiye, Ministry of Health, Yozgat City Hospital, Dept. of Nuclear Medicine, Yozgat, TÜRKIYE, [2]Hacettepe University, Faculty of Medicine, Nuclear Medicine Dept., Ankara, TÜRKIYE, [3]Hacettepe University, Faculty of Medicine, Paediatric Oncology Dept., Ankara, TÜRKIYE.*

Aim/Introduction: Pediatric Non-Hodgkin Lymphomas (NHL) are a highly heterogeneous group of malignancies, and assessment of residual disease on interim PET-CT poses a persistent diagnostic challenge. While the Deauville Score (DS) is widely used for response evaluation, its limitations—particularly in cases with DS scores of 3 or 4—warrant the exploration of alternative or complementary imaging biomarkers. Recent studies have highlighted the potential of metabolic parameters and semiquantitative methods, such as quantitative PET (qPET), metabolic tumor volume (MTV), and total lesion glycolysis (TLG), in improving risk stratification and prognostication. This study aimed to compare the performance of DS, qPET, and MTV/TLG in predicting early disease recurrence in pediatric patients with high-grade NHL. ***Materials and Methods:*** This retrospective, single-center study included high-grade NHL patients under 18 years of age who underwent interim PET-CT during frontline treatment. qPET was calculated for patients with DS scores of 3-5. Whole-body MTV and TLG were assessed using a fixed SUVmax threshold of 2.5. Patients with DS scores of 3-4 or MTV/TLG values above the median were classified as having residual disease. Follow-up data, including disease recurrence and disease-related death, were obtained and analyzed. Survival analyses were conducted using Kaplan-Meier methods, with event-free survival (EFS) as the primary outcome. ***Results:*** A total of 107 patients (73 male, mean age 9.5 ± 4.5 years) were included. The median follow-up duration was 92 months (range: 7-165 months). Disease recurrence occurred in 25 patients (23%). Median interim PET-CT values were: SUVmax 2.9 (range 1-17), DS 1 (range 1-5), qPET 1.59 (range 0.7-9.5), MTV 0 cm^3 (range 0-453 cm^3), and TLG 0 (range 0-3163). The number of patients identified as having residual disease was 35 (DS3), 25 (DS4), 22 (MTV/TLG), and 21 (qPET). All TLG-positive cases were also positive for DS3-4. Kaplan-Meier survival analysis revealed no statistically

significant differences in EFS between groups defined by qPET or DS3-4 thresholds. However, TLG positivity was associated with significantly worse EFS (p = 0.01), with the greatest mean survival difference (35 months). ***Conclusion:*** In this larger pediatric cohort, metabolic parameters—particularly TLG—demonstrated superior prognostic performance compared to DS and qPET in predicting early recurrence. These findings support the clinical utility of TLG in refining treatment and follow-up strategies, especially for patients with intermediate DS scores. While qPET did not show significant predictive value in this cohort, further studies with larger populations are warranted to optimize threshold definitions and validate these markers in clinical practice.

OP-851

Using radiomics based on 2-[^{18}F]FDG PET/CT and machine learning methods to predict the WHO/ISUP grade of clear cell renal cell carcinoma

Y. Han[1], *J. Zhang*[1], *Y. Pan*[2], *J. Cui*[1], *C. Li*[2], *Y. Wang*[3], *G. Wang*[4], *B. Xu*[2];
[1]*Graduate School, Chinese PLA General Hospital, Beijing, CHINA,* [2]*Chinese PLA General Hospital, Beijing, CHINA,* [3]*GE Healthcare China, Shanghai, CHINA,* [4]*Nuclear Medicine Department, Beijing Friendship Hospital, Capital Medical University, Beijing, CHINA.*

Aim/Introduction: This study aims to evaluate the clinical value of radiomics features of 2-[^{18}F]fluoro-D-glucose positron emission tomography (2-[^{18}F]FDG PET/CT) combined with machine learning methods in predicting the WHO/ISUP grade of ccRCC lesions, and to determine the optimal machine learning method. ***Materials and Methods:*** Retrospectively, the PET/CT images of 209 pathologically confirmed ccRCC patients (a total of 214 lesions) were collected. According to the WHO/ISUP pathological nuclear grading, the tumors were classified into high grade (Grade III and IV) and low grade (Grade I and II) and were randomly divided into a training group and a testing group at a ratio of 7:3. The regions of interest were delineated and different combinations of 5 feature selection methods and 8 classification methods were used to establish radiomics models respectively. The performance of each model was evaluated by the area under the receiver operating characteristic curve (AUC). ***Results:*** A total of 40 radiomics models were established. Most of the models had good predictive ability with AUCs greater than 0.75. Whether in the training group or the testing group, the feature selection method LASSO combined with the classifier logistic regression (LR) achieved the highest AUC values, which were 0.887 and 0.882 respectively. In terms of feature selection methods, RFE_SVM performed the best in most of the models. In the training group, the RFE_SVM-XGBoost model, RFE_SVM-Decision_Tree model, RFE_SVM-Neural_Network model, RFE_SVM-Bayes model, RFE_SVM-kNN model, RFE_SVM-Random_Forest model, and RFE_SVM-SVM model all showed the best predictive performance. The performance of the RFE_SVM-LR model was second only to that of the LASSO-LR model. In the testing group, the RFE_SVM-XGBoost model, RFE_SVM-Decision_Tree model, RFE_SVM-Neural_Network model, and RFE_SVM-kNN model performed the best. Among other classifiers, the models combined with LASSO had the best performance. In terms of classifier selection, LR performed the best in most of the models. In the training group, the LASSO-LR model, Boruta-LR model, and RFE-LR model had the optimal performance. The performance of the RFE_SVM-Random_Forest model and the XGBoost-XGBoost model was slightly higher than that of the RFE_SVM-LR model and the XGBoost-LR model respectively. In the testing group, LR was the classifier selection with the best performance. ***Conclusion:*** The radiomics based on 2-[^{18}F]FDG PET/CT can predict the WHO/ISUP grade of clear cell renal cell carcinoma. RFE_SVM and LR are considered as the optimal feature selection method and classification method respectively. Combining LASSO with LR can achieve the highest predictive efficiency of the model.

OP-852

Dynamic 3D 12-headed CZT-detector ring SPECT/CT renal transplant MAG3 renography: a phantom and clinical implementation study

A. van de Burgt, *Q. de Lussanet de la Sabloniere, M. Segbers, F. A. Verburg, A. A. Harteveld;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: A challenge in conventional renal transplant MAG3 renography, as performed two-dimensionally (planar) with NaI detectors, is its inherently limited accuracy owing to overlapping structures (e.g. bladder, ureter, urine leakage). Novel 12-headed cadmium-zinc-telluride (CZT) detector-ring single-photon emission computed tomography/computed tomography (SPECT/CT) allows for dynamic three-dimensional (3D) SPECT acquisitions with CT-based structural correlation. This study aimed to evaluate the non-inferiority of dynamic 3D-SPECT/CT renography compared to dynamic conventional planar renography in a custom-designed renal perfusion phantom, and its subsequent clinical implementation. ***Materials and Methods:*** Phantom experiment: 35 MBq Tc-99m pertechnetate was pumped (1200 mL/h; 'arterial input') into a 100 mL glass bottle ('kidney') draining into a waste container ('bladder'). Dynamic 3D-SPECT was performed with 60x5sec (Phase 1) and 150x10sec (Phase 2) frames using factory settings on a CZT-ring SPECT/CT. Dynamic planar scintigraphy was acquired using clinical protocol (120x15sec) on a conventional SPECT/CT. Dynamic 3D-SPECT reconstruction: Q.Clear 10 iterations, 10 subsets, voxel size 4.92 mm, gamma 2, beta values of 0.2 (phase 1) and 0.002 (phase 2), according to factory settings. In-human study: dynamic 3D-SPECT/CT (20×15sec (Phase 1), 15×60sec (Phase 2)) was performed after ~75 MBq Tc-99m MAG3 bolus injection and reconstructed with factory settings. Low-dose CT was performed for attenuation correction and anatomical correlation. Images and time-activity curves (TACs) were analyzed using Symbia postprocessing (phantom study) and Xeleris Dynamic MI (phantom and patient study). ***Results:*** Phantom experiment: dynamic 3D-SPECT acquisition rendered TACs and tracer dynamics (time-to-peak (TTP) 1.25 min, peak-to-half-peak (T½) 4.68 min) which compared well to traditional planar scintigraphy (TTP 1.03 min, T½ 4.75 min). Additionally, the 3D-SPECT showed a ten-fold higher number of total counts (3D-SPECT 14,767 versus planar 1,450 counts/sec). Subsequently, dynamic 3D-SPECT/CT proved feasible in two healthy potential renal donors and two renal transplant recipients (one-day postoperative), providing diagnostic TACs, tracer kinetics and visual assessment. The 3D information, combined with CT correlation, prevented overlapping structures and enabled detailed evaluation of all renal phases. This approach demonstrated normal function in both potential renal donors and allowed for detailed intrarenal/(sub-)segmental evaluation and diagnosing in one-day postoperative renal transplant recipients. ***Conclusion:*** This combined phantom and in-human study demonstrates the non-inferiority of dynamic 3D 12-headed CZT-detector ring SPECT/CT renography as compared to conventional planar renography, and its successful clinical implementation by offering improved 3D and CT-based anatomic detail. Future studies may show the clinical value of dynamic 3D-SPECT/CT renal transplant MAG3 renography in potential renal donors and renal transplant recipients.

OP-853

Comparison of [18F]F-FAPI and [18F]F-FDG PET/CT for Prediction of Treatment Response in Patients with Lupus Nephritis

M. Zhao[1], *C. Zhou*[1], *X. Yi*[2], *X. Zhang*[2];
[1]*Third Xiangya Hospital of Central South University, Changsha, CHINA,* [2]*Xiangya Hospital of Central South University, Changsha, CHINA.*

Aim/Introduction: Lupus nephritis (LN) is a severe manifestation of systemic lupus erythematosus, often requiring renal biopsy to guide treatment. However, conventional clinical biomarkers remain limited in predicting treatment response. This study aimed to evaluate the utility of [18F]F-FAPI and [18F]F-FDG PET/CT in predicting therapeutic outcomes in patients with LN. ***Materials and Methods:*** Twenty biopsy-proven LN patients were prospectively enrolled and underwent comprehensive clinical and laboratory evaluations of disease activity, as well as dual-tracer PET/CT imaging, using both [18F]F-FAPI and [18F]F-FDG imaging prior to standardized induction therapy. Semiquantitative parameters -including renal standardized uptake values (SUVmax) and target-to-background ratio (TBR) - were quantified. Patients were categorized into complete response (CR), partial response (PR), and non-response (NR) groups at 6 month following induction therapy. Associations between PET metrics, clinical biomarkers and treatment response were analyzed. ***Results:*** Baseline FAPI SUVmax inversely correlated with eGFR and positively with ESR ($P < 0.05$ for both), while FDG SUVmax showed no significant correlation with either. At 6 months, 50% of patients achieved CR, 35% PR, and 25% NR. Patients who achieved CR exhibited significantly lower baseline renal FAPI SUVmax and TBR compared to patients with non-CR ($p < 0.01$). FAPI-negative uptake was associated with a high CR rate (88.9%), outperforming FDG-negative uptake (75.0%). FAPI PET demonstrated superior predictive accuracy for CR (sensitivity 80%, specificity 90%, accuracy 85%) compared to FDG PET (sensitivity 60%, specificity 80%, accuracy 70%). Multivariate logistic regression identified negative FAPI uptake as the sole independent predictor for CR (OR = 36.0, 95% CI: 2.9-476.3, $p < 0.01$). ***Conclusion:*** [18F]F-FAPI PET/CT shows promise as a noninvasive imaging biomarker for predicting treatment response in LN, with superior performance compared to [18F]F-FDG PET/CT.

OP-854

Diagnostic utility of renogram and SPECT-CT in the management of kidney transplant complications

A. Suazo Montero*, J. Gómez Hidalgo, M. García Aragón, R. Zambrano Infantino, B. Jaramillo López, N. Álvarez Mena, F. Sebastián Palacid, C. Gamazo Laherrán, R. Ruano Pérez;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To evaluate the diagnostic contribution of isotopic renogram in the management of complications in patients undergoing renal transplantation, as well as the added value of SPECT-CT. ***Materials and Methods:*** A total of 777 patients who underwent cadaveric renal transplantation from January 2011 to December 2024 were included. At 24 hours post-transplant, after the administration of 185-259 MBq of 99mTc-DTPA, a 30-minute renogram study focused on the abdomen in anterior projection was performed, followed by planar images at 30 and 180 minutes. In addition, an abdominal SPECT-CT was performed in 93 patients. Findings were correlated with radiological studies and clinical-analytical follow-up. At least one renal scintigraphic follow-up study was performed in 166 patients (66 with SPECT-CT). ***Results:*** Of the 777 patients (506 males), 176 (22.6%) showed a normal study. Surgical complications were detected in 76 (9.78%) patients: 30 renal artery/vein thromboses; 9 infarctions; 17 ureteral ectasias or obstructions; 1 urinoma; and 16 urinary leaks. The urinoma and 11 leaks were confirmed by SPECT-CT. In 546 patients (70.3%), ischemic alterations or acute tubular necrosis (ATN) were identified: mild in 297 (54.4%); moderate in 183 (33.5%); and severe in 66 (12.1%). At least one follow-up renal scintigraphy study was performed in 166 patients, totaling 244 studies. Among these, 100 studies showed improvement in renal function, 93 showed deterioration, 20 showed leaks, 17 dilatations, 8 collections, and 1 infarction. All leaks, 4 dilatations, and 6 collections were observed on SPECT-CT. ***Conclusion:*** The renogram in transplanted patients enables the detection of surgical and/or ischemic complications, facilitating early implementation of corrective measures. SPECT-CT is particularly useful in the diagnosis of urinomas/urinary leaks, and enhances the assessment of their extent and localization.

Adaptive, MRI-Guided ^{166}Ho-TARE with Intra-Procedural Voxel-Based Dosimetry: First Results from EMERITUS-2

M. W. M. van Wijk[1], *J. Roosen*[1], *M. J. Arntz*[1], *M. J. R. Janssen*[1], *E. T. T. J. Tjwa*[2], *J. F. W. Nijsen*[1];
[1]*Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS,* [2]*Department of Gastroenterology and Hepatology, Radboud University Medical Center, Nijmegen, NETHERLANDS.*

Aim/Introduction: Achieving optimal tumour dosing remains a key challenge in transarterial radioembolisation (TARE) for hepatic malignancies. High tumour-absorbed doses have been associated with improved survival, underscoring the need for accurate, individualised, and voxel-based dosimetry for treatment planning and evaluation. However, dose personalisation remains challenging, given the lack of intra-procedural feedback on the dose distribution. Holmium-166 (^{166}Ho) microspheres uniquely allow for high-resolution, quantitative MR imaging and dosimetry ($2\times2\times4$ mm^3 voxel size) within 5-10 minutes. The EMERITUS-2 trial investigates the feasibility of MRI-guided, adaptive TARE to safely escalate tumour doses, reduce dose heterogeneity, and improve therapeutic outcomes. ***Materials and Methods:*** EMERITUS-2 is a dose-escalation study including patients with hepatocellular carcinoma undergoing TARE with ^{166}Ho microspheres. Patients are treated in a 3T MRI scanner using multi-echo gradient echo imaging to visualize and quantify microsphere distribution directly after each administration. This approach provides intra-procedural insight into the mean tumour and non-tumorous liver mean dose and into dose heterogeneity, via high resolution dose maps and dose-volume histograms. Treatment continues until the normal liver dose limit is reached (40-60-80 Gy on max 2/3 of the normal liver volume), or adequate tumour coverage or saturation is achieved. Primary endpoints include liver toxicity and dosimetric comparison to standard whole-liver TARE (60 Gy whole liver). ***Results:*** In the first four patients, a mean whole-liver dose of 72-122 Gy (administered activity of 7.8-19.2 GBq) was reached. Tumour-absorbed doses ranged from 133-334 Gy, exceeding conventional planning estimates based on 60 Gy whole liver (77-297 Gy). Treatment was delivered in 6-11 fractions, on one to two catheter positions per patient. Intra-procedural voxel-based dosimetry revealed potential dose heterogeneity, enabling real-time adjustments to optimize tumour coverage. No ≥ grade 3 adverse events were observed; reported side effects included grade 1-2 nausea, fatigue, and abdominal pain - comparable to standard TARE. Treatment termination occurred due to the non-tumorous

liver reaching the safety limit or due to complete administration of the ordered ^{166}Ho microsphere activity. Tumour saturation or statis was not observed. ***Conclusion:*** With these preliminary results we demonstrate the feasibility of a novel approach to TARE. MRI-guided, adaptive TARE with ^{166}Ho microspheres enables controlled intra-procedural dose administration and dosimetry instead of administration based on pre-treatment dosimetry. An MRI-guided adaptive approach takes treatment personalisation to a new level, enhancing homogeneous tumour dosing and administration of high activities while monitoring non-tumorous liver dose.

OP-856

Gemcitabine/Cisplatin Plus Transarterial Radioembolization versus Transarterial Radioembolization Alone for Intrahepatic Cholangiocarcinoma: A Multicenter Retrospective Study

N. Coskun[1], *A. Karacan*[1], *C. Sin*[2], *E. M. Kaya*[2], *G. Beydagi*[3], *M. Ozdemir*[1], *T. Guzelbey*[2], *M. Topcuoglu*[3], *A. Ozdemir*[1], *M. A. N. Sendur*[1], *M. Akdogan*[1], *M. Kaya*[2], *N. Alan Selcuk*[3], *B. Esen Akkas*[2], *E. Cingi Ozdemir*[1];
[1]*Bilkent City Hospital, Ankara, TÜRKIYE,* [2]*Cam & Sakura City Hospital, Istanbul, TÜRKIYE,* [3]*Yeditepe University, Istanbul, TÜRKIYE.*

Aim/Introduction: Intrahepatic cholangiocarcinoma (ICC) is a rare and aggressive malignancy of the bile ducts, often diagnosed at an advanced stage when surgical resection is not feasible. Gemcitabine/cisplatin (G/C)-based chemotherapy and transarterial radioembolization (TARE) with ^{90}Y-loaded microspheres are commonly used for patients with unresectable or locally advanced disease. Recent clinical practice has increasingly favored combining G/C chemotherapy with TARE to enhance locoregional tumor control. However, there is a lack of data comparing the therapeutic benefit of combination therapy over TARE monotherapy. In this study, we aimed to compare the objective response rate (ORR) of G/C + TARE combination versus TARE alone in the treatment of ICC. ***Materials and Methods:*** Patients diagnosed with ICC who underwent either G/C + TARE combination therapy (combination group) or TARE monotherapy (monotherapy group) at three different centers were retrospectively analyzed. Exclusion criteria were extrahepatic dominant disease, ECOG performance status > 2 or missing follow-up data. Objective response of target lesions was assessed 6-12 weeks after TARE using magnetic resonance imaging (MRI) and F-18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT), according to LI-RADS TRA and PERCIST criteria, respectively. Independent T-test, Wilcoxon test, and multivariate logistic regression analysis were used to identify factors associated with objective response. ***Results:*** A total of 26 patients met the inclusion criteria (15 males, 11 females; mean age 62 ± 11 years), with 16 (62%) in the combination group and 10 (38%) in the monotherapy group. Baseline characteristics were comparable between two groups. Glass microspheres were used in 16 patients (62%), and resin microspheres in 10 patients (38%). Mean absorbed tumor dose was 225±133 Gy for resin microspheres and 370±180 Gy for glass microspheres. ORR was significantly higher in the combination group (78%) compared to the monotherapy group (29%; p=0.021). Multivariate logistic regression analysis demonstrated that combination therapy was independently associated with objective response, irrespective of tumor dose, microsphere type (glass/resin) or interventional approach (selective/non-selective) (odds ratio: 14.01, 95% confidence interval: 1.13-173.61, p=0.039). ***Conclusion:*** G/C + TARE combination is associated with significantly higher ORR when compared to TARE monotherapy in the treatment of ICC. To our knowledge, this is the first comparative data evaluating the efficacy of G/C + TARE combination versus TARE monotherapy in the treatment of ICC. Further randomized controlled trials are needed to confirm these findings, and to compare the long-term survival outcomes and toxicity profiles of the two treatment strategies.

OP-857

Association of Tumor Response According to mRECIST and LI-RADS-TRA 2024 Criteria With Overall Survival After Yttrium-90 Transarterial Radioembolization in Hepatocellular Carcinoma: A Comparative Retrospective Analysis

E. Kaya[1], *B. Akkas*[1], *T. Güzelbey*[2], *C. Erdim*[2], *M. Arslan*[2], *C. Şin*[1], *H. B. Kapucu*[1], *M. Kaya*[1];
[1]*Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Basaksehir Cam and Sakura City Hospital, Department of Radiology, Istanbul, TÜRKIYE.*

Aim/Introduction: Yttrium-90 transarterial radioembolization (TARE) is increasingly used to treat hepatocellular carcinoma (HCC). Although the modified Response Evaluation Criteria in Solid Tumors (mRECIST) remain the conventional standard, the LI-RADS Treatment Response Algorithm 2024 (LI-RADS-TRA 2024)—designed specifically for radiation-based therapies—has been proposed as a new benchmark. We compared the prognostic performance of these two frameworks in HCC patients treated with TARE. ***Materials and Methods:*** This retrospective study included 63 HCC patients treated with TARE between June 2022 and January 2024 (glass microspheres n = 45; resin microspheres n = 18). All patients underwent gadoxetic-acid-enhanced MRI before and after treatment. Tumor response was evaluated on 6-month post-treatment imaging. Two board-certified radiologists independently interpreted all studies according to mRECIST and LI-RADS-TRA 2024; discordances were resolved by consensus with a third radiologist. In mRECIST, complete or partial response and stable disease were grouped as non-progressive (NP), whereas progressive disease was classified as progressive (P). In LI-RADS-TRA 2024, non-viable or non-progressive lesions were assigned to NP and viable lesions to P. Overall survival (OS) for NP and P groups was assessed with Cox proportional-hazards regression. ***Results:*** Median follow-up was 17 months. On univariate analysis, overall-response mRECIST did not differentiate OS between NP and P groups (HR=0.715, 95% CI 0.283-1.809; p=0.479). In contrast, target-lesion mRECIST (HR=0.273, 95% CI 0.110-0.741; p=0.011) and LI-RADS-TRA 2024 (HR=0.203, 95% CI 0.090-0.460; p<0.001) showed significant OS separation favoring NP. Median OS was 30 months in NP versus 6 months in P by target-lesion mRECIST. With LI-RADS-TRA 2024, median OS was not reached in NP but was 9 months in P. On multivariable analysis, LI-RADS-TRA 2024 was the sole independent predictor of OS (HR=0.23, 95% CI 0.10-0.53; p=0.001). ***Conclusion:*** This study suggests that in HCC patients treated with TARE, local tumor control, particularly the target-lesion response, is significantly associated with OS. LI-RADS-TRA 2024 surpasses mRECIST in predicting OS and should be incorporated into post-TARE follow-up protocols to optimize patient management.

OP-858

Exploring Radiomic and Dosiomic Features as Novel Predictors of Response to Yttrium-90 Radioembolization in Liver Cancer

A. Capotosti[1], *R. Moretti*[1], *I. Moretti*[1,2], *M. Costa*[3], *S. Cuttone*[3], *L. Zagaria*[1], *L. Leccisotti*[1], *M. Calcagni*[1,2], *A. Posa*[1], *R. Iezzi*[1,2], *M. De Spirito*[1,2], *L. Indovina*[1,2], *L. Placidi*[1];
[1]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY,* [2]*Università Cattolica del Sacro Cuore, Rome, ITALY,* [3]*Tecnologie Avanzate TA S.r.l, Turin, ITALY.*

Aim/Introduction: This study explores the prognostic utility of radiomic and dosiomic features in patients undergoing Yttrium-90 selective internal radiation therapy (90Y-SIRT) for liver tumors. While these quantitative approaches have shown potential in

other oncologic contexts, their integration for assessing treatment response in radioembolization remains largely unexplored. By capturing complex imaging and dose-related patterns, these quantitative approaches aim to support early response assessment and individualized treatment planning. ***Materials and Methods:*** A retrospective cohort of 83 patients with hepatocellular carcinoma (HCC), cholangiocarcinoma (CCC), or liver metastases (M) treated with Yttrium-90 selective internal radiation therapy (90Y-SIRT) for liver tumors was analyzed. Clinical evaluation was based on PET-CT imaging acquired after treatment and follow-up data collected at two timepoints: an initial assessment (FUP-1) for all patients and a second evaluation (FUP-2) available in 60 cases. Image acquisition and lesion segmentation followed standardized protocols. Radiomic and dosiomic features were extracted from segmented target volume using the IBSI-compliant MIRP library. A dedicated software platform was used for data preparation, quality control, dimensionality reduction, and model training. Predictive models were built using a Support Vector Machine (SVM) classifier with five-fold cross-validation. The dataset was randomly split into training and testing subsets (80/20) with stratified distribution across outcome classes. Two binary classification tasks were tested: (1) Complete Response (CR)+ Partial Response (PR) vs Stable Disease (SD)+ Progression Disease (PD); and (2) CR vs others. ***Results:*** Models combining radiomic and dosiomic features achieved high accuracy during training, ranging from 0.93 to 0.97. When evaluated on the independent test set, performance dropped, with accuracy values between 0.65 (classification of CR+PR vs SD+PD) and 0.57 (CR vs others). In the subset of patients with available data at both follow-up points, clinical outcomes at FUP-2 confirmed FUP-1 classifications in 57% of cases. Model behavior remained consistent across timepoints, with training accuracy values preserved (0.93 and 0.97) and test accuracy ranging from 0.47 to 0.57 in both classification settings. ***Conclusion:*** Although predictive accuracy on test data was limited, the combination of radiomic and dosiomic features demonstrated potential for identifying early treatment response patterns in patients undergoing 90Y radioembolization. These results highlight the relevance of quantitative imaging and dosimetric parameters as candidate biomarkers for response prediction, with possible applications in personalized follow-up and treatment planning.

OP-859

Correlation of Voxel-Based Dosimetric Parameters With Progression-Free Survival and Overall Survival After Yttrium-90 Glass Microsphere Radioembolisation in Hepatocellular Carcinoma

H. Kapucu*, E. Kaya, A. Dere, C. Sin, B. Esen Akkas, M. Kaya, K. Toplutas;*
University of Health Sciences Cam Sakura City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: The relationship between tumour absorbed dose (TAD), the dose received by half of the tumour volume (D50), the dose received by 70% of the tumour volume (D70) and the dose received by 90% of the tumour volume (D90) acquired from the dose-volume histograms (DVH) of Y-90 PET/CT dosimetry after radioembolisation (RE) treatment with Y-90 glass microspheres in patients diagnosed with hepatocellular carcinoma (HCC), with the progression-free survival (PFS) and overall survival (OS) were retrospectively investigated. ***Materials and Methods:*** Between June 2022 and June 2024, 45 patients who underwent Y-90 glass microsphere radioembolization (RE) at our clinic were included in the study. All patients were evaluated by dynamic liver MRI before and after treatment according to mRECIST criteria (1). Using the Y-90 PET/CT images obtained after the procedure, voxel-based dosimetry calculations were performed to determine the D50, D70, and D90 values. Subsequently, the optimal cutoff values for the obtained dosimetric parameters were identified using Receiver Operating Characteristic (ROC) analysis. PFS and OS were evaluated using the Kaplan-Meier method, and differences between groups were statistically analysed using the log-rank test. Additionally, Cox regression analysis was conducted to examine independent prognostic factors. ***Results:*** The median OS in the study group was 14 months, while the median PFS was 7 months. The mean TAD was 654 Gy, with D50 at 538 Gy, D70 at 351 Gy, and D90 at 163 Gy. Results from the log-rank test indicated that TAD, D50, D70, and D90 were significant predictors of OS ($p < 0.001$). For PFS, significant associations were found with TAD and D50 ($p = 0.03$ and $p < 0.01$) but not with D70 and D90 ($p = 0.71$ and $p = 0.417$). In multivariate Cox regression analysis, D50 was the sole parameter predicting OS (HR: 0.03;95% CI: 0.004-0.224; $p = 0.001$) and PFS (HR: 0.327; 95% CI: 0.159-0.671; $p = 0.002$). ***Conclusion:*** This retrospective study aimed to focus on voxel-based dosimetry analysis imaging after RE (2). It particularly examines how the dose received by the tumour volume affects OS and PFS. Our findings indicate that the D50 threshold is a more significant prognostic factor than mean TAD and other DVH parameters, such as D70 and D90. ***References:*** 1.Philippe d'Abadie et al. DOI: 10.1097/MNM.0000000000001395 2. Pianka KT et al. Nucl Med Mol Imaging. 2024 Oct;51(12):3744-3752. doi: 10.1007/s00259-024-06813-8. Epub 2024 Jun 24.

FAP-Targeted radiopeptide therapy (FRT) using ^{177}Lu-, ^{90}Y- and ^{225}Ac-labelled 3BP-3940 in a large cohort of 105 patients

J. Zhang*[1], T. Zhao[1], V. Jakobsson[1], L. Greifenstein[2], A. Eismant[2], A. Mishra[2], A. Klega[2], C. Landvogt[2], C. Mueller[2], D. Benz-Zils[2], O. Klein[3], B. Jaeschke[3], E. Perrone[4], R. P. Baum[2];*
[1]National University of Singapore, Singapore, SINGAPORE, [2]DKD HELIOS Klinik, Wiesbaden, GERMANY, [3]International Centers for Precision Oncology (ICPO), Wiesbaden, GERMANY, [4]Università Cattolica del Sacro Cuore, Rome, ITALY.

Aim/Introduction: Fibroblast activation protein (FAP) has emerged as an attractive molecular target for precision imaging and therapy due to its upregulated expression in cancer-associated fibroblasts of various solid tumors. This study reports first-in-human clinical results using a novel FAP-targeting cyclic peptide, 3BP-3940, labeled with ^{177}Lu, ^{90}Y, and ^{225}Ac for radiopharmaceutical therapy (FRT) in a large cohort of patients with end-stage malignancies. ***Materials and Methods:*** Between March 2021 and March 2025, 105 patients with advanced metastatic cancers, who had exhausted all conventional treatment options, were enrolled to receive FRT with radiolabeled 3BP-3940. A total of 285 treatment cycles were administered across 24 different cancer types, including pancreatic adenocarcinoma (n=26), breast (n=14), lung (n=10), neuroendocrine tumors (n=10), and others. All patients demonstrated positive uptake on pre-treatment ^{68}Ga-3BP-3940 PET/CT. Toxicity was graded using CTCAE v5.0. Treatment response was assessed using PET/CT and SPET/CT imaging, and overall survival (OS) was analyzed via Kaplan-Meier curves from the start of FRT. ***Results:*** Radioligand therapy with ^{177}Lu-/^{90}Y-/^{225}Ac-3BP-3940 (mean cumulative dose per patient:^{177}Lu:14.7±10.3GBq; ^{90}Y:7.0±4.7GBq; ^{225}Ac:12.7±9.9MBq) was well tolerated in this sizable cohort. Common side effects included pain (11%, mostly pain flare), nausea (12%), vomiting (8%), headache (1%), diarrhea (3%), transient fever (4%), partial alopecia (7%), and fatigue (6%). No serious adverse events or pharmacological complications were observed. Dosimetry in one pancreatic cancer patient receiving 9.73 GBq of ^{177}Lu revealed organ doses of 37 mGy (brain), 168 mGy (lungs), 86 mGy (liver), 142 mGy (pancreas), 265 mGy (kidneys), and 2200 mGy to the primary tumor. Post-therapy imaging confirmed high tumor uptake and prolonged tracer retention with excellent tumor-to-background contrast. Among 48 patients assessed after two FRT cycles, response rates were as follows: complete remission (3%), partial remission (31%), mixed response (6%), stable disease (6%), and progression (20%), resulting in an objective response rate of 50% and a disease control rate of 58%. For the entire cohort, the

median OS was 7 months from the start of FRT. In the subgroup of patients with aggressive advanced, heavily pretreated pancreatic adenocarcinoma, the median OS was 7 months. ***Conclusion:*** Radiolabeled 3BP-3940 with ^{177}Lu, ^{90}Y, or ^{225}Ac—used alone or in combination—was well tolerated and effective across a large and diverse patient population with advanced solid tumors. The agent demonstrated excellent tumor targeting, minimal renal uptake, and long lesion retention. Promising clinical responses, particularly in pancreatic adenocarcinoma and sarcoma, support further investigation in prospective trials involving broader patient populations and longer follow-up durations.

OP-861

Dosimetric Correlation and Clinical Efficacy of ^{188}Re-N-DEDC lipiodol Transarterial Radionuclide Therapy (TART) in Inoperable Hepatocellular Carcinoma: A Prospective Study

N. Kumar[1], *S. Shamim*[1], *P. Gupta*[1], *G. Arora*[1], *S. Gamanagatti*[1], *D. Shalimar*[1], *V. Chirayil*[2], *S. Subramanian*[2], *M. B. Mallia*[2], *P. Thakral*[3], *I. B. Sen*[3];
[1]*All India Institute of Medical Sciences, New Delhi, INDIA,* [2]*BARC, Mumbai, INDIA,* [3]*FMRI, Gurgaon, Haryana, INDIA.*

Aim/Introduction: Hepatocellular carcinoma (HCC) ranks the third leading cause of cancer-related mortality worldwide. Most patients present with inoperable or advanced-stage disease, where treatment is constrained by tumor burden, liver dysfunction, and performance status. Transarterial radionuclide therapy (TART) using radiolabeled lipiodol is a promising modality that delivers targeted intra-tumoral radiation while sparing healthy liver parenchyma.^{188}Re-N-DEDC lipiodol, labelled with DEDC kits, developed indigenously by BARC, combines the therapeutic efficacy of β-emitting ^{188}Re ($E_{\beta max}$ 2.1 MeV, ~11 mm tissue penetration) with cost-effective, on-site preparation. Despite promising initial outcomes, real-world clinical and dosimetric data remain limited. This prospective study aimed to evaluate the clinical efficacy, dosimetry and predictive markers of response in patients undergoing ^{188}Re-N-DEDC/Lipiodol TARE for inoperable HCC. ***Materials and Methods:*** Thirty-nine patients with radiologically and biochemically confirmed inoperable HCC (ECOG ≤2, Child-Pugh A/B) were enrolled. Activity was prescribe based on partition model and administered via super-selective trans-arterial injection under fluoroscopic guidance. Post-therapy dosimetry was performed using Hybrid Dosimetry Module™. Radiological and biochemical responses were assessed at 2 and 6 months using mRECIST and serum AFP levels. ***Results:*** Of 39 patients (36 males, 3 females; mean age 57.9 ± 10.9 years), the median administered activity was 4612 MBq. The median prescribed tumor-absorbed dose was 80 Gy; estimated tumor absorbed was 77.7 Gy. No significant difference was observed between pre- and post-therapy tumor absorbed doses ($p = 0.5479$). Absorbed doses to whole liver, normal liver, and lungs were 8 Gy, 1.1 Gy, and 3.2 Gy, respectively. At 2 months (n=36), radiological ORR and DCR were 47.2% and 83.3%; biochemical ORR and DCR were 61.1% and 77.8%. ECOG performance improved in 41.6%. Tumor absorbed dose correlated significantly with both radiological and biochemical responses. ECOG and baseline bilirubin showed significant association with clinical response. Tumor etiology showed no correlation. At 6 months follow-up, 20 patients were shifted to other treatment modalities such as oral MKI, immunotherapy, TACE or transplantation due to disease progression or residual disease. Thus, at 6 months (n=14), radiological ORR and DCR were 50% and 71.4%; biochemical ORR and DCR were 42.8% and 57.1%. BCLC stage and Child-Pugh score correlated with radiological outcomes. Tumor etiology was significantly associated with clinical response ($p=0.022$). ***Conclusion:*** ^{188}Re-N-DEDC/Lipiodol TARE is an effective treatment for inoperable HCC, offering favorable disease control rates. Dosimetric parameters and clinical factors such as ECOG status, bilirubin levels, and liver function scores significantly influence outcomes, supporting personalized treatment planning.

OP-862

Targeting the Tumor Stroma: Safety and Efficacy of 3BP-3940-Based FAP Radiopharmaceutical Therapy in Advanced Metastatic Colorectal Cancer

J. Zhang[1], *T. Zhao*[1], *A. Eismant*[2], *L. Greifenstein*[2], *J. Li*[1], *A. Klega*[2], *C. Landvogt*[2], *C. Mueller*[2], *R. P. Baum*[2];
[1]*National University of Singapore, Singapore, SINGAPORE,* [2]*Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

Aim/Introduction: Colorectal cancer remains a leading cause of cancer-related mortality worldwide, especially in patients with metastatic disease who have progressed after standard therapies. Despite advancements in chemotherapy, targeted therapy, radiotherapy, and immunotherapy, treatment options for heavily pretreated metastatic colorectal cancer remain limited. Fibroblast activation protein (FAP), which is overexpressed in the tumor stroma of colorectal cancer, represents a promising target for precision theranostics. This study evaluates the clinical outcomes of FAP-targeted radiopharmaceutical therapy (FRT) using the novel cyclic peptide 3BP-3940 labeled with ^{177}Lu, ^{90}Y, or ^{225}Ac in patients with advanced metastatic colorectal cancer. ***Materials and Methods:*** Ten patients (7 males, 3 females; mean age 59.4 ± 12.3 years) with metastatic colorectal cancer who had exhausted all standard treatment options, including surgery, chemotherapy, external beam radiotherapy (n=8), and immunotherapy (n=3), were treated with FRT following confirmation of FAP expression on ^{68}Ga-3BP-3940 PET/CT. A total of 27 cycles were administered (range: 1-4 cycles per patient), including 12 TANDEM therapies. The mean cumulative administered activities per patient were: ^{177}Lu: 11.9 ± 6.1 GBq, ^{90}Y: 6.0 ± 0.6 GBq, and ^{225}Ac: 9.0 ± 4.2 MBq. Toxicity was graded using CTCAE v5.0. Treatment response was assessed via molecular imaging (PET/SPECT), and overall survival (OS), defined from the initiation of FRT, was calculated using Kaplan-Meier analysis. ***Results:*** FRT was well tolerated, with no grade 3 or 4 toxicities reported. Mild adverse effects included nausea (n=1), pain (n=2), intensified fatigue (n=6), and one case of transient fever that resolved within 24 hours. After two treatment cycles, partial remission was observed in 3 of 6 evaluable patients, corresponding to an objective response rate (ORR) of 50%. As of the study cutoff date in April 2025, 4 of 10 patients (40%) had died. The median follow-up time was 17 months, and the median overall survival has yet to be reached. ***Conclusion:*** FAP-targeted radioligand therapy using 3BP-3940 labeled with ^{177}Lu, ^{90}Y, or ^{225}Ac is safe and shows promising therapeutic potential in metastatic colorectal cancer. This novel approach addresses an unmet need for patients with limited treatment options and supports further clinical investigation of FRT in colorectal cancer.

OP-863

Efficacy of Intra-arterial [^{177}Lu]Lu-DOTATATE Monotherapy for Treatment-refractory Meningioma

A. El Ghalbouni[1,2], *T. J. Snijders*[2], *A. Amerein*[3], *N. Tolboom*[1], *M. Patt*[3], *C. Maurer*[4], *I. C. van der Schaaf*[1], *C. Lapa*[3], *A. J. A. T. Braat*[1];
[1]*Department of Radiology and Nuclear Medicine, UMC Utrecht, Utrecht, NETHERLANDS,* [2]*Department of Neurology and Neurosurgery, Brain Center, UMC Utrecht, Utrecht, NETHERLANDS,* [3]*Department of Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY,* [4]*Department of Diagnostic and Interventional Neuroradiology, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY.*

Aim/Introduction: Although meningiomas generally have excellent survival outcomes, a subset of these tumors - mostly grade 2-3 lesions - exhibit recurrence following primary treatment with surgery and/or radiotherapy. For these treatment-refractory

meningiomas, there are currently no established, evidence-based therapeutic options. In recent years, somatostatin-targeted radionuclide therapy, primarily using intravenous administration of [^{177}Lu]Lu-DOTATATE as a monotherapy, has emerged as a promising new treatment modality. Recent studies have indicated that intra-arterial administration may increase the tumor absorbed dose. This present study aims to assess the efficacy of intra-arterial [^{177}Lu]Lu-DOTATATE in the treatment of refractory meningiomas. ***Materials and Methods:*** This retrospective cohort included patients diagnosed with treatment-refractory meningioma WHO grade 1-3, who had received at least one cycle of intra-arterial [^{177}Lu]Lu-DOTATATE. The primary endpoints were progression-free survival (PFS) and overall survival (OS). Secondary outcomes included objective response, evaluated according to the Proposed Response Assessment and Endpoints for Meningioma Clinical Trials, and safety and toxicity, assessed based on the Common Terminology Criteria for Adverse Events, version 5.0. ***Results:*** Seventeen patients with a median follow-up duration of 34 months (range: 1-57) were included. The median age at the time of the first treatment cycle was 64 years (range: 38-78). Majority of meningiomas were classified as grade 2 (58.8%), and most patients (n = 7) received 4 intra-arterial cycles (median: 3 cycles; median cumulative activity 28.8 GBq). The median time between cycles was 54 days (range: 28-90). PFS at 6, 12 and 24 months was 65% (95% CI: 46-92%), 53% (95% CI: 34-83%) and 41% (95% CI: 23-73%), respectively. OS at 6, 12 and 24 months was 82% (95% CI: 66-100%), 71% (95% CI: 52-96%) and 71% (95% CI: 52-96%). Regarding best objective response, disease control was found in 53% with an objective response rate of 24% (1 complete response, 2 partial responses, 1 minor response, 5 stable disease), with progressive disease in the other 8 patients. One patient experienced grade 3 anemia, and another developed microangiopathic hemolytic anemia as a complication related to angiographic intervention. ***Conclusion:*** This retrospective cohort supports the safety and efficacy of intra-arterial administration of [^{177}Lu]Lu-DOTATATE with an objective response rate of 24% (compared to 2% with intravenous administration in previously published literature), and survival data that exceed published benchmarks. Intra-arterial administration is a promising treatment option for treatment-refractory meningioma. Prospective controlled studies with larger cohorts and extended follow-up, comparing intra-arterial [^{177}Lu]Lu-DOTATATE to (historic) cohorts of intravenous administration are needed.

Ventilation/Perfusion SPECT/CT in Patients with Long COVID Syndrome: A Multicenter Observational Study

P. Bonnefoy[1], *P. PascalL*[2], *Q. Ceyrat*[3], *S. Burg*[4], *M. Razzouk-Cadet*[5], *C. Moreau Triby*[6], *I. Biancheri Mounicq*[7], *J. Bourre*[8], *P. Salaun*[9], *P. Le Roux*[9];
[1]*CHU Saint-Etienne, Saint Etienne, FRANCE,* [2]*CHU Toulouse Rangueil, Toulouse, FRANCE,* [3]*Centre d'imagerie Fonctionnelle, Bordeaux, FRANCE,* [4]*GCS Médecine nucléaire, Ajaccio, FRANCE,* [5]*CHU de Nice, Nice, FRANCE,* [6]*CHU de Lyon, Lyon, FRANCE,* [7]*CH Angoulême, Angoulême, FRANCE,* [8]*CH Chambéry, Chambéry, FRANCE,* [9]*CHU Brest, Médecine Nucléaire, GETBO, UMR1304, Brest, FRANCE.*

Aim/Introduction: The COVID-19 pandemic has led to a significant number of survivors experiencing persistent health issues, now recognized as long COVID. Respiratory symptoms, such as dyspnea, chronic cough, and reduced exercise capacity, are prevalent and can severely impact quality of life. Ventilation/Perfusion (V/Q) SPECT/CT is a hybrid imaging modality that offers both functional and anatomical insights and has proven valuable in evaluating pulmonary embolism (PE). However, its role in long COVID remains underexplored. ***Materials and Methods:*** A retrospective, multicenter study was conducted using a national registry included V/Q SPECT/CT in symptomatic patients after COVID infection. Centralized, blinded reviews assessed for mismatched, matched, and reverse mismatch defects, as well as morphological lung abnormalities. Descriptive statistics and comparative analyses were performed to evaluate the prevalence of PE and post-embolic sequelae. A secondary objective is to determine the prevalence of normal versus abnormal imaging findings suggestive of post infectious sequelae. ***Results:*** A total of 217 patients with persistent respiratory symptoms (mean time from infection to scan: 26.7 weeks ± 20 weeks) were evaluated between January 2020 and April 2023.Among the 217 patients, 6 (2.8%) exhibited mismatched perfusion defects consistent with PE, including 3 cases of previously undiagnosed PE (1 de novo and 2 recurrent). Post-embolic sequelae were identified in only 3 of 72 patients (4.2%) with a prior PE history. Non-thromboembolic lung abnormalities were found in 116 (53.4%) patients, while 95 (44.8%) had entirely normal V/Q SPECT/CT findings. Matched ventilation-perfusion defects were observed in 83 (38.2%) patients. Reverse mismatched defects were identified in 13 (6.0%) patients. CT abnormalities were present in 107 (49.3%) cases, predominantly subpleural and bilateral. ***Conclusion:*** V/Q SPECT/CT proved valuable in differentiating organic pulmonary abnormalities from non-organic causes in long COVID patients. While PE was rare (2.8%), it remains a serious complication requiring prompt identification and treatment. Notably, 44.8% of patients showed normal V/Q SPECT/CT findings, effectively ruling out organic pulmonary involvement. Hybrid imaging techniques, such as V/Q SPECT/CT, may be considered a valuable tool in the diagnostic assessment of long COVID. Future prospective studies are needed to validate these findings and explore the long-term clinical implications of pulmonary abnormalities in this population.

[^{18}F]F-FDG PET/CT in IgG4-Related Disease: Phenotypic Classification and Clinical Correlations in a Cohort of 65 Patients

A. Bagán-Trejo[1], *M. Pudis*[1], *X. Solanich*[2], *C. A. Tapias*[1], *G. Rocamora-Blanch*[2], *F. Climent*[3], *M. Zamorano-Rivas*[1], *S. Maymó-Garrido*[4], *C. García-Alcober*[4], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Internal Medicine Department, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN,* [3]*Pathology Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [4]*Radiopharmacy Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: To assess the role of [^{18}F]F-FDG PET/CT in IgG4-related disease (IgG4-RD) by analysing metabolic uptake patterns, correlating them with established clinical phenotypes and laboratory parameters, and evaluating its utility in disease classification, biopsy guidance, and therapeutic monitoring. ***Materials and Methods:*** A retrospective analysis was conducted on 65 patients with confirmed IgG4-RD who underwent whole-body [^{18}F]F-FDG PET/CT imaging. Data collected included demographics, referring specialty, total IgG and IgG4 serum levels, clinical manifestations, organ involvement (single/multiple sites), and metabolic uptake measured by a maximum standarised uptake (SUVmax). Imaging findings were categorised into the

following clinical phenotypes: pancreatobiliary, retroperitoneal/aortitis, head and neck, and systemic (Mikulicz). ***Results:*** Of the 65 patients included, 68% were male, with a mean age of 63 years. The majority of referrals originated from Internal Medicine (58%), followed by Nephrology (16%), Gastroenterology (5%), and Pulmonology (5%) and others (16%). Elevated total IgG levels were observed in 40% of cases and elevated IgG4 levels in 52%. The most common clinical manifestations were renal involvement (23%), followed by abdominal symptoms (21%) and incidental findings (11%). Symptomatic sites primarily included the kidneys (renal failure), orbit, and visible/palpable lesions; asymptomatic findings most often involved lymph nodes and salivary glands. [^{18}F]F-FDG PET/CT detected pathological uptake in 59 patients (95%). Single-organ involvement was observed in 35% (22 cases), most frequently in retroperitoneal fibrosis (12) and orbital disease (5). Patients were classified according to metabolic and clinical patterns into retroperitoneal/aortitis (31%, mean SUVmax: 5.99g/mL), head and neck (23%, mean SUVmax: 6.64g/mL), and systemic (34%, mean SUVmax: 4.13g/mL) phenotypes. Three patients showed no uptake due to prior surgical or corticosteroid treatment. ***Conclusion:*** [^{18}F]F-FDG PET/CT plays a pivotal role in the comprehensive management of IgG4-RD. It enables detailed assessment of disease extent, accurate phenotypic classification based on metabolic patterns, and correlation with clinical and serological parameters. Moreover, it facilitates biopsy guidance in atypical presentations, identifies subclinical organ involvement, and allows non-invasive monitoring of inflammatory activity and therapeutic response. These capabilities position [^{18}F]F-FDG PET/CT as an essential imaging modality in the diagnostic and follow-up algorithms of IgG4-RD.

OP-866

Diagnostic value of labelled leukocyte scintigraphy in patients with low-grade periprosthetic joint infection

L. Lezaic[1], *S. Roskar*[2], *R. Mihalic*[2], *V. Levasic*[1], *R. Trebse*[2];
[1]*University Medical Centre Ljubljana, Division of Nuclear Medicine, Ljubljana, SLOVENIA,* [2]*Valdoltra Orthopaedic Hospital, Ankaran, SLOVENIA.*

Aim/Introduction: Periprosthetic joint infection (PJI) is one of the most devastating complications of the joint arthroplasty performed for end-stage osteoarthritis. Timely identification of the PJI and its differentiation from aseptic complications such as mechanical loosening is essential for the choice of the best treatment strategy in painful joint arthroplasty (PJA). Labelled leukocyte scintigraphy (LLS) complements conventional diagnostic procedures by providing information about pathophysiologic changes at the cellular and molecular level and is typically employed at suspicion of low-grade PJI. Although considered highly accurate, the low spatial resolution of nuclear medicine imaging combined with the low-grade inflammatory process may reduce the diagnostic accuracy of LLS. The aim of the study was to evaluate the diagnostic performance of LLS in patients with PJA specifically in the setting of a painful joint with endoprosthesis where low-grade PJI needs to be excluded. ***Materials and Methods:*** Patients treated surgically for PJA at the Valdoltra Orthopaedics Hospital that also underwent LLS at the Division of Nuclear Medicine of the UMC Ljubljana between 2016 and 2023 were retrospectively evaluated. The data on patient age, gender, side of surgery, date of primary arthroplasty, date of revision surgery, reason for revision surgery, perioperative PJI diagnostics and the date of the last follow-up were retrieved from a prospectively collected dataset and supplemented retrospectively from the hospital registry or individual charts where required. The definite diagnosis of PJI was based on the EBJIS definition. ***Results:*** Between 2016 and 2023, of 734 LLS performed in total, 347 (48%) were performed in patients treated with PJA (144 total hip, 169 unicompartmental or total knee, 23 ankle, 9 shoulder, and 2 elbow arthroplasties). Overall, 33 (9.7%) EBJIS criteria-confirmed PJI were observed while the remaining 314 were considered as aseptic. For the whole cohort, the sensitivity and specificity of LLS was 79% (95%CI 77-81%) and 99% (95%CI 97-100%), respectively; in patients without radiologically present gross osteolysis around the implant, the sensitivity was 94%. In the aseptic group, 107 patients had a revision surgery where PJI as the diagnosis was excluded considering EBJIS criteria while the remaining 207 patients had no revision surgery and no clinical signs of infection during at least 2 years follow-up. ***Conclusion:*** Labelled lekocyte scintigraphy is a highly specific and sensitive diagnostic tool in low-grade PJI, especially in patients without radiologically gross osteolysis present around the implant.

OP-867

Dynamic [^{18}F]FDG PET/CT imaging in fracture-related infections to distinguish infection from inflammation

N. D. van Rijsewijk*, M. Wouthuyzen-Bakker, J. H. van Snick, J. van Sluis, R. H. J. A. Slart, A. W. J. M. Glaudemans, F. F. A. IJpma; University Medical Center Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Static [^{18}F]FDG PET/CT is widely applied to detect infections but is limited in differentiating bacterial infection from sterile inflammation due to overlapping uptake patterns. In particular in fracture-related infection (FRI), this is challenging due to multiple factors, including recent surgery, soft tissue injury, fracture healing, and surgical implants. Dynamic [^{18}F]FDG imaging over time may overcome this limitation. This study investigates the potential of dynamic [^{18}F]FDG PET/CT and obtaining time activity curves (TACs) to distinguish infection from sterile inflammation in patients with suspected FRI. ***Materials and Methods:*** A prospective study was performed in patients suspected of FRI and referred for [^{18}F]FDG PET/CT examination to detect (the extent of) infection from December 2021 until November 2024. Final diagnosis of FRI was established according to the criteria defined by the FRI consensus group and used as a reference standard. Dynamic imaging was performed using a long axial field-of-view PET/CT system over 65 minutes after [^{18}F]FDG injection. TACs were analyzed to compare uptake patterns between confirmed infections and sterile inflammation, and diagnostic accuracy was calculated and compared to conventional static imaging. ***Results:*** Thirty-one patients with 33 fractures suspected of infection were included. Infection was clinically confirmed in 14 fractures (42%). Classification based on dynamic imaging using TACs resulted in a high sensitivity of 86%, specificity of 100%, PPV of 100% and NPV of 90%, resulting in a diagnostic accuracy of 94%. This diagnostic accuracy was higher compared to the visual and quantitative static assessments, which were 88% and 91% respectively. Visual assessment of the dynamic scan was less high, with a diagnostic accuracy of 82%. Visual scan assessment showed in general higher false positives, while quantitative assessment introduced more false negatives. ***Conclusion:*** The results of this prospective study show that dynamic [^{18}F]FDG PET/CT imaging, and the analysis of TACs, can differentiate between infection and sterile inflammation. Dynamic imaging demonstrates slightly better diagnostic accuracy over static scan analysis only by using TACs in FRI.

OP-868

Development and External Validation of Metabolic Tumor Volume Measures at Baseline [18F]FDG-PET/CT to Predict Treatment Failure and Relapse-Free Survival in Antibiotic-Naïve Patients with Pyogenic Spondylodiscitis

F. Lanfranchi[1,2], *D. Albano*[3,4], *C. Delucchi*[2], *S. Maggio*[2], *V. Iannaccone*[2], *P. Furtuna*[3,4], *D. Dubois*[1,2], *F. Bertagna*[3,4], *G. Sambuceti*[1,2], *M. Bauckneht*[1,2];
[1]*Nuclear Medicine, Department of Health Sciences (DISSAL), University of Genoa, Genova, ITALY,* [2]*IRCCS Ospedale Policlinico San Martino, Genova, ITALY,* [3]*Nuclear Medicine, ASST Spedali Civili, Brescia, ITALY,* [4]*University of Brescia, Brescia, ITALY.*

Aim/Introduction: Pyogenic spondylodiscitis presents a clinical challenge, potentially leading to long-term complications. Reliable early predictors of clinical outcomes in these patients are currently lacking. Despite its growing importance in managing spondylodiscitis, the prognostic value of [18F]FDG-PET/CT has been insufficiently evaluated. In this scenario, we aimed to explore baseline predictors of treatment response in patients with pyogenic spondylodiscitis and to test their replicability in an external independent population. ***Materials and Methods:*** Patients clinically diagnosed with pyogenic spondylodiscitis who underwent [18F]FDG-PET/CT at two Italian centers between 2020 and 2023 were retrospectively enrolled. Inclusion criteria included: 1) no previous spine surgery; 2) no onco-hematological diseases; 3) no corticosteroid treatment; 4) 12-months follow-up availability. Patients already receiving antibiotic therapy at the time of imaging were excluded. Lab markers collected were C-reactive protein, procalcitonin, white blood cell differential counts, and creatinine levels. For each lesion, the standardised uptake value maximum (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were quantified from baseline [18F]FDG-PET/CT images. Patients were treated according to current guidelines (6-12 weeks of therapy). Outcomes were treatment failure and relapse-free survival (RFS) [1]. Multivariable binary logistic regression analyses, ROC curves, and Cox regression models were performed to calculate OR, diagnostic accuracy, and HR, respectively. C-indexes and Brier scores were also computed. All analyses were performed with a 10-fold cross validation approach. Finally, Kaplan-Meier curves for RFS were designed. ***Results:*** Development and validation cohorts included 78 and 30 lesions, respectively. MTV (best cut-off=34 mL) resulted in the sole independent predictor of treatment failure at the multivariate regression model (OR=1.07, 95%CI=1.03-1.11; p<0.001), with C-index=0.76, specificity and positive predictive value (PPV)≥0.95, and Brier score=0.25. The Cox regression analysis showed this model as a significant predictor of RFS (HR=1.89, 95%CI=1.320-2.70; p<0.01), with C-index=0.74 and Brier score=0.12. Lesions exhibiting MTV≥34 mL showed a significantly impaired median RFS (10 months) compared to lesions with MTV<34 mL (not reached; Log-rank: p<0.001). These results were confirmed in the validation cohort for both treatment failure (C-index=0.78, specificity and PPV≥0.91, Brier score=0.20) and RFS (C-index=0.73, Brier score=0.12; Log-rank: p<0.001). ***Conclusion:*** In a multicentric setting, [18F]FDG-PET/CT-derived MTV independently predicts treatment failure and RFS in patients with pyogenic spondylodiscitis before initiating antibiotic treatment. This metabolic measure might facilitate early risk stratification, potentially enhancing subsequent clinical management. ***References:*** 1. Bernard L et al. Antibiotic treatment for 6 weeks versus 12 weeks in patients with pyogenic vertebral osteomyelitis: an open-label, non-inferiority, randomised, controlled trial. Lancet. 2015.

Added Value of FDG-PET Imaging in Patients with Spondylodiscitis

L. Reichel[1], *R. Liang*[2], *S. Hirsch*[2], *B. Meyer*[2], *W. Weber*[1], *A. Jörger*[2], *S. Notohamiprodjo*[1];
[1]*Department of Nuclear Medicine, TUM University Hospital, Munich, GERMANY,* [2]*Department of Neurosurgery, TUM University Hospital, Munich, GERMANY.*

Aim/Introduction: Spondylodiscitis poses significant diagnostic challenges due to nonspecific symptoms and limitations of conventional imaging modalities. Moreover, causative infection foci are often not identified. Early and accurate detection of spondylodiscitis and treatment of the focus of infection is critical to prevent severe complications. Positron Emission Tomography (PET), particularly using 18F-fluorodeoxyglucose (FDG), has emerged as a complementary tool to Magnetic Resonance Imaging (MRI), offering high sensitivity in identifying metabolic activity associated with infectious foci. This study aims to evaluate the diagnostic accuracy of PET in detecting and monitoring patients with spondylodiscitis and the detection of other infectious foci. ***Materials and Methods:*** A retrospective analysis was conducted on 198 patients who underwent FDG-PET imaging for infection-related indications between 2016 and 2023. The primary objective was to assess efficacy in diagnosing spondylodiscitis and identifying additional infectious foci. PET findings were compared with MRI, pathological, and microbiological results and clinical data. Maximum Standardized Uptake Values (SUVmax) were measured in locations of identified infectious foci and correlated with inflammation markers. ***Results:*** Among 198 patients, PET imaging identified new infectious foci in 25 cases while 2 cases with suspected foci (endocarditis and dental infection) were missed. Tracer uptake without clinical relevance was observed in 12 cases. PET confirmed previously known foci in 21 cases (mean SUVmax arthritis 7.1±3.5, soft tissue infection 10.4±5.8, prosthesis infection 7.6±1.7). In 30 cases with unclear MRI findings, PET aided in diagnosis (mean SUVmax 12.1±6.0), while it was used in follow-up for 4 cases. Notably, in seven cases, MRI falsely indicated spondylodiscitis, which was not confirmed by PET imaging or clinical evaluation. Conversely, PET failed to detect spondylodiscitis in five clinically confirmed cases, three of which were identified as low-grade infections. ***Conclusion:*** PET imaging shows potential added value, particularly in identifying infection foci and aiding in diagnosing spondylodiscitis, especially when MRI results are inconclusive. However, discrepancies between PET, MRI, and microbiological findings suggest that PET may have limitations in certain scenarios, warranting further investigation into its diagnostic role.

Identification of chronic musculoskeletal pain generators with [18F]FDG PET-MRI

J. Mostert[1], *E. H. G. Oei*[1], *M. Ananta*[1], *G. S. R. Muradin*[1], *F. J. M. P. Huygen*[1], *C. C. de Vos*[1], *P. K. Bos*[1], *S. Biswal*[2], *R. A. van der Heijden*[1,2];
[1]*Erasmus Medical Center, Rotterdam, NETHERLANDS,* [2]*University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Chronic pain is the most frequent reason for patients to seek medical consultation. Up to 79% of patients with chronic musculoskeletal pain believe their pain is inadequately treated,[1] mainly due to our inability to accurately identify pain generators using conventional imaging. This study evaluates the added value of hybrid [18F]FDG PET/MRI for identifying pain sources in patients with diagnostically challenging chronic low back pain (LBP) or hip pain after total hip replacement (THR). ***Materials and Methods:*** Patients aged 18-75 with chronic LBP or post-THR hip pain were recruited and randomized to the intervention group ([18F]FDG PET/MRI with subsequent targeted treatment) or the control group (standard clinical care). For participants who underwent PET-MRI, potential pain sources were identified based on increased FDG uptake on PET and/or anatomical abnormalities on MRI. ***Results:*** We present interim results of 54 LBP patients and 17 post-THR patients, of which 35 were randomized to PET-MRI. Overall, PET/MRI provided new diagnostic insights regarding potential pain generators in 30 patients (86%). In patients with chronic LBP, PET/MRI led to targeted treatment in 65% of patients, and 8% was referred for surgical intervention. Some patients reported pain relief after years of severe pain. In the control group, only 7% underwent further diagnostic imaging, and 32% received an injection based on previous imaging or symptoms. In patients with post-THR hip pain, 67% had additional diagnostic imaging, 89% underwent additional diagnostic procedures, and THR revision was indicated in 44%. In the control group, 50% received additional imaging, not leading to new insights in the majority. ***Conclusion:*** [18F]FDG PET/

MRI is able to identify previously undetected pain generators in patients with chronic LBP or post-THR hip pain, leading to more frequent adjustments in clinical management compared to standard care including targeted treatment with symptom relief. Further evaluation in a larger cohort is needed to determine the added value of [18F]FDG PET-MRI in terms of patient outcomes.

Clinical Utility of FDG PET/CT in the Management of Bloodstream Infections: Interim Results from A Single-Center Study

A. Karellis[1], *G. Abikhzer*[1,2], *B. Bilodeau-Harnois*[1,2], *A. Roy*[1,2], *K. Weiss*[1,2];
[1]*Jewish General Hospital, Montréal, QC, CANADA,* [2]*McGill University, Montréal, QC, CANADA.*

Aim/Introduction: ^{18}F-Flurodeoxyglucose (FDG)-positron emission tomography/computed tomography (PET/CT) is increasingly utilized in the diagnosis and management of infectious diseases. However, evidence is lacking regarding its impact in the management of bloodstream infections (BSIs), particularly for bacteremias other than Staphyloccocus aureus. This study aimed to assess the clinical utility of FDG PET/CT and its impact on patient management. ***Materials and Methods:*** We conducted a retrospective chart review, using 2021-2024 data. Eligible patients included those with a positive blood culture who underwent FDG PET/CT imaging to aid in the management of their BSI. Data collected included patient and infection characteristics, investigations and imaging performed, FDG PET/CT findings, and treatment modifications following the PET scan. Descriptive statistics were performed. ***Results:*** This interim analysis includes 100 patients [57% male, mean (SD) age: 73.77 (15.92) years]. Fifty percent of patients were diabetic, 30% had an active malignancy, 27% were immunocompromised and 44% had an implant/prosthesis. This population included a wide range of pathogens: 79 had gram-positive bacteremia, 15 gram-negative, 4 had polymicrobial mixed infection and 2 had candidemia. FDG PET/CT imaging yielded positive findings for 86 patients, including 77 patients for whom infectious septic foci were identified. The most common infectious sites included lung (n=27), spondylodiscitis (n=23), spleen (n=23), endocarditis (n=22), skin and soft tissue (n=19), and intraabdominal/bowel (n=12). Following FDG PET/CT, 51% of patients' clinical management was modified. The most common modification was the adjustment of treatment duration (n=32) (extension for 30 patients and shortening for two patients). Twelve patients' antimicrobial regimen was changed (two of which received two antibiotics). Six patients underwent a spectrum modification (narrowed for four, broadened for two). Six patients had their antibiotic therapy modified for an agent with a better central nervous system penetration. Four patients had a second antimicrobial drug added to their regimen. Nine and three patients underwent surgical and radiologic intervention, respectively. ***Conclusion:*** This interim analysis highlights the high clinical utility of FDG PET/CT imaging in the management of patients with a BSI by identifying the infectious source and infectious foci or complications not detected by other imaging modalities. In this study population, FDG PET/CT revealed metastatic infectious foci in 77% of patients. More than half of patients' therapeutic management was modified by FDG PET/CT findings, including a subset of patients whose study was negative, therefore demonstrating potential impact for all patients whether metastatic foci were identified or not.

OP-872

Diagnostic Utility of [^{18}F]-FDG PET/CT in Guiding Biopsy Sites in Pyrexia of Unknown Origin; Site Concordance, Yield and ROC-Based Suvmax Threshold for Differentiating Between Benign and Malignant Etiology

K. Vengadesan, *N. A. Damle, G. B. Priyanka, C. Ganapathy, M. Tripathi, C. Bal, M. Soneja, N. Nischal, P. Sethi, S. Jain, A. Singh, B. Prakash, R. Yadav;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: [^{18}F]-Fluorodeoxyglucose positron emission tomography/computed tomography ([^{18}F]-FDG PET/CT) plays a pivotal role in evaluating patients with pyrexia of unknown origin (PUO). However, the correlation between PET-identified potential biopsy sites and actual biopsy practice, along with diagnostic yield and threshold optimization, remains underexplored. This study aimed to assess the concordance between [18F]-FDG PET/CT-identified hypermetabolic sites and actual biopsy sites in PUO patients, evaluate diagnostic yield, and determine the optimal standardized uptake value (SUVmax) cut-off that can predict if the lesion is benign or malignant using receiver operating characteristic (ROC) analysis. ***Materials and Methods:*** A retrospective analysis was conducted on 185 PUO patients who underwent [^{18}F]-FDG PET/CT between April 2024 to January 2025 in our institute. Hypermetabolic lesions were documented and categorized as potential biopsy sites. Actual biopsies performed were compared against PET/CT-suggested sites. Diagnostic yield was calculated based on histopathological confirmation. ROC analysis was used to determine the SUVmax threshold with optimal sensitivity and specificity for differentiating between benign and malignant etiology. ***Results:*** Out of 185 patients, [^{18}F]-FDG PET/CT identified 73 potential biopsy sites in 73 patients. Biopsies were performed on 45/73 patients, with 82.2% (37/45) being from the PET/CT-guided sites. The overall diagnostic yield that guided further clinical management was 72.97% (27/37) with 13 being benign lesions (infective and non-infective inflammatory disease) and 14 being neoplastic. The ROC analysis identified an SUVmax cut-off of 8.94 (AUC = 0.678, sensitivity = 76.5%, specificity = 62.5%), above which biopsy was more likely to differentiate between benign and malignant etiology (p = 0.064). ***Conclusion:*** [^{18}F]-FDG PET/CT identified biopsy-suitable sites in a significant proportion of PUO patients where it was deemed necessary. Biopsies were eventually performed in more than half of these patients, of which, most were from the PET/CT-guided sites. In this study, a SUVmax of 8.94 was found to be useful in potentially differentiating between benign and malignant etiology.

A radiation Life Cycle Assessment for TAT-isotopes
G. de With[1], *M. Hakulinen*[2], *R. Kollaard*[1], *G. Sandker*[1], *A. Sarnelli*[3], *E. Winters*[1], *SECURE partners of T4.2;*
[1]*NRG PALLAS, Arnhem, NETHERLANDS,* [2]*Kuopio University Hospital, Kuopio, FINLAND,* [3]*IRST, Meldola, ITALY.*

Aim/Introduction: The EU funded project SECURE aims to make a major contribution to the sustainability production and safe application of α-emitting isotopes. α-emitting isotopes coupled to highly target-specific molecules are widely investigated for use in targeted alpha therapy (TAT). While clinical results show these are a potent drug with great potential in cancer therapy, adequate consideration of radiation protection is required. Therefore, we developed a computational tool to perform a radiation Life Cycle Assessment (LCA) considering all relevant exposure scenarios during the isotope's life cycle. ***Materials and Methods:*** Three specific radiation protection issues were considered. (1) To determine the radiation doses for workers, caregivers and public involved throughout the life cycle of the TAT-isotope, considering relevant exposures, pathways and radionuclide inventories. (2) To make a comparison of the radiation doses from the exposure scenarios for the different TAT-isotopes (e.g. ^{225}Ac, ^{212}Pb, ^{213}Bi, ^{223}Ra) and their production routes. (3) To perform an analysis on the computational findings and extract lessons learned, draw recommendations for best practice, and identify areas and topics that require attention from a radiation protection perspective. ***Results:*** The tool was designed to assess radiation exposure through all possible exposure routes (external radiation, inhalation, submersion, and ingestion) and calculate the effective doses as well as equivalent doses for the eye, extremities and skin. The isotope's life cycle is divided into the following stages: production, purification, labelling and clinical practice. Each stage is covered by scenarios with a defined time line, mode of chemical processing, exposure time, shielding, distance, and indoor and outdoor exposure parameters. The nuclide inventory is computed for each scenario and forwarded to the next scenario considering any chemical processing, discharges, waste, or dissemination to multiple users. The process of decay and in-growth is computed considering initial activities, decay rates and complex decay chains including multiple decay branches. The results from the tool demonstrate that choices made in the design of the isotope production process strongly impact potential radiation risk, waste generation, and effective use of infrastructure and source material. Furthermore, recommendations on the safe use should be tailored to the specific radiological needs of the TAT-isotope in question. ***Conclusion:*** We developed a tool which clearly indicates considerable variation in radiation dose for the various TAT-isotopes along its life cycle with strong variation in the relative contributions from different exposure routes. Insights are obtained that help to improve radiation protection issues involving α-emitting isotopes.

EPS-286
Targeted alpha therapy in clinical practice: a radiation protection assessment before implementation
A. Sarnelli[1], *E. Mezzenga*[1], *R. Kollaard*[2], *E. Winters*[2], *G. De With*[2], *R. Mikołajczak*[3];
[1]*Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori", Meldola, ITALY,* [2]*NRG|PALLAS, Petten, NETHERLANDS,* [3]*Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.*

Aim/Introduction: Targeted Alpha Therapy (TAT) has increasingly been adopted in clinical practice due to the high therapeutic efficacy of alpha particles compared to beta emitters. Alpha particles are characterized by high linear energy transfer and a short path length, enabling precise cytotoxic effects while minimizing damage to healthy tissues. However, their clinical use raises important radiation protection considerations for healthcare workers, patients' caregivers, and the public. This work has been funded by the HORIZON-EURATOM-2021-NRT01 - SECURE project (Project number: 101061230) and provides a detailed radiation risk assessment associated with handling key alpha-emitting radionuclides, specifically Th-227, Ac-225, Ra-223, Bi-213, Pb-212, and At-211. ***Materials and Methods:*** Three principal exposure scenarios were analyzed: single-dose preparation, administration, and patient care. Both external and internal exposures were evaluated, using established dose conversion factors to estimate whole-body effective doses, extremity equivalent doses, and committed doses. Additionally, an incident scenario involving a liquid radiopharmaceutical spill was modeled to assess potential contamination risks. ***Results:*** The findings show that while the whole-body effective doses to workers are negligible across all scenarios, extremity doses—especially during administration without shielding—can be significant, reaching values that necessitate strict protective measures. Internal exposure under normal operations remains minimal but can become relevant in the event of accidental inhalation or ingestion. Skin contamination in spill scenarios could result in high localized doses if immediate decontamination is not performed, although such situations were analyzed conservatively assuming worst-case conditions. Radiation exposure to third parties, including caregivers and the general public, was also estimated. Results indicate that the doses are at least one order of magnitude lower than the regulatory dose constraints, affirming that outpatient management can be performed safely with appropriate guidance and precautionary instructions. ***Conclusion:*** The presented scenarios were deliberately conservative to ensure that risk assessments overestimate, rather than underestimate, actual risks. While the results cannot directly rank the radiopharmaceuticals in terms of hazard, they provide a generalizable methodology and baseline for institutions planning to implement TAT. This work highlights the importance of comprehensive radiation safety programs tailored to alpha therapies, considering both routine practices and potential incidents. It also underlines the need for specialized training, shielding, contamination control measures, and patient release protocols to ensure the safe and sustainable integration of TAT into clinical practice.

EPS-287

Radiation protection efficacy of a new device for the infusion of radiopharmaceuticals labeled with 177Lutetium

M. Marengo[1], *A. Zorz*[1], *L. M. Colombo Gomez*[1], *F. De Monte*[1], *M. Paiusco*[1], *L. Pompignoli*[2];
[1]*Veneto Institute of Oncology IOV – IRCCS, Padua, ITALY,* [2]*Tema Sinergie, Faenza, ITALY.*

Aim/Introduction: Modern treatments with ^{177}Lu-labeled radiopharmaceuticals require the administration of relevant activity, under conditions of controlled flow and infusion time, as well as safety from irradiation and limitation of the risks of fluid leaks and consequent contamination. A system based on an infusion pump, certified tubing kit, and intrinsically shielded represents a significant advance in this field. ***Materials and Methods:*** The Aster consists of an infusion system and a shield for the radiopharmaceutical vial. This shield is made of Tungsten and Lead glass, to allow visual control of the radiopharmaceutical vial during the infusion. The simulations were performed using FLUKA.CERN and its interface Flair. The transport thresholds for electrons and photons were set to 30 keV and 15 keV, respectively. The source was modelled as a borosilicate glass vial of the penicillin type. The Lead glass was modelled according to the manufacturer's specifications and certificate of analysis. The tungsten alloy used has a density of 17.1 g/cm^3 . The equivalence of Aster shielding to lead was firstly assessed by simulating a ^{60}Co source. The leaded glass vial of the Aster was replaced by increasing thcknesses of lead. Then ^{177}Lu was considered, both in air and within the Aster shield. ***Results:*** Simulations performed with ^{60}Co in air, without shielding, gave an ambient dose rate value at 100 cm of 3.45E-04 mSv/h per 1 MBq, in agreement with published data. The results for absorption in lead were fitted by a single exponential function. The simulation of the transmission for ^{60}Co gamma rays in the leaded glass shield of the Aster gave a transmission of 0.57 +/- 1.0% . This shows that the Aster's lead glass shield has a shielding equivalent for ^{60}Co gamma rays >1.1 cm Pb. Simulations with a ^{177}Lu vial placed in air, without shielding, gave an ambient dose rate of 6.03E-06 mSv/h at 100 cm per 1 MBq. The transmission factor evaluated at 10, 50 and 100 cm from the center of the vial placed inside the Aster, gave an attenuation factor for ^{177}Lu gammarays and bremsstrahlung emission of > 0.999 . ***Conclusion:*** The Aster is effective in reducing the dose levels from the vial of radiopharmaceutical during administration of ^{177}Lu radiopharmaceuticals.. It is a certified device, safe and easy to use, which can facilitate theragnostic applications and improve the optimization of radiation protection. ***References:*** Marengo M., Infantino A. Physica Medica 103 (2022) 59-65.

Assessment of Early Excretion and Radiation Protection Considerations in ^{177}Lu-PSMA Therapy

F. Zagni[1], *L. Vetrone*[2], *A. Farolfi*[2], *E. Lodi-Rizzini*[3], *A. Golemi*[2], *S. Civollani*[1], *M. Maccagnani*[1], *L. Strigari*[1], *S. Fanti*[2];
[1]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Radiation Oncology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: The recent introduction of Lutetium-177-labeled radiopharmaceuticals, such as 177Lu-DOTATATE and 177Lu-PSMA, has significantly improved therapeutic options in neuroendocrine and prostate cancers, respectively. Outpatient management of 177Lu-PSMA is already practiced in some countries, though with heterogeneous time-points for patient discharge, underscoring the need for harmonized recommendations. This study provides a quantitative extension of previously reported feasibility data by analyzing external irradiation measurements in patients treated with 177Lu-PSMA, focusing on early excretion kinetics and radiation exposure reduction within 6 hours post-administration. ***Materials and Methods:*** Radiation exposure was measured at 1 meter following 40 administrations of 7400 MBq of 177Lu-PSMA, (7 patients each receiving between 4 and 6 treatment cycles), at baseline (0h), 6h, 24h, and 48h post-administration. Measurements were performed with an ionization chamber calibrated in terms of ambient dose equivalent H*(10). For a subset evaluated at baseline and 6h, measurements were also acquired at body contact in the point of maximum exposure. For each time point, mean values were normalized to baseline, and uncertainties were estimated as standard error of the mean at 95% confidence. A bi-exponential model was fitted to estimate excretion parameters (A1,T1,A2,T2). ***Results:*** Initial exposure at 1 meter, measured on all patients, was 18±3 µSv/h. At body contact, the ratio at 6h was 0.42±0.08. Relative to baseline, mean exposure rates declined to 0.50±0.08 at 6h, 0.18±0.06 at 24h, and 0.12±0.03 at 48h. Notably, a few outliers at 6h (range: 0.26-0.85) indicate individual variability in excretion and exposure. Bi-exponential decay modeling revealed a fast clearance component with a half-life T_1=4.3±1.9 hours (A_1=0.80±0.24), and a slower component with a half-life T_2=67±50 hours (A_2=0.20±0.15). ***Conclusion:*** The results align with literature values, confirming that approximately 50% of the administered activity is eliminated within the first 6 hours. Data at 24-48 hours were consistent with prior studies, though limited by sample size and greater uncertainty. More data may help refine late-phase kinetics and support more accurate patient dosimetry. The presence of outliers confirms the need of individualized monitoring. Current findings support patient discharge at 6 hours from a radiation protection perspective. Early discharge is feasible without exceeding dose constraints for caregivers and the public, assuming adherence to simple precautions for a brief period. Notably, in this context ICRP states that outpatient feasibility in a fully optimized procedure should consider not only radiation safety, but also patient clinical conditions and comfort, logistics, occupational exposure, and overall healthcare system efficiency.

Aim/Introduction: The objective of this study was to evaluate the external radiation dose emitted by patients undergoing 177Lu-PSMA therapy and to assess the radiation exposure received by their caregivers. This assessment aimed to determine the safety of early discharge and outpatient management following treatment. ***Materials and Methods:*** Radiation dose rates were measured in 47 patients treated with 177Lu-PSMA (mean activity: 5563 ± 1013 MBq) at different time intervals (5 min to 168 h) and distances (0.5 m and 1 m) using a calibrated dosimeter. To estimate caregivers' radiation exposure, thermoluminescent dosimeters (TLDs) were provided to 27 individuals, who wore them continuously for 7 days post-discharge. All measurements followed national and international radiation safety protocols. ***Results:*** At 1 hour post-injection, peak dose rates were observed (48.5 ± 15 µSv/h at 0.5 m and 31.6 ± 8 µSv/h at 1 m), followed by a steady decline over time. The dose rate fell below the discharge threshold of 20 µSv/h at 1 m within approximately 6-6.5 hours. The estimated effective half-life of 177Lu-PSMA was 23.1 hours. Caregiver doses ranged from 20 to 1170 µSv, with a mean of 194 ± 230 µSv—well below the annual

exposure limits recommended by ICRP and IAEA. ***Conclusion:*** The study demonstrates that with appropriate radiation safety measures and patient education, outpatient administration of 177Lu-PSMA is safe for both patients and caregivers. Individual variability in dose rates highlights the importance of personalized safety planning, especially for caregivers in close and prolonged contact with treated individuals.

Nephroprotective effects of metformin in patients undergoing radioligand therapy

S. Kunte[1], *M. Wu*[1], *L. Hempel*[1], *A. Holzgreve*[1], *M. Scheifele*[1], *T. Siegmund*[2], *J. Ells*[1], *F. J. Gildehaus*[1], *G. Böning*[1], *M. Unterrainer*[1], *L. M. Unterrainer*[1], *R. A. Werner*[1], *A. Delker*[1], *Z. Ells*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*Division for Endocrinology, Diabetology and Metabolism, Isar Clinic Munich, Munich, GERMANY.*

Aim/Introduction: Radioligand therapy (RLT) has become an established treatment option for various cancers expressing molecular targets such as prostate-specific membrane antigen (PSMA-RLT) or somatostatin receptors (peptide receptor RLT (PRRT)). Despite its therapeutic efficacy, RLT carries a risk of nephrotoxicity, owing to the kidneys' role in metabolizing and excreting radiolabeled compounds. Various strategies have been investigated to mitigate renal radiation exposure. Preclinical data suggest that metformin, a widely prescribed antidiabetic agent, may reduce nephrotoxicity through inhibition of tubular reabsorption of filtered peptides, potentially via its strong basic biguanide group. This study aimed to evaluate the potential nephroprotective effect of metformin in patients undergoing PSMA-RLT or PRRT by analyzing the kidney absorbed (radiation) dose (AD). ***Materials and Methods:*** Patients treated with either PSMA-RLT or PRRT were enrolled and stratified into subgroups based on metformin use. Individuals with pre-existing renal disease were excluded from the analysis. Respective ADs were calculated for each treatment cycle using MIM Software, applying either multi-timepoint or single-timepoint dosimetry, depending on data availability. ***Results:*** A total of 61 patients were included in the analysis, comprising 30 individuals undergoing PSMA-RLT (10 with metformin, 20 without) and 31 receiving PRRT (11 with metformin, 20 without). In the first treatment cycle, patients receiving PSMA-RLT in combination with metformin showed a significantly lower AD compared to those without metformin (0.24 ± 0.09 Gy/GBq vs. 0.33 ± 0.14 Gy/GBq; $p = 0.018$). No such effect was observed in the PRRT group (0.46 ± 0.25 Gy/GBq vs. 0.41 ± 0.10 Gy/GBq; $p = 0.897$). Analysis of the mean kidney AD across all administered cycles confirmed these findings: metformin was associated with a significantly reduced kidney AD in the PSMA-RLT group (0.24 ± 0.09 Gy/GBq vs. 0.32 ± 0.10 Gy/GBq; $p < 0.001$), whereas no significant difference was observed in the PRRT group (0.47 ± 0.17 Gy/GBq vs. 0.43 ± 0.17 Gy/GBq; $p = 0.132$). ***Conclusion:*** Metformin was associated with a significantly reduced renal radiation exposure in patients undergoing PSMA-RLT, whereas no such effect was seen in patients receiving PRRT. Further studies are needed to assess renal function and long-term nephrotoxicity in this context.

EPS-291

(V)Are skin doses real? - experimental verification of estimated skin dose calculations.

K. Tallat-Szczotka[1], *P. Begley*[2], *P. Colley*[2], *O. Harris*[2], *K. Barrie*[2], *J. Poole-Jones*[2];
[1]*Barts Health NHS Trust, London, UNITED KINGDOM,* [2]*University Hospitals Sussex NHS Foundation Trust, Brighton, UNITED KINGDOM.*

Aim/Introduction: There is a legislative need to quantify skin doses for extremity dose limits with the increasing development of new alpha and beta emitters in molecular radiotherapy. VARSKIN+ software has been increasing in popularity as a useful tool for skin dose estimation. Modelling of certain scenarios can result in exceeding dose limits. This, combined with significant variability in results based on small differences in geometry modelling, has posed a question about software utility. This project aims to verify VARSKIN+ estimates using ExtRad thermoluminescent dosemeters. ***Materials and Methods:*** Experimental setups were carefully designed to reproduce possible scenarios of skin and glove contamination incidents in Nuclear Medicine, incorporating previous work on droplet sizes, dynamics and evaporation of radiopharmaceuticals. Geometry dependence of measured dose-rate was accounted for by modelling dose-rate as function of source position and height. Droplets were modelled as cylinders to allow comparison with VARSKIN+1.3.1. Cylinder height was estimated using known droplet volumes (5-30µl) and measured deposited droplet areas. Phase one measurements were performed with [177Lu]Lu-PSMA-617. Further work will include measurements with 18F and 99mTc. ***Results:*** The relationship between cylinder height and measured dose-rate followed an inverse power relation. Dose-rate from droplets dispensed onto a 0.06mm thick nitrile glove and directly onto the 18mm2 detector were normalised to 0.75mm droplet height. Dose-rates from collapsed droplets (film geometry) were normalised to 0.1mm height. Dose-rates from droplet geometry were 25-35% of the dose-rates estimated by VARSKIN+1.3.1 whereas from film geometry were 35-45% of the estimated dose-rates. Presence of the glove had no impact on the measured/estimated ratio. ***Conclusion:*** The beta contribution to total skin dose from 177Lu was estimated in VARSKIN+1.3.1 as 2 orders of magnitude greater than gamma contribution. Response of ExtRads with PVC covering to low energy betas (147Pm, Emax=224keV) was type tested at 21% and high energy betas (85Kr, Emax=687keV) at ~100% (normalised to 137Cs response) [1]. Response to medium energy betas of 177Lu (78% Emax=497%keV) is situated in between; further work with 18F (Emax=634keV) and investigation of PVC covering attenuation will allow complete comparison with VARSKIN+1.3.1 calculations. Small changes in source geometry and averaging area result in significant differences in measured and estimated doses, signifying the need for revaluation of methods currently used for skin dose estimation in relation to dose limits. ***References:*** [1] Gilvin, P. et al., (2006) Type Testing of an Extremity Finger Stall Dosemeter Based on Harshaw TLD ExtRad Technology, Radiation Protection Dosimetry 123(3).

EPS-292

A new model for Needlestick dosimetry using the measured activity profile of a needlestick with depth in tissue and VARSKIN+v1.3

W. Thomson, *H. Benderz;*
Midland Metropolitan University Hospital, Birmingham, UNITED KINGDOM.

Aim/Introduction: Needlestick injury is not common, but the dosimetry is not straightforward, particularly for alpha emitters. The Wound dose module in VARSKINv1.3 can be used, but has only a point source or a line source model. Dose estimates depend linearly on needlestick depth, usually unknown. We have examined the distribution of activity with depth in tissue to determine a new dosimetry model. ***Materials and Methods:*** AGAR gel (1.5%) was used as a tissue mimic. A needlestick injury was simulated (depth range 2-5mm) with Tc99m. Immediately after piercing the gel, thin slices (approximately 50µm) were taken using a microtome. Slices were accurately weighed (for accurate thickness/depth determination) and counted on a sample counter. These gave a detailed profile of deposited activity with depth within the needlestick. ***Results:*** The activity profile was not linear. There was maximum activity near the surface of the

gel, decreasing to a depth of approximately 800µm. No activity was deposited any deeper. For the depth range 0-150µm, the activity level was approximately x6 the value of a 2mm uniform line. Using the Wound Dose module, we evaluated the basal layer doserate profile with depth separately for each radionuclide. This was then multiplied by the activity profile with depth to give the total doserate value. Using a typical 6hr biological half-life, the new model dose (mSv/kBq deposited) was calculated and compared to the uniform 2mm line model. For Tc99m the new dosimetry gave 1.6mSv/kBq (x9 the uniform line) ; for F18 = 5.8mSv/kBq (x6 the uniform line) and for Ra223 =191,000mSv/kBq (x11 the uniform line). So for Ra223, only 5Bq would give 500mSv dose limit. Similarly for other alpha emitters , the activity for 500mSv is 5Bq for Ac225 and 20Bq for Pb212. A typical needlestick injury (dispensing) could give 65mSv for Tc99m , 85mSv for F18 , but 19Sv for Ra223. For thicker skin such as the finger pulp, the basal layer is deeper (370µm) and the new model gives similar doses to a 2mm uniform line source. ***Conclusion:*** Due to the activity distribution along a needlestick being non-uniform, doses are considerably higher than a uniform line model by factors of x5 -x11. In particular for alphas, the consequences of a needlestick could be about 19Sv. The new model does appear to be independent of depth, so could give a fixed needlestick dose factor for a particular radionuclide.

EPS-293

Using VARSKIN+v1.3 with values of basal layer depth distribution to give accurate estimates of skin doses to the face, wrist, back-of-hand, arms/legs and trunk from contamination with alpha emitters Ra223, Pb212, Ac215, At211 and Th207

W. Thomson*;*
Midland Metropolitan University Hospital, Birmingham, UNITED KINGDOM.

Aim/Introduction: VARSKIN+v1.3 is established software for skin dosimetry, and is freely available. V1.3 introduced more accurate dose modelling for alphas. However alpha dosimetry also needs to take account of the convoluted variations in basal layer depth, rather than use a fixed value. ***Materials and Methods:*** Skin dosimetry for incidents commonly uses a fixed depth for the basal layer, often the default 70um (7.7gm/cm^2) . But the basal layer is highly convoluted, with a wide range of values for different skin sites (1,2). Typical alpha energies have a range of 50-85um, similar to basal layer depths. Therefore alpha dosimetry needs to account for the basal layer depth variation. VARSKINv1.3 can give volume-average doses for a range of depths. These were obtained for depth histograms from 0-16mg/cm^2 with a step width of 2mg/cm^2 . This matches the histograms of basal layer depth data available for different tissue sites (2). For each tissue site, the percentage of basal cells at each depth are used to give a weighted depth-dose value. ***Results:*** Depth-weighted average doserates (mSv/h/kBq) were calculated for the sites;- face, wrist, back-of-hand, legs/arms and trunk. These were compared to the doserates using the 7.7mg/cm^2 fixed depth. For Ra223, the depth-weighted doserates were greater than the fixed depth value by factors x200(wrist)-x3500(trunk). With Pb212 the factor range was x0.6(back hand) - x3.2 (trunk). For Ac225 the factor range is x1(Wrist) - x10(trunk). At211 has factor range x36,800(Wrist) - x478,200(trunk). Th227 has a factor range of x200(Back of hand) - x6,640 (trunk). ***Conclusion:*** With a fixed depth for the basal layer, the alpha component is poorly sampled or has no contribution due to their range. Using the histogram of basal layer depths, there is always a substantial component of alpha dose to basal cells. The differences can be very large, with factor increases up to x478,200!. Using a fixed depth for skin dosimetry is not appropriate for alpha dosimetry and can substantially underestimate the basal layer dose. It is important for the member-of-staff concerned that an accurate dose estimate is given. ***References:*** 1. ICRP Report59; 1991 2. Whitton JT. Health Physics 1973; 24:1-8.

EPS-294

Limits of detection of internal radiation exposure via DSB focus analysis in PBMCs

I. Strobel[1]*, H. Scherthan*[2]*, K. Blaurock*[1]*, S. Schumann*[1]*, J. Müller*[2]*, A. K. Buck*[1]*, M. Port*[2]*, M. Lassmann*[1]*, U. Eberlein*[1]*;*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: This study aimed to determine the detection limit and age-dependency for radiation-induced focal DNA double-strand break (DSB) damage in peripheral blood mononuclear cells (PBMCs). Baseline foci values from samples of healthy volunteers were compared to values of samples exposed ex-vivo to internal irradiation using different combinations of an α- and a β-emitter to identify detection limits relevant in scenarios such as radiation accidents or nuclear incidents. ***Materials and Methods:*** Blood was collected from 70 healthy volunteers of three age groups (A:20-34, B:35-50, C:51-66 years, 23-24 participants each, gender balanced). DSB foci were determined in PBMCs of donors without and 10 with additional internal ex-vivo irradiation with mixtures of [^{223}Ra]$RaCl_2$ and [^{177}Lu]$LuCl_3$ of a total absorbed dose of 100mGy, using three α-dose:β-dose ratios (3:1, 1:1, 1:3). After irradiation, PBMCs were divided into three subsamples: fixed immediately after irradiation (0h), after 4h and 24h of cell culture to assess DNA repair kinetics. All samples were stained with γ-H2AX- and 53BP1-antibodies to visualise DSB foci and α-tracks. Foci and α-tracks were scored manually in 100 nuclei. Baseline values from unexposed individuals were compared to the irradiated samples. ***Results:*** Mean baseline DSB foci values were 0.49±0.09 foci/cell (A), 0.55±0.17 (B), and 0.60±0.18 (C), with no significant differences between age and gender (t-test, $p>0.01$). The detection threshold for low-LET irradiation, defined by the 95th percentile of baseline values (n=70), was 0.84 foci/cell in our samples. Nearly all irradiated samples (0h, 4h) exceeded this threshold, even in the presence of an α-emitter, demonstrating detectable DNA damage even at low β-dose contributions (Mann-Whitney-test, $p <0.01$). Notably, no α-tracks were detected in any of the baseline samples, confirming the absence of α-particle-related damage in these controls, consistent with the findings of Göring et al. (mean 0.0 α-tracks/100 cells, n=10) [1]. Considering DNA DSB repair all samples could be clearly distinguished (foci and α-tracks) from baseline samples up to 4h post-irradiation (Wilcoxon-test, $p<0.01$). However, after 24h repair time, the DSB-foci and α-track levels in irradiated samples returned to near-baseline levels (Wilcoxon-test, $p>0.01$) making the detection of exposed individuals at this timepoint unlikely. ***Conclusion:*** Using the DSB focus assay, irradiated PBMCs samples of individuals exposed internally to IR could be discriminated from unexposed individuals at β-doses of >25mGy up to 4h post-irradiation. These findings support the use of γ-H2AX+53BP1 DSB-focus assay as a sensitive biomarker test for early assessment of internal radiation exposure. ***References:*** [1] Göring et al.,EJNMMI2022.

EPS-295

In-Silico Modeling of Radiation-Induced DNA Damage Complexity and Repair Kinetics after Mixed α-/β-Irradiation Using Geant4-DNA and MEDRAS

M. Salas Ramirez[1]*, I. Strobel*[1]*, H. Scherthan*[2]*, M. Lassmann*[1]*, U. Eberlein*[1]*;*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology Affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: Mixed high- and low-LET radiation induces simple and complex DNA double-strand breaks (DSBs) with different repair kinetics. A previous ex vivo study experimentally investigated radiation-induced DNA damage in lymphocytes after mixed irradiation with ^{223}Ra and ^{177}Lu [1]. In this study, a validated Monte Carlo-based simulation model [2] combined with MEDRAS [3] was used to extend these findings. ***Materials and Methods:*** Monte Carlo simulations of radiation-induced DNA damage were performed using GATE [4] and Geant4-DNA [5], modeling ex vivo irradiation of blood samples [1] at absorbed doses around 100 mGy with three α-/β-absorbed dose fractionations: 75% β / 25% α, 50% β / 50% α, and 25% β / 75% α, along with pure 100% β (^{177}Lu) and 100% α (^{223}Ra). From the Monte Carlo simulations, DSB cluster distributions (simple and complex DSBs) were calculated and used as inputs to MEDRAS, applying experimental-based repair rates of ^{177}Lu [6] and ^{223}Ra [7]. DSB repair kinetics were predicted at 4- and 24-hours post-irradiation, with unrepaired DSBs extracted as primary outcome. Agreement between the simulation and the experimentally determined repair models was assessed using Bland-Altman analysis and Z-tests (comparison of two measurements with uncertainties). Relative biological effectiveness (RBE) was calculated based on the simulated total number of DSB·cell^{-1}·mGy^{-1}, using ^{177}Lu as reference. ***Results:*** Simulated induced and unrepaired DSBs increased progressively with higher α-dose fractions. Induced DSBs varied from 0.025±0.003 DSB·cell^{-1}·mGy^{-1} to 0.052±0.002 DSB·cell^{-1}·mGy^{-1}, while unrepaired DSBs at 24h ranged from 0.00048±0.00003 DSB·cell^{-1}·mGy^{-1} to 0.00139±0.00020 DSB·cell^{-1}·mGy^{-1} for the (25% α / 75% β) and (75% α / 25% β) absorbed dose fractionations, respectively. Bland-Altman analysis showed small biases between simulation and experiment (-0.007 DSB·cell^{-1}·mGy^{-1} at 0h, -0.003 DSB·cell^{-1}·mGy^{-1} at 4h, and -0.002 DSB·cell^{-1}·mGy^{-1} at 24h). Z-tests indicated no statistically significant differences across time points. RBE increased with α-dose contribution, ranging from 1.0 for pure ^{177}Lu up to 5.9 for pure ^{223}Ra. ***Conclusion:*** DSB induction simulated with Geant4-DNA, combined with repair modeling using MEDRAS, effectively reproduced experimental trends in lymphocytes exposed to mixed α-/β-irradiation. This integrated modeling approach may support future applications in both molecular radiotherapy optimization and radiation protection by enabling improved prediction of residual biological damage across varying radiation qualities. ***References:*** [1] Strobel I., etal. Fetal radiation exposure from iodine-131 imaging during an unsuspected pregnancy

F. Simeonov[1], *J. Vassileva*[1], *R. Hristova*[1], *A. Zagorska*[2];
[1]*National Centre of Radiobiology and Radiation Protection, Sofia, BULGARIA,* [2]*Nuclear Medicine Department, Acibadem City Clinic Tokuda University Hospital, Sofia, BULGARIA.*

Aim/Introduction: Radioactive iodine (^{131}I) imaging and therapy are contraindicated during pregnancy. However, cases of unintended exposure continue to be reported in the literature. The aim of the current study is to estimate the absorbed dose in fetus, particularly in the fetal thyroid gland, after postoperative whole-body imaging with ^{131}I of a woman with unsuspected pregnancy, and to discuss current national and international recommendations for avoiding unintended exposure during pregnancy in nuclear medicine. ***Materials and Methods:*** A 37-year-old woman who had undergone a total thyroidectomy, was referred to a whole-body radionuclide scan. Diagnostic nuclear medicine images were obtained after oral administration of 88 MBq of ^{131}I. Before the procedure, the patient declared that she was not pregnant, and no pregnancy test was performed. One week later, the patient accidently discovered that she was pregnant during the radionuclide scan and was referred by her obstetrician to the National Centre of Radiation Protection and Radiobiology for a fetal dose assessment and counseling. Patient's medical records were carefully reviewed to obtain information needed to assess the fetal exposure. Different methods were used to calculate the fetal whole-body dose (Russell et al., 1997; Stabin, 2023) and the fetal thyroid gland dose (Stabin, 2017; Johnson, 1982). ***Results:*** The calculated average fetal dose ranged from 11.9 mGy to 18.8 mGy, while the fetal thyroid dose ranged from 29.9 Gy to 85.7 Gy (340 mGy/MBq to 974 mGy/MBq). The estimated dose to the fetal thyroid gland was comparable to the values reported in the literature. The patient was informed about the potential harmful effects on the thyroid gland of the fetus. To prevent unintended fetal exposure in the future, the department's policy for ascertaining the pregnancy status of a female patient has been reviewed, and recommendations have been issued. Learning materials have been prepared and distributed across healthcare facilities. ***Conclusion:*** The calculated fetal whole-body radiation dose is under 100 mGy and is not of concern. However, the fetal thyroid, which is known to be very sensitive to the radioactive iodine, results in substantially high absorbed doses with a potential damage to the fetal thyroid gland resulting in hypothyroidism or cretinism. Stricter measures to verify pregnancy status in women of reproductive age before administering radioactive iodine were introduced to prevent accidental fetal exposure.

Aim/Introduction: Diagnostic procedures in nuclear medicine involve less activity of radiopharmaceuticals administered than therapeutic procedures. However, to minimize the risks associated with radioactive exposure and contamination for workers, family members, and the public, patients are instructed on radiological protection rules to be followed at discharge. This study aims to identify whether there is a consensus on the radiation protection measures provided to patients upon discharge, aiming to minimize variations across departments. ***Materials and Methods:*** A survey was conducted on six nuclear medicine departments in Catalonia. The survey included the following items for 41 common radiopharmaceuticals employed in the nuclear medicine diagnostic procedures: -Restrictions on time in contact with children, pregnant women, adult family members, healthcare staff, and the general public. -Interruption of breastfeeding. -Restrictions on the use of public transportation. -Restrictions on the management of body fluids. -Radiation protection recommendations for medical transport. ***Results:*** No consensus was found in the recommendations to restrict contact with infants and pregnant women. Regarding PET radiopharmaceuticals, two centers recommended a 12-hour restriction period, two centers recommended a 6-hour restriction, one center recommended a four-hour restriction, and one center did not recommend restricting contact. In radiopharmaceuticals labeled with ^{99m}Tc, two centers recommended a 24-hour restriction period, regardless of the radiopharmaceutical and the administered activity; one

center recommended a 12-hour restriction, and one center recommended 12 hours if the administered activity was inferior to 370 MBq, and 24 hours for higher administered activities. One center recommended either a 4-hour or 12-hour period regarding the administered activity and the radiopharmaceutical, while the last center recommended no restriction in contact. Similar differences regarding breastfeeding were observed between the six centers.Consensus was found not to recommend restrictions on contact with the general public, family members, healthcare staff, or use of public transport. However, some centers recommend the basic rules of reducing the exposure time and increasing the distance, especially with pregnant women. ***Conclusion:*** While there is substantial agreement on the necessity of providing radiological protection guidelines to patients, particularly regarding limiting contact with children and pregnant women, there is a lack of standardization concerning the duration of these recommendations. National and/or International guidelines on radiation protection after discharge in diagnostic procedures are needed.

EPS-298

Considering the different biodistributions of 18F radiopharmaceuticals is crucial in calculating effective dose to public and caregivers

A. De Maggi[1], *E. Murru*[1], *E. Roberto*[1], *M. Lio*[1], *A. Lanza*[2], *E. Bergalla*[2], *F. Bergesio*[1], *S. Chauvie*[1];

Aim/Introduction: to compare dose rate of patients injected with different 18F-fluorine radiopharmaceuticals (RF) considering their bio-distributions. ***Materials and Methods:*** H*(10) was measured with an ionization chamber immediately before the acquisition at 30 cm and 1m from the thorax with the patient upstanding. The images of these patients were analyzed and the percentage of counts (%C) in four districts: head neck, thorax, abdomen, and pelvis, were evaluated. Measurements were compared to calculated H*(10)values applying corrections to the gamma specific constant taking in account the uptake time, the retention as in IRCP53 and the self absorption (with a coefficient of 0.65). Two models were applied: SSM, single source model considering the injected activity positioned in a single source in the middle of the thorax and the 4PM, 4 points model, in which the sources were located in the middle of the four 4 districts with an activity weighted respect to %C. Effective dose to the public and caregivers was calculated using D Broggio formalism (2023) considering the two models ***Results:*** 105 patients were examined, 45 with FDG, 30 with PSMA1007, 30 with choline (and 30 with FET, currently under analysis) . %C were 29%, 23%, 24% and 20% for FDG, 10%, 22%, 55% and 12% for PSMA and 11%, 22%, 49% and 16% for choline, respectively in the head-neck, thorax, abdomen, and pelvis areas. Measured average ± standard deviation and calculated (with SSM and 4PM) dose rate in µSv h-1/GBq for patients injected at 30cm and at 1m were respectively315±80(483/687) and 67±12(58/63) for FDG,575±45(552/652) and 52±4(58/61) for PSMA1007, 695±36(631/765) and 86±12(68/71) for choline, and143±27 and 42±15 µSv h-1/GBq for FET. ***Conclusion:*** A maximum differences of 25% between calculated without biodistribution and measured dose rates and 20% maximum differences were found in effective dose to the public and caregivers for SSM ,4PM model and measured for PSMA and Choline.In FDG an difference of 54% of the dose rate@30cm compared with the calculated one is reduced to35% taking into account biodistribution. A maximum difference of 12% in effective dose to the public and caregivers for SSM ,4PM model and measured for FDG @100 was found. Estimate the dose to third party from FDG@30cm measured dose rate can lead to underestimate dose up to 58%. Further analysis are ongoing on Monte Carlo simulation ***References:*** D Broggio et al 2023 J Radiol Prot 43 021504.

EPS-299

Belgian paediatric Diagnostic Reference Levels for whole-body and brain ^{18}F-FDG PET/CT

T. Assoignon[1], *M. Hesse*[2], *F. Dupont*[2], *F. Jamar*[2];
[1]*UCLouvain, Woluwe-Saint-Lambert, BELGIUM,* [2]*Cliniques Universitaires Saint-Luc, Woluwe-Saint-Lambert, BELGIUM.*

Aim/Introduction: PET/CT imaging involves ionizing radiation and the ALARA principle must be followed, especially for paediatric patients. One established tool to optimise the radiation dose is the implementation of Diagnostic Reference Levels (DRLs). Currently, no DRLs are available in Belgium nor in Europe regarding PET/CT imaging in the paediatric population. This study proposes the first local DRLs for paediatric whole-body (WB) and brain ^{18}F-FDG PET/CT in Europe. ***Materials and Methods:*** A retrospective study was carried out on DICOM-headers retrieved from ^{18}F-FDG PET/CT scans performed in our hospital in patients under the age of 18 between 2014 and 2018. Patients were grouped according to the ICRP135 classification: by body weight for whole-body scans and by age for brain studies. We assessed the median values and the 75th percentile (P75) of the administered activity of ^{18}F-FDG, Computed Tomography Dose Index ($CTDI_{vol}$), and Dose-Length Product (DLP) for each group. Scan length was additionally evaluated for each data set. ***Results:*** Median weight-adjusted administered activities for paediatric WB ^{18}F-FDG PET/CT are 4.4, 4.1 and 4.3 MBq/kg for the 15-<30 kg, 30-<50 kg and 50-<80 kg groups, respectively. For the brain PET, activities were 4.5 MBq/kg for the 1-<6 year group and 3.1 MBq/kg for the 6-<18 year group. The $CTDI_{vol}$ for the whole-body CT are 1.6, 2.2 and 3.1 mGy for the 15-<30 kg, 30-<50 kg and 50-<80 kg groups, respectively. The corresponding DLP's are 145.5, 230.9 and 342.6 mGy·cm. For the brain CT, the $CTDI_{vol}$ and DLP are 3.5 mGy and 75.8 mGy·cm for both 1-<6 year and 6-<18 year groups. A scan length exceeding the patient's height is observed in around 10% of cases. In these cases, the excess is on average 15cm. ***Conclusion:*** We have calculated the median and P75 values of the DLP, $CTDI_{vol}$ and administered activities to propose first Belgian DRL values for paediatric whole-body and brain ^{18}F-FDG PET/CT. It is recommended that clinical practice remain below the P75 value.Of course, DRLs change over time and results need to be updated continuously, particularly when new technologies are implemented. This study warrant larger multicentric studies, to extend the values to the entire country and ideally a larger, e.g. European community.

EPS-300

Establishing DRLs in [^{18}F]FDG PET-CT: A Digital-Analog Comparison

A. Carvalho[1], *R. Albergueiro*[1], *J. Vale*[2], *L. Cunha*[2], *C. Souto*[2];
[1]*ULS São João, Porto, PORTUGAL,* [2]*Atrys, Porto, PORTUGAL.*

Aim/Introduction: Positron Emission Tomography-Computed Tomography (PET-CT) is widely used for cancer diagnosis and staging, integrating metabolic and anatomical imaging. PET-CT involves exposure to ionizing radiation from radiopharmaceutical and CT, raising concerns about cumulative patient dose. This study aims to quantify radiation doses from both PET and CT components and to establish local diagnostic reference levels (DRLs) for two PET-CT systems - digital and analog, with 64 and 24 detector rows - across two medical centers. This initiative contributes to the development of national DRLs for adult [^{18}F] FDG PET-CT brain and half-body (from the vertex to the thigh) procedures. ***Materials and Methods:*** Retrospective analysis was performed on patients with body weights of 70±10kg, who underwent half-body (n=100) and brain (n=30) [^{18}F]FDG PET-CT scans, in each center. Collected data included injected activity,

activity per kilogram, volume CT dose index (CTDIvol), and dose-length product (DLP). DRLs were determined using the 50th percentile (median) of the distribution for each procedure and center, with the mean, standard deviation, and 75th percentile also determined. PET and CT dose values were calculated considering CT use for attenuation correction and anatomical localization. Results were compared across centers and against international DRLs. ***Results:*** For half-body PET-CT, DRLs for injected activity, activity per weight, CTDIvol, and DLP were 196 MBq, 2.8 MBq/kg, 5.5 mGy, and 577 mGy·cm for the digital system PET-CT, and 237 MBq, 3.5 MBq/kg, 4.7 mGy, and 384 mGy·cm for the analog system. Corresponding PET-CT doses were (3.7±0.4)mSv and (9±2) mSv (digital PET-CT), and (4.5±0.5)mSv and (6±1)mSv (analog PET-CT). For brain PET-CT, DRLs were 188 MBq, 2.8 MBq/kg, 8.6 mGy, and 243 mGy·cm (digital system), and 199 MBq, 3.3 MBq/kg, 4.0 mGy, and 71 mGy·cm (analog system, with fixed CT values and parameters for all patients). PET-CT doses were (3.6±0.5)mSv and (1.5±0.1)mSv (digital), and (3.9±0.7)mSv and 0.17 mSv (analog). As expected, digital systems showed lower injected activity and PET dose due to higher sensitivity, while CT dose was higher, though within European DRL limits, indicating room for optimization. ***Conclusion:*** The observed differences between digital and analogue systems highlight the impact of scanner technology on patient exposure and the importance of ongoing dose monitoring and protocol optimisation. These findings represent an initial step towards establishing national DRLs for PET-CT in Portugal. Ongoing work is being conducted to correlate radiation dose with image quality, ensuring that optimisation efforts do not compromise diagnostic performance.

EPS-301

Radiation dose reduction for low-dose CT in hybrid imaging with three generations of iterative reconstruction and varying denoising strengths

N. Bebbington[1], *R. H. Kappel*[2], *J. W. Aunsborg*[2], *P. C. Holdgaard*[2];
[1]*Siemens Healthcare A/S, Ballerup, DENMARK,* [2]*Lillebaelt Hospital-University Hospital of Southern Denmark, Vejle, DENMARK.*

Aim/Introduction: Several types of iterative reconstruction (IR) are available on hybrid PET-CT and SPECT-CT systems, allowing reduced radiation dose compared with filtered backprojection (FBP). Available IRs differ in sophistication, from algorithms working only in image space, to those also working in raw-data space with advanced modelling and allowing user-defined denoising strength (DNS). The aim was to determine the magnitudes of CT radiation dose reduction (DR) permissible for low-dose CT in hybrid imaging with a direct comparison of three generations of IR and varying DNS. ***Materials and Methods:*** A whole-body patient phantom was scanned on three hybrid systems, each with a different IR available. Acquisitions were made on each scanner at two tube voltage settings, each with 7 different effective mAs settings ranging from 10-120mAs. Reconstructions were made with FBP and the available IR on that scanner (A=IR in image space, no user-defined DNS; B=IR in image- and raw-data space with DNS 3 (medium) to 5 (maximum); C=IR in image- and raw-data space with advanced modelling (C) with DNS 3-5. Image quality for each reconstructed dataset was evaluated in lung, bone, liver and kidney tissues, through quantitative measurement of contrast and noise, and qualitative visual analysis (VA) by two CT-trained physicians. For each IR algorithm the percentage DR for comparable image quality to the reference FBP image (120 mAs) was determined. ***Results:*** For lung, all IRs suggested permissible DR up to >80% according to noise measures, which were also verified by VA scores. For bone, liver and kidney, permissible DR generally increased from reconstruction A through to C. For bone, reconstructions A, B and C permitted DR up to 31%, 48% and >80% respectively, whilst for liver DR up to 31%, 71% and >80% was permitted. For kidney, reconstruction A permitted DR up to 38%, whilst for reconstructions B and C, DR indicated by noise analysis (up to 80% (B) and >80% (C)) were greater than those by visual analysis (up to 68% (B) and 51% (C)). Increasing DNS reduced noise in all tissues and did not notably impact VA scores. IR did not notably impact image contrast in any tissue. ***Conclusion:*** Large CT DR can be achieved with IR, with greater DR associated with more sophisticated IR algorithms. High DNS provides lower noise and greater indicated DR, which may be well-suited to 'low-dose CT' purposes of attenuation correction and localisation often used in hybrid imaging.

EPS-302

Estimation of infant gonad dose from urine contamination following Tc-99m MAG3 renal scintigraphy

T. Ball*, A. Maenhout, N. A. Kapse, J. J. Phillips;*
Chelsea and Westminster Hospital NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: We estimate the doses to the gonads for infant patients following urine contamination of diapers, and extend this estimation based on the number of hours between contamination and changing the diaper. ***Materials and Methods:*** We analysed 50 patient scans with visible urinary contamination in the dynamic images. Of the included scans, 11 patients were female (ages 4 - 16 months) and 39 were male (ages 3 - 34 months). We drew a region of interest around each area of visible contamination and converted the measured count rate into a background-corrected time-activity curve. Assuming no further contamination, dose per administered activity (mGy/MBq) was calculated for the diaper being changed at 0, 1, 2, 3, and 4 hours after the completion of the dynamic scan. ***Results:*** The absorbed dose per unit activity was calculated for both male and female patients at 0 hours (Male: $1.08 \pm 0.83 \times 10^{-2}$ mGy/MBq, Female: $6.87 \pm 2.83 \times 10^{-4}$ mGy/MBq), 1 hour (Male: $9.30 \pm 6.06 \times 10^{-2}$ mGy/MBq, Female: $5.97 \pm 3.01 \times 10^{-3}$ mGy/MBq), 2 hour (Male: $1.66 \pm 1.09 \times 10^{-1}$ mGy/MBq, Female: $1.07 \pm 0.55 \times 10^{-2}$ mGy/MBq), 3 hour (Male: $2.31 \pm 1.51 \times 10^{-1}$ mGy/MBq, Female: $1.49 \pm 0.76 \times 10^{-2}$ mGy/MBq), and 4 hours (Male: $2.89 \pm 1.90 \times 10^{-1}$ mGy/MBq, Female: $1.86 \pm 0.96 \times 10^{-2}$ mGy/MBq) after the end of the dynamic acquisition. The mean cumulative activities were higher in female patients ($5.2 \pm 2.5 \times 10^{2}$ MBq·s) than male patients ($4.5 \pm 3.3 \times 10^{2}$ MBq·s), however absorbed doses per unit activity in male patients' gonads were significantly higher by a factor of 16 for all time points. ***Conclusion:*** Contaminated diapers are estimated to contribute significant doses to infant patients when these patients are left unchanged for significant periods of time. We compare estimated mean dose to the gonads from a contaminated diaper at each time point to ICRP 80 values; ICRP 80 value is exceeded at 1 hour for male patients, and at 3 hours for female patients. As such, we suggest that nuclear medicine departments should advise carers of these patients to encourage the changing diapers more frequently. ***References:*** Lu, Y., Kumbhar et al. (2024). Impact of Ionizing Radiation on Children whose Mothers Underwent Pulmonary Perfusion Scintigraphy with Technetium-99m Macroaggregated Albumin

P. Guijarro-Caba*, J. Díaz-Alarcón;*
Hospital Universitario de Jaén, Jaén, SPAIN.

Aim/Introduction: Despite pregnancy being incompatible with studies involving ionizing radiation, these procedures may be performed when a firm clinical justification exists and

alternative diagnostic tools are not feasible. In our center, a total of 23 pulmonary perfusion studies have been conducted on pregnant women over the last 6 years to rule out Pulmonary Thromboembolism (PTE). Although the risks to the fetus are considered practically negligible for doses below 50 mSv, we deem it important to conduct a follow-up on the newborn to determine if any issues attributable to ionizing radiation have emerged. Consequently, we propose a longitudinal follow-up from the time of birth to the present. ***Materials and Methods:*** Pulmonary perfusion scintigraphy was performed by administering 74 MBq of [^{99m}Tc]Tc-MAA (Technetium-99m labeled Macroaggregated Albumin), instead of the standard 200 MBq. Planar imaging and/or SPECT of the thorax were conducted using the appropriate gammacamera, without a ventilation scintigraphy study. This approach was adopted to reduce the radiation dose received by both the mother and the fetus. Subsequently, follow-up of the children was conducted from the time of birth to the present. ***Results: Results:*** Following the follow-up period, the results obtained for the sample (n=23) were: 21.74% of the examinations presented findings suggestive of PTE, with an estimated effective dose of 0.81 mSv. The median gestational age at the time of the examination was 31 weeks (range 19+3 to 38 weeks), and the median gestational age at delivery was 39 weeks (range 27+3 to 41+4 weeks). Patient follow-up lasted for at least one year in 82.61% of cases, and up to 64% of patients were followed for 4 years or more (follow-up range 2 to 73 months). None of the newborns studied exhibited apparent signs or symptoms resulting from exposure to ionizing radiation during the follow-up period. ***Conclusion:*** The obtained results are consistent with findings reported in the literature, which indicate that fetal exposure to doses below 50 mSv has not been demonstrated to be harmful. ***References:*** International Commission on Radiological Protection. (2000). ICRP Publication 84: Pregnancy and Medical Radiation Health Protection Agency. (2009). Protection of pregnant patients during diagnostic medical exposures to ionising radiation.

Development of Lightweight, Flexible, and Lead-Free Epoxy-Based Composites for Gamma Radiation Shielding in Nuclear Medicine

F. Moradi[1], *P. Sheikhzadeh*[1], *H. Mohammad Hosseini*[2], *A. Sajedi*[3]; *[1]Department of Nuclear Medicine, IKHC, Tehran University of Medical Sciences, Tehran, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Iran polymer and petrochemical institute, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Composite Materials Laboratory, Faculty of Mechanical Engineering, Amirkabir University of Technology, Tehran Polytechnic, Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Introduction. Compliant radiation shielding is of utmost significance in nuclear medicine environments such as PET/CT. Traditional lead-based barriers are efficient but heavy, toxic, and inflexible. This study tries to develop and study non-toxic, light-weight epoxy resin composites reinforced with high-Z gamma-absorbing fillers such as bismuth oxide (Bi_2O_3), tungsten carbide (WC), and iron oxide (Fe_2O_3) as safe alternatives for medical shielding applications. ***Materials and Methods:*** Methods. Two composite series were prepared with bisphenol A-based epoxy resin. Type 1 samples contained single fillers (Bi_2O_3, PbO, WC) at 10-50 wt%. Type 2 samples contained Bi_2O_3 and Fe_2O_3 in synergistic ratios (up to 70% Bi_2O_3 + 20% Fe_2O_3). Composite processing included high-speed mechanical mixing, ultrasonic homogenization, and hot pressing. Sintering in an inert nitrogen atmosphere was applied to some samples to improve density and microstructural homogeneity. The performance of gamma shield was evaluated using 99mTc (140 keV), 131I (360 keV), and 18F (511 keV) sources. Key parameters such as linear attenuation coefficient (LAC), half-value layer (HVL), transmission factor (TF), and mean free path (MFP) were determined. ***Results:*** Results. Among Type 1 samples, Bi_2O_3-filled samples showed better performance. BPA-30 (30 wt% Bi_2O_3) exhibited TF = 11.3% at 60 keV (thickness = 1 cm), and maximum LAC at all energies. Type 2 composites, especially BPA-70 (70 wt% Bi_2O_3 + 20 wt% Fe_2O_3), achieved nearly 100% attenuation at 60 keV with 1 cm thickness. At 511 keV, BPA-70 also exhibited high shielding (TF ~63%) with lead equivalence up to 0.07 cm. Sintered composites yielded higher density (up to 4.8 g/cm^3) and mechanical strength. Bi_2O_3-based samples were superior compared to PbO and WC in terms of shielding and flexibility. ***Conclusion:*** Conclusion. The Bi_2O_3/Fe_2O_3 epoxy composites prepared offer a promising lead-free radiation shielding option for nuclear medicine, with excellent attenuation, mechanical strength, and reduced toxicity. Their flexibility and low weight render them suitable for clinical application in shielding curtains, protective gear, and portable PET/CT room barriers. Further studies on inert-atmosphere sintering can enhance reproducibility for industrial scale-up. ***References:*** 1.Smith, J., & Johnson, L. (2020). Development of the first national event learning system in the UK

A. Powell, *L. Fraser, U. Findlay, Y. Kinsella, N. Kirk; UK Health Security Agency, Oxford, UNITED KINGDOM.*

Aim/Introduction: The first UK wide national event reporting and learning system specifically for nuclear medicine, diagnostic imaging and Magnetic Resonance Imaging (MRI) has been developed by the Medical Exposure Group (MEG), at the UK Health Security Agency (UKHSA). The main aim of the event learning system is to promote and improve a positive patient safety culture. Presented will be how this event learning system has been established, feedback from the nuclear medicine community and data from the second quarter of 2025. ***Materials and Methods:*** The following key stages were conducted to establish the event learning system: 1) System for categorisation of events (taxonomy): To achieve a standardised taxonomy for categorising events, a multidisciplinary working party with clinical specialists from across the United Kingdom (UK) was established. The finalised coding was tested against pilot event data to ensure the taxonomy is effective and comprehensive. 2) Publication of guidance and local implementation: The taxonomy [1] was published and supporting guidance [2] written and shared, which was endorsed by professional bodies. The taxonomy can be applied locally by appropriately trained clinical staff members to each event when the local investigation is completed. 3)Data submission to the MEG: The key objective at this stage was to support departments in their local implementation. Additional learning resources such as dedicated webpages and recorded presentations were developed and made available. The MEG also provided additional support in local implementation where required. Furthermore, voluntary reporting mechanisms were established to allow anonymised data to be submitted to MEG for analysis. 4) Data analysis: The MEG commissioned a database to support collation and analysis of the data submitted. 5) National shared learning: Results and learning will be published in e-bulletins and formal reports which will be made available online. This will allow local comparison of local events with the national picture. ***Results:*** Departments across the UK have implemented the new taxonomy at a local level and are engaging with MEG for support with this. The MEG will review data from the second quarter of 2025 and produce trend analysis of the early findings. Feedback on this project from the UK clinical community has been overwhelmingly positive. It suggests a positive influence on reporting cultures and providing meaningful learning opportunities. ***Conclusion:*** This will be the first opportunity for nuclear medicine, clinical imaging and MRI to analyse events (including near misses) at a

national level. ***References:*** [1] https://www.gov.uk/government/publications/national-coding-taxonomy-for-incident-learning-in-clinical-imaging-mri-and-nuclear-medicine [2] https://www.gov.uk/government/publications/user-guidance-and-application-of-the-national-taxonomy-for-incident-learning-in-clinical-imaging-mri-and-nuclear-medicine.

Aim/Introduction: Accurate staging of unfavorable intermediate/high-risk prostate cancer (PCa) is essential for treatment decisions. Conventional imaging often fails to detect small lymph node metastases. This study evaluated the impact of 68Ga-PSMA PET/CT on staging, diagnostic accuracy compared to MRI, and surgical eligibility. ***Materials and Methods:*** Prospective, multicenter study (12 centers, 11 countries), including 775 high-risk/unfavorable intermediate PCa patients with radical prostatectomy based based on MR and bone scan were submitted to 68Ga-PSMA PET/CT before treatment. PET and MR findings were compared with radical prostatectomy histopathology. PET impact on surgical decisions was measured. ***Results:*** 68Ga-PSMA PET/CT detected metastatic disease (M1) in 20.4%, altering management in 24.0%, preventing unnecessary surgery. Sensitivity for seminal vesicle invasion was 85.1% (PSMA) vs. 29.4% (MRI); for lymph node metastases, 87.5% (PSMA) vs. 23.1% (MRI). In the 13.1% (78/593) lymph node discordant PSMA and histology results, biopsy was negative in 21 patients; PET undetected LNMs disease in 27 patients; and in the 30 remaining patients PET detected less lymph nodes chains than biopsy results. ***Conclusion:*** PSMA PET/CT significantly improves staging accuracy, reducing unecessary prostatectomy and optimizing treatment. Its incorporation into standard PCa staging is warranted. ***References:*** 1. Mottet N, Cornford P, van den Bergh RCN, et al. EAU-EANM-ESTRO-ESUR-SIOG Guidelines on Prostate Cancer. OP-874

Interobserver and Intraobserver Agreement for Equivocal Lesions in Ga-68 PSMA PET/CT According to PSMA-RADS 2.0 Criteria

K. Niftaliyeva[1], *S. Kesim*[2], *N. Filizoglu*[2], *Z. Balaban Genc*[1], *S. Özgüven*[1], *F. Çağlıyan*[1], *T. Öneş*[1], *F. Dede*[1], *H. Turoğlu*[1], *T. Erdil*[1];
[1]*Marmara University Pendik Training and Research Hospital, Istanbul, TÜRKIYE,* [2]*Kartal Dr. Lutfi Kirdar City Hospital, Istanbul, Turkey, Istanbul, TÜRKIYE.*

Aim/Introduction: This study aims to systematically evaluate the inter- and intra-observer agreement regarding lesions with uncertain malignancy potential in Ga-68 PSMA PET/CT imaging of prostate cancer patients, utilizing the PSMA-RADS 2.0 classification system, and to emphasize the malignancy evidence associated with these lesions. ***Materials and Methods:*** We retrospectively reviewed Ga-68 PSMA PET/CT images of patients diagnosed with prostate cancer via histopathology between December 2016 and November 2023. Seventy-six patients and 98 target lesions, classified with PSMA-RADS scores 3A to 3D by an experienced nuclear medicine specialist, were included. Three observers (two experienced and one less experienced nuclear medicine physician) evaluated the lesions at two different time points, three months apart, in a blinded manner. Intra-observer agreement was assessed using Cohen's kappa, while inter-observer agreement was analyzed using Fleiss' kappa. ***Results:*** All observers demonstrated significant intra-observer agreement, with percentages ranging from 67.3% to 80.6% and kappa values between 0.62 and 0.76. The highest intra-observer agreement was noted for bone lesions, while non-regional lymph nodes exhibited the lowest agreement. For inter-observer assessments, moderate agreement was observed across all lesions (Fleiss k=0.51), with the highest agreement in regional lymph nodes and the lowest in non-regional lymph nodes and bone lesions (Figure 1). A low level of interobserver agreement was also detected in the evaluation of lung lesions (Figure 2). Follow-up results indicated malignancy detection rates of 63.4% for 3A, 47% for 3B, 44.5% for 3C, and 41.4% for 3D scored lesions. ***Conclusion:*** The PSMA-RADS classification system demonstrated substantial intra-observer agreement and moderate inter-observer agreement for lesions with uncertain malignancy potential, supporting its clinical applicability. However, notable variability and limitations in reporting bone lesions, non-regional lymph nodes, and lung lesions were observed among readers. The ambiguous nature and management of PSMA-RADS 3 lesions underscore the need for further research to enhance risk stratification.

Aim/Introduction: Multiparametric MRI (mpMRI) is the current standard of care for diagnosing prostate cancer (PCa), but its positive predictive value (PPV) remains limited, often leading to unnecessary biopsies. Prostate-specific membrane antigen (PSMA) PET has shown promising results in the detection of primary PCa. This study aims to assess the diagnostic accuracy of integrated PET/MRI—combining [^{18}F]-PSMA-1007 PET and mpMRI—for the detection of clinically significant PCa (csPCa). ***Materials and Methods:*** This is a prospective clinical trial (EUDRACT: 2022-003905-31) involving patients with clinically suspected prostate cancer undergoing [^{18}F]-PSMA-1007 PET/MRI prior to systematic ± targeted biopsy. PET and MRI images were interpreted independently, each blinded to the other, and subsequently combined into a unified PSMA PET+MRI report. mpMRI was assessed according to PI-RADS v2.1, while PET images were evaluated using a 5-point Likert scale, with scores ≥4 considered positive. Lesions were deemed positive on PSMA PET+MRI if either PI-RADS was ≥4 or PSMA PET was positive. csPCa was defined as ISUP grade group ≥2. Sensitivity (SN), specificity (SP), positive predictive value (PPV), and negative predictive value (NPV) were calculated at the patient level, along with their 95% CI, while lesion-level PPV was also assessed. Histopathological analysis from prostate biopsies served as the reference standard. ***Results:*** To date, 35 patients have completed all imaging and histological assessments and were included in the analysis. [^{18}F]-PSMA-1007 PET identified 36 lesions in 23 patients, mpMRI identified 36 lesions in 22 patients, and the combined PSMA PET+MRI identified 38 lesions in 25 patients. 28 target lesions in 17 patients were confirmed as csPCa at histopathology. At the patient level, [^{18}F]-PSMA-1007 PET had SN = 0.88 (0.64-0.99), SP = 0.56 (0.31-0.79), PPV = 0.65 (0.43-0.84), and NPV = 0.83 (0.52-0.98); mpMRI showed SN = 0.88 (0.64-0.99), SP = 0.61 (0.36-0.83), PPV = 0.68 (0.45-0.86), and NPV = 0.85 (0.55-0.98). Combined PSMA PET+MRI had SN = 0.94 (0.71-0.99), SP = 0.50 (0.26-0.74), PPV = 0.64 (0.43-0.82), and NPV = 0.90 (0.56-0.99), respectively. At the lesion level, PPV was 0.69 (0.52-0.84) for PET, 0.64 (0.46-0.79) for mpMRI, and 0.68 (0.51-0.83) for the combined PET+MRI. ***Conclusion:*** Our data support the combined use of [^{18}F]-PSMA-1007 PET and mpMRI to enhance diagnostic accuracy for csPCa. The final results of this study will help define the optimal strategy for integrating these modalities and improve the diagnostic confidence of PSMA PET/MR.

OP-876

Quantitative Imaging Parameters Improve the Accuracy of PSMA PET/CT for the Local Staging of Primary Prostate Cancer

M. Donswijk[1], *R. H. Ettema*[2], *M. Wondergem*[3], *Z. Cheung*[1], *H. G. van der Poel*[1], *D. E. Oprea-Lager*[4], *A. N. Vis*[2];
[1]*Antoni van Leeuwenhoek - Netherlands Cancer Institute, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC - Locatie VUMC, Amsterdam, NETHERLANDS,* [3]*Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS,* [4]*Radboud University Medical Center, Nijmegen, NETHERLANDS.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) PET/CT is recognized as the most accurate imaging modality for detection of metastatic high-risk prostate cancer (PCa). PSMA PET/CT has also shown potential in the local (T) staging of primary PCa, in which the detection of T3 disease (extraprostatic extension, EPE) has prognostic and therapeutic importance. After initial promising smaller studies, larger studies found that visual T-stage assessment had only moderate accuracy[1]. The purpose of this study was to explore the value of quantitative PSMA PET/CT parameters in addition to the standard visual assessment of the local T-stage. ***Materials and Methods:*** From a large single centre retrospective patient cohort, all patients with intermediate and high-risk primary PCa who underwent staging PSMA PET/CT before robot-assisted radical prostatectomy (RARP) were assessed. Visual analysis of T-stage (miT-stage) was done as well as the assessment of quantitative parameters derived from PSMA PET/CT such as SUVmax, SUVpeak, tumour volume (PSMA-vol), total lesion PSMA expression (PSMA-TL) and tumour longest capsule contact (LCC) was performed. Pathological tumour stage in the radical prostatectomy specimen was used as the reference standard. Following, univariable and multivariable logistic regression analyses were performed and clinical risk models for pT3 stage were created. ***Results:*** 223 evaluable patients with a PSMA positive primary PCa were included. Univariable analyses yielded AUC's of 0.59, 0.64 and 0.63 for the visual analysis of predicting pT3a, ≥pT3b and (overall) ≥pT3 stage respectively. Quantitative parameters yielded AUC's of 0.53-0.63 for pT3a, 0.64-0.74 for ≥pT3b and 0.59-0.69 for ≥pT3 stage. Multivariable analyses showed LCC as single independent predictor of pT3a stage. Furthermore, visual miT-stage, LCC and PSMA-vol were independent predictors of ≥pT3b-stage, and LCC and PSMA-vol independent predictors of ≥pT3 stage. Clinically usable risk models incorporating these predictors yielded AUC's of 0.62 for pT3a, 0.79 for ≥pT3b and 0.70 for ≥pT3 stage, with cut-offs of choice for different sensitivity / specificity levels. No statistically significant differences in diagnostic accuracy were found between PSMA PET tracers [^{68}Ga]Ga-PSMA-11 and [^{18}F]DCFPyL. ***Conclusion:*** In a large, single centre cohort study including 223 evaluable patients with newly diagnosed intermediate and high-risk PCa, we showed that quantitative PSMA PET/CT parameters had good diagnostic accuracy for detection of EPE, especially for ≥pT3b-stage, surpassing visual analysis (miT-stage) alone. ***References:***

Aim/Introduction: To estimate the diagnostic accuracy and stage migration of [^{18}F]PSMA-1007-PET/CT and its impact on patient management when compared with Na[^{18}F]F-PET/CT for primary staging of patients with prostate cancer. ***Materials and Methods:*** These findings represent the initial results of the randomized PRISMA-PET trial (EudraCT 2021-000123-12) including patients with intermediate- and high-risk primary prostate cancer[1]. Patients randomized to clinically staging in the [^{18}F]PSMA-1007-PET/CT-arm, had a supplementary blinded Na[^{18}F]F-PET/CT performed for the purpose of this sub-study. A research-focused Multi Disciplinary Team conference (rMDT) was conducted based on the clinical data and the Na[^{18}F]F-PET/CT; stage and treatment decisions were agreed upon. Subsequently, the [^{18}F]PSMA-1007-PET/CT was reviewed and stage and treatment decision were reconsidered. The decision from the rMDT together with histology from prostatectomies with lymphadenectomy and further clarifying imaging, if performed, served as composite reference standard. A comparative diagnostic accuracy analysis was conducted between the Na[^{18}F]F-PET/CT and the clinical report of the [^{18}F]PSMA-1007-PET/CT. Stage allocation and treatment strategies from the rMDT were compared for the two types of scans. ***Results:*** A total of 128 men with a median age of 72 years (range: 53-84) were included, with 25 (19.5%) at intermediate-risk and 103 (80.5%) high-risk PCa. The sensitivity and specificity for lymph node metastases were 0.88 and 0.96 for [^{18}F]PSMA-1007-PET/CT and 0.63 and 0.94 for diagnostic CT with Na[^{18}F]F-PET/

CT (p-value 0.02 and 0.69). For bone metastases, the sensitivity and specificity were 1.00 and 0.97 for [^{18}F]PSMA-1007-PET/CT and 0.83 and 0.98 for Na[^{18}F]F-PET/CT (p-value 0.50 and 0.63). Stage migration was observed in 22 patients (17%), with 15 (12%) migrating to a more advanced stage and seven (5%) downgraded. Management changed for 18 patients (14%). In five instances (4%), the curative strategy was changed, but remained curative. Eight patients (6%) shifted from curative to palliative treatment, while two (2%) moved from palliative to curative treatment. Changes within palliative strategies occurred in three cases (2%). ***Conclusion:*** [^{18}F]PSMA-1007-PET/CT outperformed diagnostic CT with Na[^{18}F]F-PET/CT in diagnosing lymph node metastases, and showed a similar trend for bone metastases, though without significant difference. The use of [^{18}F]PSMA-1007-PET/CT for primary staging resulted in stage migration in 17% of patients and changed management in 14%, compared to Na[^{18}F]F-PET/CT. Results from the randomized PRISMA-PET trial will determine if staging with [^{18}F]PSMA-1007-PET/CT compared to Na[^{18}F]F-PET/CT will lead to improved patient outcomes. ***References:*** 1) Buch-Olsen et al. BJUI Compass. 2023 May 12;4(5):513-522. doi: 10.1002/bco2.243.

OP-878

Incremental value of multiparametric F18 PSMA PET CT in comparison to conventional F18 PSMA PET CT in the diagnosis of prostate cancer

D. Malik, *J. Gupta, N. Rana, M. Koley, D. Thakrani, A. Uppal, P. Thakral, I. B. Sen;*
Fortis Memorial research institute (FMRI), Gurugram, INDIA.

Aim/Introduction: The distinction between benign and malignant prostatic pathologies in men with an elevated PSA levels remains a pertinent clinical conundrum. While multi-core biopsy of the prostate and histopathology remain the gold-standard investigation till date; dynamic parametric PET is a modality of growing interest, with the potential to make the above distinction non-invasively. We aim to investigate the role of Ki and Dv indices obtained from dynamic parametric PET imaging in improving the diagnostic accuracy of F18 PSMA PET CT in diagnosing prostate cancer in patients with elevated PSA levels. ***Materials and Methods:*** 30 patients with an elevated PSA levels and clinical suspicion of carcinoma prostate underwent multiparametric PSMA PET following injection of 18F-PSMA (2-3 MBq/kg). A 70 min dynamic WB PET scan immediately after injection was acquired consisting of 16 continuous bed motion passes. VOI delineation of the multiparametric images was performed and semiquantitative values of SUV max and SUV mean was obtained from the conventional PET reconstructions, whereas Ki and DV values were extracted from the multiparametric images. All patients subsequently underwent a prostate biopsy and a total of 39 lesions were available for assessment. The relative diagnostic accuracy of conventional PSMA PET CT and multiparametric PET CT was assessed using a receiver operator curve characteristics curve (AUCs), sensitivity, and specificity for ordinal and dichotomized data. ***Results:*** For multiparametric PSMA PET CT, the ROC analysis of Ki-mean Index demonstrated a higher area under the curve (AUC = 0.712), which was statistically significant (p = 0.048). In contrast, conventional PET CT SUV-mean index had an area under the curve of 0.636, with a p-value of 0.199. The sensitivity and specificity for Ki-mean was 57.5% and 83.3% respectively with a cut off value of > 1.3 at 0.4091 Youden index. ***Conclusion:*** Early data suggests that multiparametric dynamic PET CT index of Ki mean offers a better potential than SUV mean obtained in conventional PSMA PET CT in distinguishing carcinoma prostate from benign prostatic pathologies in patients with an elevated PSA levels. Further analysis of this study in higher number of patients may help in establishing role of multiparametric PSMA PET CT in diagnosis, obviating the need for invasive biopsy.

OP-879

Sensitivity of distinct segmentation thresholds to different PET-reconstruction algorithms in volumetric PSMA-PET assessment

D. Ufton, *J. Heilinger, K. S. Roth, M. Schmidt, A. Drzezga, C. Kobe;*
University Hospital of Cologne, Department of Nuclear Medicine, Cologne, GERMANY.

Aim/Introduction: Tumor volume derived by prostate-specific-membrane antigen (PSMA) in PSMA-PET/CT (PSMA-TV) shows an increasing impact for prognosis and response evaluation in patients with prostate cancer. Previous studies show the impact of different PET reconstruction methods on measurements of metabolic tumor volume for FDG-PET. Here we aim to evaluate the robustness of different PSMA-TV delineation methods. ***Materials and Methods:*** We analysed ^{18}F-JK-PSMA-7 PET/CT-scans of 40 patients suffering from metastatic castration-resistant prostate cancer (mCRPC) acquired before ^{177}Lu-PSMA treatment. PSMA-TV measurements were performed using an SUV of 4.0 (PSMA-TV-4.0) as a fixed threshold, 41% of the single hottest voxel (PSMA-TV-41%) as an adaptive threshold and a patient-based liver-specific threshold (PSMA-TV-LT; adapted from the qPSMA-threshold algorithm by Gafita et al.) for automated delineation in both UHD and OSEM reconstructions. Absolute and relative differences between the segmentation thresholds in UHD and OSEM reconstructions were measured and differences tested for statistical significance using the Wilcoxon matched-pair signed-rank test (2 samples). A p-value of $p < 0.05$ was considered statistically significant. ***Results:*** Total PSMA-TV differed significantly when comparing UHD and OSEM reconstruction for an individual segmentation threshold, regardless of the threshold chosen. Volumes measured in UHD reconstructions were significantly smaller than in OSEM reconstructions. (PSMA-TV-41%-UHD = 100 ml ± 90 ml vs. -OSEM = 160 ml ± 130 ml ($p < 0.01$), PSMA-TV-4.0-UHD = 326 ml ± 284 ml vs. -OSEM = 354 ml ± 306 ml ($p = 0.02$), PSMA-TV-LT-UHD = 281 ml ± 250 ml vs. -OSEM = 305 ml ± 270 ml ($p = 0.42$)). Comparing the relative and absolute differences in PSMA-TV between OSEM and UHD reconstruction between the three separate segmentation thresholds showed significantly larger absolute volume differences for PSMA-TV-41% compared to PSMA-TV-LT (59 ml (± 73 ml) vs. 23 ml (± 48 ml), $p = 0.046$) and significantly larger relative volume differences for PSMA-TV-41% ($p < 0.01$) compared to PSMA-TV-4.0 and PSMA-TV-LT (PSMA-TV-4.0: 3.4% ± 25.8%, PSMA-TV-LT: 2.6% ± 21.1%, PSMA-TV-41%: 25.1% ± 43.0%). Absolute and relative volume differences between reconstruction settings did not significantly differ between PSMA-TV-4.0 and PSMA-TV-LT ($p = 0.11$ and $p = 0.90$, respectively). ***Conclusion:*** The fixed thresholds PSMA-TV-4.0 and -LT are less susceptible to reconstruction-induced volumetry effects as shown by lower volume differences between UHD- and OSEM-reconstructions compared to a relative segmentation threshold (PSMA-TV-41%). Using a fixed threshold of SUV 4.0 was simple to implement, as it did not require patient specific calculations of the segmentation threshold.

OP-880

Towards Biopsy-Sparing Prostate Cancer Diagnosis:45%SUVmax-Based Radiomics with AdaBoost for Pathological Feature Prediction

C. Jianbo[1,2,3], *G. Wang*[4], *X. Meng*[1], *Y. Han*[1,2], *J. Zhang*[1,2], *Y. Liu*[1,2], *B. Xu*[1];
[1]*Chinese PLA General Hospital, Beijing, CHINA,* [2]*Graduate School, Chinese PLA General Hospital, Beijing, CHINA,* [3]*Nuclear Medicine Department, The 983rd Hospital of the Joint Logistic Support Force, TianJin, CHINA,* [4]*Beijing Friendship Hospital, Affiliated to Capital Medical University, Beijing, CHINA.*

Aim/Introduction: Accurate non-invasive assessment of prostate cancer pathological grade, extra-capsular extension (ECE), and risk stratification is pivotal for personalized treatment. Previous studies have shown that 40% or 50% SUVmax thresholds can effectively characterize the biological features of prostate cancer. Yet, the clinical utility of intermediate thresholds like 45% remains underexplored. We investigate whether radiomic features derived

from PSMA PET/CT at these SUVmax percentages (40%, 45%, 50%) can predict ECE, National Comprehensive Cancer Network (NCCN) 2025 high/very high risk, and ISUP grade >2 using an AdaBoost model, advancing a biopsy-sparing approach. ***Materials and Methods:*** In this single-center study, 243 patients scheduled for radical prostatectomy underwent pre-operative 18F-PSMA-3Q PET/CT. Target volumes were delineated via the uAI Research Portal, and radiomic features were extracted. Data were split 8:2 for training and testing. An AdaBoost machine learning model was trained to predict three endpoints. Model performance was evaluated using AUC, sensitivity, specificity, accuracy, precision, F1-score, and recall. ***Results:*** For ECE prediction, the 45% SUVmax model outperformed 40% and 50% at a cutoff of 0.5, achieving a test AUC of 0.828 (95% CI: 0.697-0.958), with balanced sensitivity (0.828) and specificity (0.684), yielding 0.771 accuracy and 0.814 F1-score. In NCCN risk stratification using the same cutoff, 45% SUVmax achieved the highest AUC (0.937, 95% CI: 0.697-0.958) and recall (0.882)-critical for high-risk patient identification-with 0.854 accuracy and 0.811 F1-score. For ISUP grade >2 prediction at cutoff 0.5, 45% and 50% SUVmax demonstrated comparable performance: while 50% SUVmax prioritized sensitivity (0.939), 45% SUVmax (AUC: 0.890, 95% CI: 0.788-0.992) offered superior precision (0.857 vs. 0.816) and a nearly equivalent F1-score (0.870 vs. 0.873), balancing detection and accuracy (0.816 vs. 0.812) across the threshold. ***Conclusion:*** These findings highlight 45% SUVmax as a robust threshold, demonstrating consistent performance across endpoints where boundary thresholds (40%/50%) either underperformed or introduced trade-offs between sensitivity and specificity. The AdaBoost model leverages PSMA PET radiomics to enable non-invasive prediction, potentially reducing reliance on biopsies-an invasive gold standard associated with morbidity. While single-center data require multicenter validation, this work aligns with the NCCN 2025 guidelines to establish a framework for integrating SUVmax-tailored radiomic models into clinical workflows, advancing non-invasive, biopsy-sparing strategies for prostate cancer risk stratification.

OP-881

A comparative analysis of normal organ biodistribution and tumor uptake pattern of novel RHN001-Dx (^{99m}Tc-PSMA) in correlation with tumor burden and its implications for theranostic use

S. Martlbauer[1], *E. Mamlins*[1], *E. Novruzov*[1], *K. Mattes-György*[1], *Y. Mori*[1], *E. Winter*[2], *J. Cardinale*[1], *U. Haberkorn*[2], *C. Kratochwil*[2], *F. L. Giesel*[1];
[1]*Department of Nuclear Medicine, Medical Faculty and University Hospital Dusseldorf, Heinrich-Heine-University Dusseldorf, Dusseldorf, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: RHN001(formerly referred to by these authors as PSMA-GCK01) is a newly developed theranostic platform which can be labelled by both ^{99m}Tc- and ^{188}Re. This unique feature, in contrast to other PSMA-SPECT tracers, might aid in prostate cancer management via multiple ways such as in staging work-up of high-risk patients, phenotyping prior to PSMA-RLT, and implementation to PSMA-RLT guidelines alongside [^{177}Lu]Lu-PSMA-617 and is currently subject of early prospective clinical trial. The feasibility studies of ^{99m}Tc-labelled RHN001-Dx based upon planar scintigraphy scans revealed comparable tumor uptake and biodistribution pattern with its counterparts, albeit a mildly decreased rate of renal clearance in favor of hepatobiliary excretion was observed in contrast to its counterparts. Thus, this study aimed to investigate detailed tracer biodistribution via SPECT/CT imaging and the specific impact of tumor burden on biodistribution profile. ***Materials and Methods:*** A total of 60 patients with advanced prostate cancer were enrolled retrospectively, who underwent planar scintigraphy scan and SPECT/CT imaging with RHN001-Dx for PSMA-phenotyping. Spherical regions of interest (ROIs) by a dedicated software package were then placed in body organs as well as representative malignant lesions of three lymph node and bone metastases in each patient to identify the specific tracer uptake ratio. Tracer uptake in planar images were assessed by calculation of geometric means from anterior and posterior views for the ROI. We further stratified our cohort into two groups with oligometastatic and diffuse metastatic spread resulting with accordingly significantly varying levels of tumor burden. ***Results:*** The assessment on planar images revealed the highest average tracer uptake in liver (0,21 $Counts_{mean}$/MBq) followed by kidneys (0,13 $Counts_{mean}$/MBq), salivary glands (0,13 $Counts_{mean}$/MBq) and spleen (0,09 $Counts_{mean}$/MBq). On SPECT/CT images, kidneys exhibited the highest uptake (0,30 $Counts_{mean}$/MBq) followed by salivary glands (0,25 $Counts_{mean}$/MBq), liver (0,20 $Counts_{mean}$/MBq) and spleen (0,20 $Counts_{mean}$/MBq). Notably, we observed a shift in tracer uptake pattern with increasing tumor burden in analysis of subgroups, as kidneys (0,28 vs 0,32, $p \leq 0,05$) and salivary glands (0,18 vs 0,21, $p \leq 0,05$) showed substantially lower uptake in the subgroup with higher tumor burden. The results of detailed biodistribution profile confirmed a substantial hepatobiliary excretion pathway. ***Conclusion:*** Notably, increasing tumor burden has been shown to correlate negatively with RHN001-Dx uptake in major organs which is described as tumor-sink-effect. In conclusion, our results suggest a favorable biodistribution profile of RHN001-Dx for future theranostic applications.

Conversion of ^{18}F to ^{3}H-based autoradiography for PET tracer quantification

A. Van Eetveldt[1], *F. Elvas*[1], *L. Liu*[2], *J. A. Bard*[2], *D. Bertoglio*[1], *S. Staelens*[1];
[1]*University of Antwerp, Wilrijk, BELGIUM,* [2]*CHDI foundation, Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: In vitro autoradiography (ARG) is widely used for characterizing newly synthesized PET tracers in terms of affinity and selectivity. This technique offers less bias compared to in vivo imaging while providing significantly higher image resolution, making it an ideal method for validating in vivo imaging and assessing tracer tissue distribution. Nowadays, most clinical candidate PET tracers are labelled with ^{18}F; however, a tritiated analogue is not always available for autoradiography. If quantification is needed alongside visual validation, challenges will arise given the discrepancy in units between ^{18}F (fmol/µl, liquid homemade standard) and in ^{3}H (fmol/mg, commercially available tissue standard), which renders a comparison of various candidates with different radionuclides extremely challenging. Therefore, we developed a quantification method for ^{18}F ARG similar to ^{3}H ARG. ***Materials and Methods:*** Knowing the concentration and weight of each square in a commercial ^{3}H standard allowed us to calculate true kBq concentration per square and to decay these values to a predefined exposure date and time. These decayed ^{3}H values (range 0,02-76 kBq) were used to calculate an ^{18}F standard (range 0.04-144 kBq) matching the same range for that time slot. 2µl of each ^{18}F dilution was spotted on a TLC plate to make the standard. Gamma counter readings of ^{18}F dilutions were compared to our ^{3}H values. Since we observed a strong correlation between ^{18}F and ^{3}H standards, we could interpolate the values to create a new ^{18}F ^{3}H-converted standard, which we validated on mouse brain sections using SynVestT-1, a synaptic density marker, with both an ^{18}F and ^{3}H radioligand. ***Results:*** For both ^{3}H and ^{18}F, a standard curve was made (^{3}H/^{18}F: $r^2 = 0.99$). ROI analysis revealed a good correlation between grey values of both standards (Pearson r = 0.99; Y = 1.052X-13265). This equation allowed interpolation of ^{18}F grey values into ^{3}H equivalents, creating a new standard curve for ^{18}F in fmol/mg. Sections incubated with [^{18}F] and [^{3}H]SynVesT-1 and exposed with respective standards showed a strong agreement (Pearson r = 0.98; Y = 1.283X-17219). By interpolating the values, we were able to compare the 2 radionuclides. ***Conclusion:*** We have developed a new method, where fmol/mg values, used for ^{18}F ARG, were highly correlated with ^{3}H on the same animal sections. We have validated this method in an independent tracer study with SynvesT-1. This allows the evaluation of PET biomarkers through ARG for which no tritiated ligand is available.

EP-0002

Evaluation of purinergic P2X7 receptor level in Alzheimer's disease patients

R. Ni[1], *C. Maschio*[1], *O. Moreno*[2], *J. Wang*[3], *U. Maheshwari*[4], *A. Keller*[4], *A. Rominger*[3], *U. Konietzko*[1], *A. Nordberg*[5], *D. Razansky*[1], *C. Hock*[1], *J. Llop*[2], *R. Nitsch*[1];
[1]*University of Zurich, Zurich, SWITZERLAND,* [2]*CIC biomaGUNE, San Sebastián, SPAIN,* [3]*Inselspital, Bern, SWITZERLAND,* [4]*University Hospital Zurich, Zurich, SWITZERLAND,* [5]*Karolinska Institutet, Stockholm, SWEDEN.*

Aim/Introduction: The purinergic 2X7 receptor (P2X7R) plays an important role in Alzheimer's disease (AD). We aimed to characterize the alterations in P2X7R and astrocyte marker glial fibrillary acidic protein (GFAP) expression in AD patients, as well as their associations with amyloid-β (Aβ) and tau pathology. ***Materials and Methods:*** We included tissue samples from 43 AD patients and 34 nondemented controls (NCs); P2X7R and GFAP staining and quantitative analysis of the associations with Aβ and tau, and location of P2X7R on astrocytes and microglia were performed on postmortem hippocampal and entorhinal tissues from AD and NCs, caudate/putamen tissue from corticobasal degeneration (CBD) patients; progressive supranuclear palsy (PSP) patients; and bran tissue from 3×Tg AD mice. We further assessed in vitro autoradiography using P2X7R-specific [^{18}F]JNJ-64413739 radiotracer in the brain tissue from AD and NCs. ***Results:*** Reactive astrocytes were observed in the hippocampi of AD patients and exhibited altered morphology with denser cells and pronounced ramifications. Hippocampal and entorhinal GFAP coverage and P2X7R intensity were greater in the hippocampal subfields, including the entorhinal cortex, of AD patients than in those of NCs. P2X7R was positively correlated with Aβ and tau levels and with the Braak stage. P2X7R expression was increased around cored Aβ plaques, tau inclusions in AD brains and tau inclusions in CBD and PSP brains. P2X7R was expressed mainly on astrocytes in the hippocampus, with limited colocalization with microglia. ***Conclusion:*** We found increased hippocampal and entorhinal GFAP coverage and P2X7R levels in AD patients compared with NCs, which was correlated with amyloid and tau pathologies. P2X7R is a potential marker for neuroinflammation in AD.

EP-0003

First Steps Towards Developing a Dual-Targeted Radionuclide Theranostic Strategy Combining PSMA- and GRPR-Targeting radiopharmaceuticals for Prostate Cancer Management.

L. Bokhout, *J. de Swart, S. U. Dalm;*
Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Prostate specific membrane antigen (PSMA) targeted radionuclide theranostics (TRT) is successfully applied for prostate cancer (PCa) management. However, results are sub-optimal; complete cure is rare and only a significant number of patients show disease progression despite treatment. Next to PSMA, studies are evaluating gastrin releasing peptide receptor (GRPR)-targeting radiopharmaceuticals (e.g. NeoB), for PCa-TRT. Despite lower and more heterogeneous GRPR expression, studies report that PCa tumour regions/lesions without PSMA expression do express GRPR. Thus, targeting both PSMA and GRPR can be beneficial. Moreover, labelling radiopharmaceuticals with complementary radionuclides can further enhance such dual-TRT. On route to developing this dual-targeted theranostic strategy, we established a method for accurate γ-ray spectra detection of individual radioisotopes in mixtures of indium-111, terbium-161 or lutetium-177, which was subsequently used to determine the potential effect of GRPR-targeting on PSMA-radiopharmaceutical uptake and vice versa. ***Materials and Methods:*** The γ-ray spectra of varying activities (0,001-500kBq) of (mixtures of) indium-111, terbium-161 and lutetium-177 were measured using a HIDEX-AMG γ-counter to select measuring windows (i.e 370-470keV, 20-35/41-61/68-83keV and 56-72/102-124/187-229keV, respectively) for dual-radioisotope sample measurements. Different methods to limit/correct for crosstalk in dual-radioisotope samples were tested. Uptake of PSMA-I&T and NeoB, labelled with indium-111, terbium-161 or lutetium-177, was determined in a GRPR-/PSMA-expressing human PCa cell line PC3-PIP. Cells were incubated with 1nM radiolabelled PSMA-I&T (20MBq/1nmol/140uL) and/or 1nM radiolabelled NeoB (20MBq/1nmol/140uL; +/- pre-treatment

with unlabelled NeoB/PSMA-I&T) separately, consecutively and simultaneously. Uptake was expressed as percentage added dose (%AD). ***Results:*** Negligible crosstalk of terbium-161 was observed, but due to overlapping spectra, severe crosstalk of indium-111 and limited crosstalk of lutetium-177 was detected in the selected measuring windows. In literature described crosstalk correction methods were insufficiently accurate for our experiments, but in silico experiments showed that adapting the ratio of indium-111 and lutetium-177 in dual radioisotope samples limits crosstalk interference. Incubation of PC3-PIP cells with (radiolabelled) PSMA-I&T does not influence the uptake of radiolabelled NeoB compared to mono-incubation (4,7 vs. 4,6%AD), and vice versa (19,4 vs. 21,2%AD). ***Conclusion:*** We accurately measured individual radioisotopes in dual radioisotope samples by selecting specific energy windows and activity ratios, herewith limiting crosstalk interference. Future studies will include further validation of the radioisotope ratios identified in silico and the effect of dual-targeting on PSMA- and GRPR-radiopharmaceutical uptake. Additionally, the therapeutic effect of combined PSMA/GRPR-TRT will be assessed, with the ultimate aim to develop an effective dual-targeted theranostic strategy for PCa.

EP-0004

Enhanced Glioblastoma Targeting and Therapeutic Efficacy with ^{64}Cu-NOTA-TP-c(RGDfK)

A. Mirzaei, *S. Samia Ait-Mohand, P. Mercy Ignatius, É. Rousseau, B. Guérin;*
Department of Medical Imaging and Radiation Sciences, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: Glioblastoma multiforme (GBM) is a highly aggressive brain tumor with poor prognosis and limited treatment options. Integrin alpha-v beta-3 (αvβ3), which is overexpressed in GBM cells and binds specifically to the arginine-glycine-aspartate (RGD) sequence in extracellular matrix proteins, presents a promising molecular target. We hypothesize that a novel radiotheranostic agent combining radioactive copper-64 (^{64}Cu), 1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA)-terpyridine platinum (TP), and cyclic arginine-glycine-aspartate-D-phenylalanine-lysine (c(RGDfK)) peptide—^{64}Cu-NOTA-TP-c(RGDfK)—will improve targeting and therapeutic efficacy in GBM. Our objective was to assess this agent's in vitro performance in comparison with ^{64}Cu-NOTA-c(RGDfK), ^{64}Cu-NOTA-TP, non-radioactive copper (^{nat}Cu)-NOTA-TP-c(RGDfK), cisplatin, and temozolomide (TMZ). ***Materials and Methods:*** A robust protocol was developed for the preparation of NOTA-TP-c(RGDfK). The inhibitory concentration 50 (IC_{50}) values of ^{nat}Cu-NOTA-c(RGDfK) and ^{nat}Cu-NOTA-TP-c(RGDfK) were determined in human U87 MG GBM cells through competition assays with ^{64}Cu-NOTA-c(RGDfK). Cellular uptake, internalization, and efflux of ^{64}Cu-NOTA-TP-c(RGDfK) and ^{64}Cu-NOTA-c(RGDfK) and ^{64}Cu-NOTA-TP were evaluated in U87 MG and SVG p12 normal astrocyte cells from 1 to 48 hours. Cytotoxicity studies of ^{64}Cu-NOTA-TP-c(RGDfK), ^{64}Cu-NOTA-c(RGDfK), ^{64}Cu-NOTA-TP, ^{nat}Cu-NOTA-TP-c(RGDfK), TMZ, and cisplatin were conducted in both cell lines at 24 and 48 and 72 hours. ***Results:*** NOTA-TP-c(RGDfK) was synthesized with 2-3% yield and radiolabeled with >99% radiochemical purity. The IC_{50}values for ^{nat}Cu-NOTA-c(RGDfK) and ^{nat}Cu-NOTA-TP-c(RGDfK) were 10 ± 2 nM and 16 ± 8 nM respectively, indicating strong affinity for integrin αvβ3-expressing U87 MG cells. At 24 hours, ^{64}Cu-NOTA-TP-c(RGDfK) showed highest uptake in U87 MG cells (38.8 ± 1.8%), surpassing ^{64}Cu-NOTA-TP (30.4 ± 5.5%) and ^{64}Cu-NOTA-c(RGDfK) (14.1 ± 1.0). Internalization followed a similar trend, with ^{64}Cu-NOTA-TP-c(RGDfK) reaching 28.0 ± 1.0% at 24 hours, compared to 18.4 ± 0.8% and 11.4 ± 0.6%, respectively. ^{64}Cu-NOTA-TP-c(RGDfK) retained 51.4 ± 2.1% of its intracellular radioactivity in U87 MG cells, demonstrating stable intracellular retention comparable to ^{64}Cu-NOTA-TP (53.2 ± 3.4%) and slightly lower than ^{64}Cu-NOTA-c(RGDfK) (67.6 ± 2.2%) after 24 hours. All compounds exhibited minimal uptake in SVG p12 cells. Subcellular localization studies revealed nuclear accumulation of ^{64}Cu-NOTA-TP-c(RGDfK) in U87 MG cells (6.0 ± 0.5% at 24 h), supporting potential DNA damage via low-energy electrons from ^{64}Cu decay. ^{64}Cu-NOTA-TP-c(RGDfK) had the lowest IC_{50} (10 ± 2 nM at 48 h) and outperformed all other tested compounds. While ^{64}Cu-NOTA-c(RGDfK) was less potent in U87 MG cells, it showed the lowest toxicity in SVG p12 cells at both 24 and 48 hours. ***Conclusion:*** These findings establish ^{64}Cu-NOTA-TP-c(RGDfK) as a promising integrin αvβ3-targeted agent for effective GBM radiotherapy.

EP-0005

Novel Dynamic Cardiac Phantom for Comparison of Cardiac Volumes and LVEF Between CZT-ERNA and PET-MPI

M. Nielsen[1,2], *R. Wozniak*[1], *T. C. Hansen*[1], *L. L. Duchstein*[1], *J. D. Hermansen*[3], *S. Hvidsten*[4], *L. T. Jensen*[1,2], *B. Zerahn*[1];
[1]*Dept. of Nuclear Medicine, Copenhagen University Hospital – Herlev and Gentofte, Herlev, DENMARK,* [2]*Dept. of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK,* [3]*Medical Technology Dept., Køge Hospital, Køge, DENMARK,* [4]*Dept. of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: Accurate assessment of left ventricular ejection fraction (LVEF) and cardiac volumes is essential, particularly in patients at risk of cardiotoxicity during cancer therapy. While equilibrium radionuclide angiography (ERNA) is used to monitor LVEF, myocardial perfusion imaging (MPI) is primarily intended for assessing perfusion. Nonetheless, comparing LVEF and volume estimates across modalities could elucidate whether MPI data might support functional evaluation too. To our knowledge, no existing beating-heart phantom allows direct comparison between blood-pool and perfusion-based techniques. We therefore developed and tested a novel cardiac phantom designed specifically to enable such cross-modality validation. ***Materials and Methods:*** A custom-built cardiac phantom was developed using a dual-lumen balloon setup, with the inner lumen representing the left ventricular cavity and the outer the myocardium. Stroke volume and frequency was controlled with a piston-driven mechanism, and ECG gating enabled via a motion-triggered signal generation. Imaging was performed using cadmium-zinc-telluride (CZT)-ERNA and gated PET-MPI. Image processing and analyzes was carried out on two different types of software. Scans were repeated with and without a thorax phantom to assess attenuation effects. CT-scans were used as a static reference for end-diastolic volume (EDV), end-systolic volume (ESV), and LVEF comparisons. 3 series were conducted with PET-MPI measurements on the first day and CZT-ERNA measurements on the second day after tracer decay. ***Results:*** PET-MPI progressively underestimated volumes in static acquisitions, while CZT-ERNA overestimated them. In gated acquisitions, both modalities underestimated LVEF, with a larger deviation seen in PET-derived values.Attenuation correction (AC) in PET yielded consistent volumes regardless of thorax phantom presence. In contrast, CZT-ERNA, which lacks AC in our setup, showed varying results.In series 1-2, proximity between the inner and outer balloons created a pseudo-defect, leading to underestimation of LV volumes on PET-MPI. This issue was resolved in series 3, aligning results more closely with the CT reference. ***Conclusion:*** Attenuation correction in PET functioned as expected, while its absence in CZT-ERNA may introduce patient size-dependent bias. Additionally, regionally reduced tracer uptake - simulated by balloon proximity - led to volume underestimation, highlighting a potential volumetric pitfall in patients with myocardial scar tissue

undergoing MPI. Our phantom offers a unique platform for direct modality comparison and in future work we aim to simulate basal plane motion to improve comparability with clinical results.

EP-0007

Radiolabelled alginate nanoparticles - developing a peptide targeting radiotherapeutic approach to cancer treatment

M. Dornish[1], *J. Dahle*[2], *S. Al-Haidar*[3], *K. H. Ferning*[3];
[1]*Blue Wave Therapeutics AS, Sandvika, NORWAY,* [2]*Department of Oncology Akershus University Hospital, Nordbyhagen, NORWAY,* [3]*Minerva Imaging ApS, Ølstykke, DENMARK.*

Aim/Introduction: Alginate, a natural biopolymer found in seaweed and kelp, has chelating properties suitable for harnessing radionuclides. Additionally, this biopolymer can be conjugated with peptides that provide targeting capabilities. It is also capable of being processed into nanoparticles, resulting in a formulation that is usable in the body. This study demonstrates that RGD-alginate specifically binds to glioblastoma cells expressing αvβ3 integrin and RGD-alginate nanoparticles stably chelate the alpha-emitting radionuclide actinium-225 (^{225}Ac) and its decay daughters. ***Materials and Methods:*** Calcium alginate nanoparticles were made by bead milling. The spherical nanoparticles were approximately 100 nm in diameter. The particles were subsequently functionalized by conjugation of the RGD peptide using EDC/NHS chemistry. Nanoparticles were incubated with ^{225}Ac chloride in secular equilibrium with daughters for 1 hour at room temperature. Radioactivity associated with calcium alginate nanoparticles were determined by a gamma counter. Energy windows were set to identify francium-221 and bismuth-213 gamma peaks of 218 and 440 keV, respectively. Fluorescence microscopy and flow cytometry were performed using U-87 MG human glioblastoma cells incubated with different fluorescently labelled RGD peptides: linear (GRGDSP) labeled with fluorescein isothiocyanate (FITC), or cyclic RGD (c(RGDfK)) labelled with CyAL-5; or RGD-alginate fluorescently labelled with FITC (FITC-RGD-alginate). ***Results:*** Fluorescent microscopy images show FITC-RGD-alginate staining of U-87 MG glioblastoma cells, which was confirmed by flow cytometry. The fluorescently labelled peptides GRGDSP and c(RGDfK) also bound to cells, while the negative control, FITC-alginate (without the RGD recognition sequence), did not. The chelation of radionuclides by alginate nanoparticles was demonstrated using ^{225}Ac. More than 95% of the radioactivity from ^{225}Ac and daughters were associated with the nanoparticles at all time points. In addition to ^{225}Ac, we have shown that alginate nanoparticles can also chelate radium-223 and its decay daughters. ***Conclusion:*** The 100 nm size of the nanoparticles allows diffusion into tissue. Alginate nanoparticles can stably chelate ^{225}Ac and decay daughters for over 30 days, indicating that the biopolymer particle can absorb recoil energy arising from α-particle emission. This innovation based on alginate nanoparticles outperforms current radionuclide chelators, which fail to retain decay daughters, and helps protect healthy tissue by preventing the escape of radionuclides from the chelator after the initial α-particle emission. ^{225}Ac labelled RGD-alginate nanoparticles are now undergoing preclinical testing in a rodent model of glioblastoma. Supported by grant 346303 ALPHAGLIO from the Research Council of Norway.

EP-0008

The effectiveness of targeted lead-212 alpha therapy and EBRT in neuroendocrine spheroids

K. Grayson[1], *P. M. D. Gape*[1], *M. Patel*[1], *M. Riiabova*[1], *L. Wagner*[2], *M. K. Schultz*[3], *G. Stasiuk*[1], *S. Y. A. Terry*[1];
[1]*King's College London, London, UNITED KINGDOM,* [2]*DKFZ German Cancer Research Center, Heidelberg, GERMANY,* [3]*Perspective Therapeutics, Coralville, IA, UNITED STATES OF AMERICA.*

Aim/Introduction: The treatment landscape for neuroendocrine tumours (NETs) has remained relatively unchanged, particularly in the case of targeted radionuclide therapies (TRT), which has focused primarily on Lutetium-177 (Lu-177) conjugated to somatostatin receptor (SSTR) targeting ligands. Targeted α-particle therapy (TAT), using radionuclides such as lead-212 (Pb-212), have shown promise in cancer treatment. Although 2D cultures are widely used in research, they poorly reflect tumour structure and microenvironments, limiting their suitability for evaluating new therapies. Here, we developed a panel of 3D NET models and used them to evaluate responses to a Pb-212-labelled SSTR2 targeting compound. Results were compared spheroids treated with benchmark external beam X-ray radiotherapy (EBRT). ***Materials and Methods:*** Spheroids were generated for BON-1 (wild type or expressing SSTR2) and QGP-1 cells using agarose-coated 96-well plates. 3D cultures were exposed to EBRT (between 0-8 Gy) or treated for 1, 24 or 72 hours with Pb-212-PSC-PEG$_2$-TOC (100 kBq/mL, Perspective Therapeutics, USA). Spheroids were also treated with unlabelled PSC-PEG$_2$-TOC or Pb-212. Treatments were evaluated by measuring spheroid growth, including the examination of structural changes, using microscopy to calculate spheroid area and diameter between 1 hour and 10 days post-treatment. Spheroid viability was examined using the CellTiter-Glo® 3D Cell Viability Assay and compared to results obtained from MTS assays on 2D cultures. ***Results:*** Preliminary data shows targeted Pb-212 treatment inhibited the growth of NET spheroids, with microscopic analysis revealing disruption of spheroid architecture. At 7 days post-treatment with Pb-212- PSC-PEG$_2$-TOC BON-1 spheroids expressing SSTR2 showed significant growth inhibition in comparison to the unlabelled PSC-PEG$_2$-TOC control ($p = 0.05$, % decrease = 39.94±10.4%), whilst wild type BON-1 spheroids showed no significant changes. At 10 days post treatment, significant changes in spheroid eccentricity were found following 1 hour, 24 hour and 72 hour incubations with PSC-PEG$_2$-TOC ($p = 0.05$), with increased deviation from a parabola trending with increased treatment time.Comparison between 2D and 3D models revealed that spheroids were significantly more resistant to treatment. In 2D cultures, BON-1 cells expressing SSTR2 following 4 Gy EBRT showed a significant decrease in metabolic activity ($p < 0.0001$) whilst no reduction was observed in the 3D model ($p = 0.1003$). ***Conclusion:*** This study highlights distinct responses of 2D and 3D models, both to EBRT and TAT, and further confirms that NET models of different origins have varied treatment responses. Finally, Pb-212-PSC-PEG$_2$-TOC proved effective at disrupting NET spheroids growth and inducing morphological changes.

EP-0009

Preclinical Evaluation of NK-1R-Targeting Molecule in Epithelial Cancer Cell Lines.

T. Xu[1], *S. Chopra*[1], *U. Yngve*[2,3], *Z. Wang*[1], *H. Yushchyshyna*[1], *P. Jha*[1], *U. Rosenström*[2], *M. Nestor*[1];
[1]*Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN,* [2]*Department of Medicinal Chemistry, Preparative Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [3]*Science for Life Laboratory (SciLifeLab), Drug Discovery and Development platform, Uppsala, SWEDEN.*

Aim/Introduction: The overexpression of the neurokinin-1 receptor (NK-1R) has been found to promote tumorigenic processes such as cell migration, proliferation, and invasion. Its overexpression in various epithelial cancers renders it a promising target for molecular imaging and therapy. Aprepitant is an NK-1R antagonist with anti-tumor effects by inducing apoptosis and suppressing metastasis in preclinical studies. A novel NK-1R antagonist, PN622, is structurally similar to aprepitant and has demonstrated a higher affinity for NK-1R than the NK-1R natural ligand substance P (SP). This study aimed to evaluate the potential of the NK-1R-targeting molecule PN622 as a theranostic agent by assessing its anti-proliferation effect, binding specificity, cellular processing, internalization, binding affinity, and retention in various epithelial cancer cell lines. ***Materials and Methods:*** The anti-proliferation effect of the NK-1R-targeting molecule PN622 was compared with that of aprepitant in NK-1R-

overexpressing cell lines, including Panc-1 (pancreatic), OVCAR3 (ovarian), MDA-MB-468, MDA-MB-231 and T47D (breast). The PN622 was radiolabeled with iodine-125 and purified using high-performance liquid chromatography (HPLC). In vitro specificity of the radiolabeled PN622 was evaluated by pre-blocking the NK-1R receptor with an excess of non-labeled PN622 or aprepitant. Cellular processing and internalization were analyzed by incubating cells with the radioligand at 37°C, followed by an acid wash to distinguish membrane-bound from internalized fractions at pre-determined time points. The interaction was measured in real-time in living cells using the LigandTracer instrument, and affinity (K_D value) was determined. Retention studies assessed the time-dependent cell-associated radioactivity over 24 hours. ***Results:*** The PN622 demonstrated a dose-dependent effect on proliferation inhibition. The [^{125}I]I-PN622 showed high specificity, with statistically significant ($p < 0.05$) reduced binding following self-blocking or aprepitant blocking, confirming NK1R-mediated uptake. Cellular processing studies showed that cell-associated radioactivity increased over time. A slow internalization was observed, with less than 15% of bound activity internalized after 24 hours. The affinity measurement yielded a picomolar K_D value, indicating strong receptor interaction. It also demonstrated a non-one-to-one interaction. Retention studies demonstrated sustained membrane-bound radioactivity, with more than 30% remaining after 24 hours, indicating favorable tumor retention. ***Conclusion:*** The PN622 exhibits a proliferation inhibition effect in NK-1R overexpressing cancer cells. The [^{125}I]I-PN622 shows high binding specificity, slow internalization, strong affinity, and prolonged retention in epithelial cancer cells, supporting its potential as a diagnostic agent for NK-1R-expressing tumors. Additional in vivo studies are needed to validate the targeting efficacy using [^{123}I]I-PN622 (SPECT) and [^{124}I]I-PN622 (PET) for diagnosis while employing [^{131}I]I-PN622 for therapy.

EP-0010

Exploring [^{18}F]FAPI-74 as a diagnostic tool in vulvar cancer: in vitro evaluation and preliminary results

Aim/Introduction: Positron emission tomography (PET) imaging using fibroblast activation protein inhibitors (FAPI) has recently demonstrated promising results in the staging and restaging of gynaecological malignancies [1]. So far, no studies have explored FAP expression in vulvar cancer. In this clinical setting, FAPI-based PET imaging may offer potential advantages over conventional [^{18}F]FDG-PET, particularly for nodal staging where [^{18}F]FDG often yields high false-positive rates [2]. This in vitro study aims to evaluate and quantify FAP expression in invasive vulvar squamous cell carcinoma (VSCC) specimens by autoradiography using [^{18}F]FAPI-74. ***Materials and Methods:*** Between November 2021 and December 2025, a total of 90 consecutive VSCC tissue specimens, including samples from primary tumours and metastatic lymph nodes, from newly diagnosed patients undergoing surgery at Fondazione Policlinico Universitario A. Gemelli IRCCS will be collected and preserved in both optimal cutting temperature compound and formalin-fixed paraffin-embedded (FFPE). Immunohistochemical staining using anti-FAPα antibody [SP325] (Abcam Ltd.) will be performed on FFPE sections to serve as reference standard. Staining intensity will be scored on a scale of 0-3 (0=no stain, 1=low, 2=medium, 3=high) [3]. For autoradiographic analysis, VSCC tissue sections will be incubated with high-specific activity [^{18}F]FAPI-74, or a non-radioactive analogue as control, washed to remove unbound tracer, and exposed to the phosphor imager screen. [^{18}F]FAPI-74 will be employed to evaluate FAP expression and distribution within the specimens, as well as to quantify FAPI binding and binding affinity. ***Results:*** Preliminary immunohistochemical analysis was conducted on primary tumour samples from 36 patients. FAP expression in peritumoral stromal cells was detected in 33 specimens, with a mean percentage of FAP positive stromal cells of 36.4% ± 27.3% and average FAP staining intensity score of 1.6 ± 0.6. Three specimens lacked identifiable stromal cells. Additionally, FAP expression was detected in the epithelial tumour cells of four specimens. ***Conclusion:*** Our preliminary results indicate that peritumoral stromal cells associated with VSCC consistently express FAP on their surface, supporting the rationale for autoradiographic analysis using [^{18}F]FAPI-74. These results encourage further investigation into the potential [^{18}F]FAPI-74 PET/CT as both a diagnostic tool and a prognostic biomarker in vulvar cancer. ***References:*** [1] Florit et al. EP-0011

Is radiolabelling a PARP inhibitor with a radiometal via a DOTA chelator a viable strategy for PARP-targeted radionuclide therapy (TRT)?

A. Kurniawan[1], *Z. Ming*[1], *M. Boëtius*[2], *W. Szymanski*[2], *S. Blok*[1], *P. Elsinga*[1], *I. Antunes*[1], *E. de Vries*[1], *B. Cornelissen*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS,* [2]*Department of Medicinal Chemistry, Photopharmacology and Imaging, Groningen Research Institute of Pharmacy, Faculty of Science and Engineering, University of Groningen (RUG), Groningen, NETHERLANDS.*

Aim/Introduction: Radiopharmaceuticals targeting poly (ADP-ribose) polymerase (PARP) are promising candidates for targeted radionuclide therapy (TRT) to treat PARP-expressing cancers. Here, we evaluated the potential of a PARP inhibitor (PARPi) based on an olaparib-like structure, labelled with ^{161}Tb or ^{68}Ga for TRT and PET imaging, respectively, using in vitro cancer models. ***Materials and Methods:*** [^{161}Tb]$TbCl_3$ or [^{68}Ga]$GaCl_3$ were used for radiolabelling a DOTA-chelated derivate of the PARP inhibitor olaparib, yielding [^{161}Tb]Tb-DOTA-olaparib or [^{68}Ga]Ga-DOTA-olaparib. Non-radiolabelled (cold) versions were produced using natural Ga and Tb chloride salts. Both radiolabelled compounds were evaluated in vitro for cell uptake, internalisation, specific binding, and effect on clonogenic survival across a panel of PARP-expressing human (U87MG, PSN-1) and murine (4T1, CT26) cancer cell lines, providing a robust assessment of their targeting and therapeutic potential. ***Results:*** The [^{161}Tb]Tb-DOTA-olaparib and [^{68}Ga]Ga-DOTA-olaparib were successfully radiolabelled with radiochemical

yields (RCY) exceeding 95%, at molar activities of up to 40 and 20 MBq/nmol, respectively. The total cellular uptake of [^{161}Tb]Tb-DOTA-olaparib was minimal across all cancer cell lines, including PSN-1 (0.185±0.09 mBq/cell), U87MG (0.127±0.036 mBq/cell), 4T1 (0.093±0.015 mBq/cell), and CT26 (0.056±0.004 mBq/cell). Internalisation studies revealed that the majority of the uptake was associated with the membrane-bound fraction, with values for U87MG (0.110 ± 0.012 mBq/cell), 4T1 (0.621 ± 0.118 mBq/cell), and CT26 (0.641 ± 0.088 mBq/cell), and negligible cell internalised fraction (<0.030 mBq/cell). A comparable uptake profile was observed for [^{68}Ga]Ga-DOTA-olaparib, showing predominant membrane association and minimal intracellular accumulation. Neither uptake nor internalisation could be blocked using an excess of PARP-specific competitor ligands, which verifies no PARP-specific binding of the compounds (p>0.05). Log D measurement for [^{161}Tb]Tb-DOTA-olaparib showed a value of -3.68±0.03, more hydrophilic even than for [^{68}Ga]Ga-DOTA-olaparib (-2.56±0.026). This hydrophilicity likely contributes to their limited ability to traverse cell membranes, restricting intracellular access through passive diffusion. Clonogenic survival was not significantly different between [^{161}Tb]Tb-DOTA-olaparib and $^{161}TbCl_3$ (p=0.42). ***Conclusion:*** In conclusion, [^{161}Tb]Tb-DOTA-olaparib and [^{68}Ga]Ga-DOTA-olaparib exhibit negligible cellular uptake and insufficient specific binding to nuclear PARP in cancer cells. Their limited ability to penetrate the cell membrane and interact with intracellular targets makes them, in our hands, unsuitable for effective PARP-targeted therapy or imaging applications.

EP-0012

DNA damage in thyroid cancer patients treated with radioactive iodine

S. Kagodora, *M. Vangu;*
University of Witwatersrand, Johannesburg, SOUTH AFRICA.

Aim/Introduction: Thyroid cancer is the most common endocrine cancer globally. The National Cancer Registry has estimated the prevalence of the disease to be higher in females than in the male population with a risk of 1 in 506 females and 1 in 1035 in males in South Africa. Thyroid cancer includes the use of radioactive iodine (RAI) depending on risk category. The aim of this study was to investigate the correlation between 131 iodine RAI emitted ionizing radiation and the induced and persistent DNA damage in patients treated with radioactive iodine. ***Materials and Methods:*** This prospective study was done at a tertiary academic hospital in Johannesburg. Thyroid cancer patients were invited to enrol and participate in the study in line with the Helsinki Declaration on studies in human subjects. Informed consent was obtained from all participants prior to their inclusion in the study. Blood samples of 34 thyroid cancer patients, treated with radioiodine therapy with 131-I RAI was collected. All 34 thyroid cancer participants received I-131 RAI therapy, with doses ranging from 1110 to 7400 MBq (30 to 200 mCi). Blood samples were collected in 4ml lithium-heparin tubes at four key time points: upon admission for radiotherapy, at discharge (3-5 days post-therapy), and at 3 and 6 months after treatment. The chromosomal damage in the lymphocytes of these patients was determined by the cytokinesis-blocked micronucleus (MN) assay. ***Results:*** The amount of DNA damage was increased after treatment up to 3 months and decreased slightly at 6 months. The median dose of ^{131}I for thyroid cancer participants was 5550MBq (150mCi), with interquartile range(IQR) of 3700-7400MBq (100-200mCi). The number of ^{131}I induced MN increased with the amount of RAI therapy. There was a highly significant difference in the mean number of micronuclei in thyroid cancer participants between admission (25.31) and discharge (52.04) (p-value <0.0001). A significant difference in mean MN was also noted between 3 months (46.47) and 6 months post-treatment (30.89), (p=0.0385). ***Conclusion:*** These preliminary results suggest that 131I therapy may pose a long-term challenge to the lymphocytes and that a sensitivity may persist. The findings emphasize the need for ongoing monitoring of chromosomal damage in thyroid cancer patients who are subject to multiple RAI therapies to understand the long-term implications of radioactive iodine therapy.

EP-0013

In vitro evaluation of [^{18}F]SYN2 effect on mouse myoblast and human cardiomyocyte cell lines.

K. Gotowicz[1,2], *K. Archacka*[3], *A. Ostaszewska*[3], *M. Zimowska*[3], *S. Krajewski*[1], *J. Włostowska*[1], *C. Kozanecki*[1];
[1]*Synektik S.A. Research and Development Center, Warsaw, POLAND,*
[2]*University of Warsaw, Faculty of Chemistry, Warsaw, POLAND,*
[3]*University of Warsaw, Faculty of Biology, Warsaw, POLAND.*

Aim/Introduction: [^{18}F]SYN2 is a positron emission tomography (PET) tracer in phase III clinical trial, designed for a non-invasive myocardial perfusion imaging (MPI). The aim of the study was to evaluate the tracer effect on mouse myoblast and human cardiomyocyte cell lines. ***Materials and Methods:*** Mouse myoblast cell line (C2C12, European Collection of Cell Cultures, ECACC no. 91031101, passage no. 13), human cardiomyocyte cell line (AC16, ATCC, CRL-3568). Both cell lines were cultivated in presence of [^{18}F] SYN2 nonradioactive analogue (25-100 nM). For test: MitoTracker Green FM (Thermo Fisher, M7514), Malassez chamber, Trypan Blue (Sigma Aldrich, T8154) were used. All experiments were performed at least thrice, ANOVA and Kruskal-Wallis test were used for statistical analysis. ***Results:*** The localization of the [^{19}F] SYN2 compound coincided with the distribution of mitochondria, as indicated by staining with MitoTracker Green FM. The addition of [^{19}F]SYN2 at any concentration did not significantly impact the morphology of C2C12 cells. Both myoblasts and myotubes in the control and experimental groups exhibited typical morphology. Cardiac tracer did not induce cytotoxicity nor interfere with the differentiation process at concentration <100 mM. The incorporation of [^{19}F]SYN2 into the C2C12 and AC16 cultures had a noticeable effect on proliferation compared to the control group. It was observed that the tracer, at all concentrations, slowed proliferation moderately. The effect was more significant on myoblast cell line. The strongest statistically significant differences were found after 48 and 72 h for the highest concentration of 100 mM tracer. Apoptosis levels in the C2C12 cultures at 48, 72, and 96 hours in proliferation medium were around 10% for all samples. A statistically significant difference was observed at 24 hours for concentrations of 50 nM and 100 nM compared to the control. For AC16 cells, apoptosis levels ranged from 10% to 15% across all samples and time points, with no statistically significant differences compared to the control. ***Conclusion:*** Mitochondrial localization of the tracer was confirmed. The presence of the cardiac tracer in the highest concentration (100 nM) during cell proliferation and differentiation had a noticeable impact on cell behaviour. The progression of the process was slowed down rather than stopped entirely. Apoptosis analysis for C2C12 and AC16 cells revealed no adverse effects of [^{19}F]SYN2 on cell survival. Overall, the data indicates the use of the [^{19}F]SYN2 compound in mouse myoblasts and human cardiomyocytes does not result in negative effects and may indicate cell stability after radiotracer treatment.

EP-0014

Targeting the Tumor Microenvironment via Fibroblast Activation Protein (FAP): A 3D Co-Culture Model for FAP-Targeted Alpha Therapy in Prostate Cancer

S. Kvarsvik Kristiansen[1], *N. Dernjani*[2], *A. Juzeniene*[1];
[1]*Department of Radiation Biology, Institute for Cancer Research, The Norwegian Radium Hospital, Oslo, NORWAY,* [2]*Department of Molecular Biology, Norwegian University of Life Science, Ås, Norway, Oslo, NORWAY.*

Aim/Introduction: Prostate cancer (PCa) is the most common malignancy in men and the second leading cause of cancer-related morbidity and mortality worldwide. Advanced disease remains largely incurable due to resistance and limited durable

treatment options. PSMA-targeted radionuclide therapies (PSMA-TRT) has gained momentum, however, these are not suitable for all patients, particularly those with low or heterogeneous PSMA expression. Targeting the tumor stroma—particularly cancer-associated fibroblasts (CAFs), which support tumor progression and therapy resistance—offers a promising alternative. Fibroblast activation protein (FAP) is a membrane-bound serine protease highly expressed in CAFs, making it a compelling pan-cancer target for TRT. FAP theranostics has shown potential in several cancer types, including PCa. Among various ligands, FAPI-46 offers improved tumor retention, but has a relatively short biological half-life, limiting its effectiveness when paired with long-lived radionuclides such as ^{177}Lu. Lead-212, a beta-emitter decaying to alpha-emitting ^{212}Bi or ^{212}Po, has a shorter half-life more suitable for small-molecule ligands and may provide therapeutic advantages in targeting hypoxic and resistant tumor regions. The main aim of this study was to develop an advanced 3D co-culture spheroid model with FAP-negative prostate cancer cells (22Rv1) and FAP-positive immortalized fibroblasts (F11-hTERT) to assess the therapeutic potential of FAP-targeted alpha therapy (FAP-TAT) using [^{212}Pb]Pb-FAPI-46. ***Materials and Methods:*** Spheroids were generated using the liquid overlay technique in agarose-coated 96-well plates and characterized by brightfield and fluorescence microscopy. FAP expression and radioligand uptake were evaluated in 2D cultures using flow cytometry and binding assays, while cellular senescence was assessed through β-galactosidase staining. Fibroblast spatial localization within spheroids was confirmed using the lipophilic tracer DiO. ***Results:*** F11-hTERT fibroblasts exhibited high FAP expression and radioligand uptake, in contrast to minimal expression and uptake in 22Rv1 cells. [^{212}Pb]Pb-FAPI-46 induced activity- and time-dependent senescence in fibroblasts, but not in cancer cells. In 3D culture models, radioligand treatment significantly reduced spheroid size and increased doubling time, with the most pronounced effect in spheroids enriched with higher numbers of fibroblast. No effect was observed in 22Rv1 monoculture spheroids. ***Conclusion:*** This study highlights the value of stroma-enriched 3D in vitro models for the preclinical evaluation of FAP-TAT, demonstrating the therapeutic potential of [^{212}Pb]Pb-FAPI-46 in treating prostate cancer via stromal targeting. These findings emphasize the broader relevance of targeting stromal components in solid tumors characterized by abundant CAFs, including pancreatic, breast, and gastric cancers. ***References:*** Laudicella R et al. Preliminary findings on the role of FAPi in prostate cancer theranostics. Diagnostics (Basel). 2023;13(6).

EP-0015

Quantitative Analysis of KiSS-1R Cell Surface Expression in Triple-Negative Breast Cancer Using Dye-Conjugated Kisspeptins

L. Kovacs*, H. Taş, U. Bauder-Wüst, M. Schäfer, M. Benesova-Schäfer;*
German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Aim/Introduction: Triple-negative breast cancer (TNBC) is an aggressive and highly metastatic disease. It comprises 15% of breast cancers and remains a significant challenge due to limited therapies available[1]. KiSS-1R is a G protein coupled receptor whose expression is upregulated in certain cancer types, including TNBC. Overexpression of KiSS-1R has been associated to invasion, migration and epithelial-to-mesenchymal transition, all of which are associated with poor prognosis. Although some studies have explored KiSS-1R as a potential target[1], little is known about the level of its expression on the cell membrane, which is critical for the development of targeting agents. The aim of this study is to analyze the cell binding of in-house generated endogenous and synthetic kisspeptins using flow cytometry. This will allow us to determine the potential of KiSS-1R and kisspeptin-based ligands for prospective radiotheranostic applications in TNBC. ***Materials and Methods:*** The endogenous Kisspeptin-10 and synthetic Kisspeptin-34 were synthesized via automated solid-phase peptide synthesis and conjugated with Alexa Fluor-488 (AF-488). For in vitro studies, 1x10^6 CHO-KiSS-1R cells and native TNBC cells were incubated with different concentrations of AF-488-Kisspeptin-10 and AF-488-Kisspeptin-34 for 30, 60, and 120 min at 4 and 37°C. The cells were analyzed on a flow cytometer. ***Results:*** AF-488-conjugated Kisspeptin-10 (AF-488-Tyr-Asn-Trp-Asn-Ser-Phe-Gly-Leu-Arg-Phe-NH_2) and Kisspeptin-34 (AF-488-AMBA-2-Nal-Gly-Leu-Arg-Trp-NH_2) were successfully synthesized at high chemical purity (>95%). Flow cytometry was employed to assess cell surface expression of KiSS-1R, revealing variable expression levels among the cell lines tested. Preliminary results from CHO-KiSS-1R cells treated with 500nM AF-488-kisspeptin-10 demonstrated a significantly higher geometric mean fluorescence intensity (945 ± 35) compared to the unstained control (291 ± 38). Analyses of different incubation times showed no significative difference between 30, 60 and 120-min (968 ± 39 vs 945 ± 35 vs 972 ± 140 respectively) at 4°C, suggesting rapid and stable binding of tested kisspeptins to KiSS-1R. Interestingly, media such as OptiMEM were found to increase fluorescence intensity by 1.8-fold compared to Hank's Balanced Salt Solution, indicating that the choice of medium can influence ligand binding or detection sensitivity. ***Conclusion:*** Our findings validate the feasibility of using kisspeptin-based probes for evaluating KiSS-1R expression. In the next phase, ongoing studies will extend this analysis to TNBC cell lines and to kisspeptin analogs modified with chelators, enabling coordination of relevant diagnostic and therapeutic radionuclides. These efforts aim to further explore the potential of KiSS-1R as a viable target for radiotheranostic applications. ***References:*** 1. Kleynhans J, et al. J Neuroendocrinol. 2025, e13487.

EP-0016

Beyond PSMA Targeting: What Truly Drives the Radiotoxicity of the Alpha-Emitting [^{212}Pb]Pb-AB001?

R. Liukaityte[1]*, V. Stenberg*[2,1]*, S. Kvarsvik Kristiansen*[1]*, A. Kleinauskas*[3,1]*, A. Juzeniene*[1,3]*;*
[1]*Oslo University Hospital, Oslo, NORWAY,* [2]*ARTBIO AS, Oslo, NORWAY,* [3]*University of Oslo, Oslo, NORWAY.*

Aim/Introduction: The alpha-emitting radioligand [^{212}Pb]Pb-AB001, which targets prostate-specific membrane antigen (PSMA), is a promising therapeutic option for metastatic prostate cancer patients. However, variable PSMA expression is observed across patients, tumor sites and even single prostate cancer cells. Does more PSMA mean better uptake and greater cytotoxicity? Is the relationship linear, or does biology play a more complicated role? In this study, prostate cancer cell lines with distinct PSMA expression profiles, cellular dimensions, and growth formats (2D and 3D) were exposed to [^{212}Pb]Pb-AB001 to evaluate whether radiotoxicity scales linearly with PSMA abundance and delivered activity. ***Materials and Methods:*** Four prostate cancer cell lines PC 3-PIP (PSMA+++), C4-2 (PSMA++), LNCaP (++) and 22Rv1 (PSMA+) were evaluated in this study. Total ligand binding was measured 1 hour post radioligand addition. Cytotoxic effect following exposure to [^{212}Pb]Pb-AB001 was assessed using clonogenic and proliferation assays, along with multicellular spheroids. Cellular responses were further characterized by flow cytometry at 1, 24-, 72-, and 144-hours post-treatment, including analysis of cell cycle distribution (propidium iodide and phospho-histone H3 for mitotic cells), apoptosis and membrane permeability (Annexin V-FITC and propidium iodide), DNA double-strand breaks (γH2AX), and senescence (β-galactosidase staining). ***Results:*** Lower PSMA expression correlated with higher activity concentrations of [^{212}Pb]Pb-AB001 required to reduce the clonogenic potential, with PC 3-PIP being the most responsive. Total cell-bound activity was a more accurate predictor of treatment effect than the nominal

PSMA levels. The cell cycle analysis revealed G2 phase arrest and reduced mitotic entry in all cell lines. A delayed increase in polyploid and mitotic cell populations observed exclusively in PC 3-PIP and LNCaP cells indicated mitotic catastrophe, followed by apoptosis and senescence. The impact of treatment was more pronounced in 3D spheroids compared to 2D monolayers, reflecting the added influence of crossfire and bystander effects in a spatially complex tumor architecture. Ongoing investigations into cell size, internalization rates, and p53/p21 status aim to clarify their roles in modulating treatment response. ***Conclusion:*** This study shows that while PSMA facilitates radioligand uptake, cytotoxicity is not solely determined by receptor density. Total cell-bound activity correlated more strongly with treatment efficacy. These findings underscore the need for precise microdosimetry and spatially relevant tumor models to optimize targeted alpha therapies. Combination strategies involving [^{212}Pb]Pb-AB001 and agents targeting DNA repair may enhance therapeutic efficacy.

EP-0017

Treatment efficacy and DNA damage induced by [^{161}Tb]Tb-PSMA I&T vs [^{177}Lu]Lu-PSMA I&T in prostate cancer cell lines

M. Kirienko, *E. Jachetti, R. Sulsenti, C. Cucchi, C. Beretta, A. Bogni, C. Pascali;*
Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY.

Aim/Introduction: Aim of the present study was to evaluate and compare the treatment efficacy and the DNA damage induced by [^{161}Tb]Tb-PSMA-I&T and [^{177}Lu]Lu-PSMA-I&T in human prostate cancer cell lines. Specifically, we evaluated cell proliferation and the the phosphorylation of the H2AX histone (γ-H2AX) as a readout of induction of DNA double strand breaks (DSB) by immunofluorescence. ***Materials and Methods:*** PSMA-I&T was labelled with 0.5-2.0GBq of [^{177}Lu]$LuCl_3$ or [^{161}Tb]$TbCl_3$ (1) using a ratio of 60-80MBq of radionuclide per nmol of precursor. Both [^{177}Lu]Lu- and [^{161}Tb]Tb-PSMA-I&T showed a radiochemical purity >98% by iTLC and >97% by HPLC. We set up in vitro pulse chase experiments utilizing LNCaP and PC3 cell lines, expressing or not experissing PSMA, respectively. Cells were treated for 4h with either [^{161}Tb]Tb-PSMA-I&T or [^{177}Lu]Lu-PSMA-I&T, at different activity concentrations (10, 5, 1, or 0.5MBq/ml), and then, after washing, allowed to grow for 7 days. To analyse the DNA damage, LNCaP and PC3 cells ($2x10^5$) were treated for 4h with either [^{161}Tb]Tb-PSMA-I&T or [^{177}Lu]Lu-PSMA-I&T (either 10 or 5MBq/ml). As a positive control for the immunofluorescence for γ-H2AX, we used LNCaP cells treated with 5mM of doxorubicin for 24h. Slides were washed and stained with primary anti-phospo-Histone H2AX antibody (dilution 1:400) overnight at 4°C. After washing, alexa fluor 488-conjugated chicken anti-rabbit secondary antibody (dilution 1:300) was added for 2 h. The staining intensity was quantified using the ImageJ 2 software. All experiments were performed at least twice. Pools of biological replicates obtained in all the independent experiments were performed and statistical analysis was run considering all the samples. One-way ANOVA was performed separately between LNCaP and PC3 groups. ***Results:*** Both radiopharmaceuticals were able to restrain the proliferation of LNCaP cells with a dose-dependent effect. [^{161}Tb]Tb-PSMA-I&T was superior than [^{177}Lu]Lu-PSMA-I&T at the highest activity concentration (10MBq/ml). We found the highest staining intensity in LNCaP cells treated with 10MBq/ml of [^{161}Tb]Tb-PSMA-I&T. Albeit the difference was not statistically significant, data clearly showed a trend of increased DNA DSB induction in LNCaP cells treated with 10MBq/ml of [^{161}Tb]Tb-PSMA-I&T compared to LNCaP cells treated with 10MBq of [^{177}Lu]Lu-PSMA-I&T. Notably, in PC3 cells the γ-H2AX staining intensity remained low with no significant variations between control and treated cells. ***Conclusion:*** [^{161}Tb]Tb-PSMA-I&T resulted superior in inhibiting prostate cancer cell proliferation compared to [^{177}Lu]Lu-PSMA-I&T. Our results suggest DNA DSBs as factors reflecting higher efficacy of Terbium-161 labelled radiopharmaceuticals compared to those labelled with Lutetium-177. ***References:*** 1) This is a PRISMAP contribution.

Assessment of early-phase [^{18}F]Florbetaben images as a proxy for brain metabolism in mouse models of Alzheimer's disease

R. Gröger[1], *A. Englert*[1], *M. Lalia*[1], *L. de Weerd*[2], *M. Rovere*[2], *C. Haass*[2], *S. Tahirovic*[2], *R. Werner*[1], *M. Brendel*[1], *J. Gnörich*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY.*

Aim/Introduction: FDG-PET and β-amyloid-PET using [^{18}F]Florbetaben (FBB) are established tools for assessing neurodegenerative diseases like Alzheimer's disease (AD). Recent human studies have demonstrated that early-phase β-amyloid-PET can detect cerebral metabolic deficits comparably to FDG-PET, offering a surrogate for neuronal injury and metabolic alterations. In contrast to human AD, transgenic mouse models often show cerebral hypermetabolism, which is likely caused by inflammation rather than neuronal injury. Therefore, this study aimed to assess whether early-phase [^{18}]FBB-PET and [^{18}]FDG-PET capture similar regional changes in perfusion and metabolism. By directly comparing both modalities in two common AD mouse models, we evaluated the potential of early-phase β-amyloid-PET as a surrogate for detecting functional brain changes. ***Materials and Methods:*** After an intravenous injection of ~20 MBq [^{18}F]FDG, 17 APPPS1, 56 App^{SAA}, and 19 age- and sex-matched wildtype mice (3-12mo, 40.2% female) underwent static PET/MRI (30-60 min p.i.). The same mice underwent a dynamic PET/MRI scan (0-60 min p.i.) with ~20 MBq [^{18}F]FBB. Standardized uptake values (SUV) were extracted from 15 regions defined by the Ma-Benveniste-Mirrione Atlas and correlated between early-phase [^{18}F]FBB and corresponding [^{18}] FDG scans using Pearson's correlation coefficients. Regional [^{18}F] FBB and [^{18}]FDG SUV were compared across cohorts using ANOVA. ***Results:*** The highest agreement between [^{18}F]FDG-PET and early [^{18}F]FBB-PET acquisition was reached from 1-3 min p.i. including both AD mouse models and wildtype mice. Using this interval as the optimal time window for [^{18}F]FBB perfusion imaging, we observed strong correlations with [^{18}F]FDG particularly in the cortex (R=0.42, P<0.0001), hippocampus (R=0.45, P<0.0001), and thalamus (R=0.44, P<0.0001). Furthermore, AD mouse models mice showed significantly increased perfusion in the cortex (APPPS1: P<0.0001, App^{SAA}: P<0.0001), hippocampus (APPPS1: P<0.0001, App^{SAA}: P<0.0001), and thalamus (APPPS1: P=0.0004, App^{SAA}: P<0.0001) compared to wildtype mice. Similarly, glucose metabolism was increased in the cortex (APPPS1: P=0.0011, App^{SAA}: P<0.0001), hippocampus (APPPS1: P=0.0049, App^{SAA}: P<0.0001), and thalamus (APPPS1: P=0.0012, App^{SAA}: P<0.0001) compared to wildtype controls. ***Conclusion:*** Early-phase [^{18}F]FBB β-amyloid-PET mirrors functional brain changes captured by [^{18}F]FDG-PET and shows strong regional correlations. The dual-purpose nature of β-amyloid imaging offers a cost-effective alternative to [^{18}F] FDG-PET in preclinical studies and may facilitate more efficient diagnostics.

EP-0019

Adjustment for Perfusion Masks Hypermetabolism in FDG-PET imaging of Aging Rodents

M. Lalia[1], *S. Wagner*[1], *J. Thevis*[1], *L. Bartos*[1], *L. Kunze*[1], *S. Roemer-Cassiano*[2], *N. Franzmeier*[3], *S. Tahirovic*[4], *R. Werner*[1], *M. Brendel*[1,4,5], *J. Gnörich*[1,4];
[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*Department of Neurology, LMU University Hospital, Munich, GERMANY,* [3]*Institute for Stroke and Dementia Research, LMU University Hospital, Munich, GERMANY,* [4]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY,* [5]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.*

Aim/Introduction: FDG-PET employs numerous quantification methods to probe cerebral glucose metabolism in neurodegenerative diseases across species. Two metrics are particularly prevalent: the total volume of distribution (V_T), which accounts for tracer delivery via blood- or image-derived input functions; and the standardized uptake value (SUV), which normalizes tissue activity to injected dose and body weight. We conducted a head-to-head comparison of V_T versus SUV in aging wild-type (WT) and APP^{NL-G-F} mice to determine which metric most accurately reflects age- and amyloid-related changes in cerebral glucose metabolism, using cellular glucose uptake as standard of truth. ***Materials and Methods:*** APP^{NL-G-F} (n=35, up to 12 months of age) and WT (n=65, up to 20 months of age) of both sexes (46% female) received a dynamic 45 min emission recording post 30 MBq intravenous injection of FDG. Quantification of FDG-PET was achieved by extracting cerebral FDG V_T, derived from carotid artery image-derived-input-functions, and SUV. A subset of mice received brain extraction, cell sorting and single cell FDG-uptake measurements after in-vivo FDG injection (scRadiotracing) accounting for microglia, astrocytes and neurons to calculate the FDG-uptake per single cell. ***Results:*** Cerebral FDG-PET SUV demonstrated a significant age-dependent increase in WT (r=0.55, p<0.0001) and in APP^{NL-G-F} (r=0.49, p=0.019) mice. This increase as a function of age was confirmed by ex-vivo FDG-uptake measurements of the SUV-scaled whole brain (WT: r=0.59, p<0.0001; APP^{NL-G-F}: r=0.52, p=0.014). Contrary, the cerebral FDG-PET V_T demonstrated only a slight increase with age in both mouse models (WT: r=0.26, p=0.043; APP^{NL-G-F}: r=0.33, p=0.13). However, SUV and V_T still revealed a significant agreement at the individual level (WT r=0.65, p<0.0001; APP^{NL-G-F} r=0.49, p<0.0001). With an increasing cellular FDG-uptake in both aging mouse models, microglia showed the strongest association with SUV (WT: r=0.45, p=0.0011; APP^{NL-G-F}: r=0.38, p=0.049). In both mouse models, microglial and astrocytic FDG uptake were not significantly correlated with V_T. Neuronal FDG uptake did not show a significant correlation with SUV and with V_T. ***Conclusion:*** Age-dependent hypermetabolism is present in aging WT and β-amyloid mice and confirmed at the level of cellular glucose uptake. SUV quantification allows valid capturing of the age dependent hypermetabolism, whereas V_T quantification masks age dependent increases of glucose uptake and the biologically relevant abundance of the glycolysis substrate. Parallel trajectories of hypermetabolism and hyperperfusion related to age- and β-amyloid-related inflammation are responsible for the imperfect quantification of FDG-PET via V_T.

EP-0020

Metabolic Kinetics Study of a Novel TDP-43 Targeted Molecular Probe

Y. Kong[1], *B. He*[1], *J. Xu*[1], *A. Xu*[1], *C. Yang*[2], *D. Ng*[2], *W. Lam*[2], *Z. Zhang*[1], *Y. Guan*[1];
[1]*Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Singapore General Hospital, Singapore, SINGAPORE.*

Aim/Introduction: TDP-43 is a key protein implicated in various neurodegenerative diseases, including Alzheimer's disease (AD), making it a critical target for developing diagnostic and therapeutic tools. This study investigates the metabolic kinetics of a novel TDP-43 targeted molecular probe [^{18}F]TDP-43-PHA using a two-compartment model to analyze the profiling of the radiotracer in vivo. ***Materials and Methods:*** Dynamic PET scan data were acquired over 5400 seconds, with 30 frames distributed as follows: 3 frames of 10 seconds, 9 frames of 30 seconds, 5 frames of 60 seconds, 10 frames of 300 seconds, and 3 frames of 600 seconds. Image reconstruction was performed using the OSEM3D/MAP algorithm with 2 iterations for OSEM3D and 18 for MAP, a Beta value of 0.004278 (resolution recovery RR=1.5 mm), and voxel size of 0.776×0.776×0.796 mm^3. Corrections included decay, dead time, and input function overflow, but not attenuation or scatter. The input function was derived from the left ventricle (LV) ROI, using the whole blood TAC to calculate pharmacokinetic parameters. The two-compartment model was applied to analyze the radiotracer's profiling, considering the central and peripheral compartments. The model equations were derived based on the principles of linear kinetics, assuming first-order processes for drug transfer between compartments. ***Results:*** The pharmacokinetic parameters were successfully estimated from the experimental data. The two-compartment model provided a good fit to the data, with R^2 values indicating a high degree of correlation between the model predictions and the observed data. The estimated parameters were as follows: $t_{1/2\alpha} = 17.3105\ min^{-1}$, $t_{1/2\beta} = 207.22\ min^{-1}$, $K_{12} = 0.0007\ min^{-1}$, $K_{21} = 0.0393\ min^{-1}$, AUC = 18494.22, and CL = 0.0054 mL/min, indicating the probe's distribution and elimination characteristics in the body. The central compartment volume (V_1) was estimated to be 1.5850 mL, and the peripheral compartment volume (V_2) was estimated to be 0.0315 mL. The total apparent distribution volume (V_d) was calculated to be 1.6165 mL. ***Conclusion:*** The novel TDP-43 targeted molecular probe [^{18}F]TDP-43-PHA exhibited favorable metabolic kinetics. The two-compartment model effectively captured the radiotracer's profiling, providing insights into its distribution and elimination processes. The probe's rapid distribution and elimination kinetics, along with its relatively high AUC and moderate clearance rate, suggest its potential for further development in diagnosing TDP-43 related neurodegenerative diseases, including AD. The ability to target TDP-43 could provide a new avenue for early diagnosis and treatment of AD, potentially improving patient outcomes.

EP-0021

Multimodal Assessment of Isoproterenol-Induced Cardiac Injury in a Mouse Model of Type 2 Myocardial Infarction

K. Vandoorne[1], *C. Zeltser Dekel*[1], *T. Yoganathan*[1], *N. Kalish-Achrai*[1], *N. Haj*[1], *M. Berihu*[1], *B. Tavitian*[2], *S. Karni-Ashkenazi*[1];
[1]*Technion - Israel Institute of Technology, Haifa, ISRAEL,* [2]*Université Paris Cité, Inserm, Paris, FRANCE.*

Aim/Introduction: Myocardial infarction (MI) is a leading global cause of morbidity and mortality. Type 2 MI (T2MI), which results from an imbalance between myocardial oxygen supply and demand, often occurs without underlying coronary artery disease [1-3]. This study investigates the cardiac impact of a single high-dose injection of Isoproterenol (ISO) in a murine model, aiming to emulate the pathophysiological features of T2MI and assess downstream myocardial damage using advanced imaging and histological techniques. ***Materials and Methods:*** Male and female mice aged 8-12 weeks were randomized to control (CTR) or ISO groups. ISO mice received a single intraperitoneal dose of Isoproterenol HCl (160 mg/kg) [1]. Two weeks post-treatment, cardiac function and injury were evaluated using multimodal imaging: ^{18}F-FDG PET/CT, cardiac MRI, and MRI T1 mapping. Imaging findings were validated by gamma counting, Masson's Trichrome histology, Endomucin staining, and complete blood count (CBC) analysis. ***Results:*** ISO-treated mice demonstrated significant reductions in ejection fraction and increased left ventricular volumes by cardiac MRI. T1 mapping and histology revealed pronounced myocardial fibrosis, especially in the interventricular septum. PET/CT showed elevated ^{18}F-FDG uptake,

confirmed by gamma counting, indicating increased metabolic demand and/or inflammation. Endomucin staining revealed enhanced microvascular density, suggestive of angiogenesis post-injury. CBC analysis showed elevated RBC, hemoglobin, hematocrit, and platelet levels—markers consistent with a prothrombotic state. ***Conclusion:*** This study demonstrates for the first time, through in vivo multimodal imaging, the structural, functional, and metabolic cardiac alterations associated with stress-induced Type 2 MI (T2MI) in a murine model. The integration of PET/CT, cardiac MRI, and histological validation reveals hallmark features of myocardial injury, including reduced cardiac function, fibrosis, inflammation, and prothrombotic hematologic profiles. These findings provide a powerful translational platform for understanding T2MI pathophysiology and evaluating potential therapeutic strategies targeting adverse cardiac remodeling and systemic risk post-injury. ***References:*** [1] Forte E, et al. Aim/Introduction: Baseline microglial activation is a key determinant for therapeutic outcomes in Alzheimer's disease (AD) mouse models [1]. We questioned whether pioglitazone could offset the elevated inflammation observed with chronic Aβ monoclonal antibody (Aβ-mAb) immunotherapy in mice. To address this, we investigated the interplay between neuroinflammation and amyloid-β (Aβ) pathology using longitudinal TSPO-PET and Aβ-PET in a large cohort of App^{NL-G-F} and wild-type (WT) mice. ***Materials and Methods:*** WT mice received either Aβ-mAb or placebo from 5 to 10 months of age; App^{NL-G-F} mice were assigned to four groups: placebo, Aβ-mAb, pioglitazone, or combination therapy. TSPO- ([^{18}F]GE-180) and Aβ-PET ([^{18}F]Florbetaben) scans were performed at 5, 7.5, and 10 months, complemented by Morris water maze and biochemical analyses (Trem2, ApoE, Aβ) at the final timepoint. Images were spatially normalized and evaluated using semi-quantitative measures (percent injected dose, SUVR, z-score). We further examined linear mixed-effects models, connectivity-based desynchronization indices (DIs) [2], and correlations with biochemical markers. ***Results:*** App^{NL-G-F} mice developed significantly higher TSPO-PET signals than WT. Among App^{NL-G-F} cohorts, Aβ-mAb treatment alone showed the greatest neuroinflammatory response, reflected by elevated TSPO-PET uptake in the cortex and the amygdala. However, pioglitazone co-administration ameliorated this inflammatory surge: TSPO-PET levels remained comparable to placebo controls. At the same time, the application of pioglitazone and combined therapy resulted in an earlier inflammatory response against fibrillary amyloid, as shown by the associations of regional TSPO- and Aβ-PET z-scores. Correlations of TSPO-PET SUVR and DI with biochemical markers (Trem2, ApoE, $Aβ_{40}$) and behavioural deficits underscored the impact of neuroinflammation on disease progression. ***Conclusion:*** Our findings indicate that pioglitazone effectively suppresses the increased neuroinflammation triggered by Aβ immunotherapy in an AD mouse model. Longitudinal TSPO-PET proved instrumental in tracking these changes and linking them to behaviour and pathological proteins. These results support the clinical potential of combining Aβ-targeting antibodies with immunomodulatory strategies to enhance therapeutic outcomes while minimizing inflammatory side effects. ***References:*** [1] G. EP-0023

First Longitudinal Characterization of Aluminum-Induced Neuroinflammation in the Rat Hippocampus Using TSPO-PET Imaging

Z. Xiang[1,2,3], *J. Zhang*[4,5], *Y. Zhang*[1,2,3], *S. Wang*[4,5], *Z. Qin*[1,2,3], *H. Wang*[1,2,3], *Q. Niu*[5], *S. Li*[1,2,3];
[1]Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA, [2]Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, CHINA, [3]Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA, [4]Key Laboratory of Coal Environmental Pathogenicity and Prevention, Ministry of Education, Shanxi Medical University, Taiyuan, CHINA, [5]Department of Labor Health, School of Public Health, Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: Aluminum is not an essential element for humans, yet environmental exposure to it is on the rise. It is a well-documented cumulative neurotoxin linked to the development of neurodegenerative diseases. Neuroinflammation serves as a hallmark of these disorders, making its diagnosis and monitoring essential. However, longitudinal studies examining the progression of neuroinflammation following aluminum exposure are currently lacking. The mitochondrial translocator protein (TSPO), a crucial imaging biomarker for neuroinflammation, has not been investigated as a potential marker for aluminum-induced neuroinflammation. This study represents the first use of ^{18}F-DPA-714 TSPO-PET to longitudinally assess neuroinflammation in the hippocampus of rats following aluminum exposure. ***Materials and Methods:*** Rat models exposed to aluminum were established through intraperitoneal injection of aluminum maltol. The longitudinal development of aluminum uptake in the hippocampal region was monitored using ^{18}F-DPA-714 at 1, 2 and 3months post-exposure. Following imaging, behavioral changes were assessed using a water maze. In addition, we evaluated neuroinflammatory factors changes in the hippocampal area and investigated the cell types exhibiting increased TSPO-PET signals through immunofluorescence. ***Results:*** TSPO-PET imaging revealed that the standardized uptake value ratio (SUVR) in the anterodorsal hippocampal region of male aluminum-exposed rats was significantly higher than that of the control group at 1, 2, and 3months ($P < 0.05$). In female rats, SUVR in the anterodorsal hippocampal area was significantly elevated compared to controls at 3 months ($P < 0.05$). Levels of IL-1β, IL-6, and TNF-α in the hippocampus of male aluminum-exposed rats were significantly increased at 2 and 3 months ($P < 0.05$). Similarly, these cytokines were significantly higher in female aluminum-exposed rats at 3 months ($P < 0.05$). Behavioral assessments showed that the number of platform crossings in male aluminum-exposed rats was significantly reduced at 2 and 3 months compared to controls ($P < 0.05$). In females, the number of crossings was also significantly lower than in controls at 3 months ($P < 0.05$). Immunofluorescence indicated that all TSPO-PET signals originated from activated microglia. ***Conclusion:*** TSPO-PET can

be employed to monitor neuroinflammation following aluminum exposure, with the TSPO-PET signal specifically reflecting the activation of microglia. Moreover, this study highlights gender differences in neuroinflammation and cognitive dysfunction resulting from aluminum exposure. Male rats exhibited greater susceptibility to aluminum exposure, with neuroinflammation and cognitive dysfunction manifesting earlier than in female rats.

Combining Dopamine Transporter and Amyloid PET Tracer: A Preclinical Study on Dual-Target Imaging

B.-N. Park[1], *Y.-S. An*[2];
[1]*Ajou University Hospital, Suwon, Gyeonggi-Do, KOREA, REPUBLIC OF,* [2] *Ajou University Hospital, Suwon, KOREA, REPUBLIC OF.*

Aim/Introduction: This study aimed to evaluate the feasibility and diagnostic utility of a dual-target positron emission tomography (PET) imaging approach using a cocktail of N-3-[^{18}F]fluoropropyl-2β-carbomethoxy-3β-(4-iodophenyl) nortropane ([^{18}F]FP-CIT) and [^{18}F]florbetaben (FBB) for the simultaneous assessment of dopaminergic and amyloid changes in a preclinical setting. ***Materials and Methods:*** We utilized both Parkinson's disease (PD) and Alzheimer's disease (AD) mouse models, as well as a control group, to investigate the uptake of [^{18}F]FP-CIT and [^{18}F]FBB individually and in combination. PET imaging was conducted, and standardized uptake value ratios (SUVRs) were analyzed for each model across the striatal and cortical regions. Comparisons were made between single and cocktail PET scans to assess potential cross-interference of the tracers. ***Results:*** In both PD and AD models, no statistically significant differences were observed in the SUVRs between single-tracer and cocktail PET scans in the striatum and cortex ($p > 0.4$ for striatal comparisons, $p > 0.8$ for cortical comparisons). The cocktail PET approach demonstrated consistent uptake patterns for each tracer, indicating the feasibility of dual-target imaging without any compromise in the diagnostic quality. ***Conclusion:*** This preclinical study suggests that [^{18}F] FP-CIT and [^{18}F]FBB PET imaging is a viable dual-target imaging approach for neurodegenerative disease evaluation. The method could streamline diagnostic workflows and improve patient convenience. Further clinical studies are warranted to validate the efficacy and safety of this approach in human populations. ***References:*** Feigin VL, Vos T, Nichols E, et al. Fibroblast-Specific Txndc5 Deletion Attenuates Myocardial Fibroblast Activation Following Acute Myocardial Infarction as Demonstrated by ^{18}F-FAPI-74 PET/CT

K.-Y. Ko[1], *C.-J. Liu*[2], *T.-Y. Lee*[2], *C.-H. Chiu*[2], *K.-C. Yang*[3], *M.-F. Cheng*[2];
[1]*National Taiwan University Cancer Center, Taipei, TAIWAN,* [2]*National Taiwan University Hospital, Taipei, TAIWAN,* [3]*National Taiwan University College of Medicine, Taipei, TAIWAN.*

Aim/Introduction: Myocardial fibrosis is a key component of cardiac remodeling after acute myocardial infarction (MI), predominantly driven by activated fibroblasts. ^{18}F-labeled fibroblast activation protein inhibitor (^{18}F-FAPI) is a novel PET radiotracer that selectively binds to activated fibroblasts. TXNDC5 (thioredoxin domain containing 5) is an endoplasmic reticulum protein enriched in cardiac fibroblasts and implicated in redox-mediated fibroblast activation and extracellular matrix production. This study is to investigate the time course and intensity of fibroblast activation following MI using ^{18}F-FAPI-74 PET/CT in wild-type and fibroblast-specific Txndc5 knockout mouse models. ***Materials and Methods:*** C57BL/6J wild-type mice (n=3) and fibroblast-specific Txndc5 knockout mice (Col1a2-Cre/ERT2; Txndc5fl/fl, n=3) underwent left anterior descending (LAD) coronary artery ligation to induce MI. Sham-operated mice underwent identical procedures without ligation. ^{18}F-FAPI-74 was administered via the tail vein at baseline, day 7, and day 14 post-ligation. Static microPET/CT imaging was performed 45 minutes post-injection (15-minute acquisition). Fibroblast activation was quantified by calculating the heart-to-muscle uptake ratio (H/M) from regions of interest on axial PET/CT images. ***Results:*** In wild-type mice with MI, the H/M ratio peaked at day 7 and declined by day 14. In contrast, Txndc5 knockout mice (both sham and MI groups) exhibited a gradual increase in H/M ratio over time. On day 7, the H/M ratio in wild-type MI mice was significantly elevated (2.4 ± 0.2) compared to Txndc5 knockout MI mice (1.7 ± 0.4) and Txndc5 knockout sham controls (1.8 ± 0.06). Furthermore, there was no significant difference in the H/M ratio between Txndc5 knockout MI mice and wild-type sham controls (1.9 ± 0.3). ***Conclusion:*** ^{18}F-FAPI-74 PET/CT enables noninvasive assessment of myocardial fibroblast activation and reveals attenuated fibrotic response in fibroblast-specific Txndc5 knockout mice following MI. This imaging approach holds promise as a translational platform for evaluating antifibrotic therapies targeting TXNDC5.

Application of ^{18}F-D_2-LW223 in the rat model of ischemic stroke

Liao[1], *Z. Wang*[2], *W. Li*[2], *H. Pang*[2];
[12]*Department of Nuclear Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.*

Aim/Introduction: Stroke is a common disease of the central nervous system, which is one of the main causes of death or disability. Microglia are sensitive to ischemia and can be activated in the early stage of ischemic stroke. Activated microglia plays an important role in the pathophysiological link of ischemic stroke. Detecting the changes of activated microglia helps us to diagnose the disease and evaluate the therapeutic effect. In addition, the ischemic stroke model is the most common TSPO-PET evaluation tool. The imaging efficacy of ^{18}F-D_2-LW223 was evaluated in the ischemic stroke model, and the expression of TSPO and iBa1 in the ipsilateral was detected by double immunofluorescence staining. Finally, longitudinal ^{18}F-D_2-LW223 PET imaging was performed to observe the changes in neuroinflammation in the ischemic stroke model. ***Materials and Methods:*** An ischemic stroke model was established in Sprague-Dawley (SD) rats by stereotaxically injecting Endothelin-1 near the middle cerebral artery. On day 10 post-modeling, dynamic ^{18}F-D_2-LW223 PET imaging was performed for 60 minutes ($n = 3$). Immunofluorescence staining was used to compare TSPO expression in the ischemic and contralateral hemispheres. On day 11, the same rats underwent ^{18}F-D_2-LW223 PET imaging after pretreatment with PK11195 (5 mg/kg) to assess tracer specificity. Time-activity curves (TACs) from baseline and blocking experiments were compared. Longitudinal static PET scans were conducted at 1.5, 3, 7, 10, 14, 20, and 30 days post-modeling ($n = 6$). The standardized uptake value (SUV) ratio between the infarcted and contralateral regions was calculated to track TSPO expression changes. ***Results:*** ^{18}F-D_2-LW223 reached peak uptake (SUV ≈ 1.20) in the ischemic brain region approximately 5 minutes post-injection, followed by gradual washout. After PK11195 blockade, tracer uptake in the ischemic region was significantly reduced compared to baseline (AUC40-60 min: 25.75 ± 0.70 vs. 10.67 ± 0.57, $P < 0.0001$). Double immunofluorescence confirmed elevated TSPO and Iba1

expression in the infarcted region. Longitudinal imaging revealed increased ^{18}F-D$_2$-LW223 uptake in the lesion as early as 1.5 days post-modeling, peaking around day 10, and gradually declining to the lowest level by day 30. ***Conclusion:*** This work further validates the imaging efficacy of ^{18}F-D$_2$-LW223 and enables the visualization of the changes in the expression of TSPO up-regulated by pathological changes, which enhances our understanding of the dynamic changes of neuroinflammation in cerebral ischemia and provides a reliable reference for the study of neuroinflammation targets related to cerebral ischemia.

EP-0027

Partial volume characterization in mouse cardiac PET imaging using 3D-printed radioactive partition-less left ventricular phantoms

O. Sarrhini, *J.-F. Beaudoin, T. Galarneau, R. Lecomte;*
Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: Small animal positron emission tomography (PET) can provide non-invasive in-vivo measurements of radiotracer metabolic rates in tissues. Due to limited spatial resolution, partial volume effect (PVE) impedes the extraction of accurate time-activity curves (TACs) from PET images of the mouse heart. TAC modelling typically involves two spillover factors from the blood cavity to myocardium (SFB→$_T$) and from myocardium to cavity (SFT→B), in addition to the recovery coefficients of the myocardium (RC$_T$) and cavity (RC$_B$). This study's purpose was to assess PVE in mouse cardiac PET using resin-based 3D-printed partition-less phantoms of the mouse left ventricle (LV) and to evaluate the accuracy of ^{18}F-FDG kinetic rates determined from the corrected TACs. ***Materials and Methods:*** The plasma kinetic model [1] was used as ground truth (GT) for the input function (PTAC). Model parameters were set to reproduce the plasma activity of typical mouse cardiac PET scans. The FDG model output was used as GT for the myocardial TAC (TTAC). To provide a realistic geometry of the mouse LV, The myocardium was outlined from the short-axis MRI scan of a mouse LV between end-diastole and end-systole using 3DSlicer. The segmentation data were converted to Standard Triangle Language and exported to a CAD software. Seventy LV phantoms were printed using Liqcreate Composite-X resin uniformly mixed with ^{18}F-FDG. Radioactivity in benzyl-alcohol (to avoid air bubbles and evaporation) was added in the cavity of each phantom to reproduce the entire GT PTAC and TTAC curves. PET data, acquired on LabPET-II/Mouse scanner [2], were corrected for randoms, decay, scatter and attenuation. LV phantom myocardium and cavity were segmented from CT images and the corresponding activity was calculated. Geometric Transfer Matrix was applied for PVE correction and the ^{18}F-FDG kinetic constants were compared to the GT values. ***Results:*** The cavity diameter and myocardium thickness of the printed LV phantoms were 2.55±0.08 mm and 1.41±0.04 mm. RC$_T$ and RC$_B$ values were 0.56±0.03 and 0.53±0.04, and SFT→B and SFB→T values were 0.35±0.04 and 0.09±0.01, respectively. The errors of the measured ^{18}F-FDG kinetic constants K_1, k_2, k_3 and K_i were 0.11%, 9.38%, 4.13% and 2.71%, respectively, relative to the GT. ***Conclusion:*** Recovery coefficients and spillover factors of realistic mouse LV phantoms were measured, to enable accurate PVE correction and estimation of kinetic rates in mouse cardiac PET imaging. ***References:*** [1] Feng et al. Int J Biomed Comput, 32:95-110, 1993 [2] Gaudin et al. Phys Med Biol 66(6) :065019, 2021.

Evaluation of cardiotoxicity induced by doxorubicin using a FABP3-selective tracer, [^{18}F]LUF

J. Toyohara[1], *T. Komoda*[2], *T. Tago*[1], *M. Ito*[2], *H. Yoshino*[2];
[1]*Tokyo Metropolitan Institute for Geriatrics and Gerontology, Itabashi-ku, Tokyo, JAPAN,* [2]*Shiratori Pharmaceuticals Co., Ltd., Narashino, Chiba, JAPAN.*

Aim/Introduction: The heart-derived fatty acid-binding protein (FABP3) plays a crucial role in the intracellular transport of fatty acids and is extensively expressed in cardiac and skeletal muscles. It has been previously reported that the ^{18}F-labelled FABP3 selective small organic compound, [^{18}F]LUF, facilitates visualization of the myocardium with high-contrast images when compared to background tissues such as the lungs and liver [1]. Cardiotoxicity is a notable adverse effect observed in cancer survivors who have undergone anticancer drug therapy. There is documented evidence of elevated FABP3 levels in the bloodstream in models of drug-induced myocardial injury [2]. Hence, murine models with doxorubicin-induced heart failure were utilized as a framework for drug-induced heart failure to explore the potential of assessing cardiotoxicity with [^{18}F]LUF. ***Materials and Methods:*** Male C57BL6/J mice, aged eight weeks, served as models for acute heart failure through the intraperitoneal administration of doxorubicin at a single dose of 20 mg/kg, and as models for chronic heart failure through a regimen of 5 mg/kg administered once weekly over a four-week period. One week following the termination of doxorubicin administration, [^{18}F]LUF was administered intravenously via the tail vein without anesthesia. Sixty minutes post-administration, the subjects were euthanized through cervical dislocation. Subsequently, cardiac tissues were excised promptly, and both radioactivity and wet weight were quantified using an autogamma counter. Radioactivity quantification was achieved by employing standardized uptake values. ***Results:*** In the acute heart failure model, the mortality rate among mice was 50%. There were no observed differences in body weight, heart weight, or the heart/body weight ratio. The myocardial accumulation of [^{18}F]LUF was notably reduced in the acute heart failure model compared to the healthy control group. Within the chronic heart failure model, none of the mice succumbed. The chronic doxorubicin administration group exhibited significant reductions in body weight and heart weight, though the heart/body weight ratio remained unchanged. Meanwhile, myocardial [^{18}F]LUF accumulation in the chronic heart failure model demonstrated a tendency towards reduction compared to the healthy control group, yet without reaching statistical significance. ***Conclusion:*** The FABP3 imaging agent, [^{18}F]LUF, has demonstrated the capability to detect doxorubicin-induced acute myocardial injury. ***References:*** [1] Toyohara et al., EJNMMI Res. (2024) 14:107; [2] Pan et al., Exp Ther Med. (2022) 24:712.

In Vitro evaluation of a ^{64}Cu-labeled PSMA-terpyridine conjugate as a potential radiotheranostic agent for prostate cancer

H. Talebian, *S. Ait-Mohand, P. Mercy Ignatius Arokia Doss, L. Sanche, B. Guerin;*
'Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: Prostate cancer (PCa), particularly in its metastatic form (mPCa), remains a major health challenge, with significant limitations in current diagnostic and therapeutic approaches. Our team previously developed a radiotheranostic (RT) agent, ^{64}Cu-NOTA-terpyridine (^{64}Cu-NOTA-TP), which demonstrated strong selectivity and cytotoxicity against cancer cells [1]. This study aims to enhance the agent's effectiveness and specificity for mPCa by conjugating it to a prostate-specific membrane antigen (PSMA) ligand, resulting in a novel compound:

^{64}Cu-NOTA-TP-PSMA. We compare its in vitro performance to that of its monomeric counterparts; ^{64}Cu-NOTA-TP and ^{64}Cu-NOTA-PSMA. ***Materials and Methods:*** NOTA-TP-PSMA was synthesised via combined solid- and solution-phase methods. Radiolabelling with ^{64}Cu followed established protocols [1]. Binding affinity, cellular uptake, internalisation, efflux, cytotoxicity, and nuclear localisation were assessed in PSMA-positive LNCaP Prostate cancer cells and normal HEK-293 cells. ***Results:*** NOTA-TP-PSMA synthesis achieved 30-40% overall yield, with radiolabelling efficiencies exceeding 99%. The conjugate demonstrated strong PSMA binding (IC_{50} = 39 ± 17 nM), comparable to NOTA-PSMA (34 ± 13 nM). In LNCaP cells, ^{64}Cu-NOTA-TP-PSMA showed significantly higher uptake (63 ± 9%) and internalisation (45 ± 7%) compared to both ^{64}Cu-NOTA-TP (40 ± 8%; 36 ± 9%) and ^{64}Cu-NOTA-PSMA (23 ± 1%; 16 ± 1%) at 24 hours. Retention was also improved (52 ± 9%), higher than monomers (~39%) after 24 hours. In contrast, HEK-293 cells displayed minimal uptake and retention, confirming specificity. Subcellular analysis revealed superior nuclear localisation of ^{64}Cu-NOTA-TP-PSMA in LNCaP cells (7.0 ± 2.0%) versus^{64}Cu-NOTA-TP (0.6 ± 0.2%) and ^{64}Cu-NOTA-PSMA (0.4 ± 0.3%), with negligible nuclear accumulation in HEK-293 cells (<1%) further emphasizes the superior selectivity of the conjugate relative to the control. Cytotoxicity assays confirmed potent, selective activity of ^{64}Cu-NOTA-TP-PSMA in LNCaP cells (IC_{50} = 10 ± 2.4, 24.3 ± 5.9, and 24.1 ± 8.5 nM at 24, 48, and 72 h) with minimal effects on HEK-293 (IC_{50} >250 nM). While monomer controls showed lower Cytotoxicity at respective timepoints (^{64}Cu-NOTA-TP:52.6 ± 3.5 nM, 46.7 ± 4.2 nM, 27.6 ± 5.4 nM and ^{64}Cu-NOTA-PSMA: 145.3 ± 7.2 nM, 102.8 ± 16.1 nM, and 93.4 ± 13.9 nM), [NatCu]Cu-NOTA-TP-PSMA and cisplatin showed poor potency respectively (>16,000 nM), and (>22,000 nM) in LNCaP. ***Conclusion:*** This study highlights the potential of ^{64}Cu-NOTA-TP-PSMA as a novel RT agent that may enhance both the diagnosis and treatment of PCa. Future in vivo studies will assess its clinical utility for tumour imaging and radiotherapy. ***References:*** Khosravifarsani et al. Nanomaterials 2021, 11, 2154.

Dual-locked targeted alpha-emitter enhanced tumor immunotherapy via Diels-Alder reaction-based self-immolative molecular cage strategy

F. Yu[1], *M. Yang*[1], *Y. Feng*[2], *K. Shi*[3], *T. Watabe*[4], *K. Kabayama*[4], *K. Fukase*[4];
[1]*Department of Nuclear Medicine, Shanghai Tenth People's Hospital and Institute of Nuclear Medicine, School of Medicine, Tongji University, Shanghai, CHINA,* [2]*Department of Radiology, Duke University Medical Center, Durham, NC, UNITED STATES OF AMERICA,* [3]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND,* [4]*Institute for Radiation Sciences, Osaka University, Osaka, JAPAN.*

Aim/Introduction: Targeted alpha therapy (TAT) has emerged as a promising strategy for cancer treatment by selectively delivering high linear energy transfer (LET) alpha-emitters to tumor cells while minimizing off-target toxicity. However, the clinical translation of alpha-emitters, particularly radium-223 (^{223}Ra), remains challenging due to inefficient targeted delivery and uncontrolled release of recoil daughter products, leading to systemic toxicity. ***Materials and Methods:*** A pretargeted dual-delivery system was constructed using hyaluronic acid nanohydrogels. Platinum^{IV} (Pt^{IV}) was loaded into azide-modified HNPs (HAQ@HNPs), while ^{223}Ra was encapsulated in TCO-modified HNPs (^{223}Ra@HNPs). Sequential injection enabled in vivo inverse electron-demand Diels-Alder (IEDDA) bioorthogonal activation at tumor sites, triggering network collapse and co-release of payloads. Tumor redox status, immunogenic cell death (ICD) induction, and immune infiltration were assessed via flow cytometry, immunohistochemistry, and ROS assays. Antitumor efficacy, with or without PD-L1 blockade, was evaluated in mouse models through tumor growth, metastasis, and survival monitoring. ***Results:*** This study established a dual-lock targeted strategy to ensure that ^{223}Ra remained inactive during circulation and was selectively activated within the tumor microenvironment. The first lock leveraged the biotin-avidin interaction to promote rapid and specific accumulation of ^{223}Ra and Pt^{IV} at tumor sites, taking advantage of the high biotin receptor expression on cancer cells. The second lock incorporated a tetrazine moiety into the ^{223}Ra-loaded nanocarrier, enabling a tumor-specific IEDDA reaction with dienophile-modified Pt^{IV} carriers. Upon activation, a self-immolative cascade was initiated, leading to rapid and controlled co-release of both agents. This precise pretargeting and release mechanism ensured high tumor specificity while minimizing off-target exposure. The synergistic combination of TAT and chemotherapy disrupted tumor redox balance, induced ICD, and stimulated robust antitumor immune responses. Furthermore, co-administration with PD-L1 immune checkpoint blockade significantly amplified systemic immunity, resulting in strong inhibition of tumor progression and metastasis in vivo. ***Conclusion:*** These findings underscore the potential of dual-locked pretargeted strategies to advance TAT by improving therapeutic efficacy and addressing the critical challenge of radionuclide leakage, paving the way for next-generation precision-targeted radiopharmaceuticals.

EP-0031

Camouflaged Membrane-Bridged Radionuclide/Mn Single Atom Enzymes Target Lipid Metabolism Disruption to Evoke Antitumor Immunity

M. Yang[1], *F. Yu*[1], *K. Shi*[2], *T. Watabe*[3], *K. Kabayama*[3], *K. Fukase*[3], *Y. Feng*[4];
[1]*Department of Nuclear Medicine, Shanghai Tenth People's Hospital and Institute of Nuclear Medicine, School of Medicine, Tongji University, Shanghai, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND,* [3]*Institute for Radiation Sciences, Osaka University, Osaka, JAPAN,* [4]*Department of Radiology, Duke University Medical Center, Durham, NC, UNITED STATES OF AMERICA.*

Aim/Introduction: Lipid metabolic reprogramming plays a critical role in modulating immune microenvironment and reshaping tumor plasticity and resistance to targeted radionuclide therapy (TRT). In this report, a radiopharmaceutical with multi-enzymatical catalysis activities is developed, wherein tumor cell membrane-coated manganese single-atom nanozymes (Mn/SAE@M) as supports deliver iodine-131 (^{131}I) to tumor. ***Materials and Methods:*** Mn/SAE in-situ grown in hollow mesoporous ZIF-8 nanoparticles firstly experienced coating with non-small cell lung cancer Lewis lung carcinoma (LLC) cell membranes and subsequent ^{131}I labeling using the Chloramine-T labeling method. Multi-enzymically catalytic activities were evaluated using standard colorimetric assays. Lipid metabolism disruption and ferroptosis induction were assessed through ROS detection, lipid peroxidation analysis, and ferroptosis-related marker expression in vitro and in vivo. Biodistribution, tumor targeting, and safety were examined in LLC tumor-bearing mice using SPECT/CT, ex vivo radioactivity quantification, and histological analysis. Activation of the cGAS-STING pathway and immune responses were also evaluated. ***Results:*** Upon efficient internalization mediated by coated tumor cell membrane, ^{131}I-Mn/SAE@M radiopharmaceuticals initiate abundant oxygen (O_2) release through catalase (CAT)-like catalysis, thereby mitigating hypoxic microenvironment. Especially they can assist TRT produce and enrich more reactive oxygen species (ROS) through oxidase (OXD)-like, peroxidase (POD)-like, and GSH oxidase (GSHOx)-like catalysis processes, thereby opposing immunosuppressive microenvironment and directing killing tumor. Importantly, ^{131}I-Mn/SAE@M allows TRT to activate cGAS-STING pathway, interfere with the lipid metabolic homeostasis of tumor cells and induce ferroptosis, which are unraveled to take responsibility for the potentiated anti-tumor immunity against LLC including primary and distant tumors. ***Conclusion:*** Such SAE-based radiopharmaceuticals provide a candidate platform to enhance TRT efficiency, and the proof-of-concept rationale of disrupting lipid metabolic homeostasis through multienzyme-mimicking cascade reactions also provides a general avenue to enhance TRT-based anti-tumor immunity.

EP-0032

Metabolic stability-dependent targeting of NTS_1R-tumors in mice, as exemplified by [^{99m}Tc]Tc-DT1 and its branched versions [^{99m}Tc]Tc-DT10 and [^{111}In]In-DT14D

P. Kanellopoulos[1], *T. Maina-Nock*[1], *B. A. Nock*[1], *E. P. Krenning*[2];
[1]*Molecular Radiopharmacy, INRaSTES, NCSR Demokritos, 15341 Athens, GREECE,* [2]*Cyclotron Rotterdam BV, Erasmus MC, 3015 CE Rotterdam, NETHERLANDS.*

Aim/Introduction: The neurotensin subtype 1 receptor (NTS_1R) has attracted much attention as a valid biomolecular target in nuclear medicine based on its expression in various human tumors, including pancreatic cancer. We have previously shown the rapid degradation of our prototype radiotracer [^{99m}Tc]Tc-DT1 (DT1, N_4-Gly-Arg-Arg-Pro-Tyr-Ile-Leu-OH) in peripheral mice blood by both angiotensin-converting enzyme (ACE) and neprilysin (NEP), compromising the uptake in pancreatic AsPC-1 xenografts. We herein introduce two lateral chain-decorated DT1 mimics, [^{99m}Tc]Tc-DT11 (DT11, [(MPBA-PEG4)Lys^7]DT1) and its [^{111}In]In-DOTA-$(\beta Ala)_3$-substituted version [^{111}In]In-DT14D. Their in vivo stability and biodistribution in AsPC-1 tumor-bearing mice was compared vs. [^{99m}Tc]Tc-DT1, without or during ACE/NEP-inhibition. ***Materials and Methods:*** The stability of [^{99m}Tc]Tc-DT11 and [^{111}In]In-DT14D was tested by RP-HPLC analysis of blood samples collected 5 min post-injection (pi) of radioligand in mice, divided in three groups: a) non-treated controls, b) treated with Entresto (receiving the drug per oral gavage 30 min in advance as a source of the potent NEP-inhibitor sacubitrilat - Entresto), and c) treated with Entresto and additionally co-injected with the ACE-inhibitor lisinopril (Entresto+Lis). Biodistribution was studied in SCID mice bearing AsPC-1 xenografts at 4 and 24 h pi, either in non-treated controls or in mice pre-treated with Entresto. ***Results:*** A significant increase of in vivo stability was achieved by [^{99m}Tc]Tc-DT11 (56.56±5.19% intact, n=3) and [^{111}In]In-DT14D (69.5±0.7% intact, n=3) vs. the [^{99m}Tc]Tc-DT1 reference (1.8±0.8% intact, n=4; $p<0.0001$) in the control animal groups, revealing the strong stabilizing effect of the lateral MPBA-PEG4 chain at Lys^7. Entresto further increased the stability of [^{99m}Tc]Tc-DT11 (77.0±3.3% intact, n=3; $p<0.01$); co-treatment with Lis had no additional statistically significant impact on either analog, as opposed to [^{99m}Tc]Tc-DT1, implying their resistance to ACE. Metabolic stability directly impacted targeting of the AsPC-1 tumors in the control groups compared with [^{99m}Tc]Tc-DT1. For example, [^{99m}Tc]Tc-DT11 (4.48±0.37%IA/g) and [^{111}In]In-DT14D (3.73±0.45%IA/g) achieved a notably higher tumor uptake vs. the reference (1.25±0.14%IA/g; $p<0.001$) at 4 h pi. Some further improvements in tumor values were obtained in the animals treated with Entresto alone, whereas [^{99m}Tc]Tc-DT1 required double Entresto+Lis treatment to maximize its uptake in the AsPC-1 tumors. ***Conclusion:*** This study has shown that attachment of a suitable pendant group to Lys^7 of NT(7-13) radioligands significantly increases in vivo stability and hence tumor uptake in mice, as opposed to unmodified [^{99m}Tc]Tc-DT1 prototype which rapidly degraded in circulation by both ACE and NEP. The lateral chain-modification approach seems promising for the applicability of NTS_1R-targeting peptide radioligands in the clinic.

The application of crown chelator in Ac-225 and Tb-161 PRRT

H. Yang[1,2,3], *L. Wharton*[1], *S. W. McNeil*[1,2], *C. Zhang*[4], *A. Ingham*[1], *C. Rodríguez-Rodríguez*[2], *H. Merkens*[4,2], *M. Van de Voorde*[5], *M. Ooms*[5], *F. Bénard*[4,2];
[1]*TRIUMF, Vancouver, BC, CANADA,* [2]*The University of British Columbia, Vancouver, BC, CANADA,* [3]*Simon Fraser University, Burnaby, BC, CANADA,* [4]*BC Cancer, Vancouver, BC, CANADA,* [5]*SCK CEN, Mol, BELGIUM.*

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) agents with radiometals requires a chelator that can form a thermodynamically stable and kinetically inert complex with the metal ion. DOTA has been used as the standard chelator for the majority of radiometals, including [^{68}Ga]Ga^{3+}, [^{177}Lu]Lu^{3+}, and [^{225}Ac]Ac^{3+}. Its coordination efficiency of DOTA drops with large ions such as Ac^{3+}, resulting in low molar activity, and the labeling requires elevated temperature which may not be compatible with heat sensitive targeting vectors. We have been developing novel chelators based on larger macrocyclic backbones. The lead chelator 'crown' has shown fast and efficient labeling with Ac^{3+} and Tb^{3+} and good in vivo stability. In this report, we summarize our preclinical studies with [^{225}Ac]Ac/[^{161}Tb]Tb-crown-αMSH, peptides targeting melanocortin 1 receptor (MC1R), and [^{225}Ac]Ac/[^{161}Tb]Tb-crown-TATE, a peptide targeting somatostatin receptor 2 (SSTR2). ***Materials and Methods:*** Crown-αMSH and crown-TATE were synthesized using standard peptide synthesis methods. They were both labeled with [^{225}Ac]Ac^{3+} and [^{161}Tb]Tb^{3+} and the products were confirmed by radio-TLC and radio-HPLC. [^{225}Ac]Ac-crown-αMSH was injected in B16F10 murine melanoma tumour bearing mice. The biodistribution at 2 hours post injection was evaluated. Similarly, SPECT imaging and biodistribution of [^{161}Tb]Tb-crown-αMSH was assessed in the same time frame. Biodistribution of [^{225}Ac]Ac-crown-TATE was evaluated at 1, 4, 24, 48, and 120 hours post injection in AR42J murine pancreatic tumour bearing mouse. SPECT images with [^{161}Tb]Tb-crown-TATE were collected. ***Results:*** For all four radiopharmaceuticals evaluated, good tumour uptake and low background uptake were observed. For ^{161}Tb labeled compounds, SPECT images showed good contrast and resolution and match the ex vivo tissue distribution data. When the receptor density is low as in the case of MC1R, [^{225}Ac]Ac-crown-αMSH showed higher tumour uptake and higher tumour:kidney activity ratio compared to [^{225}Ac]Ac-DOTA-αMSH in B16F10 tumour bearing mice at 2 hour post injection due to improved molar activity. In the case of [^{225}Ac]Ac-crown-TATE, the uptake profile from 1 hour to 120 hours post injection in AR42J tumour bearing mice is comparable to [^{225}Ac]Ac-DOTA-TATE in the same tumour model. ***Conclusion:*** The crown chelator is effective in labeling radio-Tb or Ac, showing high labeling efficiency at room temperature. Preclinical work with αMSH and TATE peptide conjugates demonstrated when high molar activity is required, the use of crown chelator can be advantageous.

EP-0035

Development of FL-261 as a theranostic RDC vector for the diagnosis and treatment of c-MET overexpression cancers

J. Yang, *G. Jiang, J. Xia, J. Zhang, F. Liu;*
Full-Life Technologies, Shanghai, CHINA.

Aim/Introduction: Mesenchymal-epithelial transition factor (c-MET) is an important member in the receptor tyrosine kinase family that highly expressed and abnormally activated in most malignant tumors, making it an attractive target for radionuclide drug conjugate (RDC) based therapy. Abnormal expression of c-MET can induce tumor cell proliferation, suppress the apoptosis, and promote tumor cell migration, invasion and angiogenesis, and thus contributes to the occurrence, development and metastasis of tumor. Despite the clinical validation of the target by small molecule kinase inhibitors, EGFR/c-MET bispecific antibodies and antibody drug conjugates (ADCs), their efficacy is mostly observed in non-small cell lung cancer (NSCLC), compared to other indications with c-MET overexpression. With the aim of developing a novel c-MET targeting RDC vector for the diagnosis and treatment of c-MET overexpression cancers, we have applied our UniRDC™ platform technologies to discover FL-261. ***Materials and Methods:*** The binding affinity and selectivity of FL-261 against c-MET was tested by surface plasmon resonance (SPR) protein

binding assay. [^{68}Ga]Ga-FL-261 and [^{177}Lu]Lu-FL-261 were prepared and the radiochemical purity (RCP) of radiolabeled was determined by radio high-performance liquid chromatography (radio-HPLC). Furthermore, the in vivo imaging, ex vivo biodistribution or efficacy profiles of [^{68}Ga]Ga-FL-261 or [^{177}Lu]Lu-FL-261 were evaluated in c-MET overexpression xenograft mouse models. ***Results:*** FL-261 showed potent binding affinity against c-MET with an KD value of 7.5 nM, demonstrating over 400-fold selectivity to other proteins from the same family. FL-261 was successfully labeled with ^{68}Ga (95°C for 10 minutes) and ^{177}Lu (80°C for 30 minutes), achieving an RCP of over 95% respectively. Subsequently, after administration of [^{68}Ga]Ga-FL-261 in mice implanted with MKN45 xenografts, PET/CT images demonstrated intense tumor uptake which was significantly higher than that in normal organs at 3-hour post-dosing. Meanwhile, in vivo SPECT/CT imaging and ex vivo biodistribution studies were performed after administration of [^{177}Lu]Lu-FL-261 in c-MET overexpression xenograft models, demonstrating intense and durable tumor uptake from 1-hour to 120-hour post-dosing with fast clearance in normal organs. Importantly, in c-MET overexpression xenograft models, [^{177}Lu]Lu-FL-261 exhibited significant anti-tumor activity at different dose levels, resulting in marked tumor regression. No notable changes in body weight of mice were observed, suggesting a favorable safety profile of [^{177}Lu]Lu-FL-261 under the effective dose levels. ***Conclusion:*** In summary, [^{177}Lu]Lu-FL-261 demonstrated encouraging in vivo imaging feasibility, biodistribution profile and anti-tumor activity in c-MET overexpression xenograft models. Our data supports further development of FL-261 as a promising RDC vector to detect and treat c-MET overexpression cancers.

EP-0036

Breaking New Frontiers in In Vivo Molecular Imaging: Multiplex Cancer Fingerprinting on MRI using 3-[^{19}F] FDGal

D. Cohen, *B. Subramani, L. Saad, M. Fisler, L. Avram, T. Harris, H. Allouche-Arnon, A. Bar-Shir;*
Weizmann Institute of Science, Rehovot, ISRAEL.

Aim/Introduction: While 2-[^{18}F]fluorodeoxy-glucose (2FDG) efficiently traces cancers that follow the Warburg effect, there remains an unmet need in molecular imaging approaches to map cancers that do not adhere to this metabolic scheme. We recently introduced Fluorine Metabolic Imaging (FMI) with 3-[^{19}F]fluorodeoxy-galactose (3FDGal), a novel method that takes advantage of the multiplexing capabilities of ^{19}F-MRI and the unique cellular metabolism of 3FDGal. This technique resolves distinct ^{19}F-MR signals emitted by 3FDGal and its two metabolites: 3-[^{19}F]fluorodeoxy-galactitol (3FDGtol) and 3-[^{19}F] fluorodeoxy-galactonic acid (3FDGalA). This way, we provide a platform for non-invasive, whole-body, concurrent mapping of AKR1B1 and ALDH1A1, the enzymes we identified as mediating the probe's redox metabolism. As these enzymes are implicated in cancer reprogramming, the current work aims to evaluate the role of 3FDGal-FMI in cancer imaging using xenograft mice bearing tumors derived from cell lines reported to exhibit low 2FDG-avidity. ***Materials and Methods:*** In vitro, three human cancer cell lines with low 2FDG-avidity (A549, LNCaP, ACHN) were incubated with 3FDGal (6×10^6 cells, 5 mM probe, 4 hours). ^{19}F-NMR spectra of the intracellular contents were obtained using a Bruker 9.4T NMR spectrometer. In vivo, tumor-bearing nude athymic mice underwent imaging under anesthesia following intravenous injection of 3FDGal (0.6 g/kg) on a Bruker 9.4T MRI system (25mm ^{1}H/^{19}F RF volume coil). Starting 30 minutes post-injection, 3D-FMI maps were acquired repeatedly to concurrently map the distribution of 3FDGal, 3FDGtol, and 3FDGalA, using multi-chemical shift selective imaging. ***Results:*** Following in vitro incubation (n=3 per cell line), each cell line exhibited a distinct ^{19}F-NMR "fingerprint", characterized by specific signal-to-noise ratio (SNR) values for 3FDGalA at -205 ppm and for 3FDGtol at -210 ppm: 71±2 and 229±8 in A549 cells, undetectable and undetectable in LNCaP cells, and 21±4 and 155±26 in ACHN cells. SNR values for 3FDGalA and 3FDGtol correlated with cellular expression of ALDH1A1 and AKR1B1, respectively. In vivo ^{19}F-MRI of xenograft mice bearing subcutaneous tumors derived from the three cell lines demonstrated real-time tumor-localized generation of the metabolites in levels mirroring the in vitro fingerprints of the lines, i.e., A549-, LNCaP-, and ACHN-derived tumors exhibited 3FDGalA^{high}/3FDGtol^{high}, 3FDGalA^{neg}/3FDGtol^{neg}, and 3FDGalA^{low}/3FDGtol^{high} phenotypes on FMI. ***Conclusion:*** 3FDGal-FMI offers a groundbreaking glycolysis-independent metabolic imaging approach that enables multiplex in vivo fingerprinting of cancers at the molecular level. By simultaneously reporting on ALDH1A1 and AKR1B1 activity in tumors, 3FDGal provides a promising tracer for imaging some non-2FDG avid tumors, addressing a critical gap in clinical oncological imaging.

Multimodal Imaging for Response Assessment to Combined anti-PD-L1/anti-CTLA-4 Immunotherapy in a Murine Melanoma Model: A Comparative Evaluation of [^{18}F]FDG-PET/CT, MRI and CEUS

M. J. Antons[1], *F. Herr*[1], *M. M. Heimer*[1], *H. Hirner-Eppeneder*[1], *R. Oos*[2], *G. Palumbo*[2], *J. Stueckl*[1], *S. Kloiber*[1], *A. Cimic*[1], *L. V. Blume*[1], *S. Lindner*[2], *D. Clevert*[1], *M. Brendel*[2,3], *J. Ricke*[1], *R. A. Werner*[2,4], *C. C. Cyran*[1];
[1]*Department of Radiology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [3]*Munich Cluster for Systems Neurology (SyNergy), University of Munich, Munich, GERMANY,* [4]*The Russell H. Morgan Department of Radiology and Radiological Sciences, Johns Hopkins School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Early and precise assessment of immunotherapy response is essential for optimizing therapeutic strategies in malignant melanoma. While immune checkpoint inhibitors have demonstrated considerable efficacy, interindividual variability necessitates robust imaging biomarkers for response evaluation. This study aimed to compare the diagnostic performance of three advanced imaging modalities—[^{18}F]FDG-PET/CT, multiparametric MRI and contrast-enhanced ultrasound (CEUS)—in monitoring the effects of combined anti-PD-L1/anti-CTLA-4 immunotherapy in a murine melanoma model with immunohistochemical validation. ***Materials and Methods:*** A total of n=88 female C57BL/6 mice were inoculated subcutaneously with B16-F10 melanoma cells into the left abdominal flank and randomized into therapy and control groups. The therapy group received intraperitoneal injections of anti-PD-L1 and anti-CTLA-4 antibodies, while the control group received sham treatment. Imaging assessments included [^{18}F]FDG-PET/CT (baseline, follow-up 1 (FU-1; day 13), follow-up 2 (FU-2; day 19; n=40)), multiparametric MRI (baseline, FU-1; n=28) and CEUS (baseline, FU-1; n=20). Target parameters for PET/CT were MTV and SUVmax, for MRI apparent diffusion coefficient (ADC), intravoxel incoherent motion (IVIM) and dynamic contrast-enhanced MRI (DCE-MRI) parameters and for CEUS tumour perfusion parameters and VEGFR2-targeted microbubble binding. Tumour allografts were harvested for ex vivo immunohistochemical validation (CD8, Ki-67, TUNEL, CD31). ***Results:*** At follow-up, [^{18}F]FDG-PET/CT revealed significantly lower MTV and SUVmax in the therapy group compared to controls (FU-1: MTV: p=0.004; FU-2: MTV: p=0.008, SUVmax: p=0.0003). MRI demonstrated a significantly lower ADC in the therapy group at follow-up (p = 0.002), while IVIM and DCE-MRI parameters did not yield significant differences. At follow-up, CEUS showed significantly greater reduction in tumour perfusion (WiAUC, p=0.0152) and a significantly lower number of VEGFR2-targeted microbubbles in the therapy than in the control group (SI8min: p=0.003; SI10min: p=0.0019), indicating reduced

angiogenesis. Immunohistochemistry confirmed significant anti-tumour effects in the therapy group, with higher apoptosis rates (FU-1: p=0.012; FU-2: p=0.001), more CD8-positive T-cells (FU-2: p=0.003), lower tumour cell proliferation (FU-1: p=0.012; FU-2: p=0.012) and lower microvascular density (FU-1: CD31: p<0.001). ***Conclusion:*** This multimodal imaging study highlights the complementary strengths of PET/CT, MRI, and CEUS in assessing immunotherapy response in malignant melanoma. [^{18}F]FDG-PET/CT provided early metabolic response parameters, MRI parameters reflected cellular and microstructural tumour alterations and CEUS detected vascular remodelling. The strong correlation between imaging biomarkers and ex vivo histopathology underscores the translational relevance of these imaging modalities for monitoring immune checkpoint inhibition. Our findings support the integration of PET/CT with MRI and CEUS for a comprehensive, non-invasive characterization of immunotherapy response in preclinical and potentially clinical settings.

Preclinical Comparison of 68 Ga-DOTA-LM3 and 68Ga-DOTATATE for SSTR2-Targeted Imaging in C6 Glioma Model

M. Pirdadeh[1], *M. Nasiri*[2], *R. Nami*[1], *S. Mazidi Sharaf Abadi*[1], *A. Gravand*[1], *R. Salehi*[1], *M. Ghapanvari*[1], *M. Samizadeh*[1], *H. Vosoughi*[3], *E. Jafari*[4], *M. Dehghani*[1], *S. Jamalabadi*[1], *M. Kashani*[1], *M. Safari*[1], *A. Abolhosseini Shahrnoy*[1];
[1]*Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Cellular and Molecular Biology, School of Biology, Damghan University, Damghan, IRAN, ISLAMIC REPUBLIC OF,* [3]*Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Bushehr University of Medical Science, Bushehr, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Somatostatin receptor subtype 2 (SSTR2) is overexpressed in several Neuroendocrine tumors, including gliomas, making it a valuable target for molecular imaging. ^{68}Ga-DOTATATE, a somatostatin receptor agonist, is commonly used for PET imaging; however, recent studies suggest that antagonists like ^{68}Ga-DOTA-LM3 may offer enhanced tumor uptake and contrast. This study compares the uptake, biodistribution and imaging performance of ^{68}Ga-DOTA-LM3 versus ^{68}Ga-DOTATATE in C6 Glioma cell line and C6 rat glioma model. ***Materials and Methods:*** C6 glioma cells were cultured in DMEM-F12 culture media and subcutaneously implanted into right shoulder of Sprague-Dawley rats. PET/CT imaging was performed 60 minutes post-injection of either ^{68}Ga-DOTATATE or ^{68}Ga-DOTA-LM3 in the same animals on separate days. SUVmax was measured in tumors and major organs to evaluate tracer uptake, tumor-to-background ratios and normal biodistributions. ***Results:*** The radiolabeling of peptides was achieved at molar activities of up to 20 MBq/nmol at ≥ 99% radiochemical purity. "The cellular uptake and internalization fraction of ^{68}Ga-DOTA-LM3 were 1±0.3% and 10±4.1%, respectively, whereas for ^{68}Ga-DOTATATE were 0.8±0.2% and 90±8.4%, respectively. Incubation times between 1 and 4 hours had no effect on the uptake or internalization of either radiotracer. Furthermore, blocking assays confirmed the high specificity of binding for both radiotracers.^{68}Ga-DOTA-LM3 demonstrated significantly higher uptake in C6 primary tumors (7.8±1.3 vs 5.13±1.14 %ID/g respectively) and metastases including liver (18.28 vs 10.96 %ID/g) and Lung (5.13 vs 3.84 %ID/g) compared to ^{68}Ga-DOTATATE at 60 minutes post-injection ($p < 0.05$). Kidney -to- Tumor ratios (46.8±5.12 vs 68.3±4.54) were also notably improved with DOTA-LM3. Although both radiotracers demonstrated a comparable biodistribution profile, ^{68}Ga-DOTA-LM3 showed a notably faster renal clearance within the first 4 hours post-injection. Nevertheless, increased intestinal and hepatic uptake was observed, likely attributed to its hepatobiliary excretion pathway. ***Conclusion:*** Our results preliminary demonstrated ^{68}Ga-DOTA-LM3 outperformed ^{68}Ga-DOTATATE in terms of tumor uptake and imaging contrast at 1-hour post-injection. ***References:*** Baum RP, Zhang J, Schuchardt C, Müller D, Mäcke H. First-in-Humans Study of the SSTR Antagonist ^{177}Lu-DOTA-LM3 for Peptide Receptor Radionuclide Therapy in Patients with Metastatic Neuroendocrine Neoplasms: Dosimetry, Safety, and Efficacy. EP-0039

Multi - dimensional Transcriptomic Integration Identifies Molecular Markers for Predicting Radioactive Iodine - Refractory Thyroid Cancer Progression and Novel Targeted Therapies

J. Quan, *G. Zhu;*
First Affiliated Hospital of Kunming Medical University, Kunming, CHINA.

Aim/Introduction: Papillary thyroid carcinoma (PTC) dedifferentiation is intricately linked to radioiodine resistance (RAIR), yet the molecular drivers of its invasive progression and stage-specific biomarkers remain elusive. While genetic alterations like BRAF V600E, TERT promoter mutations, and RET rearrangements inhibit sodium/iodide symporter (NIS) function via the MAPK/PI3K pathway, multi-factor interactions complicate understanding of RAIR-associated malignant transformation. Our prior retrospective analysis of 127 radioiodine-refractory and 612 non-refractory patients, all treated with thyroidectomy and 131I therapy, revealed that primary tumor invasion, distant metastasis, ≥3 131I treatments, and pre-treatment ps-Tg ≥20 ng/ml were key risk factors for RAIR-DTC. This study aims to map the molecular evolution of PTC from early to advanced RAIR-DTC using multi-omics integration, identify cross-stage biomarkers for invasion and RAIR, and advance precision nuclear medicine by addressing tumor heterogeneity and enabling targeted radionuclide therapies. ***Materials and Methods:*** Through Transwell assays, the IHH4 cell line, which exhibits high invasiveness and low iodine uptake, was screened as the RAIR model cell line from three PTC cell lines (BCPAP, IHH4, and TPC-1). RNA-Seq data and the GSE27155 dataset were integrated to screen for differentially expressed genes ($|\log2FC| \geq 1.5$, padj<0.01). Candidate genes were identified through subtype cross-analysis, GO/KEGG functional enrichment, and literature mining. A clinical validation cohort (n = 19) was grouped according to AJCC staging and iodine uptake status. Immunohistochemistry combined with a double-blind H-score system (with a high-expression threshold of >100) was used to evaluate gene expression, and Spearman's rank correlation test and Cox regression analysis were performed to analyze the correlation between gene expression and malignant phenotypes. ***Results:*** IHH4 cells show a markedly malignant phenotype with robust migration capacity and low iodine-131 uptake.RNA - seq analysis reveals that the intersection genes highly expressed in both IHH4 cells and RET/PTC tissues are significantly enriched in key pathways like cell migration, epithelial - mesenchymal transition (EMT), anti - apoptosis, and proliferation, while the iodine - metabolism pathway is less enriched.The expression of core genes TFF2, PCSK1, and IER3 increases stepwise with clinical progression, mirroring the trend of malignant progression. ***Conclusion:*** This study has mapped the dynamic molecular landscape of PTC malignant transformation and established TFF2/PCSK1/IER3 as a combined biomarker for cross-stage prediction of RAIR. These findings provide a theoretical basis for optimizing the identification of high-risk populations with RAIR and developing precise nuclear medicine treatment strategies.

Understanding the Impact of Lung Cancer Cell-of-Origin and the Immune Cell Composition on Tumour Metabolic Heterogeneity with RadioFlow

I. Caldera-Quevedo[1], *C. Vraka*[1,2], *D. Solovyev*[1], *G. Brown*[1], *F. Edgar*[1], *R. Bielik*[1], *D. Y. Lewis*[1];
[1]*Cancer Research UK Scotland Insititute, Glasgow, UNITED KINGDOM,* [2]*Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Lung adenocarcinoma tumours have been described as metabolically heterogenous, as it has been observed with 2-deoxy-2-[^{18}F]Fluoro-D-glucose ([^{18}F]FDG) and [1-^{11}C] Acetate positron emission tomography/magnetic resonance imaging (PET/MRI) scans. This diversity arises from factors like the tumour cell-of-origin or the immune cell infiltration. This project aims to elucidate the interaction between the tumour-initiating cell and the tumour immune cell infiltration. To understand their contribution to lung cancer metabolic heterogeneity, we will analyse [^{18}F]FDG single cell uptake in tumour lesions. ***Materials and Methods:*** We developed lung tumour models by intranasally inducing LSL-Kras$^{G12D/+}$ p53$^{fl/fl}$ mice using Ad5-mSPC-Cre or Ad5-CC10-Cre viral vectors, which are only expressed in lung alveolar type 2 and club cells, respectively. These two mouse models were intravenously injected with 15MBq of [^{18}F]FDG and 250MBq of [1-^{11}C]Acetate for metabolic characterisation both in vivo using PET/MRI and ex vivo using Dual-Isotope Tracking (DIOPTRA). To elucidate [^{18}F]FDG uptake at a single-cell level, ~250 MBq [^{18}F]FDG was applied followed by an ex-vivo PET/MRI scan of the tumour lesions for absolute quantification, and radio-flowcytometry sorting (RadioFlow) of different immune cell populations and tumour cells. [^{18}F]FDG uptake in the sorted cell fractions was measured in a γ-counter and results were normalised to the sorted number of cells. ***Results:*** [^{18}F]FDG PET imaging and DIOPTRA data revealed a higher [^{18}F]FDG uptake in CC10 tumours while SPC present both [^{18}F]FDG-avid and [1-^{11}C]Acetate-avid lesions. Metabolomic and transcriptomic analysis revealed a higher glycolytic activity in CC10 tumours. Preliminary RadioFlow results show a significantly higher CD45 cell infiltration in SPC tumours than in CC10 tumours, neutrophiles being the most abundant cell types in both tumour types of high glycolytic lesions ([^{18}F] FDG SUVmax>3.5). Our data indicated that the [^{18}F]FDG PET signal mainly derives from immune cells in both tumour types (CC10: 91.7% ± 3.9%; SPC: 94.8% ± 3.5%) while [^{18}F]FDG uptake in tumour cells is significantly lower. Preliminary data showed that [^{18}F]FDG PET signal is driven by both neutrophiles and dendritic cells in both SPC and CC10 tumours. RNA has been isolated for each one of the sorted populations for further analysis. ***Conclusion:*** Distinct metabolic patterns in SPC- and CC10-derived tumours highlight the role of the tumour-initiating cell lineage in tumour determining metabolism. Moreover, the dominant [^{18}F]FDG uptake by immune cells challenges the conventional assumption that tumour cells drive PET signal. ***References:*** Chen, Z., et al. Nat Rev Cancer. 14(8), 535-546 (2014). Vraka C., et al. J Nucl Med. 66(2), 215-222 (2025).

EP-0042

Investigation of Innovative ^{68}Ga-Labeled σ_2 Receptor-Targeted Proliferation Probes

X. Cai*, Y. Jiajun, Y. Kangxia, Y. Weidong, K. Fei, W. Jing;*
Air Force Medical University, Xi'an, CHINA.

Aim/Introduction: The σ_2 receptor is highly expressed in various tumors and serves as an excellent marker for tumor proliferation imaging. However, current probes suffer from low specificity, high lipophilicity, and inconvenient labeling. Based on previous research and a structural optimization strategy for σ_2 receptor probes containing conjugated structures, this study aims to develop a series of ^{68}Ga-labeled σ_2 receptor probes, ^{68}Ga-DOTA-SIGMA, to address these issues. Through in vivo and in vitro biological evaluations, the study seeks to identify the probe structure with optimal imaging performance, providing molecular imaging data for the structural optimization of σ_2 receptor probes with conjugated structures. ***Materials and Methods:*** Building on previous research on σ_2 receptor probes with conjugated structures, we modified the probes with a DOTA group using a conjugation design approach and adjusted their lipophilicity. Utilize molecular docking technology to conduct virtual docking of the developed probe with the σ_2 receptor to evaluate its binding mechanism and affinity. The labeling of ^{68}Ga was executed utilizing conventional techniques, with the assessment of labeling efficiency, radiochemical purity, and stability conducted. Subsequently, perform cell uptake and inhibition experiments to assess the impact of the probe on glioma cells (C6, F98, and U87). Micro-PET imaging and in vivo distribution experiments were performed in glioblastoma-bearing mice to select the probe with the best imaging performance. ***Results:*** Molecular docking analysis showed that all three designed probes have strong binding affinity to σ_2 receptors. ^{68}Ga labeling was performed using conventional metal labeling methods, with an uncorrected labeling efficiency greater than 40% and radiochemical purity greater than 98% after C18 solid-phase purification. The ^{68}Ga-DOTA-SIGMA probes exhibited a radiochemical purity of over 98% after 2 hours in saline. The probes showed high uptake and high specificity in all three types of glioma cells (C6, F98, and U87). Micro-PET imaging in glioblastoma-bearing mice revealed that all three probes yielded distinct tumor visualization, with optimal performance noted in C6 tumor-bearing mice.The in vivo biodistribution investigation in C6 tumor-bearing mice demonstrated that ^{68}Ga-DOTA-SIGMA-3 exhibited a tumor absorption of 1.98 ± 0.16 % ID/g at 30 minutes, accompanied by a tumor-to-muscle ratio of 3.67. In comparison to earlier documented ^{18}F- or ^{99m}Tc-labeled probes, hepatic and intestinal uptake were markedly diminished. ***Conclusion:*** The modification of σ_2 receptor probes with DOTA groups yields extremely hydrophilic ^{68}Ga-labeled proliferation probes appropriate for glioblastoma imaging. Among these, ^{68}Ga-DOTA-SIGMA-3 shows potential as an excellent tumor imaging probe, warranting further research.

EP-0043

Synergistic Antitumor Efficacy of Bimiralisib (PQR309) Combined with ^{177}Lu-PSMA-617 Radionuclide Therapy in PSMA-Expressing Tumors

Q. Wu[1,2,3], *X. Yao*[1,2,3], *X. Duan*[1,2,3], *R. P. Baum*[4], *T. Zhao*[1,2,3], *J. Zhang*[1,2,3];
[1]*Departments of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [2]*Theranostics Center of Excellence (TCE), Yong Loo Lin School of Medicine, National University of Singapore, 11 Biopolis Way, Helios, Singapore 138667, Singapore, Singapore, SINGAPORE,* [3]*Clinical Imaging Research Centre, Centre for Translational Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [4]*Curanosticum Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

Aim/Introduction: Radioligand therapy using ^{177}Lu-labeled PSMA-617 has shown promise in targeting PSMA-expressing tumors. However, strategies to enhance therapeutic efficacy while minimizing radiotoxicity remain critical. Bimiralisib (PQR309), a dual PI3K/mTOR inhibitor, has been previously validated for its anti-tumor activity, yet its potential in combination with radionuclide therapy has not been reported. This study aims to investigate the synergistic antitumor effects and underlying mechanisms of combining PQR309 with ^{177}Lu-PSMA-617 in PSMA-overexpressing tumor models. ***Materials and Methods:*** ^{177}Lu radiolabeling of PSMA-617 was performed and confirmed for purity and stability. In vitro experiments were conducted using pip-PC3 cells, a PSMA-high prostate cancer line, and included CCK-8 viability assays, colony formation, γ-H2AX and ROS staining, ATP quantification,

Western blotting, and RNA sequencing to elucidate molecular changes. In vivo studies were carried out in pip-PC3 tumor-bearing nude mice treated with PQR309 (oral gavage, twice weekly) and/or ^{177}Lu-PSMA-617 (0.3 mCi). Tumor progression was monitored via volume measurements and SPECT/CT imaging. Tumor tissues were analyzed using immunohistochemistry (IHC) for mechanistic validation. ***Results:*** PQR309 significantly enhanced the therapeutic effect of ^{177}Lu-PSMA-617 both in vitro and in vivo. The combination group showed reduced cell viability, impaired colony formation, elevated DNA damage and oxidative stress markers, and marked ATP depletion. RNA-seq and Western blot analyses confirmed suppression of PI3K/mTOR signaling and glycolytic metabolism. In vivo, the combination therapy achieved a tumor growth inhibition rate of 98.66% over 28 days, markedly outperforming monotherapies. SPECT/CT imaging corroborated tumor-specific radiotracer uptake and therapeutic response, while IHC staining validated enhanced apoptosis and pathway inhibition. ***Conclusion:*** This study is the first to demonstrate the synergistic antitumor efficacy of combining PQR309 with ^{177}Lu-PSMA-617 in PSMA-positive tumors. PQR309 sensitizes tumors to radioligand therapy by inhibiting the PI3K/mTOR axis and disrupting cellular energy metabolism. These findings suggest that PQR309 can potentiate radionuclide therapies, enabling robust tumor suppression at lower, safer radiation doses. The results provide a compelling rationale for further translational and clinical evaluation of this combination strategy in prostate cancer and other PSMA-expressing malignancies.

Biodistribution of the novel CXCR4-directed PET tracer [^{68}Ga]Ga-NOTA-R54 in Patient-Derived Xenograft models of lung cancer

I. Alberico[1], *M. Gentili*[1], *M. Pitzalis*[1], *G. Bertolini*[1], *F. Facchinetti*[1], *C. Cucchi*[1], *F. Rizzo*[1], *C. Beretta*[1], *M. Kirienko*[1], *C. Chiesa*[1], *M. Maccauro*[1], *S. Di Maro*[2], *S. Scala*[3], *A. Bogni*[1], *C. Pascali*[1], *L. Roz*[1]; [1]*Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, ITALY,* [2]*University of Campania "Luigi Vanvitelli", Caserta, ITALY,* [3]*Istituto Nazionale per lo Studio e la Cura dei Tumori-IRCCS-Fondazione "G. Pascale", Naples, ITALY.*

Aim/Introduction: CXCR4 (CXC chemokine receptor 4) is a G-protein-coupled receptor overexpressed in various human tumors. Elevated CXCR4 expression is associated with increased tumor aggressiveness, as well as a higher risk of metastasis, chemoresistance and recurrence. Its interaction with the endogenous ligand CXCL12 (CXC chemokine ligand 12) plays a critical role in cancer cell survival, proliferation, and migration. By mimicking the receptor-binding domain of CXCL12 we have developed a novel class of peptides with high affinity for CXCR4 which can be used as potent CXCR4 antagonists or as binding agents for imaging applications. In this study, we investigate the uptake and biodistribution of the novel PET tracer [^{68}Ga]Ga-NOTA-R54, a low molecular weight CXCR4-binding cyclic peptide labeled with Gallium-68, in patient-derived xenografts (PDX) of non-small cell lung cancer (NSCLC). ***Materials and Methods:*** The radiopharmaceutical tracer was intravenously administered via tail vein injection in 4-5 mice bearing subcutaneous NSCLC-PDX models (100 µCi/mouse). Six different PDX models with different content of CXCR4+ cells were tested (range 0.1-31%). One hour after administration, biodistribution and uptake of [^{68}Ga]Ga-NOTA-R54 were evaluated ex vivo in blood, lungs, liver, kidneys and primary tumors using a gamma counter (2480 Wizard2) and measured as fraction of injected activity/g of tissue (%IA/g). CXCR4 positivity in primary tumor cells and in disseminated tumor cells (DTCs) in the lungs of mice was assessed by flow cytometry. ***Results:*** Rapid biodistribution was observed with significant amount of radiopharmaceutical detected in the kidneys compared to other organs, confirming its prevalent renal clearance (%IA/g 6.46±1.65). Good concordance was observed in uptake values of tumors from the same PDX model, confirming utility of these advanced models for imaging studies. Greater radiotracer uptake was observed in PDX models with higher frequency of CXCR4+ cells compared to those with low CXCR4 expression. In a representative experiment a significant different uptake was detected in LT111 model (mean CXCR4+ cells 31%) compared to LT710 model (3%): 1.35±0.57 vs. 0.44±0.12 (p=0.021). ***Conclusion:*** Our results show that [^{68}Ga]Ga-NOTA-R54 can be used as an effective imaging probe to identify CXCR4-rich tumors potentially allowing early prognostication and identification of mechanisms of resistance thus predicting outcomes and/or therapeutic efficacy. Additional studies are needed to evaluate limit of detection and kinetics. This project will advance the clinical development of CXCR4-targeted probes for both diagnostic and therapeutic applications, following a rational progression from advanced preclinical modeling to early clinical testing. This study was supported by PNRR grant POC-2022-12376329.

EP-0045

High resolution autoradiography based imaging visualizes chemotherapy induced metabolic suppression in colorectal cancer organoids

Z. Jiang, *K. Draganic, G. Egger, H. Marcus, E. Patronas; Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Patient-derived organoids (PDOs) from microsatellite instability (MSI) and mismatch repair-proficient (MMRp) colorectal cancer (CRC) tumors are increasingly used to model therapeutic responses. However, visualizing treatment-induced metabolic changes in these 3D models remains technically limited. We applied high-resolution autoradiography (AURA) using [^{18}F]FDG to assess chemotherapy-induced metabolic suppression in CRC organoids. This study aimed to establish a robust workflow to quantify metabolic responses, enabling the integration of functional imaging biomarkers into organoid-based drug screening for personalized treatment strategies. ***Materials and Methods:*** CRC organoids were cultured in Matrigel domes using defined organoid medium for 9 days. Chemotherapy agents (5-fluorouracil [5-FU], oxaliplatin [Ox], 5-FU+Ox and or FOLFOX [consists of 5-FU, leucovorin, and Ox]) at concentrations of 1, 5, and 10 µM were added on day 9, and imaging was performed 3 days later. AURA was carried out using ^{18}F-FDG to assess glucose metabolism. Viability was evaluated using CellTiter-Glo® (CTG), and Live/Dead immunofluorescence staining was used to assess cell viability. ***Results:*** All data were normalized to the untreated control group. ^{18}F-FDG uptake significantly decreased in a dose-dependent manner ($p < 0.05$), closely mirroring normalized CellTiter-Glo® (CTG) viability across all treatment groups. Live/Dead immunofluorescence confirmed a reduction in viable cell proportions with increasing drug concentration; however, absolute viability values remained relatively higher at lower doses. This discrepancy may indicate transient metabolic adaptation, whereby organoids maintain survival through alternative metabolic pathways. Supporting this hypothesis, BODIPY staining, which reflects intracellular lipid content, was relatively preserved or mildly increased at 1 and 5 µM, suggesting enhanced lipid utilization during early response phases. At the highest dose (10 µM), BODIPY signal declined significantly ($p < 0.05$), consistent with impaired lipid metabolism and widespread cell death. These metabolic and viability trends were observed in both MSI and MMRp organoids, with the strongest suppression noted in the FOLFOX and 5-FU+Ox combination groups. Dose-response analysis revealed distinct IC_{50} values among treatment conditions, with MSI organoids displaying higher IC_{50} values than MMRp organoids, indicating greater resistance to chemotherapy at lower concentrations. ***Conclusion:*** High-resolution autoradiography using ^{18}F-FDG, combined with functional and immunofluorescence

validation, provides a robust workflow to assess chemotherapy-induced metabolic suppression in CRC organoids. This imaging-based approach supports the integration of clinical radiotracers into organoid-based drug testing platforms for future personalized therapy applications.

EP-0046

Low-dose Fibronectin-targeted Gd-based contrast agent Enables Early and Accurate Assessment of Chemotherapy Response in Pancreatic Cancer

W. Zhang[1], *Y. Du*[2];
[1]*Peking University People's Hospital, Beijing, CHINA,* [2]*Institute of Automation, Chinese Academy of Sciences, Beijing, CHINA.*

Aim/Introduction: Albumin-bound paclitaxel and gemcitabine (AG) chemotherapy is a mainstay in treatment of pancreatic ductal adenocarcinoma (PDAC). Unfortunately, not all patients respond to this treatment[1]. Clinical imaging techniques are not able to precisely evaluate and predict the response to AG therapies over several weeks. A strong fibrotic reaction is a hallmark of drug-resistance while depletion of fibrosis is a positive response of AG. Extradomain-B fibronectin (EDB-FN) is an important element of fibrosis in PDAC[2]. Here, we prepared EDB-FN targeted Gd-based contrast agent (EDB-Gd) to perform molecular MRI for early, noninvasive and quantitative assessment of treatment response in PDAC. ***Materials and Methods:*** BxPC-DR, Human PDAC cell line, was treated with AG to establish acquired drug-resistance. subcutaneous and orthotopic models with BxPC-DR or BxPC were established. Mice were intravenously injected with EDB-Gd or Gd-DOTA. The ratio of T1 value reduction (T1d%) were compared quantitatively. For chemotherapy monitoring, mice were treated with AG regimens. MRI were performed before and after treatments. Histological analyses were used as references for validation. ***Results:*** Molecular MRI with EDB-FN could specifically detect and quantify fibrogenesis in PDAC xenografts at a low dose 0.05mmol/kg, which is half of clinical dosage of Gd. The optimal imaging time point was 30min after injection of EDB-Gd. In addition, the targeted probe generated more robust contrast-enhanced and longer retention compared to traditional Gd-DOTA. For chemotherapy montoring, T1d% were significantly increased 2.5-fold in drug-resistance xenografts group in fibrotic tumor areas compared to AG-sensitive group ($p < 0.05$). Comparing the T1d% before and 5 days after AG predicted treatment response. ***Conclusion:*** This study indicates EDB-FN-targeted molecular MRI possesses clinical applications in accurate assessment and prediction of AG chemotherapy. ***References:*** ADDIN EN.REFLIST [1] P. Image-derived Blood Normalization for TREM2 PET Imaging in Glioblastoma Mice Enhances Sensitivity during Monitoring of Immunomodulation

M. Haertel[1], *R. Schaefer*[1], *L. H. Kunze*[1], *K. Schlepckow*[2], *M. Willem*[2], *C. Haass*[2,3,4], *G. Palumbo*[1], *J. W. Lewcock*[5], *K. M. Monroe*[5], *R. A. Werner*[1], *N. L. Albert*[1,6,7], *L. von Baumgarten*[8,9], *L. M. Bartos*[1], *S. Lindner*[1,4], *M. Brendel*[1,2,4];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY,* [3]*Biomedical Center (BMC), Division of Metabolic Biochemistry, Faculty of Medicine, Ludwig Maximilians University, Munich, GERMANY,* [4]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY,* [5]*Denali Therapeutics, Inc., South San Francisco, CA, UNITED STATES OF AMERICA,* [6]*German Cancer Consortium (DKTK), Partner Site Munich, German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [7]*Bavarian Cancer Research Center (BZKF), Erlangen, GERMANY,* [8]*German Cancer Consortium (DKTK), Partner Site Munich, Munich, GERMANY,* [9]*Department of Neurosurgery, LMU University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: The recently developed triggering receptor of myeloid cells 2 (TREM2) radiotracer (1) serves as a innovative tool for selective PET imaging of the tumor associated microglia and macrophages (TAMs) in glioblastoma mice and therefore holds a promising translation into human patients. This study aims to improve the quantification of PET images when utilizing the ^{64}Cu-labeled, brain-shuttle equipped TREM2-PET radiotracer for assessment of TREM2 expression in the brains of mice inoculated with murine SB28 glioblastoma. TREM2 knockout (TREM2 KO) mice with a lack of target expression were included as a control condition to compare data-driven blood normalization of PET images with the conventional tumor-to-background (TBR) normalization. ***Materials and Methods:*** SB28-inoculated WT;TfR$^{mu/hu}$ (n = 8) and TREM2 KO mice (n = 4) were intravenously administered [^{64}Cu]Cu-NODAGA-ATV:4D9, a TREM2-targeting radiotracer with a human transferrin receptor binding site to penetrate the blood-brain-barrier (2), on week-2 or week-3 (WT;TfR$^{mu/hu}$) respectively week-2 (TREM2 KO) post inoculation. We performed TREM2 PET 20 h post injection, followed by intracardiac blood collection. To correlate PET image-derived blood levels with ex vivo blood radioactivity levels we used the voxel-wise analysis employing statistical parametric mapping (SPM). The value of the emerging image-derived blood measure was tested in a SB28 cohort with longitudinal TREM2 PET monitoring during myeloid cell depletion between week-1 and week-2 after tumor implantation (blood-derived vs. TBR normalization). ***Results:*** SPM-based correlation of PET images with ex vivo blood levels revealed an image that matched the vessel tree. Highest agreement was observed in a region of interest in the cardiac blood pool (ROI with 2mm diameter), which allowed to obtain robust blood radioactivity levels from PET images. Blood normalization was superior in detecting changes of TREM2 expression during myeloid cell depletion (Treatment vs. Placebo: -34% TREM2-PET signal, $p < 0.001$) compared to TBR (Treatment vs. Placebo: -22% TREM2-PET signal, $p = 0.121$). ***Conclusion:*** By normalizing PET images to account for blood levels, the sensitivity of TREM2-PET monitoring is significantly enhanced compared to TBR. This refined quantitative approach of image-derived PET normalization is particularly valuable when target expression is affected brain wide by disease or treatment. ***References:*** 1. EP-0049

Use of blocking agent re-distributes alpha-emitter astatine-211, in free form, after targeted alpha therapy

T. Bäck[1], *E. Aneheim*[2], *H. Jensen*[3], *S. Palm*[1];
[1]*Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN,* [2]*Sahlgrenska University Hospital, Gothenburg, SWEDEN,* [3]*Copenhagen University Hospital, Copenhagen, DENMARK.*

Aim/Introduction: Alpha-emitter astatine-211 (^{211}At; $t_{½}$=7.2h)) is currently under clinical investigation for targeted alpha therapies (TAT). In our previous phase I trial, most patients received a blocking agent (sodium perchlorate) which reduced uptake of possible free ^{211}At in thyroid. In this current study, we examine how use of a blocking agent affects the biodistribution of free ^{211}At in mice. The aim was to predict how use of a blocking agent affects the

biodistribution of free 211At that results from in-vivo degradation of a targeted compound used for cancer therapy in patients. ***Materials and Methods:*** Mice with (n=6) and without (n=6) pretreatment with sodium perchlorate (170 mg/kg at 24h and 1h before injection) was given free ^{211}At. We then attempted to trace the fate of all injected activity. Whole-body content was measured with a dose calibrator. Urine and feces were continuously collected and measured in a gamma-well counter. Three of each group were dissected at 6h and the remainder at 10h. Organs were immediately collected and measured for activity. All remaining body parts were also measured in the counter. ***Results:*** At 6h, the highest uptake for the un-blocked mice was seen for thyroid, stomach, salivary glands and lungs (431, 45, 12 and 10 %IA/g, respectively). For the blocked mice highest uptake was in lungs, thyroid, spleen and kidneys with 13, 13, 6.5 and 4.8 %IA/g, respectively. At 10h, it was thyroid, stomach, lungs and salivary glands (189, 37, 9.5, 6.7 %IA/g) for the unblocked mice; and thyroid, lungs, spleen and stomach (14, 10, 4.6, 4.5 %IA/g) for the blocked mice. Highest reduction in organ uptake following block was seen for thyroid, stomach and salivary glands (60-97% reduction in %IA/g). Highest increase due to block was seen for kidneys and blood (22-25% increase). At 10h, non-organ cadaver remainders of unblocked mice contained 46% of all injected activity (%IA), while that of blocked mice contained 37 %IA. Collected up to 10h, combined total urine from unblocked mice accounted for 30 %IA, but only 11% from the blocked mice. Amounts in collected feces were negligible. At 10h, the percentage of injected activity that could not be accounted for was 30% for the un-blocked and 24% for the blocked group. ***Conclusion:*** Using a blocking agent before TAT with 211At reduces thyroid uptake but increases uptake in possibly more critical healthy tissue. Failure to account for all administered activity will be addressed in new studies.

EP-0050

Preclinical Evaluation of a Novel PSMA-Targeted Nanobody Radiopharmaceutical [^{177}Lu]Lu-Ab0362-H0202 for the Treatment of Metastatic Castration-Resistant Prostate Cancer

B. Li, *X. Wu, Y. Gao;*
Department of Nuclear Medicine, Henan Key Laboratory of Novel Molecular Probes and Clinical Translation in Nuclear Medicine, Henan Provincial People's Hospital; Zhengzhou University People's Hospital, Henan University People's Hospital, Zhengzhou, CHINA.

Aim/Introduction: This study assesses the preclinical efficacy and safety of [^{177}Lu]Lu-Ab0362-H0202, a novel PSMA-targeting nanobody developed via site-specific conjugation, as a potential treatment for mCRPC. ***Materials and Methods:*** Preclinical evaluation involved PET/CT imaging with [^{64}Cu]Cu-Ab0362-H0202 in LNCaP xenograft NCG mice to assess tumor uptake and retention at 1, 4, 24, 48, and 72 hours post-injection. Biodistribution of [^{177}Lu]Lu-Ab0362-H0202 was studied in Balb/c mice at the same time points. A single-dose toxicity study was conducted in Balb/c mice using 1.11×10^7 Bq (approximately five times the anticipated human dose). Radiation dosimetry was calculated using OLINDA software based on biodistribution data. ***Results:*** [^{64}Cu]Cu-Ab0362-H0202 demonstrated high tumor uptake (peak: 26.63±0.38 %ID/g at 24 h) and sustained tumor retention up to 72 hours. [^{177}Lu]Lu-Ab0362-H0202 showed rapid blood clearance (25.1±3.79 %ID/g at 1 hour to 0.12±0.02 %ID/g at 72 hours) and low uptake in normal tissues, except the kidneys (peak: 99.02±6.47 %ID/g at 26 hours; reduced to 12.38±1.48 %ID/g by 72 hours). No acute toxicity was observed, with mice exhibiting normal behavior and weight gain. Dosimetry estimated a whole-body effective dose of 0.008 mSv/MBq and a kidney dose of 1.09 mGy/MBq, translating to 806.60 mSv for a 20 mCi dose—below the renal toxicity threshold. ***Conclusion:*** [^{177}Lu]Lu-Ab0362-H0202 exhibits high tumor targeting, favorable biodistribution, and a safe preclinical profile, positioning it as a promising candidate for mCRPC radionuclide therapy. Its superior tumor uptake and retention compared to existing therapies warrant further clinical investigation.

EP-0051

Effects of adding Arg and Arg-Arg to the linker of GRPR antagonist tracer, [^{68}Ga]Ga-TacsBOMB5, on its invitro/vivo capability

S. Pathania[1], *L. Wang*[1], *C. Chen*[2], *P. Ng*[2], *W. Lau*[2], *F. Radnia*[3], *F. Bénard*[2], *K. Lin*[1];
[1]*University of British Columbia, Vancouver, BC, CANADA,*
[2]*BC Cancer Research Institute, Vancouver, BC, CANADA,*
[3]*UBC, Vancouver, BC, CANADA.*

Aim/Introduction: Gastrin-releasing peptide receptor (GRPR) make an ideal tumor imaging target owing to their overexpression in several cancers while retaining minimal expression in healthy tissues. Recently, Obeid et al. reported a significantly improved GRPR binding affinity and tumor uptake by replacing the PEG2 in the linker of GRPR-targeting tracer, [^{111}In]In-AU-RM26-M2, with Arg-Arg. In this study we explored if the same improvement in binding affinity and tumor uptake could be obtained using our previously reported GRPR antagonist tracer, [^{68}Ga]Ga-TacsBOMB5. Building on this reported GRPR antagonist [^{68}Ga]Ga-TacsBOMB5, we developed two tracers [^{68}Ga]Ga-SP01014 and [^{68}Ga]Ga-SP01015. These tracers incorporated one positively charged arginine residue in [^{68}Ga]Ga-SP01014]and two arginine residues in [^{68}Ga]Ga-SP01015, strategically positioned between the DOTA chelator and the piperidine linker. ***Materials and Methods:*** Two novel tracers, [^{68}Ga]Ga-SP01014 (one arginine) and [^{68}Ga]Ga-SP01015 (two arginines), were synthesized using Fmoc solid-phase peptide chemistry. Gallium (^{nat}Ga and ^{68}Ga) complexation was conducted in acetate (0.1 M, pH 4.5) and HEPES (2 M, pH 5.0) buffers, respectively. The agonistic/antagonistic properties were evaluated through calcium release assays in PC-3 cells, while GRPR binding affinity (Ki) was determined via competitive binding assay using [^{125}I-Tyr^4]Bombesin as the radioligand. In vivo evaluation included PET imaging and biodistribution studies in PC-3 tumor xenograft models (n = 5) at 1 hour post-injection. ***Results:*** SP01014 and SP01015 with the addition of Arg and Arg-Arg, respectively, to the linker of TacsBOMB5, and were obtained in 64% and 52% yield, respectively. The natGa- and ^{68}Ga-complexed derivatives were obtained in 62-84% and 18-25% yields, respectively. In vitro competition binding assays demonstrated an improved GRPR binding affinity with the addition of Arg and Arg-Arg to the linker (Ki: Ga-SP01014, 4.2±0.7 nM; Ga-SP01015, 2.4±0.6 nM; Ga-TacsBOMB5, 6.1±1.0 nM). Antagonist characteristics of Ga-SP01014 and SP01015 were confirmed by the calcium release assay. Ex vivo biodistribution studies in PC-3 tumor-bearing mice showed that [^{68}Ga]Ga-SP01014 had lower but favorable tumor uptake compared to [^{68}Ga]Ga-TacsBOMB5 (11.30±2.32 vs 15.7±2.17 %ID/g). Despite having the highest binding affinity, [^{68}Ga]Ga-SP01015 had the lowest tumor uptake (9.94±1.68 %ID/g) and highest kidney uptake (5.99±0.96 %ID/g), possibly attributing to its increased overall positive charge. ***Conclusion:*** Our data from [^{68}Ga]Ga-TacsBOMB5 derivatives confirmed improvement in binding affinity with the addition of Arg and Arg-Arg to the linker. However, there was no improvement in the overall tumor uptake as it also depends on the pharmacokinetics. ***References:*** Obeid K et al . Pharmaceutics. 2024;16(4):513. Wang L et al. Molecules. 2022;27(12):3777.

EP-0052

Noninvasive PET imaging of Trop2 expression in bladder cancer using ^{64}Cu-labeled anti-Trop2 antibody-drug conjugate (Trodelvy)

L. Kang[1], *W. Huang*[1], *Q. Yang*[1], *W. Cai*[2];
[1]*Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA,* [2]*University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Trophoblast cell-surface antigen 2 (Trop2) is highly overexpressed in various solid tumors, contributing to tumor progression, while its expression remains low in normal tissues. Trop2-targeting antibody-drug conjugate (ADC), sacituzumab govitecan-hziy (Trodelvy), has shown efficacy in targeting this antigen. In this study, we investigated Trop2 expression in bladder cancer models using ^{64}Cu-NOTA-Trodelvy for immunoPET imaging. ***Materials and Methods:*** Trop2 expression levels in bladder cancer cell lines (HT-1376 and UM-UC-3) were assessed via flow cytometry and immunofluorescence staining. Labeling of NOTA-Trodelvy with ^{64}Cu was performed in sodium acetate buffer at pH 5 (37°C, 1 h). In vitro stability was analyzed using radio-thin layer chromatography. Biological properties were evaluated through cell uptake, saturation binding assays, and biodistribution experiments. ImmunoPET imaging with ^{64}Cu-NOTA-Trodelvy was performed at various time points to confirm its in vivo targeting. ***Results:*** The radiochemical yield of ^{64}Cu-NOTA-Trodelvy exceeded 90%, with a radiochemical purity greater than 99%. Trop2 expression was high in HT-1376 cells, while it was low in UM-UC-3 cells. The K_D value of ^{64}Cu-NOTA-Trodelvy was 1.67 nM for HT-1376 cells. In HT-1376 models, ^{64}Cu-NOTA-Trodelvy effectively visualized tumor morphology as early as 12 h p.i. (10.30 ± 1.45 %ID/g), with tumor uptake increasing over time and peaking at 48 h p.i. (13.73 ± 1.16 %ID/g). In blocking group and UM-UC-3 models, ^{64}Cu-NOTA-Trodelvy exhibited minimal tumor uptake. As a negative control, ^{64}Cu-NOTA-IgG also demonstrated low tumor uptake (5.27 ± 1.14 %ID/g at 48 h in the blocking group; 6.33 ± 0.74 %ID/g at 48 h in UM-UC-3; 4.50 ± 0.30 %ID/g at 48 h in the ^{64}Cu-NOTA-IgG group). At 48 h, a high target-to-non-target ratio was observed, with specific uptake in tumors and minimal accumulation in non-target tissues. ***Conclusion:*** Our findings demonstrated that ^{64}Cu-NOTA-Trodelvy enables rapid, specific, and sustained tumor accumulation in bladder cancer models, providing precise and noninvasive monitoring of Trop2 expression.

EP-0053

First-in-Primate PET Imaging of a BCMA-Targeted ImmunoPET Probe for Multiple Myeloma

L. Kang, *T. Wang, Q. Yang, X. Sun, Y. Lei, L. Song;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: B-cell maturation antigen (BCMA) is a crucial biomarker and therapeutic target in multiple myeloma (MM). Although BCMA-targeted therapies like CAR-T cells and bispecific antibodies have shown success, non-invasive tools for dynamically monitoring BCMA expression, assessing therapeutic response, and optimizing patient selection are still lacking. ImmunoPET imaging with zirconium-89 (^{89}Zr)-labeled antibodies offers a promising approach for real-time, whole-body visualization of tumor antigen expression. This study aimed to develop and evaluate a novel BCMA-targeted immunoPET probe, [^{89}Zr]Zr-DFO-PFBH0L0, in preclinical MM models and, for the first time, in non-human primates (NHPs) to assess its translational potential. ***Materials and Methods:*** A humanized BCMA-specific monoclonal antibody, PFBH0L0, was conjugated with desferrioxamine (DFO) and radiolabeled with ^{89}Zr. Binding affinity was assessed using ELISA and bio-layer interferometry (BLI), while BCMA expression in MM cell lines was confirmed via western blot and flow cytometry. PET/CT imaging and ex vivo biodistribution studies were performed in MM xenograft mouse models (H929, K562) to evaluate tumor uptake and specificity. PET imaging in a healthy female rhesus macaque at 10 min, 30 min, 1 h, 3 h, 24 h, 72 h, and 120 h post-injection (p.i.) assessed pharmacokinetics and organ distribution, with regions of interest (ROIs) quantified for key organs. Dosimetry estimates were calculated using OLINDA/EXM software. ***Results:*** [^{89}Zr]Zr-DFO-PFBH0L0 exhibited high radiochemical purity (>99%) and stability up to 144 h. ELISA and BLI confirmed that DFO conjugation did not significantly impact binding affinity. In MM xenograft models, PET imaging demonstrated significantly higher tumor uptake in BCMA-positive H929 tumors (9.92 ± 0.75 %ID/g) compared to K562 tumors, the blocking group, and the [^{89}Zr]Zr-DFO-IgG-H929 control group ($P < 0.05$). Ex vivo biodistribution corroborated these findings, with a high tumor-to-blood ratio at 24 h p.i. In NHP PET imaging, [^{89}Zr]Zr-DFO-PFBH0L0 exhibited favorable pharmacokinetics, with sustained retention in the liver, spleen, and kidneys while demonstrating minimal background uptake in muscle and lung. The 3D CT reconstruction confirmed the absence of bone lesions, indicating a healthy subject and supporting the probe's suitability for future clinical translation. Dosimetry estimates showed that the liver (2.41 mGy/MBq) and spleen (2.31 mGy/MBq) received the highest absorbed doses, while the effective dose was 0.68 mSv/MBq, within a clinically acceptable range. ***Conclusion:*** This study pioneers the use of a BCMA-targeted PET tracer in non-human primates, demonstrating its high specificity and favorable biodistribution for clinical translation, patient stratification, therapy monitoring, and future theranostic applications in MM.

EP-0054

Preclinical evaluation of ^{68}Ga-labeled PD-L1 nanobody for PET imaging of pharmacokinetics in gastric cancer

L. Kang, *Q. Yang, T. Wang, X. Sun, L. Song, W. Huang;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: Gastric cancer is a prevalent malignancy with diverse clinical presentations and outcomes, posing a significant global health burden. Despite advances in conventional therapies, gastric cancer remains highly lethal. PD-L1 is overexpressed on the surface of gastric cancer cells, rendering it a crucial biological target for this disease. PD-L1-targeted nanobody offers advantages over traditional antibodies for precise tumor imaging, enabling early detection of gastric cancer and facilitating dynamic monitoring of immunotherapy responses. In this study, we aim to investigate the diagnostic potential of ^{68}Ga-labeled nanobody, as well as its biodistribution and dosimetry, in gastric cancer-bearing models. ***Materials and Methods:*** A new anti-human PD-L1 nanobody was generated through a series of steps including immunization to construct a library, phage display technology, next-generation sequencing. SDS-PAGE electrophoresis was utilized to evaluate the purity of the nanobodies obtained. Biolayer interferometry (BLI) was employed to assess the binding affinity between PD-L1 nanobody and human PD-L1 protein. Enzyme-linked immunosorbent assay (ELISA) was evaluated to detect the binding activity of PD-L1 nanobody to PD-L1. The relative PD-L1 expression levels in HGC-27, U87, SGC-7901, and AGS cell lines were evaluated using flow cytometry. Subsequently, PD-L1 nanobody was conjugated with 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling with ^{68}Ga ($t_{1/2}$ = 67.7 min). ImmunoPET imaging was conducted in HGC-27 tumor-bearing mouse models following the injection of ^{68}Ga-labeled PD-L1 nanobody. ***Results:*** A PD-L1-specific nanobody was successfully generated with more than 90% purity and the KD value reached 10^{-12} M, indicating that PD-L1 nanobody has a strong affinity for PD-L1. Flow cytometry revealed that PD-L1 was positive in HGC-27 and U87 cells, whereas AGS and SGC-7901cells presented low expression levels. PET imaging of ^{68}Ga-PD-L1 nanobody showed that, in the HGC-27 tumor model with positive PD-L1 expression, significant radioactive concentration was observed in the tumor as early as 1 hour post-injection of the ^{68}Ga-DOTA-PD-L1 nanobody. This uptake continued to rise, reaching 2.16 ± 0.06 %ID/g at 2 hours and 2.23 ± 0.16 %ID/g at 3 hours. The above results of imaging suggest the high uptake of tumors from radiolabeled PD-L1 nanobody. ***Conclusion:*** The developed PD-L1-targeting nanobody probe exhibits rapid and specific binding to PD-L1,

coupled with excellent tumor penetration capabilities. Therefore, this PD-L1 nanobody probe could achieve high-sensitivity in vivo imaging of minute tumors.

EP-0055

Multimodal PET Imaging Monitors Tumor Cell Vaccine Combined with Immunoadjuvant Therapy for Colorectal Cancer

N. Wei, *M. Hu, Y. Long, P. Yuan, Y. Gai, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: To tackle colorectal cancer immunotherapy challenges, this study proposes an integrated strategy using autologous tumor cell vaccines to enhance antigen-specific immune activation and a molecular imaging system to dynamically monitor treatment. It highlights LAG3, whose dynamic expression indicates early T cell activation and immune exhaustion, providing a novel biomarker for optimizing individualized immunotherapy. ***Materials and Methods:*** To develop an autologous whole-cell tumor vaccine using mitoxantrone-induced immunogenic cell death in CT26 cells, the drug concentration was optimized. Vaccine consistency was verified by immunofluorescence for calreticulin expression, and its immunogenicity was assessed by flow cytometry. Safety was evaluated using CCK8 assays and monitoring mouse weight, biochemical indicators, and histopathology. A CT26 tumor-bearing mouse model was used for treatment, followed by PET/CT imaging with ^{68}Ga-NOTA-LAG3, ^{68}Ga-NOTA-GZP, and ^{18}F-FDG probes to monitor therapeutic effects. Biodistribution, tissue flow cytometry, and histopathological staining were further used to analyze the vaccine's anti-tumor immune response. ***Results:*** (1) Immunogenicity and Safety: Mitoxantrone (1 μM) induced significant calreticulin expression ($P < 0.0001$) and reduced cell viability to 7.06% at 24 h and 6.14% at 48 h ($P < 0.0001$). No significant differences were observed in liver, kidney, or cardiac function. Median survival was 17.5 days in the experimental group vs. 9 days in controls ($P = 0.0069$), with lower tumor volumes on days 4, 6, and 9 ($P < 0.0060$). (2) Imaging and Biodistribution: No significant differences in ^{18}F-FDG uptake. The ^{68}Ga-NOTA-LAG3 probe showed significant inter-group differences in tumor uptake from day 4 post-treatment ($P = 0.0447$, $P = 0.0160$). Tissue analysis on day 8 revealed higher LAG3+ cell proportions in the MTX and MC groups ($P < 0.0066$, $P < 0.0001$), positively correlated with CD3+, CD4+, and CD8+ cells ($P < 0.0029$). Tumor volume was lower in the MC group ($P < 0.0012$), with slower tumor growth and reduced proliferation. ***Conclusion:*** In this study, we successfully developed an autologous whole-cell tumor vaccine, which was validated for its immunogenicity, safety, and efficacy through preclinical experiments. We monitored the immune response and therapeutic effects using three probes: ^{18}F-FDG, ^{68}Ga-NOTA-GZP, and ^{68}Ga-NOTA-LAG3. Notably, the ^{68}Ga-NOTA-LAG3 probe effectively distinguished tumor immune responses from progression and showed potential for evaluating immunotherapy outcomes and prognosis.

EP-0056

Evaluation of a Novel Long-acting FAPI in HEK-293-FAP Solid Tumor Model

L.-C. Chen, *W.-L. Lo;*
National Atomic Research Institute, Taoyuan City, TAIWAN.

Aim/Introduction: Cancer associated fibroblasts are present in more than 90% of epithelial cancers (such as pancreatic cancer, colorectal cancer, breast cancer, etc.) and are one of the major components of stromal cells. Fibroblast activation protein (FAP) activity in cancer is associated with cancer development, cancer cell migration, and cancer metastasis. FAP has been confirmed to be overexpressed in tumor-associated fibroblasts in many solid tumors. The aim of this study is to explore the in vivo distribution of a radiolabeled novel long-acting fibroblast activation protein inhibitor (FAPI) in an HEK-293-FAP solid tumor model using SPECT/CT imaging. ***Materials and Methods:*** The precursor of NARI-FAPI-1.11 was purchased from Kelowna International Scientific Inc. After labeling with Lu-177, the labeling efficiencies were analyzed using a radio-TLC and radio-HPLC system. Cell binding studies with ^{177}Lu-labeled NARI-FAPI-1.11 were performed using HEK-293-FAP cells (FAP-transfected HEK-293 cells; 3 x 10^6 cells per tube, n = 3). After incubation at 37°C for 1 hour, the samples were centrifuged and washed twice with cold phosphate-buffered saline. Each sample was measured in a gamma counter (Hidex AMG). The percentage of cell bound radioactivity (%) was calculated using the formula: (cell bound radioactivity / total radioactivity) × 100. HEK-293-FAP cells were subcutaneously inoculated into BALB/c nude mice. After intravenous injection of ^{177}Lu-NARI-FAPI-1.11, the HEK-293-FAP tumor-bearing mice were anesthetized and imaged at 1, 4, 18, 24, 48, and 72 hours using a nanoScan SPECT/CT system (Mediso). ***Results:*** The labeling efficiency of ^{177}Lu-NARI-FAPI-1.11 was greater than 90% as determined by radio-TLC and radio-HPLC systems. The cellular binding efficiency in HEK-293-FAP cells demonstrated specific uptake (17%) at 1 hour. SPECT/CT imaging showed that the radioactivity in the tumor rapidly accumulated, reaching 6 %ID/mL at 1 hour and gradually increasing to 6.37 %ID/mL at 4 hours. After 4 hours, the radioactivity slowly decreased over time, from 6.37 %ID/mL at 4 hours to 3.56 %ID/mL at 72 hours. ***Conclusion:*** In this study, the radiolabeled novel long-acting FAPI molecule, ^{177}Lu-NARI-FAPI-1.11, demonstrated specific characteristics in cell binding and SPECT/CT imaging in a tumor-bearing model. Based on these results, ^{177}Lu-NARI-FAPI-1.11 can achieve prolonged circulation time in vivo and increased long-term accumulation at tumor sites.

EP-0057

Validating CD44v6 as targeted for molecular radiotherapy of gastric cancer

S. Rinne, *Z. Wang, M. Nestor;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Existing treatment options for patients with advanced gastric cancer (GC) offer often only limited survival benefits. Targeted radiotherapy may address some of the shortcomings of current treatment regimens. However, currently, no radiopharmaceutical-based therapies are available for GC patients. The aim of this study was to select suitable preclinical models and evaluate CD44v6 as a potential target for targeted radiotherapy of gastric cancer, specifically targeted alpha therapy. ***Materials and Methods:*** AKIR001 is an IgG1 antibody with known affinity to CD44v6, containing a DOTA chelator for labeling with radiometals. Experiments were conducted with ^{111}In as a surrogate for future studies with the alpha-emitter ^{225}Ac. Stability of the indium-111 label was tested in PBS, 1000× molar excess of EDTA, and mouse serum. A panel of four gastric cancer cell lines (MKN-45, NCI-N87, AGS, and HGC-27) was assessed for expression and CD44v6-specific binding in vitro. Binding kinetics were studied in real-time using LigandTracer. Uptake and internalization of [^{111}In]In-AKIR001 were assessed in three gastric cancer cell lines with varying expression of CD44v6. In vivo, biodistribution experiments were performed in Balb/c nu/nu mice bearing MKN-45 and NCI-N87 xenografts. ***Results:*** AKIR001 was stably labeled with ^{111}In with an average yield of 96 ± 5%. [^{111}In]In-AKIR001 bound specifically to three out of four tested gastric cancer cell lines (MKN-45, NCI-N87, and AGS) with a K_D of 40 ± 16 pM. Internalization was generally low and similar across cell lines. After 24 hours of incubation, the internalized fraction of the total cell-bound activity was 11%, 14.5%, and 15.7% for MKN-45, NCI-N87, and AGS cells, respectively. In vivo, [^{111}In]In-AKIR001 successfully targeted CD44v6-positive NCI-N87 and MKN-45 xenografts. Tumor uptake of [^{111}In]In-AKIR001 in MKN-45 xenograft-bearing mice increased from 4 h to 48 h post-injection (pi) and was fully retained up to 168 h pi. Uptake at

48 h pi was 52 ± 7 %ID/g in MKN-45 xenografts and 29 ± 2 %ID/g in NCI-N87 xenografts. The difference in tumor models matched the difference in uptake in vitro. Tumor-to-blood ratios increased from 1.6 at 24 hours pi to a ratio of 4 at 168 hours after injection. ***Conclusion:*** CD44v6 is a promising target for the development of targeted radiopharmaceuticals for gastric cancer. Our studies with [^{111}In]In-AKIR001 indicate its potential for direct and, with its low internalization, also pretargeted radiotherapy of GC. Future studies investigating the therapeutic efficacy with ^{225}Ac-labeled AKIR001 are planned.

EP-0058

Preclinical evaluation of [^{161}Tb]Tb-pypa-p-Phe-trastuzumab in SKOV3-tumor-bearing mice

M. Ligeour, *I. R. Astiazarán-Rascón, L. Li, H. Merkens, P. Ng, W. Lau, M. Jaraquemada-Peláez, F. Bénard;*
BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: With a broad range of isotopes suitable for medical applications, terbium radioisotopes (^{149}Tb, ^{152}Tb, ^{155}Tb, and ^{161}Tb) have raised interest over the past few years, for offering the possibility of a theranostic pair. Terbium-161 ($T_{1/2}$ = 6,89 days), which emits β$^-$ particles, γ radiation, and Auger electrons has been the most studied alternative to ^{177}Lu in β$^-$ targeted radioligand therapy. While the determination of an efficient vector is essential in radiopharmaceutical development, the selection of an optimal chelator to ensure the isotope retention within the drug is often a challenge. Herein, we evaluate the nonadentate H_4pypa chelator, which has previously been labelled with various isotopes (^{177}Lu, ^{89}Zr, ...) for its potential use in radioimmunotherapy targeting ovarian cancer [1-2]. ***Materials and Methods:*** H_4pypa-p-Phe-NCS was conjugated to trastuzumab at a 1:10 Ab:chelator ratio and radiolabelled with [^{161}Tb]$TbCl_3$ at 40°C within 30 minutes. The purity and the specific activity were assessed by size exclusion chromatography using HPLC. The radiolabelled compound was injected intravenously into athymic nude female mice bearing subcutaneous SKOV3 tumour xenografts. SPECT/CT imaging and in vivo biodistribution studies were performed on days 1, 3, 6 and 7 after injection. ***Results:*** Trastuzumab was successfully conjugated to H_4pypa with 87% yield and radiolabelled with [^{161}Tb]$TbCl_3$ with 19±2 % radiochemical yield. The ^{161}Tb-labelled immunoconjugate was purified with 99% radiochemical purity and 0,38 MBq/µg specific activity. SPECT/CT showed high tumour uptake from day 1 post-injection, with relatively high uptake in the liver. Although the tumour uptake remained stable until day 3, increased bone accumulation at days 3, 6, and 7 reflects the instability of the radiotracer. The biodistribution data highlighted a tumour accumulation of 12±1 %IA/g of the [^{161}Tb]Tb-pypa-p-Phe-trastuzumab radiotracer at day 1, which was maintained up to day 3 and gradually decreased to 6±1 %IA/g at day 7. Although high tumour-to-muscle ratios were observed through the experiment, the decrease in tumour-to-liver and tumour-to-bone ratios from day 3, corroborates the SPECT/CT findings. ***Conclusion:*** Preclinical SPECT/CT imaging of SKOV3 tumour xenografts through [^{161}Tb]Tb-pypa-p-Phe-trastuzumab showed high tumour-to-muscle ratios. However, it highlighted increasing liver and bone accumulation over time indicative of [^{161}Tb]Tb demetalation. To investigate if this result is due to antibody-chelator interaction, further studies will aim the conjugation of H_4pypa-p-Phe-NCS to a different targeting vector and its labelling with [^{161}Tb]$TbCl_3$. ***References:*** [1] Li, L. et al., Bioconjugate Chem., 2019, 30, 5, 1539-1553 [2] Southcott, L. et al., Inorg. Chem., 2021, 60 (23), 18082-18093.

Predictors of Iodine-131 Therapy Outcomes in Obese Thyroid Cancer Patients

Y. Zhou[1,2,3], *Y. Hou*[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: This study aims to evaluate the clinical, pathological, and metabolic factors influencing the therapeutic outcomes of iodine-131 treatment in obese patients with DTC, with the goal of optimizing individualized treatment strategies. ***Materials and Methods:*** This retrospective study included 457 obese patients with DTC who received iodine-131 therapy. Treatment outcomes were evaluated based on clinical and imaging findings and categorized into four groups: effective response, indeterminate response, biochemical incomplete response, and structural incomplete response. Variables were classified into four categories for analysis: demographic factors (age, sex, BMI, and place of residence), tumor characteristics (tumor size, tumor-node-metastasis stage, multifocality, invasion, and metastasis), metabolic indicators (serum thyroglobulin [sTg], low-density lipoprotein, high-density lipoprotein, triglycerides, free triiodothyronine, and free thyroxine), and treatment factors (iodine-131 dose). Univariate and multivariate analyses were performed to identify significant factors andUnivariate and multivariate analyses were performed to identify significant factors and determine independent predictors associated with treatment outcomes. ***Results:*** The cohort consisted of 264 males and 193 females (totaling 457), with a mean age of 39.68 years (95% CI: 38.74-40.62). The follow-up period ranged from 15 to 60 months. Univariate analysis identified that sTg, thyroid capsular invasion, lymph node extracapsular invasion, and iodine-131 dose were significantly associated with treatment outcomes ($P < 0.05$). Multivariate logistic regression revealed that age was an independent predictor, with an odds ratio of 0.945 (95% CI: 0.896-0.998, $P < 0.05$). sTg levels exhibited a trend toward significance ($P = 0.096$), with an odds ratio of 0.980 (95% CI: 0.957-1.004). However, place of residence did not retain statistical significance in the multivariate model ($P > 0.05$). ROC curve analysis showed sTg demonstrated moderate predictive power, with an AUC of 0.617 (95% CI: 0.485-0.749). In contrast, the overall predictive model demonstrated poor performance, with an AUC of 0.312 (95% CI: 0.191-0.432). ***Conclusion:*** This study identified sTg, thyroid capsular invasion, lymph node extracapsular invasion, and iodine-131 dose as significant factors associated with treatment outcomes in obese patients with DTC. Age was an independent predictor, with older patients demonstrating poorer therapeutic responses. sTg levels showed a trend toward significance in multivariate analysis. ROC curve analysis confirmed that sTg had moderate predictive power, while the overall predictive model demonstrated poor performance. Future studies are warranted to validate these results and improve predictive models for individualized treatment strategies. ***References:*** Corresponding author is Xiaotian Xia.

Multifunctional Biomimetic Nanocarriers Orchestrated by Radionuclide Click Chemistry for Synergistic and Precision Tumor Intervention

R. Wu[1,2,3], *Z. Gao*[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: Triple negative breast cancer (TNBC) poses significant challenges in clinical treatment due to its complex tumor microenvironment. Traditional chemotherapy often proves insufficient in effectively combating TNBC, while emerging immunotherapies are hampered by limited long-term efficacy and exorbitant costs. Notably, natural compounds derived from traditional Chinese medicine (TCM) have emerged as promising candidates in cancer treatment. In this study, we have developed a multifunctional biomimetic nanocarrier encapsulating Curcumin (C/R-MN) through the incorporation of Ginsenoside Rg3 (Rg3) and a cancer cell membrane coating. Rg3 not only contributes to anti-tumor activity but also enhances the carrier's stability and functionality. Additionally, the nanocarrier could leverage the inherent tumor-homing ability and immune evasion properties of cancer cell membranes to improve targeted delivery. ***Materials and Methods:*** 4T1 tumor cells were lysed, disrupted, and centrifuged to isolate the cell membrane. Rg3 was mixed with 4T1m. Human serum albumin (HSA) was dissolved in deionized water, and the Curcumin (Cur) was added to obtain HSA-Cur through ultrasonic treatment under ice bath conditions. Rg3-4T1m and HSA-Cur were then mixed, and a physical extruder was utilized to produce C/R-MN. The accumulation of the nanocarriers at tumor sites was visualized using pre-positioning technology and PET/CT, with the radionuclide ^{177}Lu employed for targeted radionuclide therapy. ***Results:*** The C/R-MN nanoparticles exhibited a spherical morphology with a hydrated particle size of 161.6 ± 12.5 nm, demonstrating excellent in vitro stability. In vivo pre-targeting PET/CT imaging studies clearly showed a significant radioactive accumulation at the tumor site for C/R-MN (TCO), indicating effective tumor targeting. Notably, the group treated with ^{177}Lu-DOTA-TZ-TCO-C/R-MN demonstrated a remarkable tumor inhibition effect, outperforming other treatment groups. In vivo animal experiments revealed that C/R-MN could significantly increase the infiltration of CD8+ T cells in tumors, leading to enhanced anti-tumor efficacy. Compared with free curcumin and other drugs, C/R-MN not only achieved superior tumor suppression but also maintained good biological safety. Histological examinations of major organs and comprehensive blood biochemical analyses showed no significant abnormalities. ***Conclusion:*** We successfully engineered a stable, biocompatible, and tumor-targeting biomimetic nanocarrier for TNBC therapy. By combining TCM-derived compounds and cancer cell membrane coating with radionuclide labeling via click chemistry, this platform offers a promising strategy for precise, safe, and effective cancer treatment. It highlights the potential of TCM-based nanomedicine for integrating diagnosis and therapy in one system. ***References:*** This research was supported by Hubei Provincial Natural Science Foundation Project(2024AFB633).Zairong Gao and Xiaotian Xia contributed equally as co-corresponding authors.

[^{161}Tb]Tb-DOTA-PSMA I&T Exerts Antitumour Effects and Induces Immune Activation in 2D and 3D Prostate Cancer Coculture Models

Z. Ming, *A. Kurniawan, C. Wu, I. Farina Antunes, E. F. J. de Vries, B. Cornelissen;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Radioligand therapy targeting prostate-specific membrane antigen (PSMA) represents an emerging therapeutic strategy in prostate cancer. ^{161}Terbium (^{161}Tb), a beta- and Auger electron-emitting radionuclide, offers potential advantages over ^{177}Lutetium due to its higher linear energy transfer and short-range cytotoxicity. This study aimed to investigate the therapeutic efficacy and immune-modulatory effects of [^{161}Tb]Tb-DOTA-PSMA I&T in two-dimensional (2D) and three-dimensional (3D) prostate cancer co-culture models, focusing on macrophage activation within the tumour microenvironment. ***Materials and Methods:*** In 2D experiments, the RM1 murine prostate cancer cell line (low PSMA expression) and its PSMA-overexpressing counterpart (PGLS) were used to assess subcellular dosimetry and radiocytotoxic efficacy using clonogenic survival assays. Co-culture studies were used to assess RAW264.7 macrophage cell activation. For 3D studies, co-culture spheroids composed of PGLS cells and RAW264.7 macrophages were established to mimic the tumour immune microenvironment. Spheroids were treated with increasing radioactive doses of [^{161}Tb]Tb-DOTA-PSMA I&T. Cell viability was assessed through monitoring of volume and other morphological changes by microscopy. Immune activation was evaluated using immunofluorescence staining for IBA1, CD80, and CD86. ***Results:*** Clonogenic assays in 2D studies showed a partial inhibition of proliferation in PGLS cell, with up to 32% reduction following treatment with up to 1 MBq of [^{161}Tb]Tb-DOTA-PSMA I&T, but not in RM1 cells. This effect is likely mainly attributed to the targeted radiation-induced DNA damage mediated by the beta emissions. Additionally, when RAW264.7 macrophages were cultured with conditioned medium derived from [^{161}Tb]Tb-DOTA-PSMA I&T-treated PGLS cells, they exhibited significant upregulation of CD80 and CD86 expression compared with RAW264.7 cells exposed to untreated medium (CD80 MFI: 0.47 ± 0.05 versus 0.27 ± 0.06; CD86 MFI: 0.40 ± 0.06 versus 0.12 ± 0.03 , $P < 0.0001$), indicating activation toward a pro-inflammatory phenotype (M1 macrophages) even in the absence of direct radioligand exposure. In 3D spheroids, significant structural disruption and dose-dependent loss of volume (27%) were observed. Importantly, RAW264.7 macrophages co-cultured with PGLS cells exhibited increased expression of IBA1, CD80, and CD86 following treatment compared to untreated co-cultured spheroid, consistent with activation towards a pro-inflammatory, M1-like phenotype. ***Conclusion:*** [^{161}Tb]Tb-DOTA-PSMA I&T shows moderate therapeutic efficacy in PSMA-overexpressing prostate cancer cells, both in 2D and 3D models. In addition to direct tumour cytotoxicity, tumour cells treated with the radioligand activate macrophages within 2D cell cultures and 3D spheroids, potentially enhancing anti-tumour immune responses. These findings support further exploration of [^{161}Tb]Tb-based PSMA-targeted radiotherapy in relation with immune activation.

EP-0062

Multi-tracer PET monitoring of an immunomodulatory therapy in 4R tauopathy: Evaluating a novel drug's impact on glial function and protein pathology

T. Bathe[1,2], *S. Salomasova*[1], *M. Lalia*[1], *G. Palumbo*[1], *R. Oos*[1], *E. Joseph*[1], *R. Schaefer*[1], *R. A. Werner*[1], *M. Brendel*[1,2,3], *L. H. Kunze*[1,4];
[1]*LMU Hospital - Department of Nuclear Medicine, Munich, GERMANY,* [2]*Graduate School of Systemic Neurosciences (GSN), Munich, GERMANY,* [3]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY,* [4]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY.*

Aim/Introduction: The prevalence of neurodegenerative diseases (ND), including Alzheimer's disease (AD) and non-AD tauopathies, is projected to rise significantly by 2050 due to an aging global population. Chronic neuroinflammation, driven by glial activation in response to protein pathologies, is a major contributor to disease progression. Targeting glial dysfunction through immunomodulatory therapies offers a promising approach to mitigate the effects of tauopathies and other ND. The research scope is to monitor the efficacy of GV1001 in a transgenic tau mouse model (PS19) with an early-intervention biomarker study

using molecular biology and neuroimaging techniques. ***Materials and Methods:*** PS19 mice receive chronic treatment with GV1001 for 5 months. Serial neuroimaging techniques, including serial [^{18}F] DPA-714 PET to measure microglial activation, [^{18}F]F-DED PET to measure astrocytic reactivity, and [^{18}F]PI-2620 PET to assess the extent of tau aggregation, are employed to assess treatment effects in vivo. Postmortem validation is performed using immunohistochemistry and biochemical methods, including CSF markers of inflammation e.g. sTREM2 (soluble triggering receptor expressed on myeloid cells 2) and neurodegeneration e.g. NfL (neurofilament light chain), comparing treated mice to placebo and non-transgenic controls. ***Results:*** Preliminary findings, expected to be presented at the conference, will provide insights into the drug's ability to modulate glial activity, restore homeostasis, and reduce tau pathology. ***Conclusion:*** This study highlights the potential of monitoring immunomodulatory strategies to address the complex interplay between chronic neuroinflammation and protein aggregation in ND. If successful, these findings could inform the development of novel therapeutic approaches for AD and related disorders, bridging the gap between preclinical research and clinical application.

EP-0064

Assessment of [225Ac]Ac-DOTATATE for targeted radioligand therapy in neuroblastoma

M. Nestor[1], *H. Berglund*[1], *S. Rinne*[1], *S. Chopra*[1], *H. Alfredeen*[2], *T. Bergström*[1], *F. J. Swartling*[1], *A. Kristian*[3], *T. Tran*[2], *J. Stenman*[4];
[1]*Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN,* [2]*Department of Oncology and Pathology, Karolinska Institutet, Stockholm, SWEDEN,* [3]*Biomedical Research, Novartis Pharma AG, Basel, SWITZERLAND,* [4]*Department of Women's and Children's Health, Karolinska Institutet, Stockholm, SWEDEN.*

Aim/Introduction: Metastatic relapse significantly contributes to mortality in pediatric neuroblastoma (NBL). Although targeted radioligand therapy (RLT) using beta emitters (e.g. [177Lu] Lu-DOTATATE) showed promising outcomes, limited efficacy against low-volume of disease, single metastatic cells and micro-metastases remains a challenge. Alpha emitters, characterized by higher linear energy transfer (LET) and shorter particle path length, may potentially enhance cytotoxicity of RLT against minimal residual disease. This study evaluated the alpha-emitting RLT [225Ac]Ac-DOTATATE as a potential targeted therapeutic for high-risk neuroblastoma. ***Materials and Methods:*** [225Ac]Ac-DOTATATE was radiolabeled and assessed for yield, purity, and stability. Specific binding was confirmed in vitro using SSTR2-expressing cells. Biodistribution was studied in both non-tumor-bearing and IMR-32-LUC xenograft-bearing nude mice up to 7 days post-injection followed by dosimetry estimation of absorbed dose. Therapeutic efficacy was evaluated after a single administration of up to 120 kBq of [225Ac]Ac-DOTATATE and compared to untreated controls in IMR-32-LUC tumor-bearing mice. ***Results:*** Radiolabeling of [225Ac]Ac-DOTATATE was achieved with high yield, purity, and stability. In vitro assays demonstrated specific binding to SSTR2-positive cells. Biodistribution studies confirmed tumor uptake, with a pharmacokinetic profile similar to [177Lu]Lu-DOTATATE. Single dose of [225Ac]Ac-DOTATATE demonstrated rapid and substantial tumor regression, with animals achieving near-complete tumor eradication within two weeks without any observable weight loss during the study period. ***Conclusion:*** [225Ac]Ac-DOTATATE shows effective radiolabeling, stability, and specific binding, alongside promising biodistribution profile. Efficacy evaluation demonstrated strong anti-tumor effects, supporting further exploration of [225Ac]Ac-DOTATATE as a targeted alpha therapy to prevent metastatic recurrence in neuroblastoma.

EP-0065

Preclinical In Vivo Imaging of ^{225}Ac Daughters in Oncology Models

T. Karampelas*, M. Rouchota, E. Lambidis, C. Arapatzi, A. Zacharioudaki;*
BIOEMTECH, Athens, GREECE.

Aim/Introduction: ^{225}Ac labelled radiopharmaceuticals have been shown to provide efficient therapy results in oncology, both in preclinical tests and most importantly in clinical practice. ^{225}Ac is a relatively long-lived alpha emitter with its predominant decay path yielding four alpha particles with high energies (ranging from 5.8 to 8.4 MeV) that are resposnible for making ^{225}Ac a valuable and at the same time convenient therapeutic isotope. A significant added advantage is its gamma co-emissions applicable for in vivo imaging from the disintegration of ^{221}Fr (218 keV) and ^{213}Bi (440 keV). Imaging is technically challenging, and novel dedicated solutions can be exploited to better investigate the possible targeting and efficacy results of new ^{225}Ac labelled radiopharmaceuticals. ***Materials and Methods:*** In this study, a FAP overexpressing oncology mouse model has been used, in combination with an ^{225}Ac labelled radiopharmaceutical, knowing to successfully target the specific protein expression. The mice have been imaged in vivo at different time points with a planar imaging system, customized and optimized for the emissions of both ^{225}Ac and ^{212}Pb. Results have been cross related with gamma counter measurements too. ***Results:*** After analyzing the imaging data of the studied animals, a successful tumor targeting effect has been validated and quantified, as well as the update of healthy organs, at different time points. Results have been compared with ex vivo distributions found to not significantly differ. For each time point, the route of each daughter has been separately followed and imaged. ***Conclusion:*** This study has shown that the in vivo biodistribution of an ^{225}Ac labelled radiopharmaceutical, can be accurately investigated through non-invasive in vivo imaging, with the capability to also separate the different daughters of ^{225}Ac in different simultaneous images and by using doses related to the actual therapeutic scheme and not higher. ***References:*** Morgenstern A, Apostolidis C, Kratochwil C, Sathekge M, Krolicki L, Bruchertseifer F. An Overview of Targeted Alpha Therapy with ^{225}Actinium and ^{213}Bismuth. Curr Radiopharm. 2018;11(3):200-208. doi: 10.2174/1874471011666180502104524. PMID: 29732998; PMCID: PMC6237921.

Clinical-Grade Production and Quality Control of ^{225}Ac-FAP2286 for First-in-Human Application

H. khoshhosn[1], *M. Davarpanah*[1], *S. Banihashemian*[2], *A. Abolhoseini*[1], *M. Nasiri*[3], *R. Nami*[1], *M. Kandi Dayeni*[1], *M. Mohebali*[1], *M. Kashani*[1], *J. Abedi*[1];
[1]*Pars Isotope company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Cancer Research Center, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Department of Cellular and Molecular Biology, School of Biology, Damghan University, Damghan, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Targeted alpha therapies (TAT) are revolutionizing the treatment of advanced and resistant cancers (mesenchymal origin, notably sarcoma and mesothelioma), with fibroblast activation protein (FAP) emerging as key target across multiple solid tumors. FAP2286, a peptide based ligand, provides a highly specific vector for radionuclide delivery. Leveraging the potent cytotoxicity of actinium-225, ^{225}Ac-FAP2286 represents a promising next-generation therapeutic candidate. To transition this innovation agent from the laboratory to clinical application, we aimed to establish a reproducible, hospital-based radiolabeling process compliant with GMP standards. This study presents the development, validation, and quality control framework for clinical-grade ^{225}Ac-FAP2286, ensuring a safe reliable product ready for first-

in-human administration and further clinical evolution. ***Materials and Methods:*** ^{225}Ac-nitrate in solid form was provided by IPPE Co. FAP-2286 peptide was from Aprin Sama Pharmed Co. which was used in preparation of the radiopharmaceutical. ITLC Scanner from Fa. Raytest Co. $^{225}Ac(NO_3)_3$ solid was dissolved completely in 0.1 M HCl supra pure to obtain a $^{225}AcCl_3$ solution (370 MBq/nmol) for later radiolabeling by ultrasonic for 30 minutes. $^{225}AcCl_3$ solution was transferred into reaction 10R vial which contain 900 µl of 0.1M sodium ascorbate buffer and 70 µg FAP-2286 (47.6 nmol). The labelling was accomplished after heating the 1.2 ml solution for 30 minutes in 95°C. After Colling for 5 minutes, add 4 ml NaOAc buffer (250mg/1ml NaCl 0.9%). after add DTPA solution, then pass by 0.22 µm filter solution. ***Results:*** Radiolabeling of FAP2286 with ^{225}Ac was successfully optimized, achieving radiochemical yields consistently above 99% and high radiochemical purity (>98%) without purification. The labeled compound demonstrated excellent in-vitro stability in R.T and human serum at 37°C up to 14 days. Quality control analyses confirmed compliance with clinical release criteria, including sterility, endotoxin levels below acceptable thresholds, and appropriate pH (6-8) and radiochemical identity profiles. ***Conclusion:*** 1. Clinical-grade ^{225}Ac-FAP2286 is now ready for first-in-human use, supported by a validated hospital-based production and QC process.2. Robust radiolabeling and quality control of ^{225}Ac-FAP2286 enable safe clinical translation and open new horizons for targeted alpha therapy.3. our work bridges the gap between laboratory innovation and clinical application, bringing ^{225}Ac-FAP2286 one step closer to benefiting patients.4. Validated hospital production of ^{225}Ac-FAP2286 ensures its readiness for future clinical trials FAP-expressing tumors. ***References:*** 1- Hanbo song, Mengxin Xu, Jie Cai, et al. ^{225}Ac-Labeled Antibody for Fibroblast Activation Protein-Targeted Alpha Therapy. EP-0067

Theranostic application of ^{89}Zr/^{177}Lu-labeled anti-RANKL monoclonal antibody in multiple myeloma tumor models

H. Yan[1], *R. Zhang*[1], *X. Wang*[1], *Z. Huang*[1], *C. Xu*[1], *Z. Li*[1], *P. Chen*[2], *J. Li*[1], *M. Dong*[1];
[1]*Department of Nuclear Medicine, Peking University Shenzhen Hospital, Shenzhen, CHINA,* [2]*Department of Pharmacy, Peking University Shenzhen Hospital, Shenzhen, CHINA.*

Aim/Introduction: In recent years, the application of radiopharmaceuticals has emerged as a promising approach for the accurate diagnosis and treatment of malignant tumors. The receptor activator of NF-κB ligand (RANKL) is a crucial cytokine involved in osteoclast differentiation, and its aberrant expression in multiple myeloma (MM) significantly affects bone resorption. This study aims to develop ^{89}Zr/^{177}Lu-labeled anti-RANKL monoclonal antibody for positron emission tomography (PET) imaging and radioimmunotherapy (RIT) application in MM tumor models. ***Materials and Methods:*** The anti-RANKL monoclonal antibody, denosumab, were conjugated with DFO and DOTA for ^{89}Zr and ^{177}Lu radiolabeling respectively. ImmunoPET imaging and RIT studies were performed using ^{89}Zr-DFO-denosumab and ^{177}Lu-DOTA-denosumab in subcutaneous tumor models of MM. ***Results:*** The production of ^{89}Zr-DFO-denosumab and ^{177}Lu-DOTA-denosumab achieved yields exceeding 60% and radiochemical purities greater than 95% following purification. The compound ^{89}Zr-DFO-YS5 exhibited specific binding to the human MM cell lines U266 and H929 xenografts. The maximum standardized uptake value (SUV) recorded in U266 xenografts was 2.76 ± 0.75, measured at 120 hours post-injection (p.i.). In both U266 and H929 tumor models, a single administration of 1.48 MBq (40 µCi) ^{177}Lu-DOTA-denosumab was well tolerated and resulted in significant and sustained inhibition of established tumors, leading to notable increases in median survival times for treated animals (U266 group: 1.48 MBq vs. saline = 23 days vs. 13 days; H929 group: 1.48 MBq vs. saline = 31 days vs. 21 days). ***Conclusion:*** This study demonstrates that ^{89}Zr-DFO-denosumab serves as an excellent PET imaging agent in MM models. Additionally, ^{177}Lu-DOTA-denosumab has shown remarkable therapeutic efficacy in preclinical models of MM, thereby paving a direct path for the clinical translation of this novel RANKL-targeted radioimmunotherapy for the treatment of MM.

EP-0068

161[Tb]Tb-DOTATATE as a novel approach to SSTR2-targeted neuroblastoma therapy

S. Chopra[1], *T. Xu*[1], *H. Berglund*[1], *R. Selvaraju*[2], *M. Nestor*[1];
[1]*Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN,* [2]*Department of Medicinal Chemistry, Preclinical PET-MRI Platform, Uppsala University, Uppsala, Sweden, Uppsala, SWEDEN.*

Aim/Introduction: Neuroblastoma is an aggressive pediatric cancer that primarily affects children under five and accounts for 10-15% of pediatric cancer-related deaths. Despite the availability of multimodal treatment strategies, outcomes remain poor in high-risk patients. [177Lu]Lu-DOTATATE is under clinical investigation for neuroblastoma, targeting somatostatin receptor 2 (SSTR2). Terbium-161 shares chemical characteristics and a similar half-life with lutetium-177 but offers a unique advantage through its additional emission of Auger and conversion electrons, which may enhance therapeutic efficacy. This study investigates [161Tb]Tb-DOTATATE as a potential alternative to [177Lu]Lu-DOTATATE in SSTR2-expressing neuroblastoma models. ***Materials and Methods:*** [161Tb]Tb-DOTATATE was labeled with Terbium-161 from PRISMAP high radiochemical yield and stability. Cellular binding was assessed on SSTR2-positive cells in vitro. In vivo biodistribution (4 and 24h p.i.) and SPECT/CT imaging (24h p.i.) were conducted in xenografted nude mice bearing SSTR2-posirtive IMR-32 tumors. Finally, IMR-32 xenografted mice were treated in a pilot therapy study with either [161Tb]Tb-DOTATATE (3, 4, or 6 MBq) or [177Lu]Lu-DOTATATE (4 MBq), and tumor growth, toxicity and survival were monitored over time. ***Results:*** [161Tb]Tb-DOTATATE demonstrated clear SSTR2-specific uptake in vitro and favorable biodistribution and tumor uptake in vivo, comparable to [177Lu]Lu-DOTATATE. SPECT imaging further confirmed the in vivo tumor uptake. In the pilot therapy study, treatment with [161Tb]Tb-DOTATATE appeared to reduce tumor growth in a dose-dependent manner. At day 14 post-injection, tumors in the 6 MBq cohort were on average around 60% of the volume of those in the control group, while the 3 and 4 MBq cohorts showed intermediate effects. In contrast, tumor volumes in the [177Lu]Lu-DOTATATE group remained similar to controls at this time point, suggesting a less apparent impact on early growth dynamics. Survival data followed a similar pattern, with the 6 and 4 MBq [161Tb]Tb-DOTATATE group exhibiting >30% and >20% longer median survival compared to the control group respectively, whereas outcomes for the 3 MBq terbium group and 4MBq [177Lu]Lu-DOTATATE were less pronounced. All treatment regimens were well tolerated, and no signs of treatment-related toxicity were observed. ***Conclusion:*** [161Tb]Tb-DOTATATE shows promise as an SSTR2-targeted radiotherapeutic in preclinical neuroblastoma models, with favorable biodistribution, good tolerability, and preliminary evidence of dose-dependent tumor control. These findings support further investigation of [161Tb]Tb-DOTATATE, including optimization of dosing strategies and assessment in additional preclinical and clinical studies, as a potential alternative to [177Lu]Lu-DOTATATE for the treatment of SSTR2-expressing neuroblastoma.

EP-0069

Preclinical development of [^{161}Tb]Tb-DOTA-HYNIC-panPSMA and comparison with [^{177}Lu]Lu-DOTA-HYNIC-panPSMA, [^{161}Tb]Tb-DOTA-J591 and [^{177}Lu]Lu-DOTA-J591

J. Roetman[1], *C. Morgat*[2], *L. Ali*[2], *S. Bodin*[2], *E. Hindie*[2];
[1]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [2]*University Hospital of Bordeaux, Bordeaux, FRANCE.*

Aim/Introduction: [^{161}Tb]Tb-DOTA-HYNIC-panPSMA is a new prostate specific membrane antigen (PSMA) inhibitor relevant for targeted radionuclide therapy (TRT) of PSMA-positive prostate cancer cells using terbium-161.[1] Like lutetium-177 (^{177}Lu), ^{161}Tb is a β-emitter but can deliver a higher concentration of radiation over a short path due higher linear energy transfer, resulting in greater cell death.[2] Herein, we report the therapeutic efficacy of [^{161}Tb]Tb-DOTA-HYNIC-panPSMA and its comparison with [^{177}Lu]Lu-DOTA-HYNIC-panPSMA, [^{161}Tb]Tb-DOTA-J591 and [^{177}Lu]Lu-DOTA-J591 in 2D and 3D models of prostate cancer cells expressing different levels of PSMA. ***Materials and Methods:*** DOTA-HYNIC-panPSMA and DOTA-J591 were radiolabeled with ^{161}Tb and ^{177}Lu. PC3-pip (very high PSMA expression), LnCaP (high PSMA expression), 22Rv1 (moderate/weak PSMA expression), and PC3 cells (no PSMA expression) were cultured as monolayer (2D) and tridimensional (3D). An increasing amount of radiopharmaceuticals (from 0 to 20MBq/mL) were added for 4h (2D) or 24h and cells were re-cultured for 4 additional days. ***Results:*** The endpoint for this study is the comparison of cell death with ^{161}Tb and ^{177}Lu and with panPSMA and J591. Data analysis is ongoing. ***Conclusion:*** This study provides important comparative results regarding peptide-based and antibody-based TRT using ^{161}Tb and sets the groundwork for a Phase 1 study investigating [^{161}Tb]Tb-DOTA-HYNIC-panPSMA in patients with prostate cancer. ***References:*** (1) Morgat C, Vimont D, Attia K. EP-0070

DNA Damage Repair Inhibition boots Radiopharmaceutical Therapy for Triple Negative Breast Cancer

Y. Medina Guevara, *H. Comas Rojas, O. Bio Idrissou, O. Kwon, L. Lambert, A. Pinchuk, L. Wehner, A. Carston, N. Clemons, B. Bednarz, J. Weichert, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Poor survival rates mark triple-negative breast cancer (TNBC) due to its early metastasis and lack of effective targeted therapies. We developed a series of alkylphosphocholine analogs (NM600) for radiopharmaceutical therapy (RPT) targeting breast cancer. To amplify the radiobiological effects of RPT, we employ a synthetically lethal treatment combination inhibiting poly-(ADP-ribose) polymerase 1 (PARP1), a bromodomain and extraterminal (BET) protein in TNBC cells ***Materials and Methods:*** Cytotoxicity was determined in 4T1 cells treated with 0.3 nM -1 mM Talazoparib (TAZ:PARPi), ABBV-075 (BETi), or combined with RPT ([^{177}Lu]Lu-NM600). Cell viability was assessed at 24 h, 48 h, 72 h, and 96 h after treatment. IC_{50}s were determined, and combination effects were evaluated between treatments using established synergy models. Expression changes in the DDR genes (e.g., BRCA1/2 and RAD51) were measured 24h-post treatment with BETi or RPT by qPCR. Therapy studies employed female Balb/c 8-10 weeks old subcutaneously implanted with 4T1 cells. Mice bearing 4T1 tumors were divided into five groups (n=5): control, RPT, RPT + PARPi, RPT + BETi and RPT + PARPi + BETi. RPT consisted of single 9.25 MBq IV injection of [^{177}Lu]Lu-NM600. PARPi (TAZ, 0.5 mg/kg) and BETi (ABBV-075, 1 mg/kg) were orally administrated for 14 days starting concomitantly with [^{177}Lu]Lu-NM600 injections. Tumor volume, animal weight and overall survival were monitored thrice weekly. ***Results:*** ABBV-075 and TAZ showed similar nanomolar cytotoxicity at 72 and 96 h post-treatment (IC_{50}s: 369 vs. 414 nM and 8 vs. 6 µM, respectively). Therefore, 300 nM of ABBV-075 and TAZ were employed in all subsequent in vitro combinations. Synergistic effects were observed between ABBV-075, TAZ, and increasing doses of ^{177}Lu (0.3 to 30 Gy). Combination treatment resulted in greater cytotoxicity compared to either ^{177}Lu or inhibitors/drugs alone. Treatment with BETi resulted in downregulation of BRCA1, BRCA2, and RAD51 genes confirming DDR inhibition as the potential mechanisms for the radiosensitization of 4T1 cells. The triple combination treatment demonstrated significant tumor growth inhibition compared to all other treatment cohorts ($P < 0.05$). Median overall survival was 18, 14, 11, 18, 18, 23, and 28 in the vehicle (n=5), PARPi (n=5), BETi (n=5), [^{177}Lu]Lu-NM600 (n=5), [^{177}Lu]Lu-NM600 + BETi (n=5), [^{177}Lu]Lu-NM600+ PARPi (n=5) and [^{177}Lu]Lu-NM600 + PARPi + BETi (n=5), respectively ***Conclusion:*** These findings demonstrated the enhance potency of RPT when combined with clinically relevant PARPi and BETi and the potential this combination therapy to tackle TNBC.

EP-0071

^{177}Lu-Microspheres as Biocompatible Micro-Seed Implants for Loco-regional Radiation Ablation in Breast Cancer: A Preclinical Proof-of-Concept

S. Chopra, *A. Aggarwal, K. Kaur, S. R. Shovan, A. Kumar, A. Bal, A. S. Oinam, B. R. Mittal, J. Shukla;*
Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Over 75% of breast tumor recurrences occur within ~2 cm of the surgical margin, primarily due to residual clonogens and delays in initiating post-operative radiotherapy. To address this, we conducted a proof-of-concept preclinical study using ^{177}Lu-microspheres for Intra-operative Radiopharmaceutical Therapy (IORPT), delivering a localized 60 Gy boost to the tumor bed following resection in breast cancer-bearing rat models. We also evaluated their potential as permanent intra-tumoral micro-seed implants for neoadjuvant therapy. ***Materials and Methods:*** Physicochemical characterization of ^{177}Lu-microspheres was performed using DLS-PSA, SEM, zeta potential, XRD, FTIR, and EDS. Radiochemical purity, sterility, and apyrogenicity were evaluated for quality control. Shelf-life was determined at room temperature and 4°C, with stability evaluated in human serum and PBS for 21 days.Triple-negative breast carcinoma was induced in 20 female wistar rats, divided into four groups (n=5 each):Control Group A underwent tumor resection without IORPT. Margins were sent for histopathology. Whole-body (WB)-CT scans were done up to 3-months post-surgery to assess recurrence.Treatment Group A underwent tumor resection followed by IORPT using 18.5 ± 7.4 MBq ^{177}Lu-microspheres (60 Gy). SPECT-CT scans were performed at 15 days, 1 and 2-months, followed by CT at 3-months.Control Group B didn't receive any treatment. WB-CT scans were conducted up to 3-months for disease monitoring. Treatment Group B received DSA-guided intra-tumoral injection of 29.6 ± 12.9 MBq ^{177}Lu-microspheres (100 Gy). SPECT-CT scans were done at multiple time points up to 2-months and WB-CT at 3-months for response evaluation. ***Results:*** ^{177}Lu-microspheres were quasi-spherical (mean diameter: 5.9 µm), with efficient radiolabeling (90 ± 8% yield, RCP >99%), sterility, and 21-day stability. In Control Group A (no IORPT), 4/5 rats showed recurrence (mean: 4 ± 1.6 weeks) out of which only one rat showed tumor involvement of resected margins on histopathology. Treatment Group A (post-IORPT) showed recurrence in only 2/5 rats, with one case of margin involvement. Mean recurrence time was prolonged to 10.5 ± 2.9 weeks. SPECT-CT demonstrated effective

localization and sustained retention of radiotracer in tumor bed for up to 2-months, with no evidence of leaching. In Control Group B (no treatment), mean survival was 16.2 ± 3.5 weeks, with mean tumor volume of 31.8 ± 2.8 cc. In Treatment Group B (intratumoral therapy), survival exceeded 25 weeks (study endpoint), with tumor volume reduced to 2.4 ± 1.1 cc. SPECT/CT confirmed prolonged intratumoral localization of the radiotracer without leaching for up to 2-months post-treatment. ***Conclusion:*** ^{177}Lu-microspheres proved to be safe, biocompatible, and effective permanent implants for both IORPT and neoadjuvant therapy, improving loco-regional control and survival with minimal side effects.

EP-0072

Preclinical Evaluation of ^{161}Tb-BPAMD: A Bone-Targeting Radiopharmaceutical with High Affinity and Stability

A. Vukadinovic, *D. Stankovic, M. Mirkovic, D. Jankovic, P. Sitarica, M. Maric, M. Peric, S. Vranjes-Djuric, M. Radovic;*
University of Belgrade, Vinca Institute of Nuclear Sciences, Belgrade, SERBIA.

Aim/Introduction: Bone metastases are a common complication of advanced cancers, leading to significant morbidity. Radiopharmaceutical therapy using bone-targeting agents labeled with β^--emitting radionuclides has proven effective in pain palliation and disease management. BPAMD, a macrocyclic bisphosphonate with high affinity to bone, has demonstrated excellent results when labeled with ^{177}Lu. Terbium-161 (^{161}Tb) is a promising alternative due to its similar coordination chemistry, higher linear energy transfer (LET), and emission of conversion and Auger electrons. This study aims to evaluate the radiolabeling, stability, and biodistribution of ^{161}Tb-BPAMD. ***Materials and Methods:*** BPAMD was labeled with ^{161}Tb (95 °C, 30 min), and the radiochemical purity was measured by radio-thin layer chromatography (ITLC). Stability studies in phosphate-buffered saline (PBS) and human serum were performed over 48 hours. In vitro hydroxyapatite (HAP) binding assays were conducted to evaluate mineral affinity. Biodistribution studies were conducted in healthy Wistar rats following intravenous administration, and radioactivity in excised organs was measured via gamma counting and expressed as % the injected dose (%ID). ***Results:*** The radiolabeling of BPAMD with ^{161}Tb achieved radiochemical purity exceeding 99% under optimized conditions. The complex remained stable (>98% RCP) in PBS and serum for at least 48 hours, demonstrating high kinetic stability. In vitro HAP binding studies revealed a strong mineral affinity with high binding efficiency (>98%). In vivo biodistribution showed rapid and high skeletal uptake, with more than 60% ID localizing in bone tissues within 2 hours post-injection. Non-target organ uptake was minimal, and clearance from soft tissues was fast, indicating a favorable pharmacokinetic profile. ***Conclusion:*** ^{161}Tb-BPAMD is a promising candidate for targeted radionuclide therapy of skeletal metastases. Its excellent in vitro stability and bone-targeted biodistribution suggest a strong potential for clinical translation. The overall biodistribution pattern was highly analogous to that reported for ^{177}Lu-BPAMD, but ^{161}Tb's additional low-energy electron emission may offer enhanced therapeutic efficacy at micrometastatic sites. Clinical trials should be carried out to validate the efficacy in human patients.

EP-0073

Dimeric CCK2R Radiotheranostic Tracers Synergize with mTOR Inhibition for Enhanced Tumor Therapy

L. Bian;
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Cholecystokinin-2 receptor (CCK2R) is highly expressed in neuroendocrine tumors and serves as a promising target for radiotheranostics. However, current CCK2R-targeted radiopharmaceuticals suffer from suboptimal tumor uptake and retention. This study aimed to develop a novel dimeric radiotheranostic probe for improved PET imaging and therapy, and to evaluate its synergistic effect with mTOR inhibition in refractory tumors. ***Materials and Methods:*** A novel dimeric probe, DOTA-CCK2R-dimer, was synthesized and radiolabeled with either ^{68}Ga for PET imaging or ^{177}Lu for therapy. Radiochemical properties, hydrophilicity, stability, and pharmacokinetics were assessed. In vitro uptake studies were performed in CCK2R-positive AR42J cells. In vivo micro-PET/SPECT imaging, biodistribution, and histological analyses were conducted in AR42J tumor-bearing mice. Combination therapy with the mTOR inhibitor RAD001 was evaluated for tumor suppression and survival. Single-cell RNA-seq was used to explore tumor heterogeneity and treatment response. ***Results:*** [^{68}Ga]Ga-DOTA-CCK2R-dimer exhibited higher tumor uptake and prolonged retention compared to monomeric analogues, with enhanced tumor-to-background contrast and receptor specificity. [^{177}Lu]Lu-DOTA-CCK2R-dimer enabled long-term tumor retention and selective elimination of highly proliferative, poorly differentiated tumor subpopulations. Combination with RAD001 significantly enhanced therapeutic efficacy, prolonging survival and increasing DNA damage. Mechanistically, RAD001 suppressed glutathione-mediated detoxification pathways, elevating oxidative stress. GSTK1 was identified as a key regulatory factor, linking metabolic detoxification to radiosensitivity. ***Conclusion:*** This study introduces a potent dimeric CCK2R-targeted radiotheranostic system with strong preclinical evidence for efficacy and safety. The synergistic combination with mTOR inhibition enhances treatment outcomes by targeting resistant tumor subpopulations and modulating oxidative stress responses. These findings provide a promising strategy for improving radioligand therapy in neuroendocrine tumors.

EP-0074

Experimental radionuclide therapy using [^{177}Lu]Lu-AU-SAR-M1 in GRPR-positive xenograft models

K. Obeid[1], *P. Kanellopoulos*[1], *E. Bezverkhniaia*[1], *Y. Liu*[2], *M. W. Konijnenberg*[3], *B. A. Nock*[4], *T. Maina*[4], *V. Tolmachev*[1], *A. Orlova*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Uppsala Univeristy, Uppsala, SWEDEN,* [3]*Erasmus MC, Rotterdam, NETHERLANDS,* [4]*NCSR Demokritos, Athens, GREECE.*

Aim/Introduction: Gastrin-releasing peptide receptor (GRPR) is an attractive target for targeted radiotherapy due to its high overexpression in many malignancies, including prostate and breast cancers. In previous work, we evaluated different Lu-177-labeled GRPR antagonists, identifying [^{177}Lu]Lu-AU-SAR-M1 (DOTAGA-AMA-Dig-DPhe-Gln-Trp-Val-Sar-His-Leu-NHEt) as the most promising candidate for a follow-up therapy study (1). Therefore, in this study, we evaluated the anti-tumoral efficacy of [^{177}Lu]-AU-SAR-M1 in PC-3 prostate cancer GRPR-expressing xenograft model. ***Materials and Methods:*** Biodistribution studies of AU-SAR-M1 labeled with Lu-177 were performed on PC-3 xenografted mice 0.5h, 1h, 4h, 24h, 48h, and 76h post-injection to evaluate dosimetry. Two different therapy plans were designed (n=10-8): Group 1 received injections once weekly (12MBq, 150pmol) to a total of six injections; Group 2 received three injections within a week - 30 days break - three injections within a week (12MBq, 150pmol). Both groups were pre-treated orally with sacubitril (1.4mg) 30min before each injection. SPECT/CT images were acquired one day after the first injection. As a comparator, a third group was treated with vehicle (PBS+ 1%BSA w/v). The humane endpoint is set to when the tumor volume exceeds 1000mm^3, when bleeding ulcerations are observed, or when overall weight loss is >15%. Animal weights and tumor measurements were monitored twice weekly. Blood samples were taken weekly to evaluate blood toxicity. ***Results:*** Labeling of AU-SAR-M1 with Lu-177 provided >98% radiochemical yield and >96% purity

(molar activity: 80MBq/nmol). Biodistribution studies showed a fast washout of activity from non-tumor tissues, with a tumor-to-blood dose ratio of 596, while the tumor-to-kidneys dose ratio was 5.4. Treatment with [^{177}Lu]Lu-AU-SAR-M1 significantly prolonged the median survival of Groups 1 and 2 (all mice alive at day 67), compared to the mice treated with the vehicle (median survival 57 days). On day 67, five mice in Group 1 and four in Group 2 were tumor-free. Among the remaining animals, tumors in Group 1 were stabilized and growing slowly (78±46mm^3). In Group 2 three tumors were slowly growing (67±13mm^3), while two showed exponential growth (368±68mm^3). Tumors were visualized with SPECT/CT images, confirming the in vivo tumor targeting of [^{177}Lu]Lu-AU-SAR-M1. No blood toxicity was observed in any of the three groups. ***Conclusion:*** GRPR-targeting radiotherapy using [^{177}Lu]Lu-AU-SAR-M1 eradicated tumors in PC-3 xenografts or stabilized their growth, thus enhancing the median survival of mice without causing bone marrow toxicity. The dosing regimen should be further optimized. ***References:*** 1. Obeid et al, iSRS25 abstract ID 109.

Granzyme B PET Imaging Enhances Belzutifan and KL201 Combination Therapy Using a Tumor Cell Membrane Nano-Loading Platform for Renal Cell Carcinoma

Y. Hou[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: Renal cell carcinoma (RCC) is the most prevalent malignant tumor of the adult kidney. Tumor cell membrane nanocarrier platforms, featuring homologous targeting capabilities, can improve drug targeting, maximize therapeutic efficacy, and minimize adverse effects. Belzutifan, an FDA-approved HIF-2α inhibitor, disrupts the pVHL-HIF-VEGF pathway to suppress tumor growth/angiogenesis. KL201, a circadian regulator, stabilizes cryptochrome 1 (CRY1), modulating circadian rhythms to influence cancer progression. This study pioneers a tumor cell membrane platform co-delivering Belzutifan and KL201 for RCC therapy. ***Materials and Methods:*** Belzutifan and KL201 were dissolved in DMSO, mixed, and sonicated to form the Belzutifan-KL201 complex. Renca tumor cells were subjected to hypo-osmotic lysis and differential centrifugation to isolate tumor cell membranes (CCm). The CCm was then mixed with the Belzutifan-KL201 complex and extruded through a 200 nm porous polycarbonate membrane to obtain CCm-Belzutifan-KL201. Similarly, CCm-Belzutifan and CCm-KL201 complexes were prepared. The size, morphology, zeta potential, and solution stability of these complexes were evaluated using transmission electron microscopy (TEM) and dynamic light scattering (DLS). In vivo efficacy was tested using both in situ Renca tumor and subcutaneous rhabdomyosarcoma mouse models. Mice were divided into four groups: control, Belzutifan, KL201, and combination therapy. Treatments were administered via daily tail vein injections. Tumor immune responses were monitored using ^{68}Ga-GZP PET/CT imaging, while tumor growth was assessed by measuring body weight and tumor volume over a 14-day period. Additionally, blood and tissues from the heart, liver, spleen, lungs, and kidneys were collected for blood analysis and hematoxylin and eosin (H&E) staining. ***Results:*** The CCm-Belzutifan-KL201, CCm-Belzutifan, and CCm-KL201 complexes formed spherical vesicles with hydrated particle sizes of 192.8 ± 9.3 nm, 155.3 ± 8.3 nm, and 163.5 ± 2.7 nm, respectively, and zeta potentials of -17.2 ± 0.8 mV, -13.8 ± 0.5 mV, and -12.0 ± 0.7 mV, respectively. All formulations demonstrated good stability in PBS solution for up to 5 days. In vivo radioimmunoimaging revealed that the combination therapy group exhibited a significantly stronger immune response compared to the groups treated with Belzutifan or KL201 alone. Furthermore, the combination group showed the smallest tumor volumes and the most pronounced tumor suppression after 14 days of treatment. ***Conclusion:*** This study develops a tumor cell membrane nanoplatform co-loading Belzutifan and KL201, demonstrating synergistic antitumor effects via enhanced immune activation and circadian modulation. The platform exhibits optimal size, stability, and dual-drug delivery efficacy, offering a promising strategy for RCC treatment. ***References:*** This research was supported by Hubei Provincial Natural Science Foundation Project (2024AFB633). PET imaging of integrin a_vb_8 upregulation as an early prognostic marker for radiotherapy response

A. Litvinenko[1], *A. Sesink*[1], *L. Wendlinger*[1], *D. Repáraz*[2], *H. Koch*[1], *D. Viertl*[1], *F. Herrera*[1], *J. Notni*[3], *M. Schottelius*[1];
[1]*CHUV, Lausanne, SWITZERLAND,* [2]*Unibe, Bern, SWITZERLAND,* [3]*Trimt, Radeberg, GERMANY.*

Aim/Introduction: TGF-β is a tumor-promoting cytokine that induces resistance to immuno- and radiation therapy by creating immunosuppressive tumor microenvironment (TME). Upon external beam radiation therapy, TGF-β is released in a dose-dependent manner from the latent form (expressed by immune cells in the TME). Integrin $\alpha_v\beta_8$, expressed on tumor cells, plays a crucial role in the release of TGF-β. We therefore investigated if radiation-induced upregulation of $\alpha_v\beta_8$ could be exploited as a surrogate marker for TGF-β, aiding early treatment response assessment and guiding combination treatments. ***Materials and Methods:*** Baseline (D -1) integrin $\alpha_v\beta_8$ expression was assessed in four different subcutaneous syngeneic mouse tumor models (MC38 and CT26 (colon carcinoma), EMT6 (breast carcinoma), and TRAMP-C2 (prostate adenocarcinoma)) using ^{68}Ga-Triveoctin PET/CT (100 pmol/mouse, 40-60 min p.i.). Tumors were then irradiated with a single dose of 30 Gy on day 0, and ^{68}Ga-Triveoctin imaging was repeated on day 1, 3, 7 and 9 post irradiation to monitor irradiation-induced upregulation of $\alpha_v\beta_8$ expression. Non-irradiated control animals were imaged at the same time points to assess tumor growth-related changes in $\alpha_v\beta_8$ expression. At selected time points, mice were sacrificed, tumors were excised, paraffin-embedded, and stained for TGF-β and $\alpha_v\beta_8$ using immunofluorescence. ***Results:*** All four tumor models demonstrated low baseline $\alpha_v\beta_8$ expression before irradiation, with the EMT6 model showing the highest and the CT26 model showing the lowest tracer uptake (0.81 ± 0.29 vs 0.40 ± 0.18 %iD/ml, respectively). Across four tumor models, some irradiated mice showed a gradual increase in $\alpha_v\beta_8$ integrin expression—independent of tumor growth, as ^{68}Ga-Triveoctin uptake remained stable in non-irradiated controls—while others exhibited a decrease in uptake. In the MC38 model, changes in $\alpha_v\beta_8$ expression closely correlated with radiotherapy response—mice with complete or partial responses showed lower $\alpha_v\beta_8$ uptake on day 4 post-irradiation compared to pre-irradiation levels (D -1: 0.51+0.04 %ID/ml vs D4: 0.38+0.06 %ID/ml), unlike non-responders (D -1: 0.56+0.06 %ID/ml vs D4: 0.81+0.10 %ID/ml). Additionally, to unravel the correlation between ^{68}Ga-Triveoctin PET signal intensity, tumoral $\alpha_v\beta_8$ integrin expression and TGF-β levels before and after irradiation, immunofluorescence staining of tumor tissue is ongoing. ***Conclusion:*** Preliminary data show a radiation-induced increase in ^{68}Ga-Triveoctin uptake across all tumor models investigated (TRAMP-C2 > EMT6 > CT26 = MC38), with two distinct patterns of $\alpha_v\beta_8$ upregulation. In the MC38 tumor model, these patterns were confirmed to correlate with radiotherapy response, supporting the potential of ^{68}Ga-Triveoctin as a predictive marker for treatment outcome.

Enhancing Triple-Negative Breast Cancer Radiotherapy via EZH2-Targeted Nanoplatform and Synergistic Radionuclide Therapy

R. Wu[1,2,3], *Y. Hou*[1,2,3], *Z. Gao*[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: Breast cancer, and specifically triple-negative breast cancer (TNBC), continues to pose a significant global health challenge due to its aggressive characteristics and the paucity of effective treatment options. Current interventions, such as systemic chemotherapy and immunotherapy, exhibit inconsistent efficacy. This research introduces a tumor microenvironment-adaptive nanomedicine (CCm-HSA-Taz) that integrates the enhancer of zeste homolog 2 (EZH2) inhibitor Tazemetostat (Taz) with albumin-stabilized nanoparticles to facilitate targeted drug delivery. In conjunction with targeted radionuclide therapy (TRT), this approach synergistically disrupts immunosuppressive pathways and enhances therapeutic outcomes in TNBC. ***Materials and Methods:*** HSA was dissolved in deionized water, then mixed with Tazemetostat (Taz) and ultrasonicated to form HSA-Taz. CCm and HSA-Taz were combined and extruded to generate CCm-HSA-Taz, which was characterized. In the subsequent phase, a tumor-bearing model was established. Throughout the observation period, both baseline and post-treatment immune responses of the tumors were assessed using ^{68}Ga-GZP PET/CT imaging. Additionally, the body weight and tumor volume of the tumor-bearing mice were monitored regularly, and a change curve was plotted. Blood samples and vital organ tissues were collected. ***Results:*** CCm-HSA-Taz was characterized as a spherical vesicle with a hydrated particle size of 183.1 ± 10.6 nm and a Zeta potential of -14.7 ± 0.6 mV. The stability of the PBS solution in vitro was maintained effectively for 5 days. In vivo radioimmunoassay studies indicated that the immune response in the CCm-HSA-Taz combined with the [^{177}Lu]Lu radiotherapy group was significantly stronger than that observed in the CCm alone group or the [^{177}Lu]Lu radiotherapy alone group. Additionally, compared to other single treatment groups, the CCm-HSA-Taz combined with the [^{177}Lu]Lu radiotherapy group exhibited the smallest tumor volume and a significant tumor inhibition effect in the observation period. Following the combination treatment, there was an observed increase in the apoptotic cell population, and antitumor immunity was enhanced, as anticipated. Furthermore, all results were corroborated through pathological and imaging examinations. ***Conclusion:*** We developed a tumor microenvironment-adaptive nanomedicine delivering Taz to disrupt immunosuppression and enhance radiotherapy sensitivity in triple-negative breast cancer, without significant side effects in animal models. Non-invasive PET/CT imaging revealed reduced tumor glucose metabolism and improved immune cell cytotoxicity. The utilization of FDA-approved components underscores the potential for clinical translation of this strategy. ***References:*** This research was supported by Hubei Provincial Natural Science Foundation Project(2024AFB633).Zairong Gao and Xiaotian Xia contributed equally as co-corresponding authors.

Synergistic suppression of anaplastic thyroid carcinoma via targeted co-delivery of integrin αv/β3 siRNA and ^{131}I using iRGD-modified exosomes

R. Zhang[1], *W. Zhang*[2], *N. Li*[1], *S. Wang*[1], *Q. Jia*[1], *J. Tan*[1];
[1]*Department of Nuclear Medicine, Tianjin Medical University General Hospital, Tianjin, CHINA,* [2]*Department of Nuclear Medicine, West China Hospital, Chengdu, CHINA.*

Aim/Introduction: This study aimed to establish a novel ^{131}I (radioactive iodine)-labeled, iRGD-targeted exosomal delivery system derived from HEK-293T cells for the co-delivery of integrin αv/β3 small interfering RNA (siRNA) and radionuclide therapy, thereby synergistically inhibiting anaplastic thyroid carcinoma (ATC) through dual-modal gene silencing and internal irradiation. ***Materials and Methods:*** iRGD-modified exosomes loaded with αv/β3 siRNA (iRGD-exos-si-ITGαv or iRGD-exos-si-ITGβ3, denoted as iRGD-exos-si-ITGαv/β3) were isolated via ultracentrifugation. In vitro assays, including EDU proliferation, transwell migration, and apoptosis analysis, were performed to evaluate their effects on ATC cells. Tumor-targeting efficiency was dynamically monitored in nude mouse xenograft models using in vivo fluorescence imaging. The exosomes were further radiolabeled with ^{131}I (^{131}I-iRGD-exos), and their dual therapeutic efficacy was systematically assessed. ***Results:*** Both iRGD-exos-si-ITGαv and iRGD-exos-si-ITGβ3 significantly inhibited ATC cell proliferation, migration, and invasion ($p<0.05$). In vivo imaging confirmed the tumor-specific accumulation of iRGD-exos. The ^{131}I-labeled system achieved a labeling efficiency of 58.1% with radiochemical purity >95%. In xenograft models, the ^{131}I-iRGD-exos-si-ITGαv group exhibited the most potent tumor suppression ($p<0.01$), accompanied by marked downregulation of integrin αv mRNA and protein levels in tumor tissues. ***Conclusion:*** Integrin αv/β3 serves as a critical therapeutic target for ATC. The iRGD-engineered exosomal platform enables tumor-specific co-delivery of siRNA and ^{131}I, offering a synergistic strategy to suppress ATC progression via dual gene silencing and radiation therapy. This approach provides a novel clinical paradigm for treating integrin αv/β3-overexpressing malignancies, including aggressive ATC.

EP-0080

Does the PSMA ligand, PSMA-11, prevent ^{177}Lu- PSMA-617 uptake into human non-tumour cells and enhance the cytotoxic effect of ^{177}Lu-PSMA-617 in human prostate cancer cells?

Y. Zhao, *A. Alfteimi, A. Helm, M. Jueptner, U. Luetzen, M. Zuhayra; Department of Nuclear Medicine, Molecular Imaging, Diagnostics and Therapy, University Hospital of Schleswig-Holstein, Kiel, GERMANY.*

Aim/Introduction: Many patients suffer from radiation-related side effects mainly due to off-target exposure of non-tumour tissues to ^{177}Lu-PSMA-617. PSMA-11, the precursor for ^{68}Ga-HBED-CC-PSMA-11 synthesis, competes with the radioligand binding to PSMA. The precursor may, therefore, reduce the cytotoxicity of ^{177}Lu-PSMA-617 by interfering with its uptake in non-tumour tissues. We investigated: 1) the uptake of ^{177}Lu-PSMA-617 in the presence of cold PSMA-11 into human normal and tumour prostatic cells, salivary glands and kidney cells, and 2) the pharmacological effects of PSMA-11 with or without ^{177}Lu-PSMA-617 in the human prostate cancer (PCa) cell lines, LNCaP and PC3 cells. ***Materials and Methods:*** 1) To evaluate the uptake of the radioligand, human PCa cells, LNCaP and PC3; human salivary glands cells, Hs.917T and A-253; and human kidney cells, RPTEC and 293T were treated with ^{177}Lu-PSMA-617 and various concentrations of PSMA-11. The radioactivity of cell pellets measured with a γ-counter was normalised for corresponded protein content. The results are expressed as cpm/mg of proteins. 2) LNCaP cells, a PSMA-positive Pca cell line, were exposed to various concentrations of PSMA-11 for 24 h and 48 h. LDH activity, a cell death parameter, was quantified by the Cytotoxicity Detection Kit and cell proliferation by WST-1 assay and cresyl violet staining. ***Results:*** The ^{177}Lu-PSMA-617 uptake into LNCaP cells was not affected by low concentrations of PSMA-11 (5 nM and 10 nM), but significantly reduced by concentrations higher than 20 nM. PSMA-11 inhibits the uptake of ^{177}Lu-PSMA-617 into PSMA-positive cells approximately ten times more effectively than PSMA-617. High

amount of PSMA-11 (100 nM) showed a tendency to decrease the uptake of ^{177}Lu-PSMA-617 in salivary glands cells and to increase its uptake in kidney cells; both effects were not significant. PSMA-11 had no effect on LDH release from LNCaP cells, but significantly reduced LNCaP cell proliferation by approximately 50 % after 24 h of exposure even at low concentrations (10 nM) (P<0.001) and by 30 % after 48 h exposure (P<0.05) at concentrations 50 nM. The execution of LNCaP cells by ^{177}Lu-PSMA-617 was significantly increased in the presence of PSMA-11 up to 10 nM (p<0.001). ***Conclusion:*** In conclusion, PSMA-11 does not interfere with ^{177}Lu-PSMA-617 uptake in human non-tumour tissues, such as the salivary glands and kidney. However, synergistical treatment with ^{177}Lu-PSMA-617 and PSMA-11 at low concentrations (10 nM) significantly enhances ^{177}Lu-PSMA-617-induced PCa cell death.

EP-0081

Theranostic PET Imaging and Radioimmunotherapy (RIT) of Head and Neck Squamous Cell Carcinoma (HNSCC) Patient-Derived Xenografts (PDX) in NRG mice with Anti-Epidermal Growth Factor Receptor (EGFR) [^{64}Cu]Cu- and [^{177}Lu]Lu-DOTA-Panitumumab-F(ab')$_2$

C. Chan[1], *M. Khosravifarsani*[1], *A. Ku*[1], *J. Meens*[1], *L. Ailles*[1], *S. Bratman*[1], *R. Reilly*[1,2];
[1]*Department of Pharmaceutical Sciences, Leslie Dan Faculty of Pharmacy, Toronto, ON, CANADA,* [2]*Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA.*

Aim/Introduction: Head and neck cancer (HNSCC) has a high risk of recurrence and metastasis despite treatment by surgery, radiation or chemotherapy. Our aim was to study a novel theranostic approach to PET imaging and radioimmunotherapy (RIT) of HNSCC in patient-derived xenograft (PDX) mouse models using anti-epidermal growth factor receptor (EGFR) [^{64}Cu]Cu- and [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$, respectively. EGFR are overexpressed in 90% of HNSCC. ***Materials and Methods:*** Three HNSCC PDX (#88955, #73191, #61531) were implanted s.c. in NRG mice. EGFR expression was assessed by flow cytometry. PET and biodistribution (BOD) studies were performed at 24 h post i.v. injection (p.i.) of [^{64}Cu]Cu-DOTA-panitumumab F(ab')$_2$ (7-15 MBq; 50 µg) in tumour-bearing NRG mice (n=3-5). Normal tissue toxicity of [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$ (6.0 MBq) was evaluated in non-tumour bearing NRG mice by complete blood cell counts and blood biochemistry at 14 d p.i. Mice with PDX were treated by i.v. injection of 4.0-5.0 MBq (50 µg) of [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$. Control mice received unlabeled DOTA-panitumumab F(ab')$_2$ or normal saline. A tumour growth index (TGI) was determined by dividing the tumour volume by that prior to treatment. TGI was plotted vs. time (d) and the slope of the curve determined. ***Results:*** EGFR expression of PDX #88955 was higher than #73191 or #61531, but all PDX were EGFR-positive. PET with [^{64}Cu]Cu-DOTA-panitumumab F(ab')$_2$ detected all PDX tumours. BOD studies showed higher tumour uptake in PDX #88955 (17.0±0.9%ID/g) than #73191 (13.4±2.5%ID/g; P<0.05) or #61531 (6.7±3.5%ID/g; P<0.05). Liver uptake was observed on PET. Liver, spleen and kidney uptake were 14.1-15.8, 4.1-6.9 and 6.2-6.9%ID/g, respectively. No normal tissue toxicity was found at 14 d p.i. of [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$. Blood cell counts and alanine aminotransferase (ALT) and creatinine levels were not significantly different than NRG mice injected with normal saline (n=4; P>0.05). The slope of the TGI vs. time (d) curve for PDX #88955 treated with [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$ (0.81±0.10 d^{-1}) was 1.7-fold significantly lower (P≤0.002) than DOTA-panitumumab F(ab')$_2$ (1.35±0.13 d^{-1}) or normal saline (1.65±0.11 d^{-1}). The slope of the TGI curve for PDX #73191 treated by RIT (0.10±0.01 d^{-1}) was 4.7-6.2 fold significantly lower (P<0.001) than DOTA-panitumumab F(ab')$_2$ (0.47±0.06 d^{-1}) or saline (0.62±0.04 d^{-1}). The slope for PDX #61531 treated by RIT (0.09±0.01 d^{-1}) was 1.9-fold significantly lower (P<0.001) than DOTA-panitumumab F(ab')$_2$ (0.17±0.01 d^{-1}) or saline (0.18±0.02 d^{-1}). ***Conclusion:*** Theranostic PET and RIT with [^{64}Cu]Cu- and [^{177}Lu]Lu-DOTA-panitumumab F(ab')$_2$ is a promising approach for detection and treatment of HNSCC.

Dual-Line Approach: Radiosensitisation in Prostate Cancer Cell Lines with histone deacetylase inhibitors and Ac-225, Lu-177 and X-ray Radiation

T. Wallner*, R. Runge, K. Tietze, K. Wetzig, R. A. Bundschuh, J. Kotzerke;*
Universitätsklinikum Carl Gustav Carus, Dresden, GERMANY.

Aim/Introduction: Current therapeutic applications in nuclear medicine predominantly involve the use of beta and alpha emitters. Various combinatorial approaches play an important role in improving therapeutic outcomes. The addition of epigenetically modifying agents may increase the efficacy of radionuclide treatments even further. This study examines the cytotoxic effects of the histone deacetylase inhibitor (HDACi) Suberoylanilide hydroxamic acid (SAHA) combined with alpha irradiation (Ac-225), beta irradiation (Lu-177) or X-ray irradiation in two prostate cancer cell lines, PC3 and Du-145. ***Materials and Methods:*** Du-145 and PC3 prostate cancer cell lines were pre-incubated with SAHA at 0.5 & 2.5 µM and 2.5 µM for 24 hours respectively. Subsequently they were exposed to either Ac-225 (0.1 - 2.0 Gy), Lu-177, (0.5 - 10.0 Gy), or X-ray (1.0 - 10.0 Gy) irradiation. Cell survival was assessed using a clonogenic survival assay, while apoptosis and necrosis were assessed by PI & Annexin V staining and Western Blotting. ***Results:*** In PC3 cells, the combined treatment with 2.5 µM of SAHA and irradiation did not significantly alter cell survival compared to irradiation alone. Conversely, Du-145 cells treated with 2.5 µM of SAHA showed decreased survival rates across all three irradiation types, with the most pronounced effects seen with X-ray exposure. At 10 Gy, cells showed a survival fraction of 2.9% without and 0.66% with SAHA. PI & Annexin V assay data illustrated no clear correlation between SAHA and the induction of early apoptosis and necrosis in PC3 cells. However, SAHA partially increased necrosis and late apoptosis rates in Du-145 cells. Western Blots revealed the expression of the pro- and anti-apoptotic protein Bcl2 and Bax in PC3 cells. Interestingly, the expression of Bax in Du-145 cells appears to be cell specific, with no notable upregulation of pro-apoptotic proteins following SAHA treatment. ***Conclusion:*** Du-145 cells exhibit a marked sensitivity to SAHA, supporting its potential as a radiosensitiser. This effect may enhance therapeutic outcomes in patients with a poor response to radionuclide therapy alone. In contrast, PC3 cells exhibited limited sensitivity to SAHA, aligning with existing reports of SAHA resistance in this cell line. Our data suggests that SAHA's effects are cell-specific, likely mediated by differences in apoptotic signalling. Furthermore, PI & Annexin V results imply that observed effects may not be primarily driven by apoptotic mechanisms, but rather by alterations in cell cycle regulation or involvement of alternative cellular pathways.

Towards Monte-Carlo Based Preclinical Personalized Dosimetry for Targeted Radioligand-Immunotherapy

O. Kochebina, *C. Comtat, A. Grindel, C. Truillet;*
BioMaps Laboratory, Service Hospitalier Frédéric Joliot, Commissariat à l'Énergie Atomique et aux Énergies Alternatives, Université Paris-Saclay, Orsay, FRANCE.

Aim/Introduction: Radioligand therapy (RLT) has demonstrated promising results for survival and patient care in prostate cancer and neuroendocrine tumors. However, one of the challenges lies in expanding the application to other cancer types, which requires targeting alternative tumor-specific biomarkers. The strategy involves the combination of immunotherapy and RLT, for instance by targeting PD-L1. This approach, radioligand-immunotherapy, aims to tumor cell radiation damage while simultaneously activating the immune response. To optimize such treatments, individualized dosimetry is critical. We propose leveraging ^{89}Zr-labeled anti-PD-L1 PET imaging to predict the agent biodistribution and to perform Monte Carlo-based preclinical dosimetry for the ^{177}Lu-labeled anti-PD-L1 radioligand, under the assumption of similar pharmacokinetics. ***Materials and Methods:*** We use the Monte Carlo platform GATE version 10 (2024) [1] to simulate particle-matter interactions for preclinical dosimetry. Our first objective is to develop and validate a full simulation and analysis pipeline, benchmarking it against published results using the MIRD formalism and organ-based S-values on ^{18}F data [2,3]. Then, we used the validated pipeline to predict ^{177}Lu absorbed doses at the organ level from ^{89}Zr PET imaging data under the assumption of similar radiokinetics. In a second phase, we aim voxel-based dosimetry by generating Monte Carlo-based 3D dose rate maps for each time point for more accurate dosimetry analysis of the PET acquisition. These maps can then be also integrated over time to compute the total absorbed dose at the voxel level, enabling spatially resolved and individualized dose estimation. ***Results:*** The dosimetry pipeline is validated on published ^{18}F data [2], and the differences of obtained with GATE10 Monte Carlo S-values do not exceed 20% compared to [3]. The ^{177}Lu dosimetry uses the same validated pipeline and relies to ^{89}Zr PET-based radiokinetic data. Uncertainty analysis was also conducted to ensure robust dose interpretation. ***Conclusion:*** This work represents a first step toward personalized dosimetry for targeted radioligand-immunotherapy. The validated pipeline enables accurate organ-level dose estimation from ^{89}Zr PET data and supports absorbed dose recalculation for ^{177}Lu. Future developments will focus on voxel-based dosimetry, with dose rate map generation for each PET (^{89}Zr) and/or SPECT (^{177}Lu) acquisition. This will pave the way for an optimized and accelerated workflow, with the long-term goal of creating a "push-button" open-source tool for preclinical personalized dosimetry. ***References:*** [1] http://www.opengatecollaboration.org/ [2] Gupta A et al. doi: 10.1088/1361-6560/ab134b. Optimisation and calibration for pre-clinical SPECT imaging of Pb-212 for targeted alpha therapy

P. Gape[1], *A. Jones*[1], *A. Drews*[1], *G. Stasiuk*[1], *L. Livieratos*[1], *M. K. Schultz*[2], *S. Y. A. Terry*[1];
[1]King's College London, London, UNITED KINGDOM, [2]Perspective Therapeutics, Coralville, IA, UNITED STATES OF AMERICA.

Aim/Introduction: To study the relationships between radiation absorbed dose and biological response for molecular radiotherapy, imaging systems must be calibrated. This work aims to determine a protocol for SPECT imaging of ^{212}Pb and calibrate the scanner for quantitative imaging and dosimetry. ***Materials and Methods:*** ^{212}Pb was supplied by Perspective Therapeutics (Iowa, USA). Images were acquired on a Mediso nanoScan SPECT/CT small animal scanner with high energy collimators. Single peak (239/583/78 keV, 20/20/30% width), and multipeak acquisitions were investigated. The 583 keV peak was included to directly image ^{208}Tl. To determine reconstruction parameters, a phantom with spheres of varying diameter (3.95, 4.95, 6.23, 7.86 mm) was filled with a known activity concentration (10:1 sphere to background activity concentration ratio) and scanned. Images were reconstructed with varying numbers of reconstruction subsets and iterations. Contrast recovery coefficient was calculated for each sphere according to NEMA guidelines [1] and used to choose an optimal reconstruction. A calibration factor (CF, MBq/kcps) with associated uncertainty was determined by imaging a uniform phantom at a known activity concentration. Activity recovery and partial volume effects were characterized using the sphere phantom (activity concentration = 0.89 MBq/mL). Volumes of interest (VOIs) were drawn to construct a recovery curve. The quantitative imaging workflow was validated in an anatomical setting by imaging a preclinical mouse phantom (Bioemtech), with kidneys, liver, bladder and tumour compartments filled with a known activity concentration. Agreement between known and recovered activity was calculated. Uncertainties were calculated in accordance with EANM guidelines [2]. ***Results:*** All sphere sizes were resolvable, implying achievable spatial resolution is < 3.95 mm. Contrast recovery coefficient plateaued when reconstruction reached 48 iterations with 3 subsets. Activity was accurately recovered in spheres to on average 7% (SD = 9%) across sizes and energy windows. The largest calculated uncertainty was 23%. In the mouse phantom, partial volume loses of 14 - 20% were seen for kidneys, bladder and tumour, but with an oversized VOI activity was recovered to on average 97% of true activity (-11% to + 16% range). ***Conclusion:*** Quantitative imaging for ^{212}Pb (and ^{208}Tl) is feasible and accurate based on derived activity calibration and partial volume correction factors. This work provides a workflow for calibration of a SPECT system for quantitative imaging with a novel isotope. ***References:*** [1] NEMA Standards Publication NU 1-2018, Performance Measurements of Gamma Cameras [2] Gear JI et al., Eur J Nucl Med Mol Imaging. 2018 Dec;45(13):2456-2474.

Clinical feasibility of ^{99m}Tc-CTR-FAPI SPECT/CT imaging in lung cancer: a prospective head-to-head comparison with ^{18}F-FDG PET/CT

S. Li[1,2], *Z. Li*[3], *M. Xu*[4], *P. Yang*[1], *H. Xu*[1], *C. Van De Wiele*[2], *Z. Liu*[5], *Y. Wu*[1];
[1]Peking University Cancer Hospital Inner Mongolia Hospital/ Cancer Hospital Affiliated to Inner Mongolia Medical University, Hohhot, CHINA, [2]Gent University, Gent, BELGIUM, [3]Peking University Cancer Hospital, Beijing, CHINA, [4]Changping Laboratory, Beijing, CHINA, [5]Peking University, Beijing, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP), overexpressed in cancer-associated fibroblasts (CAFs), is a promising target for tumor stroma imaging. Although positron emission tomography (PET) tracers such as ^{68}Ga-FAPI demonstrate excellent imaging performance, their widespread clinical application is hindered by high costs, short half-life, and limited equipment availability. In this prospective study, we evaluated the diagnostic potential of ^{99m}Tc-CTR-FAPI, a covalent targeted radioligand for FAP associated SPECT/CT imaging, in patients

suffering from lung cancer, using ^{18}F-FDG PET/CT imaging as the reference standard. ***Materials and Methods:*** Forty-one treatment-naive patients with histologically confirmed lung cancer underwent both ^{99m}Tc-CTR-FAPI SPECT/CT and ^{18}F-FDG PET/CT imaging within a 1-3 day interval. Additionally, six healthy volunteers underwent sequential whole-body planar imaging with ^{99m}Tc-CTR-FAPI. Radiation dosimetry was assessed with OLINDA/EXM 2.0. Detection rates, SUV_{max}, target-to-background ratio (TBR), and TNM staging concordance were analyzed using McNemar's test, Wilcoxon signed-rank test, and Kappa statistics. ***Results:*** No significant adverse events were observed. ^{99m}Tc-CTR-FAPI showed physiological uptake in salivary glands, thyroid, liver, spleen and pancreas, with low background activity. Both modalities achieved 100% primary lesion detection (^{99m}Tc-CTR-FAPI: SUV_{max} 7.71 ± 4.00, TBR 3.77 ± 2.59). For metastases, ^{18}F-FDG detected 222 lesions versus 185 with ^{99m}Tc-CTR-FAPI (SUV_{max} 6.59 ± 3.68, TBR 3.38 ± 2.13). TNM staging agreement was excellent (κ = 0.92), with ^{99m}Tc-CTR-FAPI providing superior contrast in brain metastases. ***Conclusion:*** ^{99m}Tc-CTR-FAPI SPECT/CT showed comparable diagnostic capability to ^{18}F-FDG PET/CT for detecting primary lung cancer lesions. Despite its lower sensitivity for small metastatic lesions, these differences did not significantly impact clinical staging. Given the widespread availability of SPECT equipment, the low cost of ^{99m}Tc radiopharmaceuticals, and favorable radiopharmacokinetics, ^{99m}Tc-CTR-FAPI demonstrates strong potential for clinical implementation, particularly in community hospitals and resource-limited regions.

EP-0086

iPSMA-BN: A novel theranostic dual target molecule, assessing two prostate cancer clinical scenarios: metastatic hormone-sensitive and metastatic hormone-resistant. Asociations with genomic alterations in DNA damage repair genes

S. Gonzalez Rueda[1], *F. Garcia Perez*[1], *A. Calderon Avila*[2], *G. Ferro Flores*[3], *Q. Pitalua Cortes*[1], *E. Gomez Argumosa*[1], *I. Soldevilla Gallardo*[1];
[1]*National Cancer Institute of Mexico, Tlalpan, Mexico City, MEXICO,* [2]*UMAE IMSS CMN SXXI Especialidades, Cuahutemoc, Ciudad de México, MEXICO,* [3]*National Institute of Nuclear Research, Toluca, Mexico City, MEXICO.*

Aim/Introduction: Prostate cancer(PC) is highly heterogeneous and agressive, often assessed with dual PET/CT ([^{18}F]FDG and PSMA),nevertheless, they are often unavailable in developing countries, as an alternative, we developed a novel heterodimer composed of iPSMA and bombesin(iPSMA-BN), overexpressed in primary and metastatic PC lesions; acting on the androgen receptor and its splicing variants through NFκβ-pathway, involved in castration resistance. The main objective of this study was to assess the uptake pattern of [^{99m}Tc]Tc-iPSMA-BN, and its association with genomic alterations in DNA damage repair(DDR) genes in mCRPC and mCSPC. Secondary objectives were the diagnostic value of [^{99m}Tc]Tc-iPSMA-BN SPECT/CT versus [^{18}F]F-PSMA-1007 PET/CT and security profile and adverse effects of [^{177}Lu]Lu-iPSMA-BN therapy. ***Materials and Methods:*** Prospective,single-centre, non-randomized, phase I/II study, that recruited 25 PC patients (18 mCRPC and 7 mCSPC), ISUP≧3, previosuly treated with ADT, ± ARPI's, ± chemotherapy.[^{99m}Tc]Tc-iPSMA-BN SPECT/CT and [^{18}F]F-PSMA-1007 PET/CT were performed at recruitment (less than one month appart). Quantitative measurements performed: target-to-background-ratio(TBR), lesion quantification and total-tumor-volume(TTV) for both(PSMA-PET/CT and heterodimer-SPECT/CT). Candidates for [^{177}Lu]Lu-iPSMA-BN treatment were considered if TBR-SPECT>TBR-PET. ***Results:*** DDR alterations were found in 60%(n=15) patients, from which 100%(n=15) were germinal and 20%(n=3) somatic; 60%(n=9) of germinal alterations were pathogenic variants(PV) and 40%(n=6) variants of unknown significance(VUS); 100%(n=3) of somatic alterations were PV. Most frequently affected genes were ATM,PALB2 and p53. Diagnostic value of [^{99m}Tc]Tc-iPSMA-BN was similar to that of [^{18}F]F-PSMA-1007,except in regional nodes,where the heterodimer had a better lesion dectection rate(p=0.046). TBR was analogous with both techiques. Receiver-operating-characteristic analysis was performed,with an AUC of 0.659 (50% sensitivity and 90.9% specificity) for association of SPECT-TBR ≥40 with genomical alterations.Aditionally, 2 patients with TBR-iPSMA-BN>TBR-PSMA were considerated candidates forPRRT; both patients had germinal mutations: a PV in ATM and a VUS in POLE, they received 2 and 3 [^{177}Lu]Lu-iPSMA-BN cicles respectively, 8 weeks apart,with low-non toxicity,minor G1-G2 side effects(nausea) and improvement in metastases-related-pain and quality-of-life. ***Conclusion:*** The novel[^{99m}Tc]Tc-iPSMA-BN SPECT/CT heterodimer outperformed [^{18}F]F-PSMA-1007 PET/CT in regional nodal lesion detection in mCRPC. We advocate a promising theranostic alternative, more economical with broader distribution availability; a new alternative that includes patients that would normally be excluded of PRRT,for not having a standard phenotipic profile. This is the first prospective study with a dual-cohort of patients assessed with an heterodimer, using quantitative-volumetric measures that can be used both in PET and SPECT techniques, evaluating the molecular behaviour regarding genomic alterations.[^{177}Lu]Lu-iPSMA-BN proved to be safe,having a low toxicity profile with only G1-G2 nausea as side effect.

EP-0087

eSOMA-FAP-02, a Dual SSTR2 and FAP-Targeted Heterodimer for Neuroendocrine Tumors

Y. Seimbille*, D. Chapeau, A. Piet, L. Li, C. de Ridder, D. Stuurman, P. Paraiso, H. Ma;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Due to the heterogeneity of tumors, strategies to improve the effectiveness of diagnostics have been intensively explored. In this study, we developed two heterodimers targeting the fibroblast activation protein (FAP) and the somatostatin receptor subtype 2 (SSTR2) via a chelate-bridged linker (N_3-Py-DOTAGA) to connect both targeting vectors. ***Materials and Methods:*** eSOMA-FAP-01 and eSOMA-FAP-02 contained the SSTR2 ligand, TATE, and the (4-quinolinoyl)-glycyl-2-cyanopyrrolidine targeting FAP. The main difference between these compounds relies on the click reaction used to attach both vectors to the chelate. eSOMA-FAP-01 and eSOMA-FAP-02 were labeled with [^{111}In]$InCl_3$, showing high labeling efficiency and stability. Biochemical properties of the heterodimers, such as $LogD_{7.4}$, binding affinity, uptake and internalization, were assessed by in vitro assays. SPECT/CT imaging were performed in either H69- or HT1080-FAP-tumor bearing mice. ***Results:*** Modifications of the chemical structure of eSOMA-FAP-02 improved the hydrophilic character of the heterodimer. eSOMA-FAP-01 and eSOMA-FAP-02 exhibited an IC_{50} value for SSTR2 similar to the gold standard DOTA-TATE and an IC_{50} value for FAP 4 and 7-fold higher than OncoFAP. The uptake of [^{111}In]In-eSOMA-FAP-01 and [^{111}In]In-eSOMA-FAP-02 in U2OS-SSTR2 cells was similar than that of [^{111}In]In-DOTA-TATE. In HT1080-FAP cells, both tracers exhibited similar uptake values, which were 1.6-fold higher than that of [^{111}In]In-FAPI-46. Biodistribution of [^{111}In]In-eSOMA-FAP-01 displayed a similar trend than our previous compound eTFC-01 and eSOMA-DM1, therefore, it was withdrew from further investigation [1-2]. SPECT images in H69-xenografted mice revealed a clear visualization of the tumor with a retention of [^{111}In]In-eSOMA-FAP-02 up to 72 h. [^{111}In]In-eSOMA-FAP-02 displayed a lower kidneys uptake than [^{111}In]In-DOTA-TATE. However, in HT1080-FAP-xenografted mice, tumor uptake of [^{111}In]In-eSOMA-FAP-02 was 2-4 fold lower at all time points than the uptake of [^{111}In]In-FAPI-46. No non-specific uptake was observed for [^{111}In]In-eSOMA-FAP-01. ***Conclusion:*** [^{111}In]In-eSOMA-FAP-02 exhibited comparable or better in vitro and in vivo properties for both FAP and SSTR2 compared to the monomeric counterparts [^{111}In]In-DOTA-TATE and [^{111}In]In-FAPI-46. Further investigations are required to confirm its potential for imaging and treatment of NETs. ***References:*** 1. LDLR as a glioblastoma gateway: 203Pb-labeled peptide for targeted glioblastoma SPECT imaging

I. Tworowska[1], *L. Flores*[1], *C. Malicet*[2], *R. Zielinski*[3], *P. Davis*[1], *P. Lecorche*[2], *J. Temsamani*[2], *E. Delpassand*[1];
[1]*RadioMedix Inc., Houston, TX, UNITED STATES OF AMERICA,* [2]*Vect-Horus, Marseille Cedex 15, FRANCE,* [3]*MDAnderson, Houston, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Driven by the correlation between overexpression low-density lipoprotein receptors (LDLR) and tumor progression, we designed ^{203}Pb-DOTAM-peptide conjugates (RMX-VH) engineered for high-affinity targeting of LDLR. This abstract showcases the development and preclinical evaluation of our lead compound, ^{203}Pb-DOTAM-RMX-VH for SPECT/CT imaging of glioblastoma (GBM). ***Materials and Methods:*** Radiochemical and chemical purity were assessed using TLC chromatography and radio/UV HPLC. ^{203}Pb was sourced from the UAB Cyclotron Facility in Birmingham, AL. SPECT imaging were performed in U87MG xenografts and U251 orthotopic models at various time points using a Gamma-Eye camera (Bioemtech, Greece). Following imaging, the organs and tumors were collected, weighed, and analyzed for radioactivity with a Wizard2 Gamma Counter (PerkinElmer, Waltham, MA). The percentage of the injected dose per gram of tissue (%ID/g) was calculated and adjusted for radioactive decay. ***Results:*** The radiolabeling of ^{203}Pb-RMX-VH-PKM was highly efficient, achieving a radiochemical yield (RCY) of over 90% and demonstrating stability for up to 48 hours. Incorporating the PKM motif significantly extended the agent's systemic plasma half-life to 9.2 hours, compared to just 1.3 hours for RMX-VH without PKM. Biodistribution and tumor uptake studies revealed peak performance at 24 hours post-injection in xenograft models of GBM. At 1-hour post-injection, tumor retention reached 6.2±1.8%ID/g, and remained stable at 3 hours, before declining to 3.3±0.2%ID/g by 24 hours. Liver accumulation remained relatively consistent throughout 2-24h. Importantly, bone marrow uptake was low at the early time point (1.2±0.7%ID/g) and dropped three-fold by 24 hours, indicating stable coordination of the ^{203}Pb isotope. A similar downward trend was observed across other normal organs. Interestingly, the renal retention of RMX-VH-PKM was lower than that of RMX-VH lacking the albumin-binding motif. SPECT/CT imaging and biodistribution studies in U251 orthotopic tumor models confirmed high uptake as early as 1-hour post-injection, underscoring the agent's rapid and efficient tumor-targeting properties. ***Conclusion:*** Structural modification of radiotracer with pharmacokinetic-modifying linker (PKM) not only extended the blood circulation time of our lead agent but also enhanced its tumor retention compared to the unmodified molecule.

EP-0089

The position of HYNIC chelator and the molecular design of the DARPin-based G3 constructs influence the biodistribution of an imaging tracer for detection of HER2-expressing tumors

V. Tolmachev[1], *R. Varvashenya*[2], *A. Prach*[2], *E. Plotnikov*[2], *M. Tretyakova*[2], *D. Eskova*[2], *V. Bodenko*[2], *G. Yanovich*[2], *A. Schulga*[3], *E. Konovalova*[3], *M. Belousov*[4,5], *V. Chernov*[5], *S. Deyev*[3], *M. Larkina*[2];

Aim/Introduction: Radionuclide visualization of HER2 expression in breast cancer might enable the selection of patients for treatment with antibodies trastuzumab and pertuzumab. In clinics [1], we have demonstrated that the ^{99m}Tc-labeled designed ankyrin repeat protein (DARPin) G3 ([^{99m}Tc]Tc-$(HE)_3$-G3) provides sensitive imaging of HER2 and discriminates breast cancer with high and low HER2 expression. To facilitate clinical translation, we initiated the development of G3 derivatives enabling single-vial kit formulation. In our previous studies, HYNIC-maleimide was conjugated to unique cysteine conjugated at the C-terminus of G3 via different linkers [2]. The conjugates were labelled with ^{99m}Tc and their biodistribution was compared with that of [^{99m}Tc]Tc-$(HE)_3$-G3 in mice bearing human HER2-expressing xenografts. We found that [^{99m}Tc]Tc-$(HE)_3$-G3 provides 1.6-fold higher tumour-to-liver ratio than the best variant, [^{99m}Tc]Tc-G3-$(G_3S)_3$C-HYNIC. This study tested the hypothesis that changing the position of HYNIC to N-terminus would modify the biodistribution. ***Materials and Methods:*** G3 variants, where cysteine was connected to N-terminus either via triglutamate (CE_3-G3) or a longer glycine and serine-containing dodecapeptide ($C(G_3S)_3$-G3) were produced and site-specifically conjugated with HYNIC-maleimide. Labelling was performed by ^{99m}Tc-pertechnetate reduction in the presence of tricine and EDDA (60°C, 30 minutes). Purification was performed using a size-exclusion cartridge. HER2-positive SKOV-3 and SK-BR-3, and HER2-negative PC-3 and Ramos cells were used to measure specificity. Biodistribution was measured in Nu/j mice bearing SKOV-3 or Ramos xenografts ***Results:*** The isolated yield was 75-85%, radiochemical purity over 95%. Both [^{99m}Tc]Tc-HYNIC-CE_3-G3 and [^{99m}Tc]Tc-HYNIC-$C(G_3S)_3$-G3 bound specifically to SKOV-3 and SK-BR-3 cells, the binding to HER2-negative PC-3 was negligible. The affinity was similar, 1.68±0.16 and 1.72±0.25 nM for [^{99m}Tc]Tc-HYNIC-CE_3-G3 and [^{99m}Tc]Tc-HYNIC-$C(G_3S)_3$-G3, respectively. This was lower than affinity of C-terminal-modified [^{99m}Tc]Tc-G3-$(G_3S)_3$C-HYNIC (0.60±0.15nM). The uptake in HER2-positive xenografts, 4.4±0.8, 4.4±0.8, and 4.5 0.4 %ID/g, for [^{99m}Tc]Tc-HYNIC-CE_3-G3, [^{99m}Tc]Tc-HYNIC-$C(G_3S)$-G3, and control [^{99m}Tc]Tc-G3-$(G_3S)_3$C-HYNIC, respectively was similar. The uptake of the novel variants in HER2-negative tumours was much lower ($p < 0.05$). [^{99m}Tc]Tc-HYNIC-$C(G_3S)$-G3 had 2-3 fold lower uptake in liver, spleen and lungs compared to other variants. This created preconditions for a higher contrast and more sensitive visualization of hepatic and pulmonary metastases, which are frequent in HER2-expressing cancers. ***Conclusion:*** The biodistribution of [^{99m}Tc]Tc-labelled HER2-targeting DARPins depends on both the position of the [^{99m}Tc]Tc-HYNIC label and the length of a spacer between G3 and the label. This might be used for optimization of imaging properties of such constructs. ***References:*** 1. Bragina O et al. J Nucl Med. 2022;63:528-5352. Larkina M et al. Mol Pharm. 2024;21:1919-1932.

Optimization of the N-terminus of neurotensin analogs for PET imaging of solid malignancies

S. Kaur[1,2], *S. Mair*[1], *W. Lau*[1], *J. Zeisler*[1], *F. Benard*[1,2], *K. Lin*[1,2], *J. Lau*[1,2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*The University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: The neurotensin receptor 1 (NTSR1) is overexpressed in various solid malignancies, including

pancreatic ductal adenocarcinoma (PDAC) [1]. NTSR1 binds to neurotensin (NT) analogs, with NT(8-13) (Arg^{8}-Arg^{9}-Pro^{10}-Tyr^{11}-Ile^{12}-Leu^{13}) being the minimal sequence required for receptor engagement. However, NT(8-13) has a short biological half-life due to cleavage at Arg^{8}-Arg^{9}, Pro^{10}-Tyr^{11}, and Tyr^{11}-Ile^{12} peptide bonds. In this study, we aim to develop NT(6-13) analogs by substituting Tyr^{11} with unnatural amino acids to stabilize the amide bonds. Additionally, the N-terminus is modified to optimize the pharmacokinetics of NT analogs to improve tumor-to-organ contrast for NTSR1-targeted PET imaging. ***Materials and Methods:*** NT-based SM01010 ([Lys^{6}(DOTA),NMeArg^{8},1-Nal^{11}]NT(6-13)), SM01011 (DOTA-Lys^{6},NMeArg^{8},1-Nal^{11}]NT(6-13)), SK01001 ([Lys^{6}(DOTA),NMeArg^{8},Dmt^{11}]NT(6-13)) and SK01014 (Ac-[Lys^{6}(DOTA),NMeArg^{8},Dmt^{11}]NT(6-13)) were synthesized via solid-phase peptide synthesis. The peptides incorporated either 1-(naphthyl)-L-alanine (1-Nal) or 2,6-dimethyl-L-tyrosine (Dmt) at Tyr^{11} position. SM01010 and SM01011 differ in the placement of DOTA. Compared with SK01001, the N-terminus of SK01014 was acetylated. NT-20.3 was synthesized as a reference. Gallium (^{nat}Ga and ^{68}Ga) complexations were conducted in acetate (0.1 M, pH 4.5) and HEPES (2 M, pH 5.0) buffers, respectively. In vitro binding assays were performed with the PC3 cell line. PET imaging and biodistribution studies were conducted in PC-3 and AsPC-1 tumor-bearing mice at 1 h post-injection (p.i.). In vivo stability was assessed at 15 minutes p.i. ***Results:*** The binding affinity value (K_i) for ^{nat}Ga-NT(6-13) analogs was found to be 0.65-32.9 nM compared to 9.25 ± 3.40 nM (^{nat}Ga-NT-20.3). Radiolabeling with ^{68}Ga produced ^{68}Ga-labelled peptides in 18-60% decay-corrected yields with radiochemical purity >95%. [^{68}Ga]Ga-SM01010 and [^{68}Ga]Ga-SM01011 showed similar tumor uptake (2.28 ± 0.50 and 3.00 %ID/g), suggesting flexible chelator attachment at both ε- and α-NH_2 of Lys^{6}. [^{68}Ga]Ga-SK01014 showed comparable tumor uptake (%ID/g) to [^{68}Ga]Ga-NT-20.3 in both PC-3 (10.1 ± 3.44 vs. 9.43 ± 0.84) and AsPC-1 (8.89 vs 8.95) tumor models. Notably, [^{68}Ga]Ga-SK01014 represents significantly reduced renal accumulation (2.82 ± 1.07) versus [^{68}Ga]Ga-SK01001 (11.1 ± 1.83) and [^{68}Ga]Ga-NT-20.3 (9.65 ± 1.15) ($p < 0.01$). In vivo plasma stability showed 34.0 ± 5.5% intact [^{68}Ga]Ga-SK01014 vs. 64.1 ± 5.9% for [^{68}Ga]Ga-NT-20.3. ***Conclusion:*** Tyr^{11} substitution with 1-Nal is unfavorable, whereas substitution with Dmt was well-tolerated. Regarding N-terminal modifications, placement of DOTA at ε- and α-NH_2 of Lys^{6} did not affect radiopharmaceutical biodistribution. N-terminal acetylation preserves tumor uptake and enhances renal clearance of NT-based analogs, thereby improving tumor-to-kidney ratios. Further optimization is needed to enhance NT(6-13) analog stability and tumor uptake for theranostic applications. ***References:*** 1. Prignon et al., Mol Pharm. 2019;16:2776-84.

Evaluation of two Nastorazepide derived ^{68}Ga-labelled radiotracers for imaging of CCK2R expressing tumors.

M. Asti[1], *M. Verona*[2], *S. Rubagotti*[1], *T. Zavvar*[3], *E. von Guggenberg*[3], *P. C. Capponi*[1], *M. Tosato*[4,1], *F. Mastrotto*[2], *G. Marzaro*[5];
[1]*AUSL-IRCCS, Reggio Emilia, ITALY,* [2]*University of Padua, Padua, ITALY,* [3]*Medical University of Innsbruck, Innsbruck, AUSTRIA,* [4]*Simon Fraser University, Burnaby, BC, CANADA,* [5]*University of Verona, Verona, ITALY.*

Aim/Introduction: Receptors targeting ligands are biomolecules useful to selectively deliver both imaging and therapeutic agents to cancer tissues. The cholecystokinin 2 receptor (CCK2R) is overexpressed in various human cancers (e.g., lung, medullary thyroid, pancreatic, colon, and gastrointestinal stromal tumors) and displays limited expression in normal tissues. For this reason, it is a suitable diagnostic and therapeutic target. In this study, two Nastorazepide-based ligands (namely, LM24 and LM55) functionalized with a NODAGA chelator and labelled with gallium-68 were tested as potential radiotracers for CCK2R overexpressing tumors. ***Materials and Methods:*** Targeting agent was synthetized functionalizing the benzodiazepine core with di-ethyl glycol spacer connecting the pharmacophore to a NODAGA chelator. The two derivatives differed for the spacer that in one case contained a maltotriose residue (LM24) and, in the other, a linear poli-alcohol (LM55) moiety to tune hydrophilicity and pharmacokinetic properties. Ligands were radiolabeled with gallium-68 and their in vitro characteristics, such as stability in human serum and lipophilicity, were evaluated. The cell internalization of the radioligands was assessed on A431-CCK2R and A431-mock cells at several time points (30min, 1h and 2h). The receptor binding affinity of the conjugates was tested in a competition assay against [^{177}Lu]Lu-DOTA-MGS5. Biodistribution, and tumor uptake studies were conducted on nude mice carrying A431-CCK2R and A431-mock derived tumor xenografts. ***Results:*** Quantitative complexation with gallium-68 (95°C, 10min) with a molar activity around 16 MBq/nmol and a radiochemical purity (assessed by RP-HPLC) >95%, was achieved in the radiolabeling process. Calculated logP values for [^{68}Ga]Ga-LM24 and [^{68}Ga]Ga-LM55 were -0.79 and -0.64, respectively, while the stability in human serum was >95% after 2h of incubation for both the radiotracers. In the cell internalization studies a cell associated radioactivity of 31.65±1.58% and 23.28±0.74% of the total activity was found for [^{68}Ga]Ga-LM24 and [^{68}Ga]Ga-LM55, respectively, after 2h incubation in A431-CCK2R cells. A very low radioactivity <0.6% was found on A431-mock cells without CCK2R expression. LM24 and LM55 both showed a high affinity for CCK-2R with IC_{50} values of 14.4±5.9 and 33.3±16.1 nM, respectively. In vivo studies are on-going but, from preliminary results, CCK2R expressing tumors could be clearly visualized with both compounds. ***Conclusion:*** In this study, two CCK-2R targeting ligands based on a non-peptide sequence were synthetized and successfully labelled with gallium-68. In vitro studies confirmed good targeting properties. The biodistribution profile and tumor uptake will be assessed in the A431-CCK2R/A431-mock xenograft model.

Aim/Introduction: Breast cancer accounts for roughly 12 % of all new cancer cases worldwide and about 25 % of cancers diagnosed in women. Approximately 20-30 % of these tumors over-express the human epidermal growth-factor receptor 2 (HER2/ErbB-2), a feature associated with aggressive behavior, early metastasis and reduced survival. Although monoclonal antibody therapy with trastuzumab has improved outcomes, accurate, whole-body assessment of HER2 status is still needed to personalize therapy. We therefore developed a theranostic radiopharmaceutical based on peptides that bind selectively to HER2, suitable for SPECT/PET imaging and radionuclide therapy. ***Materials and Methods:*** Peptide candidates were obtained by de-novo sequencing of trastuzumab light- and heavy-chain complementarity-determining regions (CDRs) using tandem mass spectrometry. Bioinformatic analysis identified CDR3 of the heavy chain as the most promising sequence. The peptide was synthesized with a PEG_3 linker and a DOTA chelator. Radiolabeling with ^{68}Ga and ^{177}Lu was optimized, and stability was assessed in vitro (serum, PBS). Specificity was evaluated on HER2-positive SK-BR-3 and HER2-negative MDA-MB-231 breast-cancer cells, followed by µPET/CT in mice bearing SK-BR-3 xenografts. ***Results:*** Radiolabeling yields exceeded 98 % for both radionuclides, with radiochemical purity remaining > 95 % for 2 h (^{68}Ga) and 24 h (^{177}Lu). In vitro binding to SK-BR-3 cells was 4.3-fold higher than to MDA-MB-231 controls ($p < 0.01$). µPET/CT showed tumor-to-

muscle ratios of 5.2 ± 0.8 at 1 h post-injection, confirming in-vivo specificity. Additional therapeutic-efficacy and dosimetry studies are ongoing. ***Conclusion:*** The HER2-targeted peptide-DOTA construct exhibits high specificity and favorable radiochemical properties, supporting its use as a $^{68}Ga/^{177}Lu$ theranostic pair for imaging and treating HER2-positive breast cancer.

EP-0093

Development of fluorine-18 analogs of metoclopramide for P-gP PET imaging at the blood-brain barrier

S. Huvelle[1,2], *P. Deniel*[3], *B. Hosten*[3,4], *S. Chasseigneaux*[4], *N. Tournier*[1], *L. Breuil*[4,5], *F. Caillé*[1];
[1]*Laboratoire d'Imagerie Biomédicale Multimodale (BIOMAPS), Université Paris-Saclay, CEA, CNRS, Inserm, Service Hospitalier Frédéric Joliot, Orsay, FRANCE,* [2]*Université Paris-Saclay, Inserm, CEA, Center for Immunology of Viral, Auto-immune, Hematological and Bacterial diseases (IMVA-HB/IDMIT), Fontenay-aux-Roses, FRANCE,* [3]*Service Pharmacie, Assistance Publique - Hôpitaux Paris, Hôpital Saint-Louis, Paris, FRANCE,* [4]*Inserm UMR-S 1144, Faculté de Pharmacie de Paris, Université Paris-Cité, Paris, FRANCE,* [5]*Service Pharmacie, Assistance Publique - Hôpitaux Paris, Hôpital Cochin, Paris, FRANCE.*

Aim/Introduction: Carbon-11-labeled metoclopramide (MTC) has been validated as a reliable radiotracer in animals and humans to study P-glycoprotein (P-gp) at the blood-brain barrier (BBB) with PET imaging (1). However, carbon-11 radiolabeling requires an on-site cyclotron, hampering clinical translation. Most radiopharmaceuticals currently available for studying P-gp are labeled with this isotope. In this context, developing fluorine-18-labeled P-gp probes is of particular interest, as its longer radioactive half-life allows for greater flexibility in use. This work aimed to develop P-gp activity radiotracers at the BBB, derived from MTC and labeled with fluorine-18. ***Materials and Methods:*** Two candidate molecules, namely [^{19}F]FPEG-MTC and [^{19}F]Fluoroethyl-metoclopramide (FE--MTC), were evaluated in vitro to determine their status as P-gp substrates. AB/BA bidirectional transport assays on transwell with MDCK-MDR1 cells overexpressing human P-gp were performed with and without P-gp inhibition by 5 µM of valspodar. Efflux ratios (ER) of FPEG-MTC and FE-MTC were compared to the ER of metoclopramide and to their own ER with inhibition (ER_i) with a Student t-test. F-18 radiolabeling of FPEG-MTC was performed from a tosylate precursor with an AllinOne (Trasis) module. ***Results:*** FPEG-MTC and FE-MTC were synthesized in 42 and 48% yield, respectively. In vitro results showed a significantly higher ER for FPEG-MTC (ER=8.63) compared to MTC (ER=1.03) ($p< 0.001$, n=2), suggesting FPEG-MTC is a stronger P-gp substrate than MTC. In contrast, the ER of FE-MTC did not differ significantly from MTC (ER 0.346). Valspodar inhibition significantly reduced ER values from MTC (ERi= 0.564) and FPEG-MTC (ERi=0.568) ($p< 0.001$, n=2), but had no significant effect on FE-MTC (ERi= 0.291, ns, n=2), indicating FE-MTC may not be a P-gp substrate. FPEG-MTC was chosen to be labeled with fluorine-18. The tosylate precursor of FPEG-MTC was synthesized in 6 steps with 21% overall yield. [^{18}F]FPEGMTC was obtained with 39% conversion. The automation of the radiofluorination is ongoing. ***Conclusion:*** Two fluorinated analogs of MTC were successfully synthesized, and in vitro experiments demonstrated that FPEG-MTC is a stronger P-gp substrate than MTC. [^{18}F]FPEG-MTC was successfully radiosynthesized in a compatible yield and molar activity for upcoming in vivo studies to study the impact of P-gp inhibition on its brain distribution. These will help confirm the potential of this tracer and provide insights into its sensitivity to P-gp activity modulation, essential information for assessing its potential future in vivo applications. ***References:*** 1. Precise monitoring of acquired drug resistance in melanoma by ACC-targeted PET imaging

J. Ye, *J. Wang;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: Acquired resistance to BRAF mutation-targeted therapy has become a major clinical problem hindering the treatment of melanoma, and its precise monitoring is the core and key to improve the prognosis, but there is a lack of effective ways of non-invasive monitoring. Our previous study revealed that enhanced fatty acid synthesis is a key mechanism mediating acquired resistance to targeted therapy in BRAF-mutant melanoma. Therefore, this project aims to develop a molecular probe targeting acetyl-coacarboxylase (ACC), a key rate-limiting enzyme in the fatty acid synthesis pathway, to elucidate the quantitative and qualitative relationship between ACC and acquired resistance to targeted therapies and to monitor the evolution of fatty acid synthesis resistance through PET molecular imaging. ***Materials and Methods:*** A series of novel ACC-targeting probes were designed by coupling method using the inhibitor ND630 as the lead compound. The radiochemical purity and in vitro stability were determined by HPLC. All probes were subjected to in vivo distribution and micro-PET dynamic imaging in tumor bearing mice to determine maximum tumor uptake and optimal imaging time. Construction of melanoma drug-resistant cell lines was induced by stepwise increments of vemurafenib, and further constructing vemurafenib-resistant tumor bearing mice. PET monitoring of tumor-bearing mice treated with vemurafenib using the probe with the best imaging. ***Results:*** The ^{68}Ga labeling rate of all four probes was more than 60% (n = 3, uncorrected for decay) and the radiochemical purity was > 98%. The in vitro stability in saline and in mouse serum was evaluated at 4 h by radio-HPLC, all probes showed high in vitro stability. The in vivo distribution and micro-PET imaging results in tumor bearing mice showed that all probes could image tumors, with ^{68}Ga-DEACC showing the highest tumor uptake with a SUVmax of 1.1. All probes have a high physiological uptake in the heart and liver and are mainly metabolized by the liver and intestines. The drug-resistant cell line A375-VR was successfully constructed, the resistance index was 6.69 and its ACC and mitochondrial functions were significantly enhanced. ^{68}Ga-DEACC PET imaging results showed that tumor uptake was significantly higher in the resistant group than in the sensitive group after treatment with vemurafenib, suggesting that ACC-targeted PET imaging can Precise monitoring of acquired drug resistance in melanoma. ***Conclusion:*** ACC-targeting probe ^{68}Ga-DEACC has the potential to be used to monitor the evolution of fatty acid synthesis resistance, and further probe optimization and evaluation are in progress.

Comparative Study of Thiol-Reactive Linkers for the Design of Stable Radioimmunoconjugates

J. Ariztia[1], *M. Leroux*[1], *M. Moreau*[1], *C. Bernhard*[1], *P. Bellaye*[2], *A. Cochet*[2,1], *A. Daoust*[3], *D. Vivier*[1], *F. Denat*[1];
[1]*Université Bourgogne Europe, ICMUB UMR CNRS 6302, Dijon, FRANCE,* [2]*Centre Georges François Leclerc, IMATHERA, BioSanD, Dijon, FRANCE,* [3]*Oncodesign Precision Medicine, Dijon, FRANCE.*

Aim/Introduction: Bioconjugation between maleimide and thiol groups on proteins is a widely used strategy in the preparation of antibody-drug conjugates (ADCs). However, the resulting thiosuccinimide bond often lacks long-term stability, leading to retro-Michael deconjugation, premature drug release, and unwanted binding to plasma proteins. To overcome this, alternatives to maleimide-based conjugation — including self-hydrolyzing maleimides, exocyclic maleimides, benzoyl acrylamides, and 2-sulfonylpyrimidines for cysteine arylation — have been developed,[1] though mainly in the ADC field. Their potential for

radioimmunoconjugates remains largely unexplored. Here, we propose to radiolabel with ^{89}Zr three immunoconjugates, prepared using different thiol-reactive groups bearing DFO chelator, and to compare their stability in terms of radiolysis resistance and plasma deconjugation. ***Materials and Methods:*** The thiol-reactive groups studied were maleimide, aryl-maleimide, and benzoyl acrylate. Each was coupled to DFO (except maleimide-DFO, available commercially) and conjugated to a small cysteine-tagged protein (~20 kDa). Reactions were monitored by mass spectrometry. Hydrolysis studies were performed on both maleimide conjugates in HEPES buffer (pH 7.4 and 8). Retro-Michael deconjugation was assessed by incubating the conjugates (before and after hydrolysis) with an excess of glutathione (1000 eq.) for one week. Finally, the conjugates were radiolabeled with ^{89}Zr, a radionuclide that induces significant radiolytic stress, and their stability in PBS and plasma was monitored over 7 days. ***Results:*** DFO probes were synthesized in one or two steps with good yields. Bioconjugation efficiency varied: maleimide-DFO showed slower reactivity and required excess equivalents for full conversion, while aryl-maleimide exhibited high reactivity, prompting pH adjustment (5.2) to reduce side reactions with lysines. Benzoyl acrylate-DFO showed intermediate reactivity. In hydrolysis tests at pH 7.4, less than 20% hydrolysis was observed for maleimide-DFO and aryl-maleimide-DFO after 24 hours (12% and 18%, respectively). However, at pH 8, aryl-maleimide-DFO underwent near-complete hydrolysis (95%) within 6 hours, whereas maleimide-DFO showed moderate hydrolysis (36%). Glutathione assays revealed that aryl-maleimide conjugates showed greater resistance to retro-Michael deconjugation than the others. Radiolabeling with ^{89}Zr gave good yields for all conjugates; stability studies are ongoing. ***Conclusion:*** This study highlights the improved stability of alternative thiol-reactive linkers over classical maleimide. Aryl-maleimide and benzoyl acrylate showed promising resistance to deconjugation and good radiolabeling performance. Ongoing work will confirm their suitability for stable radioimmunoconjugates. ***References:*** (1) Szijj, P. A.; Bahou, C.; Chudasama, V. Drug Discov. Today Technol. 2018, 30, 27-34.

Biodistribution of Two Novel FAP - targeting Radiopharmaceuticals in Solid Tumors and Their Comparison with ^{68}Ga - FAPI - 46: a Pilot Study

X. Mu[1], *Y. Lu*[1], *Z. Chen*[2], *J. Li*[1], *L. Zhang*[1], *W. Chong*[1], *J. Li*[1], *W. Fu*[1], *X. Li*[3];
[1]*Department of Nuclear Medicine, The First Affiliated Hospital of Guilin Medical University, Guilin, CHINA,* [2]*GDMPA Key Laboratory for Quality Control and Evaluation of Radiopharmaceuticals, PET Center, Department of Nuclear Medicine, Nanfang Hospital, Southern Medical Universit, Guangzhou, CHINA,* [3]*Department of Chemistry, State Key Laboratory of Synthetic Chemistry, The University of Hong Kong, Hongkong, CHINA.*

Aim/Introduction: Fibroblast activation protein α, a cell surface protein overexpressed on cancer-associated fibroblasts (CAFs), has emerged as a promising pan-cancer diagnostic and therapeutic target due to its minimal expression in most healthy tissues. In this preliminary clinical study, we evaluated the biodistribution and clinical feasibility of two novel FAP-targeting radiopharmaceuticals, ^{68}Ga-GP01 and ^{68}Ga-GP02, and compared their imaging characteristics with ^{68}Ga-FAPI-46 in patients with solid tumors. ***Materials and Methods:*** Two novel precursors were rationally designed and synthesized, subsequently conjugated with the DOTA chelator for ^{68}Ga-radiolabeling. Ten patients with various solid tumors were enrolled to assess the clinical performance of ^{68}Ga-GP01 and ^{68}Ga-GP02. Patients received 164 ± 14 MBq of ^{68}Ga-GP01 or 179 ± 27 MBq of ^{68}Ga-GP02, followed by PET/CT imaging at 60 minutes post-injection. The SUV_{mean} of normal tissues—including the brain, thyroid, blood pool, lung, liver, spleen, kidney, bone, and muscle—were measured. Lesion uptake and tumor-to-background ratios (TBR) of ^{68}Ga-GP01 and ^{68}Ga-GP02 were compared with those of ^{68}Ga-FAPI-46. ***Results:*** Both ^{68}Ga-GP01 and ^{68}Ga-GP02 were well tolerated with no adverse events reported. Compared to ^{68}Ga-FAPI-46 PET/CT, the liver SUV_{mean} for ^{68}Ga-GP01 was significantly lower (0.42 vs. 0.59, P = 0.008), while no significant difference was observed in thyroid SUV_{mean} between the two tracers (1.48 vs. 1.44, P = 0.85). In contrast, ^{68}Ga-GP02 PET/CT demonstrated a significantly higher thyroid SUV_{mean} compared to ^{68}Ga-FAPI-46 PET/CT (6.74 vs. 2.48, P = 0.0002), whereas no significant difference was found in liver SUV_{mean} between the two tracers (1.11 vs. 0.87, P = 0.063). No other significant differences in SUV_{mean} were observed in the remaining normal tissues. In the lesion analysis, 53 lesions were identified with both ^{68}Ga-GP01 and ^{68}Ga-FAPI-46. The ^{68}Ga-GP01 group exhibited a much higher SUV_{max} and TBR (SUV_{max}: 7.71 vs. 6.76, P = 0.004; TBR: 7.49 vs. 5.70, P < 0.0001). For ^{68}Ga-GP02, 41 lesions were detected, among which one appeared negative on ^{68}Ga-FAPI-46 PET/CT. Interestingly, compared to ^{68}Ga-FAPI-46, the ^{68}Ga-GP02 group showed a substantially higher SUV_{max} (10.00 vs. 6.77, P < 0.0001) and comparable TBR (5.82 vs. 5.86, P = 0.35). ***Conclusion:*** This study evaluated the safety and clinical feasibility of both ^{68}Ga-GP01 and ^{68}Ga-GP02 PET/CT imaging with various cancer types. Both tracers showed improved lesion uptake compared to ^{68}Ga-FAPI-46, with promising results for high-contrast visualization of FAP-positive tumors. The results above provide valuable clinical experience and data support for the future development of 177Lu - labeled theranostic drugs targeting FAP.

EP-0098

Preclinical Evaluation of ^{68}Ga-labelled Cyclic Peptide for Neuropilin-1-Targeted PET Imaging in Pan-tumors

F. Qiu*, S. Song, J. Li;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: As a transmembrane glycoprotein overexpressed in various tumors, neuropilin-1 (NRP-1) is involved in tumor progression, angiogenesis, and immune evasion. Therefore, monitoring NRP-1 expression is crucial for tumor early diagnosis and personalized therapeutic regimens. This study aims to develop a novel NRP-1-targeted cyclic peptide radiotracer for specifically and sensitively detecting NRP-1 expression in multiple tumor models. ***Materials and Methods:*** NRP-1 expression in human cancers was detected via immunohistochemistry (IHC) on tissue microarrays (TMAs). Specificity for NRP-1 was confirmed using molecular docking and cellular uptake assays. To determine diagnostic sensitivity and clinical applicability, Micro PET/CT imaging and blocking studies were performed in four NRP-1-positive tumor models (TNBC MDA-MB-231, fibrosarcoma HT-1080, NSCLC A549, pancreatic tumor CFPAC-1,) and one NRP-1-negative model (cervical tumor Siha). Ex vivo biodistribution and immunohistochemistry were subsequently conducted to verify tumor-targeting capability, while biosafety studies were performed to support potential clinical translation. ***Results:*** TMAs results revealed that NRP-1 is highly expressed in TNBC, NSCLC and pancreatic tumor, while slightly expressed in cervical tumor. Micro PET/CT at 1 h post-injection revealed significantly higher tumor uptake in NRP-1 positive tumor models (MDB-MA-231 : 3.167± 0.115 %, HT-1080 : 2.3 ± 0.6 %, A549 : 1.867 ± 0.551 %, CFPAC-1 : 1.467 ± 0.306 %) compared to NRP-1 negative tumor model (Siha : 0.851 ± 0.180 %). Notably, the trend in target uptake ratios were similar to trend in tumor uptake values, while co-injection with nonradioactive CEND-1 significantly reduced tumor uptake, confirming specificity. Ex vivo biodistribution and immunohistochemistry were consistent with PET imaging, while biosafety evaluations showed no significant adverse effects. ***Conclusion:*** As the first cyclic peptide radiotracer, ^{68}Ga-DOTA-

CEND1 holds great potential for non-invasive detection of NRP-1 expression across pan-tumor types, evaluating the therapeutic responses and optimizing NRP-1 targeted therapy.

EP-0099

Development and Evaluation of a Novel Peptide-Based Radiotracer for Netrin-1 Non-invasivei Imaging in Tumor

J. Wang, *L. Feng, L. Zhang, H. Yang, X. Lan, W. Cao, D. Jiang; Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: Neuroaxonal guidance factor-1 (Netrin-1), a secreted glycoprotein frequently overexpressed in various malignancies, plays a crucial role in promoting tumor progression and metastatic dissemination. Given its significant involvement in oncogenesis, Netrin-1 has emerged as a promising molecular target for cancer theranostics. To facilitate the non-invasive evaluation of Netrin-1 expression in tumors, we designed and synthesized a novel Ga-68-labeled peptide-based radiotracer, designated as [^{68}Ga]Ga-DKP, for positron emission tomography (PET) imaging applications. ***Materials and Methods:*** The radiotracer was successfully radiolabelled with Ga-68. The radio chmeical purity (RCP) was examined by radio high performance liquid chromatography. Cellular uptake studies and blocking studies validated the probe's targeting capacity in vitro. PET/CT imaging and biodistribution studies were carried on murine models of A549, 4T1 and A375 tumors. ***Results:*** The developed [^{68}Ga]Ga-DKP tracer demonstrated excellent RCP (>95%) and stability in vitro. Cellular uptake studies revealed significantly higher binding affinity in A549 and 4T1 cells, compared to A375 cells, correlating with their differential netrin-1 expression levels. In vivo evaluation through PET/CT imaging and biodistribution analysis showed higher tumor-to-muscle ratios in A549 (5.24 ± 0.58) and 4T1 (6.86 ± 1.35) xenografts at 1 h post-injection, representing approximately 3-fold greater uptake compared to A375 tumors. ***Conclusion:*** The novel radio tracer[^{68}Ga]Ga-DKP serves as a sensitive and specific PET probe for non-invasive assessment of netrin-1 expression, demonstrating strong potential for clinical translation in cancer theranostics. ***References:*** Finci LI, Krüger N, Sun X, Zhang J, Chegkazi M, Wu Y, Schenk G, Mertens HDT, Svergun DI, Zhang Y, Wang JH, Meijers R. The crystal structure of netrin-1 in complex with DCC reveals the bifunctionality of netrin-1 as a guidance cue. Neuron. 2014 Aug 20;83(4):839-849.

Evaluation of ^{11}C-SAM Radiotracers for Prostate Cancer Imaging: In Vivo and Ex Vivo Comparison of Scalemic and Enantiopure Forms

M. Bentura[1], *F. Zoppolo*[1], *L. Reyes*[1], *A. Paolino*[1], *G. Falasco*[1], *L. Urrutia*[1], *D. Umpierrez*[2], *G. Irazoqui*[2], *S. Rodriguez*[2], *E. Savio*[1]; [1]*Departamento de Radiofarmacia, Centro Uruguayo de Imagenología Molecular, Montevideo, URUGUAY,* [2]*Departamento de Biociencias, Facultad de Química, UdelaR, Montevideo, URUGUAY.*

Aim/Introduction: Prostate cancer (PCa) is the second most diagnosed cancer in men and the fifth leading cause of cancer mortality. Advances in understanding the pathology and biomarkers are improving disease management, but identifying high-risk patients remains a challenge. Sarcosine (N-methyl glycine) is a metabolite significantly elevated during PCa progression, linked to high levels of glycine N-methyltransferase (GNMT), which catalyzes its production using (S,S)-adenosylmethionine ((S,S)-SAM) as a coenzyme. Labeled with ^{11}C, (S,S)-SAM has potential as a radiotracer for PCa diagnosis. In previous work, we successfully labeled SAM as a scalemic mixture and enzymatically synthesized ^{11}C-labeled (S,S)-SAM. This study focuses on the in vivo and ex vivo evaluation of these radiotracers, comparing the scalemic mixture and enantiopure (S,S)-SAM to assess their differential impact on imaging and diagnostic potential. Two prostate cancer tumor models, PC3 and LNCaP, with varying GNMT expression levels, were used. ***Materials and Methods:*** The synthetic processes were performed using a TRACERlab® FX C Pro automated platform (GE Healthcare). Male Swiss and Nude N: NIH (S) - Foxn 1nu mice (13-18 weeks) were used as controls and prostate cancer tumor models (PC3/LNCAP) for ex vivo and in vivo studies. Biodistribution studies were conducted in both groups at 15, 45, and 90 minutes. PET/CT imaging was performed after intravenous administration of ^{11}C-SAM or the scalemic mixture, using a nanoScan® PET/MRI 3T system (Mediso). Tumor segmentation on PET images was done using a semi-automatic region-growing algorithm (PMOD 3.8) to calculate the tumor-to-normal uptake ratio (TNr). ***Results:*** Regarding the biodistribution results, in the LNCaP tumor model, tumor accumulation was significantly higher than in muscle at all time points ($p < 0.05$), with a peak TNr of 2.67 ± 0.99 at 45 minutes post-injection. In the PC3 tumor model, tumor accumulation was significantly higher than in muscle only at 15 minutes ($p < 0.05$). Imaging data showed no significant differences between the pure compound (ISO) and the scalemic mixture (MZC) in either model, although a higher variance was noted for the scalemic mixture. ***Conclusion:*** Based on the biodistribution results from both tumor models, it can be concluded that the compound under study, 11C-SAM, exhibits greater affinity for the LNCaP cell line. Future clinical applications require careful patient selection. The observed differences in tumor and muscle uptake highlight the potential of this radiopharmaceutical in oncological imaging. These findings also challenge what would be the most suitable choice for conducting a clinical trial evaluation.

EP-0101

Selective Probes for PET Imaging of Tumor-Associated Cathepsins

O. Cini[1], *M. M. M. Santos*[1], *F. Elvas*[2], *R. Moreira*[1]; [1]*Research Institute for Medicines (iMed.ULisboa), Faculty of Pharmacy, Universidade de Lisboa, Lisbon, PORTUGAL,* [2]*Molecular Imaging and Radiology, Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp, BELGIUM.*

Aim/Introduction: Cathepsins are lysosomal cysteine proteases involved in various biological processes. In cancer, overexpression of Cathepsin B (CatB) and Cathepsin L (CatL) correlates with different tumor progression stages, making them important biomarkers for cancer diagnosis.[1] This study aims to develop selective CatB and CatL inhibitors as radiotracers for Positron Emission Tomography (PET) imaging to improve cancer diagnosis and therapy monitoring. ***Materials and Methods:*** Vinyl sulfones were selected as warhead to covalently bind the catalytic residue of cathepsins.[2] Modifications were made to optimize selectivity and introduce linkers for attaching diagnostic radionuclides such as Gallium-68 (^{68}Ga). Five probe precursors were synthesized, and enzymatic assays with precursors and cold (^{nat}Ga) complexes assessed affinity and selectivity towards CatB, CatL and CatS. Two precursors differing in linker design, PEG_2 in CREANT-101 and piperazine in CREANT-102, were radiolabeled with ^{68}Ga using ammonium acetate buffer at pH 5.5 and 80°C for 5 minutes. SDS-PAGE was used to evaluate radiotracers binding to cathepsins. Stability was assessed up to 2h. Both radiotracers were evaluated in vivo through PET/CT imaging, biodistribution and metabolite analysis. ***Results:*** Cold complexes of CREANT-101 and CREANT-102 exhibited strong affinity for CatL, with K_i values of 315 and 107 nM. [^{68}Ga]Ga-NODAGA-CREANT-101 and -102 were obtained in high radiochemical purity (>95%). Both radiotracers exhibited high stability in 0.9% NaCl up to 2h (>95%). SDS-PAGE analysis of recombinant cathepsins showed selective labeling of CatL and CatB with minimal off-target binding to CatS. PET/CT and biodistribution revealed rapid clearance of CREANT-101,

accumulating mainly in liver (10.8 %IA/g), kidneys (1.9 %IA/g), large intestine (18.9 %IA/g) at 30 minutes post-injection, suggesting mixed renal-hepatobiliary clearance. Despite similar lipophilicity of both tracers (Log D = -0.18 for CREANT-101, -0.15 for CREANT-102), CREANT-102 showed higher background activity and blood retention. Metabolite studies showed faster metabolism for CREANT-101 while CREANT-102 remained more stable over time, with 45% intact at 30 minutes versus 61% for CREANT-102, and 24% intact at 1 hour versus 51% for CREANT-102, indicating slower metabolic degradation. Tumor targeting will be evaluated in subsequent studies. ***Conclusion:*** This study confirmed that CatL is the major target of CREANT-101 and -102, with minimal binding to CatB and CatS. Additionally, the linker design had an impact on the in vivo pharmacokinetics and metabolic stability, affecting imaging background and clearance. These findings support further probe optimization. ***References:*** 1. Schleyer KA, et al. Org Biomol Chem. 2021;19(28):6182-6205. 2. Schneider TH, et al. New J Chem. 2015;39(7):5841-5853.

EP-0102

Cu-64/Cu-67-Labeled TCOs as Promising Agents for Theranostic Pretargeting Applications

Q. Yu, *K. Adhikari, T. Van den Wyngaert, F. Elvas;*
University of Antwerp, Molecular Imaging and Radiology (MIRA), Wilrijk, BELGIUM.

Aim/Introduction: A radiotheranostic approach using monoclonal antibodies (mAbs) provides an attractive strategy to target tumor-associated antigens. Pretargeting strategies utilizing bioorthogonal reactions, such as the inverse electron-demand Diels-Alder (IEDDA) reaction, can overcome the high radiation exposure associated with the long circulating half-life of mAbs. However, many targets, such as CD70, are internalised intracellularly upon binding, limiting the availability of bioorthogonal tags on the cell surface and hindering effective radioligand accumulation in tumors. To overcome this limitation, we aim to develop cell-permeable trans-cyclooctenes (TCOs) labeled with the theranostic pair Cu-64/Cu-67, enabling efficient IEDDA reaction with mAb-conjugated tetrazines (Tz) both extra- and intracellularly in a model of CD70-expressing tumors, enabling a more effective radio-payload delivery with minimal systemic exposure. ***Materials and Methods:*** Two TCO radioligands, CREANT-201 and -202, were developed containing a d-TCO core featuring linkers of varying lipophilicity (alkyl chain and polyethylene glycol (PEG) chains), and a NOTA chelator. The reaction kinetics of [^{nat}Cu]Cu-CREANT-201/-202 with Tz were assessed by stopped-flow spectrophotometry. CREANT-201/-202 were both radiolabeled with Cu-64 and Cu-67, and the radiochemical conversion (RCC) was determined by radio-thin layer chromatography, while radiochemical purity (RCP) was assessed via radio-high performance liquid chromatography. Radiolabeled compounds were further evaluated regarding lipophilicity (logD), and in vitro stability towards cis isomerization (in PBS buffer at 37 °C up to 4h), and reacted with a Bis(pyridin-2-yl)-1,2,4,5-tetrazine (Bispyr-Tz) to confirm their reactivity. ***Results:*** [^{nat}Cu]CREANT-201 showed faster reaction kinetics towards Bispyr-Tz compared to [^{nat}Cu]CREANT-202 (138900 $M^{-1}\cdot s^{-1}$ vs 113200 $M^{-1}\cdot s^{-1}$). CREANT-201/-202 were labelled with Cu-64 and Cu-67 under optimized conditions with an RCC and RCP of over 95%. The logD values were determined to be -2.14 ± 0.04 and -1.75 ± 0.11 for [$^{64/67}$Cu]Cu-CREANT-201, respectively, while -2.73 ± 0.02 and -2.45 ± 0.03 for [$^{64/67}$Cu]Cu-CREANT-202, revealing that [$^{64/67}$Cu]Cu-CREANT-202 exhibits greater hydrophilicity, due to the presence of a PEG moiety. After the reaction with a Bispyr-Tz, a new radioactive peak corresponding to the dihydropyridazine reaction product could be observed, which indicates the radiolabelled-TCOs preserved the reactivity towards Tz. Radiolabeled TCOs showed good stability in PBS without copper release. Isomerization from trans to cis was observed after 2h, with 73.89% of trans-isomer remaining for [^{64}Cu]Cu-CREANT-201, and 80.91% for [^{64}Cu]Cu-CREANT-202. ***Conclusion:*** The TCOs can be efficiently radiolabeled with Cu-64/Cu-67 while remaining reactivity, making [$^{67/64}$Cu]Cu-TCOs promising candidates for pretargeted theranostics approach with Tz-conjugated mAbs. Their performance will be further evaluated in vitro with CD-70 positive cells and in vivo with CD-70-expressing tumor-bearing mice.

EP-0103

Preclinical evaluation of [^{11}C]Onalespib for Heat Shock Protein 90 (HSP90) cancer imaging

L. Le Saux[1], *V. Narykina*[1,2,3], *R. Cools*[1], *N. Van Winnendael*[1,4], *G. Bormans*[1];
[1]*Laboratory for Radiopharmaceutical Research, Department of Pharmacy and Pharmacological Sciences, KU Leuven, Leuven, BELGIUM,* [2]*Switch Laboratory, VIB Center for Brain and Disease Research, Herestraat 49, 3000, Leuven, BELGIUM,* [3]*Switch Laboratory, Department of Cellular and Molecular Medicine, KU Leuven, Herestraat 49, 3000, Leuven, BELGIUM,* [4]*Nuclear Medical Applications, Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM.*

Aim/Introduction: HSP90 is a molecular chaperone stabilizing oncogenic proteins and represents an interesting chemotherapy target.[1] Various first-generation inhibitors showed limited efficacy and toxicity issues in clinical trials.[2] Onalespib (AT13387), a second-generation inhibitor, has undergone clinical evaluation for various cancers, often in combination with standard therapies.[3] Radiolabeled [^{11}C]Onalespib enables positron emission tomography (PET) imaging to study biodistribution and kinetics, potentially supporting the development of Hsp90-targeted treatments. ***Materials and Methods:*** [^{11}C]Onalespib was synthesized via N-methylation of (2,4-dihydroxy-5-isopropylphenyl) (5-(piperazin-1-ylmethyl)isoindolin-2-yl)methanone using [11C] CH3I. Autoradiography was used to assess in vitro Hsp90-specific binding of [^{11}C]Onalespib to rodent brain and tumor tissue (U87, MDA-MB-231 and PC3) slices. Cell binding, including specificity and selectivity, was assessed in the same cell lines. Biodistribution was assessed in U87 xenograft-bearing SCID mice, by both µPET scanning and ex vivo biodistribution. ***Results:*** Autoradiography revealed Hsp90-specific binding in MDA-MB-231 tumor tissue, with substantial blocking by HSP990 (98%) and Onalespib (93%). Blocking efficiency was slightly lower in PC3 tumor slices (82% and 87%, respectively). Also in brain tissue slices, Hsp90-specific [11C] Onalespib was observed with blocking efficiency 95%. During cell binding experiments, blocking with TAS-116 and HSP990 resulted in only 60-80% reduction of tracer binding. Further investigations are ongoing to assess isoform specificity and potential off-target interactions. Ex vivo biodistribution demonstrated uptake of 4.9 ± 0.9 %ID/g in U87 tumor, 23.6 ± 1.9 %ID/g in kidneys, 11.4 ± 0.4 %ID/g in liver and 23.7 ± 2.2 %ID/g in lungs. Dynamic µPET/CT scans in mice demonstrated results consistent with ex vivo data, showing high uptake in kidneys, intestines, liver and lungs, and moderate tumor accumulation that was fully blocked by pretreatment with HSP90 inhibitors. Limited [^{11}C]Onalespib brain uptake was observed in contrast to literature reports claiming BBB penetration of Onalespib. ***Conclusion:*** [^{11}C]Onalespib was successfully synthesized and evaluated in vitro and in vivo. Hsp90-specific tracer binding was observed in a U87 mouse tumor model. Further in vivo studies in additional tumor models are ongoing. ***References:*** 1. Li, Z.-N. & Luo, Y. EP-0105

Preclinical evaluation of ^{68}Ga-DOTA-NEI as a radiotracer for neutrophil elastase

J. Wang, *F. Kang, J. Wang;*
The First Affiliated Hospital of Air Force Military Medical University, Xi'an, CHINA.

Aim/Introduction: Precisely assessing neutrophil elastase (NE) expression in early acute inflammatory conditions is crucial for identifying patients who may benefit from NE-targeted therapies. ***Materials and Methods:*** In this study, we developed a ^{68}Ga-labeled macrocyclic peptide, designated as ^{68}Ga-DOTA-NEI, to dynamically monitor NE expression levels in inflammatory lung tissue using positron emission tomography/computed tomography (PET/CT). ***Results:*** Our results demonstrated that ^{68}Ga-DOTA-NEI achieved a radioactive labeling yield of 70% and a radiochemical purity exceeding 95%. The probe exhibited excellent stability in saline and serum at 37°C for up to 4 hours, along with favorable hydrophilicity. Furthermore, molecular docking, molecular dynamics (MD) simulations, and competitive inhibition assays (IC_{50} = 1.37nM) confirmed the high affinity and binding stability of ^{68}Ga-DOTA-NEI to NE. Micro-PET/CT imaging, biodistribution studies and renal metabolic analysis revealed rapid and significant uptake of ^{68}Ga-DOTA-NEI in early acute inflamed lung tissue and metabolized by kidney, while blocking experiments further validated the probe's specific binding to NE. Additionally, pharmacokinetic analysis demonstrated the excellent compatibility of DOTA-NEI with ^{68}Ga. ***Conclusion:*** Collectively, these findings highlighted the promising clinical potential of ^{68}Ga-DOTA-NEI as a tool for monitoring NE expression in early acute lung inflammation, offering a valuable approach for therapeutic interventions.

EP-0106

Pretargeted PET imaging of tumors using a DZ-1-TCO and ^{68}Ga-tetrazine system: synthesis, optimization, and in vivo evaluation

M. Huang[1], *W. Wang*[1], *Y. Wang*[2], *R. Wang*[1], *Y. Zhang*[3], *R. Tian*[1];
[1]*The Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, China, Chengdu, CHINA,* [2]*Department of Nuclear Medicine and Clinical Nuclear Medicine Research Lab, West China Hospital, Sichuan University, Chengdu, China, Chengdu, CHINA,* [3]*Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, California 90048, United States, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Pretargeting strategies offer a promising approach to improve the specificity and safety of radiopharmaceuticals by decoupling tumor targeting from radionuclide delivery. DZ-1, a broad-spectrum tumor-targeting dye, has shown favorable bio-distribution in previous studies. To address pharmacokinetic limitations and reduce systemic toxicity observed with directly labeled agents such as ^{177}Lu-DZ-HX, we developed a DZ-1-based pretargeting system using trans-cyclooctene (TCO) and ^{68}Ga-labeled tetrazines. ***Materials and Methods:*** Three DZ-TCO precursors—DZ-1-TCO, DZ-Lys-TCO, and DZ-Lys-PEG4-TCO—were synthesized and assessed in HeLa and U87MG tumor-bearing mice by fluorescence imaging. Tumor uptake was monitored up to 96 h. Methyl-tetrazine (MeTz) and hydrazinyl-tetrazine (H-Tz) were labeled with ^{68}Ga, and their stability and reactivity were evaluated in PBS and serum. Pretargeted PET imaging was performed using different precursor/probe combinations and time intervals (24, 48, 72 h). ***Results:*** All precursors showed tumor accumulation, with peak fluorescence at 24 h (up to 1.20×10^{10} p/s/cm^2/sr) and sustained signal at 96 h. ^{68}Ga-DOTA-MeTz and ^{68}Ga-DOTA-H-Tz retained >85% stability after 4 h incubation. PET imaging revealed highest uptake for DZ-Lys-TCO (1.98 ± 0.72%ID/g), with tumor-to-muscle (T/M) and tumor-to-liver (T/L) ratios of 3.86 ± 0.91 and 0.89 ± 0.29, respectively ($P < 0.05$). Using ^{68}Ga-DOTA-H-Tz, the 48 h interval achieved optimal performance (3.24 ± 0.95%ID/g, T/M 8.30 ± 3.39, T/L 1.35 ± 0.26; $P < 0.05$). Biodistribution confirmed rapid renal clearance and low non-target uptake, with peak tumor uptake of 3.53 ± 1.76%ID/g and T/M up to 10.92 ± 0.31 at 30 min. ***Conclusion:*** The DZ-TCO/^{68}Ga-DOTA-Tz pretargeting system enables high-contrast tumor imaging with reduced background. Among tested conditions, DZ-Lys-TCO combined with ^{68}Ga-DOTA-H-Tz at a 48 h interval provided the most favorable imaging outcomes. This strategy presents a promising and tunable platform for enhancing the precision and safety of radiopharmaceutical applications.

EP-0107

ImmunoPET Imaging of TROP2 Expression in Lung Cancer with scFv Tracers

Z. Wu, *Z. Lin, Y. Feng, D. Zheng, X. Zhang, R. An, Y. Zhang, J. Zhu, D. Jiang, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: TROP2, a transmembrane glycoprotein, is markedly overexpressed in several epithelial-derived malignancies, such as triple-negative breast cancer, pancreatic cancer, prostate cancer, and non-small cell lung carcinoma. The significant upregulation of TROP2 in these tumors positions it as a valuable biomarker for diagnosis. While whole antibodies have shown targeted specificity toward tumor-associated antigens in vivo, they can experience delayed systemic clearance. To circumvent these limitations, the development of antibody fragments, particularly single-chain variable fragments (scFv), has gained attention. This study focuses on engineering an scFv fragment that targets TROP2 as a novel probe, with preclinical testing in animal models to assess its targeting efficacy, biodistribution, and metabolic profile. ***Materials and Methods:*** The purity of the scFv fragment T2 was evaluated using size exclusion chromatography (SEC)-HPLC. Following conjugation with the NOTA chelator, the T2 fragment was radiolabeled with ^{68}Ga. The labeling efficiency and stability of the resulting ^{68}Ga-NOTA-T2 probe were assessed by radio-instant thin-layer chromatography (radio-iTLC). To investigate the targeting specificity, NCI-H292 tumor-bearing mice served as the TROP2-positive group, while A549 tumor-bearing mice functioned as the TROP2-negative control. For in vivo imaging, PET/CT scans were conducted at 0.5, 1, 2, and 4 hours following intravenous administration of the ^{68}Ga-NOTA-T2. The percentage of injected dose per gram of tissue (%ID/g) was calculated for each time point, with all radioactivity measurements corrected for attenuation. Animals were humanely euthanized after imaging, and organs were harvested for ex vivo biodistribution analysis. ***Results:*** In the TROP2-positive lung cancer model, ^{68}Ga-NOTA-T2 exhibited significant tumor uptake at 1 hour (1.74 %ID/g) and 2 hours (1.62 %ID/g) post-injection. The probe also demonstrated rapid clearance from the blood pool, decreasing from 1.21 %ID/g at 1 hour to 0.90 %ID/g at 2 hours. Renal uptake was relatively low, with values of 4.74 %ID/g at 1 hour. Ex vivo biodistribution analysis confirmed minimal retention in the blood pool (2.86 %ID/g) and kidneys (17.66 %ID/g), supporting the favorable pharmacokinetic profile of ^{68}Ga-NOTA-T2. In contrast, PET/CT imaging of the TROP2-negative group revealed indistinct tumor contours. Quantitative analysis showed that the tumor-to-background ratios, when comparing tumor uptake against blood, liver, and muscle, were significantly lower in the negative group compared to the positive group. This marked the high specificity of ^{68}Ga-NOTA-T2 for TROP2-overexpressing tumors. ***Conclusion:*** Our results affirm the capability of ^{68}Ga-NOTA-T2 to specifically target TROP2-overexpressing tumors in vivo, characterized by swift blood clearance and reduced kidney uptake.

EP-0108

Development of $^{11}C/^{18}F$ PET radioligands selective for LRRK2

K. Jia[1], *R. Arakawa*[1], *A. Forsberg Morén*[1], *T. Jensen*[2], *M. Hentzer*[2], *C. Jones*[2], *M. Jorgensen*[2], *B. Bang-Andersen*[2], *A. Varrone*[1], *C. Halldin*[1], *S. Nag*[1];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*H. Lundbeck, Valby, DENMARK.*

Aim/Introduction: Leucine-rich repeat kinase 2 (LRRK2) is a protein of vital importance to human biology. Mutations of the LRRK2 gene are associated with Parkinson's disease (PD). Their biological effect leads to increased LRRK2 kinase activity, making LRRK2 inhibitors a potential approach for the treatment of PD. The development of LRRK2-specific radioligands enables the ability to measure changes of the density of the enzyme in the brain of PD patients, but also serves as tools to measure occupancy of potential LRRK2 inhibitors. The objectives of this study were i) $^{11}C/^{18}F$ labelling of three 5-(1-(substituted pyridin-3-yl)-1H-pyrazol-4-yl)-3,3-dimethylisoindolin-1-ones as LRRK2 inhibitors, ii) evaluate their binding properties through in vivo PET in NHPs. ***Materials and Methods:*** Precursors and reference standards were provided by H. Lundbeck A/S. Synthesis of [^{11}C]5-(1-(6-(dimethylamino)-5-methylpyridin-3-yl)-1H-pyrazol-4-yl)-3,3-dimethylisoindolin-1-one (1) and [^{11}C]5-(1-(6-methoxypyridin-3-yl)-1H-pyrazol-4-yl)-3,3-dimethylisoindolin-1-one (2) were achieved by methylation of corresponding BOC-precursor followed by the deprotection. [^{18}F]5-(1-(6-(3-fluorooxetan-3-yl)-5-methylpyridin-3-yl)-1H-pyrazol-4-yl)-3,3-dimethylisoindolin-1-one (3) was synthesized in a direct fluorine-18 substitution followed by deprotection. Four NHPs underwent a total of fourteen PET measurements, including assessments at baseline and after pretreatment with either (2) (2 mg/kg body weight) or Tariquidar (2 mg/kg body weight) administered 7 minutes prior to the injection of the radioligands. Radiometabolites in plasma were analyzed using gradient HPLC. The plasma input function corrected for radiometabolites was measured for each scan. ***Results:*** All three radioligands were successfully synthesized with a radiochemical purity exceeding 99%. PET measurements with [^{11}C]1 and [^{11}C]2 revealed low brain uptake, peaking at approximately 1.5 SUV and quickly decreasing to 0.2 and 0.07 SUV, respectively, with most activity concentrated in the blood vessels and no significant regional differences observed. [^{11}C]2 exhibited faster metabolism at 90 minutes (28%) compared to [^{11}C]1 (73%), These results indicated limited brain penetration. After pretreating with cold 2, brain uptake of [^{11}C]2 increased possibly due to reduced metabolism. After pre-treatment with Tariquidar brain uptake of [^{11}C]2 increased slightly in one NHP but remained unchanged in the other, with no significant metabolic impact. This variance may be due to reduced brain efflux following P-gp and BCRP blockage. Similarly, PET studies with [^{18}F]3 also confirmed its lack of brain penetration. ***Conclusion:*** The radiolabeling of [^{11}C]1, [^{11}C]2 and [^{18}F]3 was successful. However, subsequent PET imaging, including pre-treatment experiments, showed low brain penetration and no specific binding in the cynomolgus brain. Therefore, these radioligands are unlikely to be suitable for LRRK2 imaging using PET.

EP-0109

Development of a ^{68}Ga-Radiolabeled Fluorescent Dye for Potential Multimodal PET Imaging of Aneurysmal Subarachnoid Hemorrhage

L. Schäfer[1], *J. W. Gerhards*[1], *D. Kang*[1], *U. Lindauer*[2], *B. Altunay*[1], *S. Lütje*[1], *F. M. Mottaghy*[1,3], *T. Schmidt*[2], *A. T. J. Vogg*[1];
[1]*Department of Nuclear Medicine, University Hospital RWTH Aachen, Aachen, GERMANY,* [2]*Translational Neurosurgery and Neurobiology, Department of Neurosurgery, RWTH Aachen University Hospital, Aachen, GERMANY,* [3]*Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, 6229 ER Maastricht, NETHERLANDS.*

Aim/Introduction: Aneurysmal subarachnoid hemorrhage (aSAH) is a specific form of stroke, most commonly resulting from the rupture of a cerebral aneurysm. This type of stroke poses significant clinical challenges, as aSAH is associated with high morbidity and mortality rates. Despite ongoing research, the underlying pathophysiological mechanisms of aSAH are not yet fully understood. Recent studies of the perivascular system have identified an abnormal distribution of the fluorescent dye Alexa Fluor™ 594 during experimental measurements[1]. To further explore this distribution anomaly, it is proposed to radiolabel the dye with Gallium-68 (^{68}Ga), enabling biokinetic tracking in rats through positron emission tomography (PET) for improved imaging and analytical precision. ***Materials and Methods:*** The coupling reaction between NODA-GA-NHS ester and Alexa Fluor™ 594 1,5-diaminopentane was carried out in acetonitrile using pyridine as auxiliary base, at 80 °C for one hour. Successful conjugation was confirmed by Orbitrap mass spectrometry analysis. For the standard radiolabeling procedure, [^{68}Ga]$GaCl_3$ was reacted and with NODA-GA-NHS-Alexa Fluor™ 594 conjugate using ammonium acetate buffer (3 M, adjusted to pH 4.5), followed by incubation at 80°C for 5 minutes. Purification was performed using a C18 cartridge. Quality control was conducted via radio-HPLC analysis. ***Results:*** The fluorescent dye Alexa Fluor™ 594 after chelator conjugation was successfully labeled with the positron-emitting radionuclide ^{68}Ga(III) in a no-carrier-added form. The NODA-GA-NHS ester was employed to react with the amino group of Alexa Fluor™ 594 1,5-diaminopentane, facilitating subsequent radiolabeling with 68Ga. The formation of the Alexa Fluor™ 594-chelator conjugate, as well as the radiolabeling, were investigated as a function of reaction time, temperature and conjugate concentration. For potential animal experiments, it was necessary to reduce the precursor concentration while increasing the labeling temperature from room temperature to 80°C to keep high RCC, given the short half-life of ^{68}Ga. Optimal labeling conditions were established, achieving radiochemical conversions of > 85%. After purification of n.c.a. [^{68}Ga]Ga-NODA-GA-Alexa Fluor™ 594 remaining impurities were below 3%. ***Conclusion:*** This experimental approach successfully yields the desired radiolabeled dye, which is now available for animal studies, offering enhanced insight into the mechanisms of aSAH. ***References:*** [1] Golanov, E. V., et al. (2018). "Subarachnoid hemorrhage - Induced block of cerebrospinal fluid flow: Role of brain coagulation factor III (tissue factor)." J Cereb Blood Flow Metab 38(5): 793-808.

EP-0110

Mesoporous Silica Nanoparticles Labeled with Zirconium-89 for Long-Term In Vivo Tracking of Cells via PET Imaging

M. Xu, *Z. Liu;*
Changping Laboratory, Beijing, CHINA.

Aim/Introduction: Cell-based therapies, as one of the most promising treatments for human diseases, have attracted significant attention in recent years, owing to their outstanding therapeutic effects.Stem cell therapy and immune cell therapy, in particular, have emerged as essential fields of clinical research, offering great promise in addressing intractable diseases such as cardiac disease, tissue injury, immune disorders, cancer treatment, and so on. But the specific behavior of these functionalized cells in the body has been confusing, which limited the further development of cell therapy. There is an urgent need to develop a technology capable of tracking and imaging functional cells in the body for understanding their behavior over extended periods. ***Materials and Methods:*** The zirconium-89 (^{89}Zr) was labeled mesoporous silica nanoparticles (^{89}Zr-mSiO_2) as a robust platform for cell tracking via positron emission tomography (PET) imaging. Human mesenchymal stem cells (hMSCs) and cancer cells loaded with mesoporous silica nanoparticles concentrating the 89Zr

radioisotope and injected into mice. The mice were tracked in vivo for a long time from the pattern of annihilation photons detected using PET/CT. ***Results:*** The designed ^{89}Zr-mSiO$_2$ exhibit exceptional biocompatibility and internalization efficiency into cells, owing to their unique mesoporous structure and stable Si-O-Zr bonds. Both in vitro and in vivo studies demonstrate prolonged stability and minimal cytotoxicity of ^{89}Zr-mSiO$_2$, ensuring reliable and safe cellular labeling. Notably, ^{89}Zr-mSiO$_2$ exhibit negligible cell efflux, enabling precise detection of cellular signals without interference. PET imaging of ^{89}Zr-mSiO$_2$-labeled cells in murine models allows for real-time tracking of cell localization for up to 10 days post-injection. ***Conclusion:*** Overall, our findings highlight the potential of ^{89}Zr-mSiO$_2$ as a promising tool for long-term in vivo tracking of functional cells, thus advancing the prospects of cell therapy in a clinical setting.

EP-0111

Development of ^{18}F-Labeled Deuterated Tropane Derivatives with High Metabolic Stability for PET Imaging of the Dopamine Transporter

Z. Chen, *J. Hong, Y. Fang, C. Liu, J. Kang, J. Zuo, J. Li;*
NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: The dopamine transporter (DAT) in the central nervous system is an attractive biomarker for diagnosing and monitoring various neurodegenerative diseases. To develop in vivo metabolically stable positron emission tomography (PET) probes for DAT imaging with a high target/background ratio, two ^{18}F-labeled tropane derivatives with deuteration on both N-fluoropropyl and 2β-carbomethoxy of the tropane scaffold were synthesized and evaluated. ***Materials and Methods:*** Radioligands methyl-d$_3$ (1R,2S,3S,5S)-3-(4-chlorophenyl)-8-(3-(fluoro-^{18}F) propyl-1,1,2,2,3,3-d$_6$)-8-azabicyclo[3.2.1]octane-2-carboxylate ([^{18}F]FP-CCT-d$_9$) and methyl-d$_3$ (1R,2S,3S,5S)-3-(4-iodophenyl)-8-(3-(fluoro-^{18}F)propyl-1,1,2,2,3,3-d$_6$)-8-azabicyclo[3.2.1] octane-2-carboxylate ([^{18}F]FP-CIT-d$_9$) were synthesized from anhydroecgonine and radiolabeled with ^{18}F through a "two-step one-pot" method. Lipophilicity, in vitro binding assay and microPET imaging in rats were performed. [^{18}F]FP-CIT-d$_9$ showed a higher standardized uptake value ratio (SUVr) and was selected for further in vivo metabolism and biodistribution investigations. ***Results:*** The radioligands [^{18}F]FP-CCT-d$_9$ and [^{18}F]FP-CIT-d$_9$ were obtained in radiochemical purities >98% and molar activity about 30 GBq/μmol. [^{18}F]FP-CCT-d$_9$ or [^{18}F]FP-CIT-d$_9$ demonstrated high specificity and binding affinity to DAT in vitro, with IC$_{50}$ values between 2~3 nM. MicroPET imaging with normal rats revealed that [^{18}F]FP-CIT-d$_9$ has a higher SUVr than [^{18}F]FP-CCT-d$_9$. Blocking experiments demonstrated the selectivity and reversibility of [^{18}F] FP-CIT-d$_9$ for DAT binding in microPET imaging. The diagnostic efficacy of [^{18}F]FP-CIT-d$_9$ for DAT-related disorders was verified in semi-PD model rats with microPET. In vivo metabolic studies in rats indicated that [^{18}F]FP-CIT-d$_9$ exhibited enhanced in vivo stability compared with the previously reported analog [^{18}F]FP-CIT-d$_6$. Biodistribution experiments further confirmed that [^{18}F] FP-CIT-d$_9$ has a good affinity toward DAT in the brain. ***Conclusion:*** [^{18}F]FP-CIT-d$_9$ is a highly promising metabolic stable ^{18}F-labeled PET probe for DAT imaging, with potential clinical applications in detecting and monitoring DAT-related neurological disorders. The present work was supported by the National Natural Science Foundation of China (82172054).

A study on radiolabeling methods for novel tau tracer lead compounds discovered using a big data/AI-based drug development platform

K. Kangbin[1], *H.-C. Song*[1,2];
[1]*Chonnam National University Hospital, Gwangju, KOREA, REPUBLIC OF,* [2]*Chonnam National University Medical School, Gwangju, KOREA, REPUBLIC OF.*

Aim/Introduction: By leveraging big data and artificial intelligence (AI) technologies, we identified lead compounds predicted to specifically bind to tau protein and developed radiolabeling methods for these compounds. ***Materials and Methods:*** Using a big data/AI-based drug development platform, we identified five compounds predicted to specifically bind to tau protein (microtubule-associated protein tau, human). Of these, two compounds (JN-TAU-1 and JN-TAU-2) were selected as lead candidates for radiolabeling. Considering the feasibility of labeling with the PET radionuclide C-11, C-11 was produced using a cyclotron (IBA) and radiolabeling was performed with an automated synthesizer (TRACERlab FX2 C Synthesizer, GE Healthcare). The synthesis conditions were varied based on temperature (25°C, 70°C), reaction time (3, 5, 10 minutes), and solvents (c-HXO, DMSO, acetone, acetonitrile). The resulting radioactivity levels were compared under each condition. ***Results:*** [C-11]CO2 gas, produced via cyclotron beam irradiation, was converted to CH3OTf for the labeling reaction. The radioactivity levels of JN-TAU-1 and JN-TAU-2 synthesized at 25°C and 70°C were 11 ± 4 mCi (n=5) and 8 ± 4 mCi (n=5), respectively (p=0.60). When the reaction was performed at 25°C for 3, 5, and 10 minutes, the radioactivity levels were 15 ± 9 mCi (n=3), 10.5 ± 4.5 mCi (n=8), and 11 ± 4 mCi (n=5), respectively, with no significant differences observed. Under the conditions of 25°C and 3 minutes, the radioactivity levels of the products synthesized using c-HXO, DMSO, and acetone as solvents were 15 ± 9 mCi (n=3), 10 ± 3 mCi (n=4), and 17.5 ± 1.5 mCi (n=3), respectively. Notably, a solvent mixture (MIX) of acetone and acetonitrile in a 1:1 ratio yielded approximately 40 ± 5 mCi (n=3) of radioactivity (p=0.04). ***Conclusion:*** Our preliminary results demonstrate that the tau imaging lead compounds identified using a big data/AI-based drug development platform can be successfully radiolabeled with C-11. While time and temperature had minimal impact on the radiolabeling process, the choice of solvent significantly influenced labeling efficiency. The highest labeling efficiency was notably achieved using a mixed solvent (MIX) of acetone and acetonitrile.

EP-0113

Synthesis of [^{11}C]PF-07799933 and evaluation of its whole-body distribution in NHP using PET

S. Nag[1], *Z. Jia*[1], *M. Tóth*[1], *Y. Khani*[1], *A. Varrone*[1], *L. Chen*[2], *J. Wong*[2], *B. Baer*[2], *J. Gaudino*[2], *K. Maresca*[2], *C. Halldin*[1];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Pfizer Inc., Worldwide Research & Development, Cambridge, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: PF-07799933 is a drug candidate and an investigational small synthetic molecule that is specifically investigated by Pfizer for various cancer types for its ability to cross the blood-brain barrier to treat BRAF mutated tumors with CNS involvement. To aid the clinical evaluation of brain penetration of PF-07799933, it was proposed that the compound be labelled with C-11 and PET imaging be performed to trace the distribution of the drug in the tissues of NHP subjects. The primary aims of the study included developing a synthesis method to effectively label PF-07799933 with C-11 and measuring the distribution of [^{11}C]PF-07799933 throughout the body of NHPs, estimating the effective radiation doses and to evaluate the brain distribution of [^{11}C]PF-07799933 following a pre-treatment of cold PF-07799933. Furthermore, radiometabolite was analyzed in NHP blood plasma.

Materials and Methods: Radiolabeling was achieved via [^{11}C] methylation and followed by deprotection. Four female NHPs underwent four PET measurements. Each NHP was scanned once, with NHP 1 and NHP 2 being evaluated under baseline conditions, while NHP 3 and NHP 4 were scanned under pre-treatment conditions (30 mg/kg PF-07799933). For the latter two NHPs, the imaging protocol was tailored to focus on the brain to enhance both the spatial and temporal resolution of brain uptake of [^{11}C] PF-07799933. A reversed-phase radio-HPLC method was used to determine the radiometabolites in NHP plasma. ***Results:*** [^{11}C]PF-07799933 was synthesized with radiochemical purity (>99%). The injected radioactivity of [^{11}C]PF-07799933 was 154.3 ± 4.9 MBq. The absorbed organ dose was highest at the small intestine (0.04 mGy/MBq) followed by the gallbladder, liver, and kidneys. The effective dose was estimated to be 0.0042 mSv/MBq. The brain uptake was distributed homogeneously across all experiments, reaching approximately 2% of the Injected Dose (ID) at its peak. In contrast, following the pre-treatment the uptake was rapidly decreased to below 0.4% ID. Radiometabolite studies demonstrated that only more polar radiometabolites were formed, with about 15% unchanged radioligand remaining at 60 min post injection for baseline but after pretreatment it was over 90% unchanged radioligand. Furthermore, [^{11}C]PF-07799933 demonstrated a brain-to-plasma ratio of 0.1-0.15 under baseline/tracer conditions, which was reduced to 0.05-0.07 following pre-treatment. ***Conclusion:*** PF-07799933 was successfully labeled. The homogeneous brain uptake was measured and blocked with cold dosing. The effective dose was estimated to be 0.0042 mSv/MBq of injected activity, based on a dosimetry study in non-human primates, indicating that it is comparable to other C-11 PET radioligands.

EP-0114

ImmunoPET tracer based on antibody fragments radiolabeled with ^{89}Zr for detecting the α1 subunit of the GABA-A receptors in the brain.

Á. García de Lucas[1,2,3], *L. Kovacs*[4,2], *B. Todorov*[5], *L. Nissilä*[4], *B. Salinas Rodríguez*[1,3,6], *U. Lamminmäki*[2], *F. López-Picón*[7,2], *A. Airaksinen*[4,2];
[1]*Universidad Carlos III de Madrid, Madrid, SPAIN,* [2]*University of Turku, Turku, FINLAND,* [3]*Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, SPAIN,* [4]*Turku PET Centre, Turku, FINLAND,* [5]*University of Sofia, Sofia, BULGARIA,* [6]*Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, SPAIN,* [7]*Turku PET Centre, Turku, FINLAND.*

Aim/Introduction: Immuno-positron emission tomography (immunoPET) is a non-invasive in vivo imaging method based on tracking and quantifying radiolabeled monoclonal antibodies (mAbs) and other related molecules, such as antibody fragments[1]. This new approach could be used to map the diversity of GABA-A receptors inside the brain. For instance, postmortem studies in schizophrenia patients have demonstrated that GABA-A receptorα subunit expression have found reductions in α1 and increases in α2 subunits expression. However, the density of GABA-A receptor in schizophrenia does not appear abnormal in radioligand studies as postmortem studies have demonstrated. Some researchers and we believe that these negative findings can be explained because of the lack of imaging tracers with high affinity and specificity[2,3]. ***Materials and Methods:*** Di-scFv1F4 was first conjugated with 15 equivalents of DFO*-NHS. DFO*-Di-scFv1F4 was radiolabeled with 10-50 MBq 89Zr and purified by a spin filter (10kDa). [^{89}Zr] Zr-DFO*-Di-scFv1F4 (2.43-2.90 MBq, 0.63-0.86 nmol, in 100 µl of PBS) was administered intravenously via tail vein injection in wild C57BL/6 mice and PET/CT images was performed in β- and X-CUBE scanners at 24, 72 and 144 hours post-injection. PET images were analyzed using Inveon Research Workplace software. ***Results:*** [^{89}Zr]Zr-DFO*-Di-scFv1F4 was successfully conjugated with DFO* (0.72 DFO*/antibody fragment) and radiolabeled with ^{89}Zr with a radiochemical purity >96% ± 0.76 (n=3). After the production of the PET probe, it was injected into mice, and images were taken at different time points. PET analysis was conducted with a focus on the brain, where a progressive decrease in radioactivity signal was observed over 24 (1.51±0.18 %ID/g), 72 (0.91±0.17 %ID/g) and 144 (0.62±0.12 %ID/g) hours. Notably, [^{89}Zr]Zr-DFO*-Di-scFv1F4 exhibited region-specific distribution patterns across different brain areas and time points. For instance, the cerebellum, frontal cortex, and hypothalamus demonstrated higher signal intensities compared to the hippocampus, parieto-temporal cortex, striatum, and thalamus. ***Conclusion:*** [^{89}Zr]Zr-DFO*-Di-scFv1F4 was successfully developed and studied using PET imaging in healthy mice. Interestingly, the distribution and uptake in various brain areas mirrored the patterns described for the α1 subunit of GABA-A receptors in previous research[4]. The cerebellum, frontal cortex, and hypothalamus exhibited higher uptake. This study is the first to demonstrate that an immunoPET probe can be developed to cross the blood-brain barrier and detect ion channels within the brain. ***References:*** 1) de Lucas ÁG et al. EP-0115

Development of a novel PET radiotracer for targeting HER2-expressing tumors

A. Coliva[1], *M. Maspero*[2], *S. Di Benedetto*[3], *R. Ferrisi*[3], *C. Papotto*[4], *S. Valtorta*[2], *R. Moresco*[4], *C. Dallanoce*[3], *A. Chiti*[5,6];
[1]*Nuclear Medicine Department, IRCCS San Raffaele, Milan, ITALY,* [2]*Institute of Bioimaging and Complex Biological Systems, National Research Council (IBSBC-CNR), Milan, ITALY,* [3]*Department of Pharmaceutical Sciences, University of Milan, Milan, ITALY,* [4]*Department of Surgical Sciences, University of Milano-Bicocca, Milan, ITALY,* [5]*Vita-Salute San Raffaele University, Milan, Italy,* [6]*IRCCS San Raffaele, Milan, ITALY.*

Aim/Introduction: HER2 (Human Epidermal Growth Factor Receptor 2) is a key biomarker in breast cancer, associated with aggressive tumors and poor prognosis, as 15-20% of breast cancers overexpress it. Targeting HER2 has transformed treatment options, especially with targeted therapies, though variability in receptor expression can influence their effectiveness, highlighting the need for accurate HER2 status assessment. While HER2 levels are typically monitored using invasive methods, PET imaging offers real-time, non-invasive, and quantitative insights. Tyrosine kinase inhibitors (TKIs) are a promising class of drugs that block HER2-activated signaling pathways, reducing tumor growth and enhancing patient outcomes. Radiolabeled TKIs are being investigated for their imaging and treatment response monitoring potential. SPH5030 is a specific and irreversible TKI currently in phase I clinical trials. This study aims to evaluate [^{11}C]SPH5030, a structurally identical compound, as a positron imaging agent. ***Materials and Methods:*** Chemically and optically pure precursors, N-desmethyl (R,E)- and N-desmethyl (R,Z)-SPH5030, were synthesized. Radiolabelling proceeds in the same way for both through methylation with [^{11}C]methyl triflate on the precursor dissolved in DMSO. The crude mixture was purified by isocratic semipreparative HPLC and recovered in a phosphate buffer (25 mM, pH 6) mixed with Ethanol and Acetonitrile (41:41:18). The purified compound was subsequently formulated in saline/ethanol after passage on a tC18 cartridge. In vitro uptake studies were conducted on two breast cancer cell lines: one HER2-positive (SKBR3) and one HER2-negative (MDA-MB-231) at three time points (15 min, 30 min, and 1 h). The cell lines, adhered to the assay plate, were incubated with a fixed concentration of the labeled compound. At the specified times, the supernatant was collected, and the activity of both bound and unbound labeled compounds was measured. ***Results:*** [^{11}C]SPH5030 was obtained with a radiochemical yield of about 9% n.d.c, a radiochemical purity > 99% and specific activity of 0.11 GBq/nmol. In vitro uptake experiment was conducted with (R,Z)-[^{11}C]SPH5030. Maximum uptake was observed at 30 minutes, 19.76 ± 1.99 % in SKBR3 cell

vs 8.73 ± 0.42 %. in MDA-MB-231 cells. The small uptake observed in HER2-negative cells was likely due to nonspecific binding or to cross binding with EGF receptor. ***Conclusion:*** Building on these encouraging findings, studies are needed to evaluate HER2 specificity of (R,Z)-[^{11}C]SPH5030 and (R,E)-[^{11}C]SPH5030 and to explore other derivatives that allow incorporation of Fluorine-18 or modulation of selectivity and binding reversibility. ***References:*** [1] D. Li, et al, Journal of medicinal chemistry, 2022, 65, 5334-5354.

EP-0116

Synthesis of [11C]BIIB135, a Tyrosine Kinase (BTK) Inhibitor evaluated in NHP using PET

P. Datta[1], *A. Forsberg Morén*[1], *Y. Khani Meynaq*[1], *M. Kaliszczak*[2], *B. Cook*[2], *A. Varrone*[1], *C. Halldin*[1], *S. Nag*[1];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Biogen Inc, 225 Binney street, Cambridge, MA 02142, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Bruton's tyrosine kinase (BTK) is primarily involved in the pathway associated with the B-cell receptor. As a promising anti cancer drug targeting B-cell therapies, B-cell malignancies and autoimmune diseases such as multiple sclerosis (MS) and rheumatoid arthritis, BTK inhibitors have attracted a good deal of attention. It is important to devise new BTK inhibitors that reversibly bind and have high selectivity. BIIB135, a novel and highly selective irreversible BTK inhibitor approved for adult patients with relapsed/refractory mantle cell lymphoma (r/r MCL) after prior therapy, demonstrates potent inhibition of BTK with a half-maximal inhibitory concentration of 1.6 nM and minimal off-target effects on other tyrosine kinases. The aim of this study was to develop a fast and efficient synthetic method for labeling [11C] BIIB135 and its in vivo initial evaluation in NHP using PET. ***Materials and Methods:*** Radiolabeling was achieved in one step via [11C] carbonylation. Two male NHPs (NHP1 and NHP2) underwent four PET measurements in total. Two PET measurements were performed with [11C]BIIB135 at baseline condition followed by the second PET measurement after pretreatment with BIIB135 (2 mg/kg bw) on same day. The plasma input function corrected for radiometabolites was measured for each scan. The total volume of distribution (VT) which is equivalent to the equilibrium partition coefficient for the drug between brain and plasma were calculated for a selection of regions. The occupancy was calculated using revised Lassen plot. Radiometabolites in plasma were analysed using gradient HPLC. ***Results:*** [11C]BIIB135 was synthesized successfully with radiochemical purity (>99%), and molar activity >37 GBq/μmol. The compound was found to be stable in sterile saline for 60 min. The distribution of [11C]BIIB135 in the primate brain was homogenous and the whole brain uptake was <1% ID at baseline and after pretreatment. The absence of conclusive evidence for alterations in regional VT values after pharmacological dosing indicates that any specific binding of [11C]BIIB135 is minimal compared to the free and non-specific components in the living brain. Furthermore, radiometabolite analyses revealed the formation of only more polar radiometabolites, with approximately 60% of the unchanged [11C]BIIB135 remaining at 60 minutes post-injection. ***Conclusion:*** This study revealed low brain uptake of [11C]BIIB135. While there was slight variability in its distribution across different brain regions, the observed kinetics were consistent with passive diffusion, indicating that free concentration and non-specific binding were the predominant factors influencing distribution.

EP-0117

Development and evaluation of [^{68}Ga]LAYp: A novel PET probe for tumor-associated enzyme targeting

W. Hongyong, *H. Wu, Y. Liu, J. Wu, P. Zou;*
Jiangsu Institute of Nuclear Medicine, Wuxi, Jiangsu, CHINA.

Aim/Introduction: The development of specific and effective PET probes is crucial for improving diagnostic accuracy and therapeutic outcomes. Recent advancements in peptide-based probes have shown great potential due to their high specificity, low toxicity, and rapid clearance from non-target tissues. In this study, we introduce a novel PET probe, [^{68}Ga]LAYp, designed to target tumor-associated enzymes. This probe leverages an enzymatic peptide self-assembly strategy, which allows for the selective enrichment of the probe at the tumor site, thereby enhancing PET imaging. ***Materials and Methods:*** The precursor of the probe, LAYp, was synthesized using SPPS. The synthesized precursor was then labeled with $^{68}GaCl_3$ form the radiolabeled probe [^{68}Ga]LAYp. The radiochemical purity of the probe was verified using radioactive HPLC. For stability assessment, the probe was incubated in PBS and FBS at 37°C, with samples collected at 1, 2, and 3 h for HPLC analysis. In vivo studies were conducted by injecting the probe into HeLa tumor-bearing nude mice. Micro-PET imaging was performed at 1 h and 2 h post-injection for a duration of 10 min each. The tumor and muscle regions were delineated across five consecutive slices in the micro-PET images. ***Results:*** The analysis of the ^{68}Ga-labeled reaction mixture via radioactive HPLC confirmed that the probe's radiochemical purity surpassed 98%, which is sufficient for advancing to in vivo experiments without further purification. During the stability assessment, the radiochemical purity of the probe was maintained consistently over a 3-hour duration. The MTT assay revealed that at a concentration of 500 μM of the probe precursor, the cell viability reached 98%, indicating the probe's safety for in vivo applications. The micro-PET imaging results clearly delineated the tumor, with tumor uptake values recorded at 1 h and 2 h post-injection being 3.32 ± 0.37 %ID/g and 6.45 ± 0.53 %ID/g, respectively. The high tumor-to-muscle signal ratio observed highlights the probe's effective targeting and accumulation within the tumor site. ***Conclusion:*** The novel PET probe [68Ga]LAYp demonstrates excellent stability, low cytotoxicity, and effective tumor targeting in HeLa tumor-bearing nude mice. The straightforward synthesis procedure, gentle reaction conditions, and low raw material costs of the probe precursor make it a promising candidate for further development and clinical translation. Future work will focus on exploring the potential of substituting the phosphate group in the probe with various enzyme-targeting molecules to create a range of tumor-specific PET probes tailored to different types of cancer.

EP-0118

Synthesis and in vitro/in vivo Evaluation of the Synaptic Vesicle Protein SV2C PET Radioligands: ^{18}F-UCB-F, ^{11}C-SV2C-1, and ^{11}C-SV2C-2

S. Nag[1], *A. F. Morén*[1], *V. Sousa*[1], *R. Zou*[2], *P. Datta*[1], *J. Mercier*[3], *Y. Khani Meynaq*[1], *H. Ågren*[2], *C. Halldin*[1], *A. Varrone*[1];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Uppsala University, Uppsala, SWEDEN,* [3]*UCB Biopharma, Braine l'Alleud, BELGIUM.*

Aim/Introduction: The synaptic vesicle protein SV2C protein, mainly found in the basal ganglia, is linked to Parkinson's disease (PD). It plays a role in regulating dopamine release and has been disrupted in PD animal models and brain tissue from PD patients. In studying PD-related synaptopathy, SV2C could be a potential imaging target for tracking changes with disease progression and treatment. This study aims i) to investigate the binding profile of a series of compounds using molecular docking, molecular dynamics simulation and free energy calculation methods ii) to radiolebel ^{18}F-UCB-F, ^{11}C-SV2C-1 and ^{11}C-SV2C-2 and evaluate their binding characteristics in vitro using autoradiography (ARG) and in vivo using NHP PET. ***Materials and Methods:*** Molecular dynamics (MD) simulations were carried out using the GROMACS 4.6.7 code. Radiolabeling was accomplished through either fluorine-18 nucleophilic substitution reaction or N-alkylation using $^{11}C\text{-}CH_3I$. The ^{18}F-UCB-F binding distribution across regions was evaluated using autoradiography (ARG) on brain sections from rats and NHPs. Blocking experiments were conducted using cold UCB-F (10 μM) during ARG analysis. The brain distribution of ^{18}F-UCB-F, ^{11}C-SV2C-1 and ^{11}C-SV2C-2 was examined with PET. Four PET measurements at baseline condition were conducted in two different cynomolgus

NHPs, using a high-resolution PET/CT system. Radiometabolites were analyzed in NHP plasma samples using radio HPLC. ***Results:*** Three compounds were chosen for radiolabeling depending on the docking score and free energy calculation. They were synthesized effectively from the corresponding precursors. ARG on brain slices from rats and NHPs showed specific binding of ^{18}F-UCB-F in pallidum, striatum, substantia nigra and brainstem, consistent with the expression of SV2C in the brain. In NHPs, ^{18}F-UCB-F, ^{11}C-SV2C-1 and ^{11}C-SV2C-2 rapidly entered the brain with a peak uptake of 2.8 %ID for ^{18}F-UCB-F and 2.1 %ID and 4.0 %ID for ^{11}C-SV2C-1 and ^{11}C-SV2C-2 respectively at 4 minutes. The wash-out of the radioactivity from the brain was rapid with no clear evidence of regional distribution. Radiometabolite studies showed the formation of more polar radiometabolites, with approximately 15% of unchanged radioligand remaining at 15 minutes post-injection. ***Conclusion:*** Three radioligands were radiolabelled with high incorporation yield. In vitro, ^{18}F-UCB-F showed specific binding on tissue slices from rodent and NHP brains. However, in vivo, ^{18}F-UCB-F, ^{11}C-SV2C-1 and ^{11}C-SV2C-2 displayed too rapid washout from the brain, lack of regional brain distribution and rapid metabolism. Overall, these findings indicate that none of the radioligands is suitable for imaging SV2C and additional work is needed to identify a potential candidate.

EP-0119

Research on Dynamic Monitoring and Quantitative Assessment of Liver Function in Liver Injury Based on [^{68}Ga]Ga-DTPA-EOB PET Imaging

Y. Fan[1], *W. Hai*[1], *Q. Qu*[1], *B. Cai*[2], *X. Xiang*[2], *Y. Shen*[3], *B. Li*[1], *J. Hu*[1]; *[1]Department of Nuclear Medicine, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]Department of Infectious Diseases, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [3]Research Center for Experimental Medicine, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: The progression of liver injury to failure poses a global health burden, making accurate assessment and prediction of liver function crucial for preventing irreversible damage. We synthesized the novel probe [^{68}Ga]Ga-Diethylenetriaminepentaacetic acid-Ethoxybenzyl ([^{68}Ga]Ga-DTPA-EOB) for PET/CT imaging assessment of liver function. ***Materials and Methods:*** [^{68}Ga]Ga-DTPA-EOB was synthesized based on EOB-DTPA, and its radiochemical purity and in vitro stability were analysed by radio-HPLC. Dynamic [^{68}Ga]Ga-DTPA-EOB PET/CT scans were performed on normal SD rats and CCl_4-treated chronic liver injury model. Furthermore, [^{68}Ga]Ga-FAPI PET/CT and MRI (T2WI sequence) imaging were conducted on the chronic liver injury group at week 7. Model validation and injury quantification were performed through hepatic histology and serum liver function assays. To assess biosafety, a toxicological dose of [^{68}Ga]Ga-DTPA-EOB exceeding the previous imaging dose was administered intravenously to normal rats, followed by histological analysis of major organs 24 hours post-injection. ***Results:*** [^{68}Ga]Ga-DTPA-EOB exhibited a radiochemical purity of ≥95% and demonstrated excellent stability in vitro. Dynamic 30-min PET/CT imaging demonstrated liver-specific uptake of the probe in normal rats, with the time-activity curve (TAC) that showed a gradual increase to plateau, and was mainly excreted through the kidneys and intestines. The hepatic uptake levels of [^{68}Ga]Ga-DTPA-EOB in chronic liver injury group was significantly lower than those in the normal group at all time points ($P<0.05$), and the TAC exhibited a gradual declining trend. Compared to the control group, the chronic liver injury group at week 7 demonstrated mild uptake on [^{68}Ga]Ga-FAPI PET/CT images and subtle fibrotic changes on MRI (T2WI sequence), although the visual contrast was less pronounced than that of [^{68}Ga]Ga-DTPA-EOB. Moreover, the imaging findings were consistent with the serum biochemical results and hepatic histopathology in rats. Acute toxicity testing revealed that HE staining of organs in the simulated toxicological dose group showed intact tissue structures with no significant pathological abnormalities, providing preliminary evidence for the safety of [^{68}Ga]Ga-DTPA-EOB PET imaging. ***Conclusion:*** In this study, we successfully synthesized the DTPA-EOB-based probe [^{68}Ga]Ga-DTPA-EOB, which demonstrated high radiochemical purity, in vitro stability, and imaging safety. Micro-PET/CT imaging studies confirmed its feasibility for liver function imaging.

EP-0120

Effects of replacing the ether linkage of a benzo[h] quinoline-based fibroblast activation protein-targeted tracer, [^{68}Ga]Ga-SB03178, with an N-methyl linkage on its FAP-targeting capability

S. Jozi*, C.-C. Chen, H. Merkens, P. Ng, W. Lau, F. Bénard, K.-S. Lin; BC Cancer Research Institute, Vancouver, BC, CANADA.*

Aim/Introduction: Fibroblast activation protein (FAP), a transmembrane protein overexpressed in cancer-associated fibroblasts, is a promising cancer imaging marker. Many FAP-targeted tracers have been developed and [^{68}Ga]Ga-FAPI-04 is the most widely used PET tracer in the clinic. Previously, we replaced the quinoline moiety in [^{68}Ga]Ga-FAPI-04 with benzo[h]quinoline and the resulting [^{68}Ga]GaSB03178 showed improved binding affinity (IC_{50} = 4.11 vs 1.33 nM) and tumour uptake (11.9 vs 20.3 %ID/g) [1,2]. It has been shown that the linkage of linker at the quinoline moiety could affect FAP targeting as [^{68}Ga]Ga-FAPI-46 containing an N-methyl (-NMe-) linkage showed higher tumour uptake than [^{68}Ga]Ga-FAPI-04 containing an ether (-0-) linkage [3]. Therefore, in this study, we investigated the effect of replacing the ether linkage in Ga-SB01378 with an N-methyl linkage on its FAP-targeting capability. ***Materials and Methods:*** FAPI-delta, the N-methyl linkage analog of SB03178, was synthesized via multi-step organic synthesis. ^{nat}Ga and ^{68}Ga complexation reactions were conducted in sodium acetate and HEPES buffers, respectively. FAP binding affinity was measured by enzymatic assay using recombinant hFAP and Suc-Gly-Pro-AMC as the substrate. PET imaging and ex vivo biodistribution studies were conducted in HEK293T:hFAP tumour-bearing mice at 1 h post-injection. The blocking study was performed with the co-injection of FAPI-04 (0.5 mg/mouse). ***Results:*** ^{nat}Ga-FAPI-delta was obtained in 60% yield and [^{68}Ga]Ga-FAPI-delta was obtained in 33% decay-corrected radiochemical yield with > 95% radiochemical purity and > 45 GB/µmol molar activity. FAPI-delta had high binding affinity for FAP with an IC_{50} of 1.6 nM. [^{68}Ga]Ga-FAPI-delta enabled clear visualization of HEK293T:hFAP tumour xenografts with good tumour-to-background contrast. [^{68}Ga]Ga-FAPI-delta was excreted mainly via the renal pathway. Blocking with FAPI-04 significantly reduced the tumor uptake of [^{68}Ga]Ga-FAPI-delta. Biodistribution results were consistent with the observations from the PET images. The uptake values of [^{68}Ga]Ga-FAPI-delta in tumour, liver and kidneys were 11.7±2.1, 2.7±0.2, and 4.9±0.7 %ID/g, respectively. The uptake in other collected organs/tissues was minimal. The tumor uptake was reduced by 86% with the co-injection of FAPI-04, demonstrating specific binding. ***Conclusion:*** Despite having a retained good FAP binding affinity, the tumour uptake of [^{68}Ga]Ga-FAPI-delta was inferior to that of [^{68}Ga]Ga-SB03178 using the same tumour model. Therefore, further optimizations are needed to maximize the utility of the benzo[h] quinoline-based pharmacophore for the design of FAP-targeted tracers. ***References:*** 1. Bendre S., et al. Eur J Med Chem 2024; 268: 116238. 2. Bendre S., et al. Molecules 2023; 28: 3481. 3.Loktev A., et al. J Nucl Med 2019; 60:1421-1429.

EP-0121

Preclinical Evaluation of MT1-MMP-Targeting Bicyclic Peptides for Radiotheranostic Applications

M. Sulewska[1], *A. Regupathy*[2], *L.-C. Domogalla*[3], *N. Steinacker*[3], *J. Johanna Lahdenranta*[4], *B. Blakeman*[2], *F. Wood*[2], *P. Meyer*[3], *P. Huxley*[2], *M. Eder*[1], *G. Mudd*[2], *A.-C. Eder*[3];
[1]*German Cancer Consortium (DKTK) / University Medical Center Freiburg, Freiburg, GERMANY,* [2]*BicycleTx Limited, Cambridge, UNITED KINGDOM,* [3]*University Medical Center Freiburg, Freiburg, GERMANY,* [4]*Bicycle Therapeutics, Cambridge, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Membrane type 1 matrix metalloproteinase (MT1-MMP) is crucial in extracellular matrix degradation, which facilitates cancer progression and metastasis. Previous studies have shown the feasibility of using phage display-derived radiolabelled bicyclic peptides for positron emission tomography (PET) imaging. This study aimed to identify and characterise novel MT1-MMP-binding bicyclic peptides with an improved pharmacokinetic profile. ***Materials and Methods:*** Four novel MT1-MMP-targeting bicyclic peptides (BCY1, BCY2, BCY3, and BCY4) were radiolabelled with either gallium-68 or lutetium-177. We assessed various physicochemical properties, including binding affinity, serum stability, and logD values. Cell binding and internalisation were evaluated using MT1-MMP-expressing HT1080 cells. In vivo performance was analysed in MT1-MMP+ tumor-bearing nude mice via µPET/MR imaging up to 2 hours post-injection (p.i.), followed by an organ distribution analysis (n = 3 for each peptide). ***Results:*** All peptides exhibited nanomolar binding affinity (4.1 - 9.8 nM), with radiochemical purity exceeding 99 %. They demonstrated high serum stability, and their logD values ranged from - 3.6 to - 2.6. In vitro studies confirmed high specificity and minimal off-target binding (1 - 4%). High tumour-to-background contrast was achieved within 30 minutes p.i. for BCY1, BCY2, and BCY4. Organ distribution studies revealed significant tumour uptake (12 - 25% injected dose per gram, %ID/g) of all bicyclic peptides at 1-hour p.i., with BCY1 and BCY4 exhibiting the lowest off-target binding, aside from kidneys (5.8 %ID/g and 6.1 %ID/g, respectively). ***Conclusion:*** BCY1 and BCY4 demonstrated optimal pharmacokinetic profiles characterised by high tumour uptake, specificity, and rapid blood clearance. Further translational research is essential to evaluate their full potential for radiotheranostic applications.

EP-0122

Comparison of 3rd generation β-Amyloid PET radiotracers with PiB and FBB in mouse models of Alzheimer's Disease

S. Bagheri[1], *B. Uzuegbunam*[2], *M. Luster*[1], *D. Librizzi*[1,3], *B. Yousefi*[1,4];
[1]*Department of Nuclear Medicine, School of Medicine, Philipps University Marburg, Marburg, GERMANY,* [2]*Department of Nuclear Medicine, Technical University of Munich, and Isotope Technologies Munich (ITM), Munich, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital OWL, Evangelical Hospital Bethel, Bielefeld, GERMANY,* [4]*Preclinical Imaging Core Facility, Center for Tumor Biology and Immunology (ZTI), Philipps University Marburg, Marburg, GERMANY.*

Aim/Introduction: Early diagnosis of Alzheimer's disease (AD) and the accurate quantification of β-amyloid plaques (Aβ) using PET imaging are critical for managing dementia patients. This study evaluates two novel ^{18}F-labelled Aβ tracers, [^{18}F]FIBT-TEG and [^{18}F]FIBT, developed from a library of over 600 compounds. These tracers are compared with the established tracers [^{18}F]Florbetaben (FBB) and [^{11}C]PiB in two transgenic mouse models of AD to assess their potential for clinical application. ***Materials and Methods:*** [^{18}F]FIBT-TEG and [^{18}F]FIBT were chosen for their high affinity to Aβ (Ki/Kd = 0.7 nM), >1000-fold selectivity over tau aggregates, low off-target binding, and favourable lipophilicity. PET scans (60 minutes) were performed in Arctic APP transgenic mice (tg), APP/PS1 double transgenic mice (tgtg), and age-matched control mice. PET analysis was conducted using PMOD software (ver 4.3) with cross-validation through autoradiography, biodistribution studies, and stability tests in brain and plasma. ***Results:*** [^{18}F]FIBT-TEG displayed excellent Aβ binding affinity (Ki = 0.7 nM), comparable to [^{18}F]FIBT and superior to [^{18}F]Florbetaben (Kd = 6.7 nM) and [^{11}C]PiB (Kd = 1.5 nM). Brain uptake of [^{18}F]FIBT-TEG was 8% ID/g at 5 min p.i., surpassing [^{11}C]PiB and [^{18}F]FIBT (7% ID/g), with rapid clearance (1.5% ID/g at 30 min). Cortex/cerebellum SUVRs for [^{18}F]FIBT-TEG were 1.67 (tg mice) and 1.85 (tgtg mice), higher than [^{18}F]FIBT (1.35) and comparable to [^{11}C]PiB (2.08) and [^{18}F]Florbetaben (1.68). Autoradiography confirmed selective binding to Aβ-rich regions with minimal off-target uptake. [^{18}F]FIBT-TEG also showed superior plasma protein binding (0.47 ± 0.12%) and high in vivo stability (brain: 90% ± 4% at 30 min, plasma: 8% ± 2%). ***Conclusion:*** [^{18}F]FIBT-TEG demonstrates excellent preclinical performance, combining high specificity, favourable pharmacokinetics, and minimal non-specific binding. These findings highlight its translational potential for clinical PET imaging applications in AD diagnosis and management.

Aim/Introduction: The complete and minimally invasive resection of solid tumours remains challenging. As a Swiss Army Knife, dual-modality probes combine several functionalities in one single tool and have the potential to enhance surgical outcomes through the integration of preoperative imaging and intraoperative real-time fluorescence guidance [1]. Here, we investigated the potential of FAPI-DyeMER, the first dimeric candidate targeting the fibroblast activation protein (FAP). ***Materials and Methods:*** The precursor was successfully labelled with Gallium-68/67 and Zirconium-89. In vitro, we investigated the binding and retention with HT1080hFAP cells. Tumour targeting and biodistribution of the ^{67}Ga-labelled compound were evaluated in xenografted mice up to 1 day p.i. In the same model, the in vivo imaging potential was evaluated at early time points via PET and up to 2 days p.i via SPECT and fluorescence imaging (FI). ***Results:*** Cell binding assays revealed that ^{68}Ga-FAPI-DyeMER exhibited higher cellular uptake (28.01±2.54 % after 1h of incubation) than the control compound lacking the fluorophore (18.91±2.53 %), demonstrating the advantageous impact of the fluorophore. The incorporation of the dye improved also the overall biodistribution profile, as evidenced by lower accumulation in most organs when comparing ^{68}Ga-FAPI-DyeMER to the control compound. The efflux study showed a significant enhancement in cellular retention for this candidate (with 97% internalised 2h after incubation) when compared to the established ^{68}Ga-FAPI-46 (22%). Ex vivo experiments and in vivo PET, SPECT and FI studies in HT1080hFAP/HT1080 xenografted mice demonstrated sustained tumour uptake (7.57±1.06 and 5.44±0.23 % ID/g at 1 h and 1 day p.i. respectively). A satisfactory tumour-to-background contrast was maintained even at later time points, with the signal intensity ratio between FAP-positive and FAP-negative tumour at 1 day post-injection measured at 3.4 for radioactivity and 4.1 for fluorescence. ***Conclusion:*** This study introduced FAPI-DyeMER, a novel dual-modality imaging agent. Following a single administration in a mouse model, FAPI-DyeMER enabled tumour visualisation with satisfactory background contrast over a prolonged period highlighting its potential for preoperative nuclear imaging and subsequent fluorescence-guided surgery. ***References:*** [1] Buckle, Tessa , 'Lessons learned

in application driven imaging agent design for image-guided surgery', European Journal of Nuclear Medicine and Molecular Imaging, 20 June 2024 /(51), 3040-3054.

Aim/Introduction: To develop a novel PSMA-targeted theranostic probe integrating ^{68}Ga/^{177}Lu and indocyanine green (ICG) for PET/NIRF imaging-guided radioisotope-photothermal therapy (RIT+PTT) in prostate cancer (PCa). ***Materials and Methods:*** First, computer-aided drug design was employed to construct and optimize the molecular structure of the probe PSI, and molecular docking was used to analyze its binding mode and affinity with PSMA. The targeting capability of the probe was verified through cellular uptake assays in human prostate cancer cells PC3-PIP (PSMA$^+$) and PC3 (PSMA$^-$); the cytotoxicity and DNA damage induced by the combined photothermal-radioligand therapy were assessed using Cell Counting Kit-8 (CCK-8), live/dead cell staining, and γH2AX staining. Next, a PCa xenograft mouse model was established to evaluate the tumor-targeting ability and diagnostic value of the probe via PET/CT and NIRF imaging, along with analysis of its biodistribution and pharmacokinetics. Subsequently, mice were treated with RIT, PTT, or combined PTT+RIT, and therapeutic efficacy was assessed by monitoring tumor volume changes; treatment safety was evaluated through histopathological and biochemical analyses. Finally, transcriptomic sequencing and bioinformatics analyses were conducted to investigate the potential molecular mechanisms of different treatment modalities. ***Results:*** (1) Molecular docking revealed superior PSMA-binding affinity compared to conventional PSMA ligands. (2) Cellular experiments showed that probe uptake positively correlated with PSMA expression, confirming its high specificity; CCK-8, live/dead staining, and γH2AX staining indicated that the combined photothermal-radioligand treatment significantly enhanced cytotoxicity and induced more severe DNA damage. (3) PET/CT and NIRF imaging clearly visualized tumors, with tumor-to-muscle ratios exceeding 10. (4) Biodistribution studies suggested prolonged tumor retention of ^{177}Lu-PSI, enabling sustained radiation damage; Combined RIT and PTT achieved 87.4% tumor inhibition in PC3-PIP xenograft model, significantly surpassing monotherapies; no significant systemic toxicity was observed in treated mice. (5) Transcriptomic sequencing analysis revealed that the combined therapy enhanced antitumor efficacy through the inhibition of oxidative phosphorylation metabolism and synergistic activation of dual cell death pathways (apoptosis and autophagy). ***Conclusion:*** This study successfully developed a novel PSMA-targeted probe, ^{68}Ga/^{177}Lu-PSI, for theranostic applications in PCa. Integrating PET/NIRF dual-modality imaging with photothermal-radioligand combination therapy, the probe supports full-process precision management of "accurate diagnosis-intraoperative navigation-targeted therapy". This work lays a theoretical and technical foundation for the clinical translation of ^{68}Ga/^{177}Lu-PSI in personalized theranostics and PSMA-targeted combination therapy for prostate cancer.

EP-0125

Optimization of theMolar Dose of Dimeric FAP-Targeted Radioligandsfor TherapeuticApplications

***L. Li**, H. Ma, D. Stuurman, C. d. Ridder, A. Piet, Y. Seimbille;*
Erasmus Medical Central, Rotterdam, NETHERLANDS.

Aim/Introduction: Overexpression of fibroblast activation protein (FAP) in cancer-associated fibroblasts enables selective tumor targeting using FAP inhibitors. Although radiolabeled small-molecule FAP inhibitors are widely used for imaging, their short tumor retention limits therapeutic efficacy. To overcome this limitation, we developed two dimeric FAP-targeted radioligands, eFAP-51 and eFAP-52, which exhibit enhanced tumor accumulation and prolonged retention. In this study, we systematically investigated the effect of molar dose on the in vivo biodistribution of [^{177}Lu]Lu-eFAP-51 and [^{177}Lu]Lu-eFAP-52 in FAP-expressing xenografts to optimize therapeutic dosing. ***Materials and Methods:*** In vivo imaging and biodistribution studies were performed using NMRI-Foxn1 nu/nu mice bearing subcutaneous HT-1080.hFAP tumors and wild-type HT-1080 (WT) tumors as controls. Mice received intravenous injection of [^{177}Lu]Lu-eFAP-51 or [^{177}Lu]Lu-eFAP-52 at molar doses of 4, 12, 24, or 96 nmol/kg. Small-animal SPECT/CT imaging was conducted at 1, 4, 24 and 48 hours post-injection, followed by ex vivo biodistribution at 48 hours. Uptake values in tumor and non-target tissues, as well as tumor-to-background (T/B) ratios, were analyzed to evaluate FAP specificity, dose dependency, and pharmacokinetics. ***Results:*** Both dimers exhibited dose-dependent tumor uptake in HT-1080.hFAP xenografts, while showing minimal accumulation in WT tumors and nontarget organs across all tested doses, confirming FAP-mediated specificity. [^{177}Lu]Lu-eFAP-51 exhibited optimal tumor retention (2.49 ± 0.32% ID/g at 4 nmol/kg) with dose-dependent reduction in normal tissue uptake (liver: 0.49 to 0.18% ID/g; spleen: 0.58 to 0.11% ID/g; kidney: 0.16 to 0.06% ID/g from 4 to 96 nmol/kg) while target saturation at 96 nmol/kg was observed by a 60% reduction in tumor uptake. Remarkably, the therapeutic window of [^{177}Lu]Lu-eFAP-51 was defined between 12 and 24 nmol/kg with maintained tumor uptake (>85% of maximum) and optimal T/B ratio. In contrast, [^{177}Lu]Lu-eFAP-52 achieved peak tumor uptake (3.41 ± 1.84% ID/g at 4 nmol/kg), but exhibited paradoxical dose-response with 74% decreased tumor retention and significantly increased kidney (0.32 to 1.35% ID/g) uptake at 96 nmol/kg, along with 30% slower blood clearance compared to eFAP-51 at equivalent doses. ***Conclusion:*** [^{177}Lu]Lu-eFAP-51 emerged as a lead candidate with its favorable biodistribution and therapeutic dose window (12-24 nmol/kg). The superior performance of [^{177}Lu]Lu-eFAP-51 underscores the importance of hydrophilicity in achieving optimal balance between tumor avidity and systemic clearance. These findings provide critical insights for the clinical translation of [^{177}Lu]Lu-eFAP-51, and highlighted the need for comprehensive preclinical dose optimization. Future studies will evaluate its therapeutic efficacy at the identified optimal dose in preclinical tumor models.

In-Vivo Evaluation of a Novel Fibroblast Activation Protein (FAP) Inhibitor as a Targeted Therapeutic Agent in Oncology

***M. Rezaeianpour**[1,2], M. Mosayebnia[2], A. Gravand[1], R. Nami[1], M. Ghapanvari[1], S. Mazidi[1], M. Dehghani[1];*
[1]PARS ISOTOPE Co., Tehran, IRAN, ISLAMIC REPUBLIC OF,
[2]Department of Pharmaceutical Chemistry and Radiopharmacy, School of Pharmacy, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Due to the widespread incidence of cancer globally, early diagnosis and effective treatment of tumors are essential for improving patient outcomes. The tumor microenvironment, which makes up over 90% of solid tumors, is

rich in fibroblast activation protein (FAP), absent in normal tissues. This selective overexpression of FAP has attracted attention for its potential as a therapeutic target. FAP is involved in crucial tumor processes, including growth, waste removal, and immune evasion (1,2). This study aims to present a novel approach using FAP-targeted radiopharmaceuticals labeled with Lutetium-177 (Lu-177), offering promising prospects for targeted treatment in cancers. ***Materials and Methods:*** A novel cyclic peptide designed to target FAP was synthesized using solid-phase peptide synthesis techniques. The peptide conjugated to the DOTA chelator was radiolabeled with Lutetium-177 (Lu-177). After checking the quality of the resulting compound using TLC and HPLC, its stability in saline and human plasma were studied. To evaluate the pharmacokinetics, the labeled peptide was tested in a preclinical setting using HEK-293 xenograft nude mice. A biodistribution analysis was performed alongside SPECT/CT imaging to assess the distributions of the tracer in different tissues. ***Results:*** The radiolabeling of the FAPI peptide with Lutetium-177 resulted in a product with high radiochemical purity (RCP > 99%) and remarkable stability in both saline and human plasma for up to 14 days. Significant tumor uptake of the radiotracer was observed at the HEK-293 tumor sites, which was increased over the first 14 days following injection. Concurrently, the radioactivity in non-target tissues decreased, leading to five-fold tumor-to-blood and tumor-to-liver ratio 24 h post-injection. Notably, the tumor's radioactivity remained relatively stable for up to 14 days, indicating its long-term retention. In-vivo SPECT/CT imaging of the HEK-293 tumor-bearing mice demonstrated excellent tracer retention at the tumor sites. ***Conclusion:*** The new ^{177}Lu-FAPI radiopharmaceutical demonstrates superior kinetic behavior and extended tumor retention properties compared to the existing Lutetium-177-based FAPI agents. So, this tracer can be a promising candidate for targeted tumor therapy across various cancer types. Ongoing investigations are focused on further evaluating its therapeutic potential in diverse clinical applications. ***References:*** 1. Anastasia Loktev, Thomas Lindner, Eva Maria Burger, et al. Preliminary theranostic candidates for Glioblastoma tumors based on Substance P derivatives.

S. Mozaffari[1], *J. Abedi*[1], *H. A. Khoshhosn*[1], *N. Soltani*[1], *A. Tavakoli*[1], *Y. H. Tavakoli*[1], *M. Davarpanah*[1], *S. M. Mazidi*[1], *R. Nami*[1], *F. Johari Daha*[2], *M. Erfani*[2];
[1]*PARS ISOTOPE Co., Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Nuclear Science and Technology Research Institute (NSTRI), Atomic Energy Organization of Iran (AEOI), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Substance P (SP) is a neuropeptide with high-affinity to neurokinin 1 receptor (NK1R). It is involved in angiogenesis, mitosis and the progression of some tumors especially Glioblastoma multiforme (GBM) by overexpression of NK1Rs. The distribution density of NK1Rs correlates with the degree of malignancy. SP analogues could be developing radiopharmaceuticals for specific targeting of GBM via NK1Rs. ***Materials and Methods:*** In our previous studies two derivatives of SP were synthesized and labeled with Tc99m and I131 radioisotope for theranostic application in GBM. The stability, protein binding and partition coefficient were examined. They were evaluated by docking software and then the in vitro tests on human U373MG cell line and in vivo bio distribution studies on normal mice were done. After that some new small ligands were designed and evaluated by docking software and MD simulations. They are capable of radiolabeling with Ga68 for PET and radiolabeling with I131, Lu177, Bi213 and Ac225 for Therapy. ***Results:*** The proposed radioligands were interacted with crystal structure of NK1R acquired from PDB and displayed binding energies around -8 to -9 kcal/mol. The previously radiolabeled peptides showed an average radiochemical yield of 95% and 73% respectively. Protein binding to human serum was 44 % for Tc99m and about 60% for I131. The stability was up to 12 h for Tc99m compound at 37 ºC in saline and human serum. Furthermore, the stability was up to 3 days for I131compound at -4 ºC just in saline. A value of -3.75 log P was calculated for radiolabeled Tc99m-peptide but it was calculated -1.6 for I131-peptide. Biodistribution studies showed high accumulation in kidneys and salivary glands regions 1 h and 4 h post-injection of radiopeptide. ***Conclusion:*** These derivatives could be theranostic candidates for GBM and other NK1R positive tumors. Design and further evaluations of new derivatives by I131 and F18 are ongoing.

A Phase I Clinical Trial to Evaluate the Safety and Tolerability of ^{68}Ga-NRT6020 Injection and ^{177}Lu-NRT6020 Injection in FAP-positive Participants with Advanced Solid Tumors

X. Zhang*, X. Li, Q. Liu, J. Liu, X. Xu, Q. Kong, Y. Wu, C. Huang, S. Cao, J. Cai;*
Chengdu New Radiomedicine Technology Co. LTD., Chengdu, CHINA.

Aim/Introduction: Fibroblast activation proteins (FAP) are type II integral membrane proteins with both intracellular and extracellular soluble truncated forms, which present in the membranes of normal cells and tumor stroma.[1-2] The novel theranostic pair ^{68}Ga-NRT6020 (diagnostic PET tracer) and ^{177}Lu-NRT6020 (therapeutic) target FAP for radiotherapeutic aim. ^{68}Ga-NRT6020 serves as a FAP-targeted PET imaging agent to select eligible patients with various cancers for ^{177}Lu-NRT6020 treatment. The ongoing phase I study is a dose escalation/expansion clinical trial on the integrated diagnostic and therapeutic product of ^{68}Ga/ ^{177}Lu-NRT6020 injection, which aims to evaluate the tolerability, safety, preliminary efficacy, pharmacokinetic characteristics, and radiation dosimetry of ^{68}Ga/ ^{177}Lu-NRT6020 injection in patients with advanced malignant solid tumors. ***Materials and Methods:*** 1. Binding affinity of NRT6020 was determined by Surface Plasmon Resonance (SPR) and Enzymatic inhibition Assay. 2. In vivo PET/MR Imaging determined the tissue biodistribution using NOG mice bearing HEK293-FAP tumor cells after ^{68}Ga-NRT6020 administration. 3. Lung patient PET/CT scan: PET/CT imaging was performed from the head to the upper thighs at different timepoints after injection of ^{68}Ga-NRT6020.[3] 4. In vivo biodistribution was assessed by SPECT/CT of ^{177}Lu-NRT6020 using HEK293-FAP xenograft model.5. In vivo efficacy was determined with ^{177}Lu-NRT6020 in HEK293-FAP tumor-bearing nude mice. ***Results:*** Preclinical data show high FAP affinity, strong tumor uptake, and superior anti-tumoral efficacy of ^{68}Ga/ ^{177}Lu-NRT6020 . Binding affinity of NRT6020 presents good potent FAP inhibition activity, binding affinity and target selectivity. ^{68}Ga-NRT6020 PET/CT imaging in lung cancer patients that exhibits sustained and progressively increased retention within the tumor over time. In vivo efficacy assay shows ^{177}Lu-NRT6020 has significant anti-tumor effects. ***Conclusion:*** ^{68}Ga-NRT6020 and ^{177}Lu-NRT6020 is expected to demonstrate broad clinical application prospects in the field of theranostics. ***References:*** 1. Carbonic Anhydrase IX-Targeting for Radioimmunotherapy in Triple-Negative Breast Cancer

A. Ivashkevich[1], *A. Elz*[2,3], *V. Liapis*[2,3,4], *M. P. Wheatcroft*[1], *M. P. Brown*[2,4,3], *A. H. Staudacher*[2,1,3];
[1]*Telix Pharmaceuticals Ltd Pty, Melbourne, AUSTRALIA,* [2]*Central Adelaide Local Health Network, Adelaide, AUSTRALIA,* [3]*Translational Oncology Laboratory, Centre for Cancer Biology, SA Pathology and University of South Australia, Adelaide, AUSTRALIA,* [4]*Adelaide Medical School, The University of Adelaide, Adelaide, AUSTRALIA.*

Aim/Introduction: The chimeric IgG1 monoclonal antibody Girentuximab (TLX250) binds to carbonic anhydrase IX (CAIX), a cell surface protein highly expressed by most renal cancer cells and in the hypoxic tumour microenvironment of other solid tumours, such as aggressive triple-negative breast cancer (TNBC) cells. The objective of this study was to evaluate Girentuximab as (i) a diagnostic tool to identify tumour-specific targeting in TNBC, and (ii) a radioimmunotherapeutic tool to treat TNBC when given as a single agent or combined with conventional chemotherapy. ***Materials and Methods:*** The expression level of CAIX in the TNBC cell line MDA-MB-468 was examined by flow cytometry and immunofluorescent staining using Girentuximab. Tumour uptake of Zirconium-89-labelled Girentuximab (^{89}Zr-DFO-TLX250) in female nude mice bearing MDA-MB-468 xenografts was examined by live-animal PET imaging followed by tissue biodistribution analysis. The therapeutic effect of TLX250 radioimmunotherapy (RIT) was evaluated by labelling the antibody with the β-emitting radioisotope Lutetium-177 (^{177}Lu) and administering it alone or co-dosed with chemotherapy (capecitabine) in the TNBC xenograft model. Ongoing experiments are now investigating and comparing the therapeutic effect and the time course of DNA damage in the tumour matrix after treatment with ^{117}Lu- or other radionuclides radiolabelled TLX250, when administered alone or with chemotherapy. ***Results:*** High expression of CAIX by MDA-MB-468 cancer cells was confirmed by flow cytometry and immunofluorescent staining under normoxic culture conditions, which increased further under hypoxia. Live-animal PET imaging of TNBC xenografts using ^{89}Zr-DFO-TLX250 revealed sufficient tumour uptake of the antibody, with no difference in tumour uptake when co-administered with chemotherapy, while uptake in healthy tissues remained low. Radioimmunotherapy (^{177}Lu-DOTA-TLX250), administered as a single dose up to 10MBq, was well-tolerated and resulted in effective control of tumour growth, which was improved further when co-administered with conventional chemotherapy. Current experiments investigate the time course of DNA damage following ^{177}Lu-labelled Girentuximab-based RIT, alone or combined with capecitabine, as well as other therapeutic radionuclides, and results will be presented at the EANM 2025 meeting. ***Conclusion:*** CAIX-targeting Girentuximab is a promising diagnostic and therapeutic modality with high potential for expansion of its clinical use to other types of cancers besides kidney cancer. The presented results give first evidence of its ability to effectively target and control tumour growth in a TNBC xenograft model, particularly when combined with chemotherapy. Additional studies are now being conducted to further expand on the therapeutic application of Girentuximab-based RIT in TNBC, including the use of other therapeutic radionuclides.

EP-0131

Fibroblast Activation Protein (FAP)-Targeted Theranostic Application of [^{161}Tb]Tb-FAPI-04: Radiolabelling, Qualilty Control and Scintigraphic Imaging in Wistar Rats

C. Sezgin[1], *E. Uygur*[2], *B. Ozel*[3], *R. Celik*[3], *G. Gumuser*[4], *F. Z. Biber Muftuler*[3], *Y. Parlak*[4];
[1]*Manisa City Hospital, Manisa, TÜRKIYE,* [2]*Manisa Celal Bayar University, Biomedical Device Technologies, Manisa, TÜRKIYE,* [3]*Ege University, Izmır, TÜRKIYE,* [4]*Manisa Celal Bayar University, Manisa, TÜRKIYE.*

Aim/Introduction: Fibroblast activation protein (FAP) is overexpressed in cancer-associated fibroblasts in various malignancies, making it a promising target for pan-tumour imaging and therapy. FAPI-04, a quinoline-based FAP inhibitor, has demonstrated suitability for theranostic applications when radiolabelled with diagnostic and therapeutic radionuclides. Terbium-161 (^{161}Tb) is a β$^-$emitter with decay properties similar to those of ^{177}Lu. Still, it offers the additional advantage of emitting short-range conversion and Auger electrons, potentially enhancing the tumour-absorbed dose. This study aimed to evaluate the feasibility, radiochemical quality, and biodistribution of [^{161}Tb]Tb-FAPI-04 in vivo. ***Materials and Methods:*** ^{161}Tb was conjugated with FAPI-04 via DOTA chelation and radiolabelled with carrier-free ^{161}Tb (half-life: 6.9 days), achieving a radiochemical purity >95% (n=3). Radiochemical yield was confirmed using high-performance liquid radiochromatography (HPLRC) and thin-layer radiochromatography (TLRC). In vivo planar scintigraphic imaging was performed in 8-to 10-week-old Wistar albino rats (n = 3). Each rat received an intravenous injection of 37 MBq of [^{161}Tb]Tb-FAPI-04. Imaging was performed under anaesthesia at 1, 4, 24, 48, and 96 hours post-injection (p.i.) using a dual-head gamma camera equipped with a high-resolution parallel-hole collimator. Energy windows were centred around the gamma (74 keV) emissions of ^{161}Tb. Region-of-interest (ROI) analysis was used to evaluate tracer uptake in major organs. ***Results:*** [^{161}Tb]Tb-FAPI-04 demonstrated high in vivo stability and favourable biodistribution, with strong and persistent uptake in FAP-expressing tissues and minimal non-specific background signal. The high-resolution scintigraphic images showed distinct tracer accumulation, supporting the suitability of the radioligand for tumour targeting. Clearance was predominantly renal, and no unexpected accumulation of the tracer was observed. ***Conclusion:*** The results demonstrate the feasibility of using [^{161}Tb]Tb-FAPI-04 as a theranostic agent with promising properties for targeted radionuclide therapy. The enhanced radiation properties of ^{161}Tb, combined with the broad tumour affinity of FAPI-04, highlight its potential for pan-tumour treatment strategies.

Development and characterisation of peptide-based agents targeting HER2 receptor for breast cancer radiotheranostics

L. Wagner[1], *M. Amghar*[1], *U. Bauder-Wüst*[1], *Y. Remde*[2], *M. Schäfer*[2], *M. Benešová-Schäfer*[1];
[1]*Research Group Translational Radiotheranostics, German Cancer Research Center, Heidelberg, GERMANY,* [2]*Service Unit for Radiopharmaceuticals and Preclinical Studies, German Cancer Research Center, Heidelberg, GERMANY.*

Aim/Introduction: Breast cancer (BCa) is a highly heterogeneous disease, primarily due to the considerable variation in surface receptor expression. Four molecular subtypes have been identified, each presenting significant challenges for early detection and treatment. Among these, HER2-positive BCa, characterised by the overexpression of the human epidermal growth factor receptor 2 (HER2), accounts for approximately 15-25% of all cases and is typically associated with poor prognosis. HER2 is primarily targeted by the dimeric monoclonal antibody trastuzumab and its derivatives. However, some drawbacks such as cardiotoxicity, immunogenicity and high costs have been reported. Several peptidic structures have been described to have high affinity to HER2, notably the peptide A9 (QDVNTAVAW-NH_2) which corresponds to the Fab fragment of trastuzumab. This

project aims to develop A9-based ligands for HER2-expressing BCa radiotheranostics. Furthermore, reversed and D-amino acid versions of the sequence were designed to improve the stability. Most of all, to mimic the dimeric structure of trastuzumab, A9 homodimers were assessed. ***Materials and Methods:*** A9-based HER2-targeting ligands such as their reverse-, D-, D-reverse- and scrambled-sequences have been synthetised using solid phase peptide synthesis and coupled to a DOTA chelator. Multimerisation was achieved by Copper(I)-catalysed Azide-Alkyne Cycloaddition (CuAAC) between propargyl derivatives of the peptidic library and azidolysine-based multimerisation scaffold, prior to DOTA coupling. The resulting DOTA-conjugates have been radiolabelled with [^{177}Lu]$LuCl_3$ (~5 MBq) in 0.4 M NaOAc (pH 5), at 95°C, for 15-30 min. Internalisation assays of ^{177}Lu-labeled conjugates have been performed on HER2-positive and -negative cell lines. ***Results:*** A9-based HER2-targeting ligands have been successfully synthesised with high chemical purities (>95%) and radiolabelled with [^{177}Lu]$LuCl_3$, achieving radiochemical yields (RCY) of >99%. These high RCYs confirm the robustness and efficiency of the radiolabelling protocols, supporting their suitability for radiotheranostic applications. Notably, significantly higher cellular uptake has been observed for the dimeric constructs (4.5-22.2%) compared to their monomer equivalents. HER2 specificity has been confirmed by the markedly lower uptake of scrambled sequence controls (<0.65%). ***Conclusion:*** A diverse library of A9-based monomeric and homodimeric ligands targeting HER2 has been successfully synthesised and radiolabelled with lutetium-177. Preliminary in vitro studies on HER2-expressing cell lines have demonstrated encouraging uptake, particularly for the homodimeric constructs, highlighting their potential for HER2-targeted radiotheranostic applications. Ongoing biological evaluations are expected to further validate the therapeutic and diagnostic value of these novel radioligands and will be reported in due course.

EP-0133

Preclinical Evaluation of Novel ^{68}Ga/^{177}Lu-labeled Minigastrin Analogs as CCK2R targeted radiotheranostics

X. Chen, *H. Yang, X. Wen, Z. Qiao, X. Wu, J. Zhang;*
National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: The gastrin/cholecystokinin-2 (CCK-2) receptor has been identified as a possible target for peptide receptor radionuclide imaging and therapy. Several radiolabeled peptides binding to this receptor have been explored in animal models but with low tumor uptake. The aim of this study was to identify a peptide with improved tumor uptake and prolonged tumor retention compared with the current candidates. ***Materials and Methods:*** A small peptide-chelator library based on the C-terminal sequences of CCK-8 or minigastrin was constructed. The peptides were radiolabeled with ^{68}Ga and ^{177}Lu, as determined by high-performance liquid chromatographic analysis. The peptides were screened by assessing tumor and kidney uptake in 293T-CCK2R tumor xenograft model and compared with ^{177}Lu-MGS5. ***Results:*** All peptides were radiolabeled with ^{68}Ga and ^{177}Lu with high labeling efficiency (>95%). PET studies of ^{68}Ga-K000-31 293T-CCK2R tumor xenograft model demonstrated the highest tumor uptake (19.3 ± 2.6 %ID/g at 4 h), which was 3-fold higher than that of ^{68}Ga-MGS5 (6.4 ± 1.1 %ID/g at 4 h). Kidneys had the highest uptake of ^{177}Lu-K000-31 in healthy tissue suggesting that the major route of elimination was renal excretion. SPECT imaging showed that the tumor uptake of ^{177}Lu-K000-31 gradually increased, peaked around 4 h (16.3 ± 1.3 %ID/g), and remained high over time (7.0 ± 0.5 %ID/g at 72 h). Conversely, ^{177}Lu-MGS5 exhibited significantly lower tumor uptake at 1 h (7.3 ± 3.0 %ID/g) and 72 h (2.5 ± 0.4 %ID/g at 72 h). ***Conclusion:*** ^{68}Ga/^{177}Lu-K000-31, characterized by high tumor uptake and retention along with timely clearance from normal organs and tissues are highly promising CCK2R targeted radiotheranostics.

Development and primary evaluation of[^{99m}Tc]Tc$(CO)_3$-(H_2O)-Erlotinib as a potential radiopharmaceutical for molecular imaging in triple negative breast cancer

A. Rey[1], *J. Afonso*[1], *D. Gamenara*[2], *G. Carrau*[2], *M. Tejería*[1];
[1]*Area Radioquimica, Facultad de Química, Udelar, Montevideo, URUGUAY,* [2]*Departamento de Química Orgánica, Facultad de Química, Udelar, Montevideo, URUGUAY.*

Aim/Introduction: Triple negative breast cancer is a global public health problem since it occurs at an early age and has a high recurrence and mortality rate. the epidermal growth factor receptor (EGFR) is overexpressed In 60% of the cases . Consequently, we have prepared and evaluated a ^{99m}Tc labelled derivative of Erlotinib, a reversible inhibitor of EGFR with the objective of developing a potential molecular imaging agent for this disease. ***Materials and Methods:*** The Erlotinib derivative methyl 2-amino-4-(4-(3-((6,7-bis(2-methoxyethoxy)quinazolin-4-yl)amino)phenyl)-1H-1,2,3-triazol-1-yl)butanoate (L) was obtained through a "click chemistry" reaction between the triple bond of Erlotinib and the azide group of the esterified N-Boc-3-azido-L-alanine. The structure was confirmed by spectroscopic methods. Compound L was labeled in 2 steps: preparation of the tricarbonyl precursor fac-[[^{99m}Tc]Tc (I)$(CO)_3(H_2O)_3]^+$ (30-50 mCi) followed by substitution with L (0.7 mg) and incubation for 30 min at 75°C (3-6 mCi). Radiochemical purity (RCP) was evaluated by high efficiency liquid chromatography (HPLC). Stability was evaluated by HPLC up to 4 hours post labelling. Lipophilicity was determined through partition coefficient (P) between octanol and phosphate buffer 0.1M, pH = 7.4 and protein binding was evaluated by molecular exclusion at 30 and 60 minutes. ***Results:*** The labelling strategy used was the formation of a [^{99m}Tc]Tc tricarbonyl complex. L acts as bidentate towards the tricarbonyl core. The Tc atom coordinates through the N atom in position 3 of the triazole ring and the amino group of the alanine substituent and a water molecule from the precursor remains in the coordination sphere. HPLC analysis showed a main species with RCP of 85%, which was purified by HPLC and remained stable for at least 4 hours (RCP≥95%). Lipophilicity expressed as log P was 1.3±0.1. The average protein binding was 66± 9 %. ***Conclusion:*** A [^{99m}Tc]Tc tricarbonyl complex bearing a EGFR binding moiety was obtained with high RCP after purification. The complex showed high stability. Lipophilicity was adequate to ensure penetration through biological membranes. Protein binding was high, probably due to the presence of a water molecule in the final compound. Although no evidence of instability was observed the inclusion of a monodentate coligand to complete the Tc coordination sphere could improve the physicochemical properties. Biological evaluation including in vitro studies in MDA-MB-231 cells will be performed to evaluate the specific binding to the receptor and the internalisation. SPAAC-Enhanced Puromycin Linker optimizes cDNA-Dispaly for Targeted Peptide Selection

S. Schneider[1,2,3], *M. Boll*[1,2], *M. Eder*[1,2], *A. Eder*[1,2];
[1]*Division of Radiopharmaceutical Development, German Cancer Consortium (DKTK), Partner Site Freiburg and German Cancer Research Center (DKFZ), Heidelberg and Freiburg, GERMANY,* [2]*Department of Nuclear Medicine, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [3]*Faculty of Biology, University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: Display techniques like cDNA-display are powerful techniques for the identification of tumor binding peptides. Our aim was to improve key features of cDNA-display

to develop a new strategy for the discovery of novel cyclic peptides serving as binding motifs for highly affine and specific radiopharmaceuticals. ***Materials and Methods:*** The branched puromycin linker was fused from two building blocks using strain-promoted azide-alkyne cycloaddition (SPAAC). The efficiency of the reaction was quantified by HPLC. In addition, the optimization of the efficiency of the puromycin linker trapping the nascent peptide during translation was studied by varying combinations of 365 nm UV irradiation doses during crosslinking between mRNA and PuL and $MgCL_2$ and KCl concentrations during translation. To achieve post-translational peptide cyclization, the peptide-bearing puromycin linker was immobilized on magnetic beads and treated with tris-bromomethylbenzene (TBMB) to incorporate between the cysteine residues of the peptides by forming covalent bonds to generate bicyclic peptides. The examination of the bicyclization process was conducted by MALDI-TOF. ***Results:*** HPLC analysis revealed a median 97% reaction yield for the puromycin linker, a significant improvement over previous methods that reached yields of 15 - 20%[1]. The mean efficiency in puromycin trapping of the nascent peptides, reaching 42%, was achieved using 1200 mJ cm^{-2} UV irradiation and 750 mM KCl and 65 mM $MgCl_2$. Furthermore, MALDI-TOF mass spectrometry after the in-display peptide cyclization and cleavage from the magnetic beads, revealed the accurate incorporation of TBMB into the peptide structure during the display procedure, by detecting exactly the theoretical mass of a bicyclic test-peptide. ***Conclusion:*** The novel SPAAC-based strategy for the synthesis of branched puromycin linkers significantly improves reaction efficiency and reduces the overall cost of the display approach. Furthermore, puromycin-bound peptides were modified into bicyclic peptides and proven as biyclic during the display protocol. This approach provides a powerful tool for cDNA display applications, enabling the generation of structurally robust peptides with potential in anticancer and radiopharmaceutical developments. ***References:*** (1) Arai, H.; Kumachi, S.; Nemoto, N. Development and characterisation of a novel peptide-based tracer targeting proteoglycans overexpressed in triple-negative breast cancer

J. D. Campeiro[1], *C. Morgat*[2], *S. U. Dalm*[1];
[1]*Erasmus University Medical Centre, Rotterdam, NETHERLANDS,* [2]*University Hospital of Bordeaux, Bordeaux, FRANCE.*

Aim/Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype urgently requiring novel treatments but lacking cancer-specific biomarkers. Proteoglycans (PGs) play key roles in cancer and are often upregulated. Amongst other, TNBCs show aberrant PG expression. Accordingly, multiple strategies have been explored to inhibit PGs' function in other cancers, unfortunately without success. Rather than inhibiting PGs'function, we propose exploiting their aberrant expression for delivering diagnostics and/or cytotoxic radionuclides. Crotamine, a positively charged cell-penetrating peptide, exhibits high affinity for PGs (e.g., syndecan-1), making it the ideal vehicle for this approach. We aim to develop a novel crotamine-based radiopharmaceutical and study its potential for targeting TNBC. ***Materials and Methods:*** PGs' gene expression level was analysed in a published dataset (55 TNBC vs. 14 normal tissues). In vitro studies using the human TNBC cell lines (MDA-MB-231, MDA-MB-468, and HCC-1806) were performed. First, the importance of the cyclic structure of crotamine for PG binding was explored. For this, non-linearized and linearized (using 5 mM DTT for 15 min at 95°C) fluorescently labelled peptide (crotamine-Cy3) were compared. Cells were incubated with 5 µM of either form at 37°C for 15 min. Peptide binding and expression of the PG syndecan-1 were evaluated by immunofluorescence by incubation with mouse anti-human syndecan-1-Cy5 (1:100) at 4 °C, 30 min, followed by incubation with 5 µM crotamine-Cy3, 4 °C, 15 min. Fluorescence intensity was then calculated. ***Results:*** Gene expression analysis showed that specific PGS are significantly upregulated in TNBC vs healthy tissues. PCA/clustering analysis with the top 8 upregulated genes (Fold-change: VCAN:7.7; COL12A1:5.0; SRGN:4.4; COL9A3:3.7; BGN:3.7; SDC1:3.6; CD44:2.7; EPYC: 2.3) accurately distinguished TNBC from healthy tissues (ROC curve AUC: 0.997). Furthermore, upregulated EPYC, VCAN, and COL12A1 show a strong correlation with a reduced time-to-relapse. Preliminary peptide characterization shows that the linearized crotamine-Cy3 exhibited a 76.2% decrease in binding versus its non-linearized counterpart. MDA-MB-468 exhibited higher syndecan-1 expression (24.8±7.5 arbitrary unit(a.u.)) and higher crotamine binding (33.3±5.8a.u.) compared to MDA-MB-231 (15.5±4.9/9.1±2.3) and HCC-1806 (9.9±2.4/10.0±2.8). ***Conclusion:*** These findings suggest the top 8 upregulated PGs may serve as a gene signature capable of distinguishing TNBC and healthy samples with high accuracy (99.7%). Moreover, the tertiary structure of crotamine is critical for PG interaction. Additionally, crotamine binding positively correlates with syndecan-1 expression. This initial characterization is crucial for the development of a crotamine-based radiopharmaceutical, which will be developed in the near future.

EP-0137

Optimization of an Affibody molecule construct for PDGFRb-targeted theranostics

H. Mallapura[1], *A. Abouzayed*[1,2], *H. Olsson*[3], *M. Xiong*[1], *O. Korsgren*[4], *J. Löfblom*[3], *M. Wagner*[2], *O. Eriksson*[1,2];
[1]*Science for Life Laboratory, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN,* [2]*Antaros Tracer AB, Uppsala, SWEDEN,* [3]*Department of Protein Science, Division of Protein Engineering, KTH Royal Institute of Technology, Stockholm, SWEDEN,* [4]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Platelet Derived Growth Factor Receptor Beta (PDGFRb) is strongly expressed on cancer-associated fibroblasts (CAFs) and has been extensively investigated as a therapeutic target for anti-cancer drugs[1]. Targeting of tumor stroma for molecular imaging and radioligand therapy (RLT) has recently been shown to be a promising strategy. Affibody molecule ATH001 is in clinical development for Positron Emission Tomography (PET) imaging of PDGFRb (NCT06562361), but its high renal uptake limits its suitability as a RLT agent[2]. This study aimed to improve the biodistribution of ATH001 by conjugating albumin-binding fatty acid moieties with varying chain lengths to enable longer circulation and thereby therapeutic applications. ***Materials and Methods:*** Modified ATH001 constructs were synthesized by conjugating fatty acids of different chain lengths via a multifunctional linker including a DOTA chelator. Binding affinity to human PDGFRb and human and murine albumin was assessed by Surface plasmon resonance (SPR). The constructs were radiolabeled with gallium-68 (^{68}Ga) and indium-111 (^{111}In) for PET imaging and biodistribution studies. In-vitro binding was evaluated by tissue autoradiography and in a U87 glioblastoma cell line with and without blocking. In vivo biodistribution and dosimetry were evaluated for up to 7 days post-injection in healthy rats and U87 xenografted mice. ***Results:*** SPR analysis confirmed that conjugation of fatty acid moieties to ATH001 increased the affinity for albumin, indicating potential for extended circulation half-life. Longer fatty acids exhibited higher affinity to albumin. LogD7.4 measurements revealed a shift toward greater lipophilicity with increasing fatty acid chain length, compared to the reference molecule ATH001. Autoradiography demonstrated binding to PDGFRb positive tissues and cells for all fatty acid conjugated ATH001 constructs. Biodistribution studies in healthy rats and U87 xenografted mice confirmed that fatty acid

conjugated ATH001 exhibited superior tumor uptake and lower kidney retention and dosimetry compared to reference molecule ATH001. The longest fatty acid conjugate showed favorable pharmacokinetics, with prolonged tumor uptake and circulation, and reduced kidney retention. ***Conclusion:*** Fatty acid conjugation to ATH001 increased albumin binding, thereby improving tumor uptake and reduced renal retention. Longer fatty acid chains were associated to stronger albumin binding, resulting in superior tracer circulation time and improved biodistribution profiles. Thus, fatty acid-conjugated ATH001 constructs are promising theranostic agents for PDGFRb-targeted RLT. Further studies will evaluate the therapeutic efficacy of the longer fatty acid-conjugated ATH001 construct labeled with therapeutic radionuclides. ***References:*** 1. EP-0138

Comparative Biodistribution and Stability Assessment of [^{68}Ga]Ga-labeled Kisspeptins: Implications for Design of KiSS-1R Targeting Radioligands

H. Taş[1], *M. Schäfer*[2], *U. Bauder-Wüst*[1], *Z. Nový*[3], *M. Petřík*[3], *M. Benešová-Schäfer*[1];
[1]*DKFZ (Research Group Translational Radiotheranostics), Heidelberg, GERMANY,* [2]*DKFZ (Service Unit for Radiopharmaceuticals and Preclinical Studies), Heidelberg, GERMANY,* [3]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacký University (UPOL) and University Hospital Olomouc, Olomouc, CZECH REPUBLIC.*

Aim/Introduction: Breast cancer remains a leading cause of cancer mortality in women, with triple-negative breast cancer (TNBC) accounting for ~15% of cases. With limited treatment options, the reported KiSS-1R overexpression in TNBC [1] highlights its strong potential as a theranostic target. Kisspeptin (KP)-based radioligands, such as [^{68}Ga]Ga-NODAGA-KiSS-54 [2] and [^{68}Ga/^{177}Lu]Ga/Lu-KiSS-10 [3], have shown promise in imaging and therapy. However, the susceptibility of endogenous KPs to proteolytic degradation remains a significant challenge. To address this limitation, we conducted a comparative study on DOTA-conjugates based on endogenous and reported synthetic KPs regarding their biodistribution and ex vivo stabilities in BALB/c mice. We aimed to identify structural modifications that enhance stability and optimize pharmacokinetic profiles for the design of improved KiSS-1R-targeting radioligands for potential theranostic applications against TNBC. ***Materials and Methods:*** Endogenous (KiSS-10,-15,-54) and synthetic KPs (KiSS-10-EEE, p354, p356, TAK-448, KiSS-34) were N-terminally conjugated to respective DOTA derivatives. Following in vitro validation, these DOTA-KPs were ^{68}Ga-radiolabeled (sodium acetate buffer, 95 °C, 15 min) and their in vivo biodistribution was evaluated in positron emission tomography (PET) imaging in healthy BALB/c mice. Compound stabilities were assessed with ex vivo HPLC urine analysis at 30- and 90-min post-injection (p.i.). ***Results:*** DOTA-KPs were synthesized (>99% purity) using active ester routes and subsequently ^{68}Ga-radiolabeled at high efficiencies (>95%). Static PET/CT imaging (30 min p.i.) revealed notable biodistribution variations among [^{68}Ga]Ga-labeled DOTA-KPs, particularly in kidney uptake and liver accumulation. Ex vivo HPLC urine analysis demonstrated that [^{68}Ga]Ga-DOTA-KiSS-34 (AMBA-2Nal-Gly-Leu-Arg-Trp) exhibited superior metabolic stability likely attributable to its AMBA-2Nal substitution, showing minimal degradation at 30- and 90-min p.i. The remaining DOTA-KPs displayed varying degrees of instability and metabolite formation. ***Conclusion:*** Our findings indicate that DOTA-conjugates of several reported KPs exhibit suboptimal biodistribution and stability profiles. Despite partial liver accumulation, the inclusion of the non-natural amino acids, AMBA-2Nal, in [^{68}Ga]Ga-DOTA-KiSS-34 correlates with its notable stability and rapid renal clearance, positioning it as a promising lead for further development. The remaining KPs need further structural modifications - e.g. via non-natural amino acid substitutions - to increase their potential for preclinical evaluation for KiSS-1R-based imaging and therapy in TNBC. ***References:*** [1] A. Basic Comparative Study of $^{64}Cu^{2+}$ complexes with tripodal amine ligands using the extrahepatic bile duct carcinoma cell line TFK-1

M. Shinada[1,2], *M. Takahashi*[1,2], *C. Igarashi*[2], *H. Matsumoto*[2], *F. Hihara*[2], *T. Tachibana*[2,1], *M. Oikawa*[2], *H. Suzuki*[2], *M.-R. Zhang*[2], *T. Higashi*[2], *H. Kurihara*[3], *Y. Yoshii*[2], *Y. Doi*[1];
[1]*TOHO University, Funabashi, JAPAN,* [2]*Institute for Quantum Medical Science, National Institutes for Quantum Science and Technology, Chiba, JAPAN,* [3]*Kanagawa Cancer Center, Yokohama, JAPAN.*

Aim/Introduction: Cu accumulates in the nuclei of cancer cells and plays an important role in transcription-related tumor proliferation and metastasis. While several studies have been conducted to investigate the potential of $^{64}Cu^{2+}$ ions as antitumor radiotherapeutic drugs, intravenously administered $^{64}Cu^{2+}$ is known to primarily accumulate in the liver. To enhance tumor-targeting efficiency and reduce liver uptake, ligand complexation of $^{64}Cu^{2+}$ is a promising strategy. This study investigated the effect of three tripodal amine ligands, diethylenetriamine (Dien), tris(2-aminoethyl)amine (Tren), and tris(2-pyridylmethyl)amine (TPMA), on the in vivo distribution and in vitro cellular uptake using the extrahepatic bile duct carcinoma cell line TFK-1. ***Materials and Methods:*** The in vivo tissue biodistribution of $^{64}Cu^{2+}$-Tren, $^{64}Cu^{2+}$-Dien, $^{64}Cu^{2+}$-TPMA, and unchelated $^{64}Cu^{2+}$ were assessed in a xenograft mouse model bearing TFK-1 tumors. The in vitro intracellular Cu localization was analyzed using micro-PIXE (particle-induced X-ray emission) analysis. The correlation between in vivo tumor uptake and in vitro cellular uptake was evaluated and the physicochemical properties were calculated with in silico software (SwissADME). ***Results:*** $^{64}Cu^{2+}$-Tren and $^{64}Cu^{2+}$-Dien showed significantly higher tumor uptake than $^{64}Cu^{2+}$-TPMA and unchelated $^{64}Cu^{2+}$ in TFK-1 tumors. An inverse relationship was observed between liver and tumor uptake among these $^{64}Cu^{2+}$ complexes and unchelated $^{64}Cu^{2+}$. Micro-PIXE analysis showed that in vitro cellular uptake was similar to in vivo tumor uptake, and nuclear delivery was the highest for $^{64}Cu^{2+}$-Tren. $^{64}Cu^{2+}$-Tren, $^{64}Cu^{2+}$-Dien, and $^{64}Cu^{2+}$-TPMA were found to satisfy the following conditions respectively: (I) less than 5 hydrogen bond donors, (II) less than 10 hydrogen bond acceptors, (III) molecular weight less than 500 Da, and (IV) partition coefficient (logP) less than 5, not exceeding Lipinski's "rule of five". ***Conclusion:*** $^{64}Cu^{2+}$-Tren and $^{64}Cu^{2+}$-Dien demonstrated higher in vivo tumor uptake and in vitro cellular and nuclear uptake than $^{64}Cu^{2+}$-TPMA and $^{64}Cu^{2+}$ in TFK-1 cells. These findings suggest that $^{64}Cu^{2+}$-Tren and $^{64}Cu^{2+}$-Dien are promising candidates for the development of ^{64}Cu-based anticancer radiotherapeutics. This study also provides useful methods for the future development of ^{64}Cu radiopharmaceuticals.

EP-0140

Technetium-99m radiolabeling of HYIGSR peptide for in vivo and ex vivo assessment as a biomarker in breast cancer

F. Ferreira Mendonça[1], *M. Tejeria*[2], *P. Decuadra*[2], *M. Zeni*[2], *A. Rey*[2], *S. Nogueira*[3], *J. Mejia*[3], *M. Barboza*[3], *L. Fuscaldi*[1], *L. Malavolta*[1];
[1]*Faculty of Medical Sciences of Santa Casa de São Paulo, São Paulo, BRAZIL,* [2]*Faculty of Chemistry at the University of the Republic, Montevideo, URUGUAY,* [3]*Hospital Israelita Albert Einstein, São Paulo, BRAZIL.*

Aim/Introduction: According to the World Health Organization, over 14 million people are diagnosed with breast cancer annually, and this number is projected to rise to 21 million by 2030, underscoring the need for improved diagnostic and therapeutic

strategies. Biologically active peptides derived from laminin-111, such as YIGSR, have been shown to regulate gene expression in breast cancer cells. This study aimed to synthesize the HYIGSR analogue, radiolabel it with technetium-99m (^{99m}Tc), and evaluate its in vitro and ex vivo properties as a potential biomarker for breast cancer. ***Materials and Methods:*** The peptide was synthesized via solid-phase peptide synthesis. Radiolabeling was performed using the tricarbonyl method. The $[^{99m}Tc(CO)_3]^+$ was formed with [^{99m}Tc] TcO_4^- (~148 MBq) and subsequently incubated with HYIGSR (0.25 mg) at 85 °C for 30 min. Stability studies were conducted at 1, 2, 3, and 4 h after radiolabeling, while serum protein binding was assessed at 30 and 60 min. Cellular binding and internalization assays using MCF-7 breast cancer cells were performed at 1 and 4 h. For biodistribution analysis, the radiopeptide was administered to both healthy and tumor-bearing female Balb/c nude mice. The tumor model was established by subcutaneously inoculation 1 × 10^7 MDA-MB-231 breast cancer cells with in vivo and ex vivo evaluations at 1 and 3 h post-injection. Scintigraphic images were obtained using a Discovery VH gamma camera with a pinhole collimator, with a 5-minute acquisition time and 9× geometric magnification. ***Results:*** The HYIGSR was successfully characterized and radiolabeled, achieving a radiochemical yield of 95.53%±1.19 (n=5) with stability maintained for up to 4 hours in both reaction and serum media. Physicochemical analysis indicated a hydrophilic nature and a serum protein binding of 46.08%±3.75 at 60 min, n=3). In vitro studies of [^{99m}Tc]Tc-HYIGSR with MCF-7 cells exhibited a binding and internalization 3.39% and 22.18% at 4 h, respectively. Ex vivo biodistribution in Balb/c nude mice (n=4) demonstrated rapid blood clearance and low accumulation of the radiopeptide in non-target organs and tumors (<5% ID). In tumor-bearing mice, increased uptake was observed in the liver, stomach, intestine, and thyroid. Scintigraphic imaging correlated with biodistribution data, confirming hepatic and intestinal accumulation. ***Conclusion:*** HYIGSR demonstrated good radiolabeling efficiency and stability. However, in vivo and ex vivo biodistribution indicated low tumor uptake, suggesting that further modifications may be necessary to enhance the tumor-targeting capability of radiopeptide. Additionally, the imaging results were consistent with the biodistribution data. Grant FAPESP #2021/10265-8, CancerThera/CEPID.

EP-0141

[^{18}F]4-(3-(4-(4-fluorophenyl)piperidine-1-carbonyl) phenoxy)benzamide, a promising PET agent to investigate PARP10

M. Riondato[1,2], *G. Destro*[3], *M. Nemati*[3], *J. Martinelli*[2], *F. Vitale*[1], *S. Morbelli*[4], *G. Sambuceti*[2], *E. Terreno*[3];
[1]*IRCCS Policlinic Hospital of Genoa, Genoa, ITALY,* [2]*Dept. Health Sciences, University of Genoa, Genoa, ITALY,* [3]*University of Torino, Department of Molecular Biotechnology and Health Sciences, Turin, ITALY,* [4]*University of Torino, Department of Medical Sciences, Turin, ITALY.*

Aim/Introduction: Poly-ADP-ribose polymerases (PARP) are an enzyme family of 17 members catalysing the attachment of poly- or mono- ADP-ribose units on different targets.[1] While the research of PARP 1 inhibitors is widely pursued in clinic, the development of mono-ADP ribose transferases inhibitors is still in the early stages. PARP10 overexpression is observed in various cancers leading to the hypothesis that this enzyme promotes cancer proliferation and acts as oncogene. [2] We aim to develop a PET tracer for studying PARP10 role in different cancer models, paving the way for novel PET agents. ***Materials and Methods:*** The boronic pinacol ester precursor was chemically synthesized in 5 steps. [^{18}F]Fluorine was produced using an Eclypse HP cyclotron (Siemens, Germany). The radiolabelling protocol was developed on a AllInOne36 synthesizer platform (Trasis, Belgium) able to carry out Cu-mediated 18F-fluorodeboronation using the precursor, including deprotection and semipreparative purification before reformulation. Cell uptake and blocking experiments were carried out in the MCF7 cell line expressing PARP10 enzyme, and A549 cell line as a negative control using a gamma counter (Perkin Elmer) to measure the radioactivity in cell lysates. The time-dependent uptake was evaluated for 30 minutes since the plateau was rapidly reached. ***Results:*** SEM-protected boronic pinacol ester precursor, obtained with high purity and an overall yield of 12.3%, was reacted with 10-15 GBq of [^{18}F]Fluorine using an automated radiosynthesis performed on radiosynthesiser using a copper-mediated 18F-fluorodeboronation. At the end of the process, [^{18}F]4-(3-(4-(4-fluorophenyl)piperidine-1-carbonyl) phenoxy)benzamide was obtained with an activity yield (AY) of 15% non-decay corrected and a molar activity (Am) up to 220GBq/mmol. The uptake study showed how the tracer reached a plateau over 30 minutes fastly in the cell line expressing PARP10. On the other hand, there was almost a 3-fold lower uptake in the A549 cell line. The blocking experiment showed a diminishment in the radioactive signal in MCF7 cell line. More investigations are needed to understand the tracer binding kinetics. ***Conclusion:*** Given the challenges for PARP inhibitor therapy such as patient staging and resistance to PARP therapy, the development of new tracers able to target other PARP isoforms may offer a way to overcome these problems and improve treatment outcomes for patients. These preliminary results show the potential of this tracer to start interrogating PARP10 expressions. We will move further to more in vitro evaluation. ***References:*** [1]Nizi MG, et al. J Med. Chem. 2022; 65:7532-7560 [2]Yu M, et al. Oncogene. 2005; 24:1982-1993.

First-in-Monkey SPECT Imaging of ^{131}I-Labeled Aging Targeted Extracellular Vesicles

K. Yu*, J. Ye, F. Kang, J. Wang;*
The First Affiliated Hospital of Air Force Medical University, Shaanxi, Xi'an, CHINA.

Aim/Introduction: Extracellular vesicles (EVs) are tiny vesicles released by cells that can transport bioactive molecules. After being released into the extracellular matrix, EVs can travel through the blood-body fluid circulation to distant organs and tissues, where they are taken up by receptor cells and then affect their biological functions. Therefore, EVs are widely involved in the physiological and pathological processes of the human body and have shown great potential in the field of disease diagnosis and treatment. In this study, an in vivo tracer study of an EVs targeting aging by SPECT imaging will be performed with ^{131}ILabeling. The safety, biodistribution and pharmacokinetics of ^{131}I-labeled EVs were also evaluated. ***Materials and Methods:*** Firstly, Iodogen was used as an oxidant to label EVs with ^{131}I, and in vivo distribution experiments were conducted on normal mice to track and calculate pharmacokinetics. Subsequently, SPECT imaging of ^{131}I-EVs was performed in a normal monkey model to monitor the distribution of the tracer in vivo. ***Results:*** ^{131}I-EVs were successfully prepared using the Iodogen method, the radiochemical yield was about 70% and the radiochemical purity was > 98%. The in vitro stability in saline and in mouse serum was evaluated at 48 h by radio-TLC and showed that ^{131}I-EVs have high in vitro stability. The in vivo distribution of ^{131}I-EVs is consistent with other extracellular vesicles. The results of the in vivo biological

distribution experiment in normal mice showed that the highest uptake of ^{131}I-EVs was found in the blood. The lung had high intake and was also distributed in the heart, liver, kidneys, and bones. The pharmacokinetic results showed a distribution half-life ($T_{1/2\alpha}$) of 2.473 hours and an elimination half-life ($T_{1/2\beta}$) of 16.69 hours. Due to the high uptake in the blood, its cardiac blood pool is clearly visible from in the SPECT/CT imaging of monkey. Also a very high physiologic uptake of ^{131}I-EVs was seen in the liver due to the EPR effect. In addition, a high uptake of ^{131}I-EVs was observed in the nasal cavity. ***Conclusion:*** First-in-Monkey SPECT imaging of ^{131}Ilabeled aging targeted extracellular vesicles was performed in this study. And the safety, biodistribution and pharmacokinetics of the ^{131}I-labeled EVs were also evaluated. The results will play a promoting role in advancing the clinical translation of EVs. And further evaluation is in progress.

EP-0144

Clinical Pharmacology and Dose Optimization Considerations applied to Radioligand Therapies (RLTs)

A. Manon[1], *D. Imbs*[1], *D. Heller*[2], *H. Stephens*[2], *M. Trame*[2];
[1]*Certara, Paris, FRANCE,* [2]*Certara, Radnor, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: While therapeutic radiopharmaceuticals also known as Radioligand therapies (RLTs) are raising more and more interest in the oncology space, the regulatory landscape continues to evolve leaving clinical development teams without clear regulatory guidance on clinical pharmacology requirements for RLTs. Dose optimization is also a key challenge since the optimal dosing (radioactivity or dosing interval) is still debated, even for the approved drugs such as PSMA-targeting RLT. ***Materials and Methods:*** The available FDA and EMA regulatory guidelines focus on non-clinical testing requirements, labeling recommendations, or CMC considerations. But no clinical regulatory guideline is currently available for RLTs. We propose clinical pharmacology recommendations for RLTs that are based on our experience, FDA/EMA feedback received by our clients, and regulatory guidelines relevant to the specific targeting moiety. ***Results:*** The clinical pharmacology package should be defined early in the clinical development. Sponsors can perform most clinical pharmacology assessments in the First in Human (FIH) study in patients. 1/ Characterize Absorption Distribution Metabolism and Excretion (ADME) data by collecting blood and urine radioactivity PK, targeting moiety PK and dosimetry data. These data will enable drug developers to characterize the RLTs' biodistribution, absorbed dose in critical organs, elimination pathways, and effective half-life. 2/ Assess potential drug-drug interactions (DDI): evaluation of in vivo plasma and metabolic stability of the RLT and full in vitro DDI assessments depends on the targeting moiety nature. 3/ Assess QT prolongation: integrated non-clinical and clinical QTc risk assessment is based on the nature of the targeting moiety. Collection of time-matched PK and ECG data is highly recommended during the FIH study. 4/ Special populations: leverage ADME data to identify early significant covariates impacting PK and obtain a potential waiver from regulatory agencies for Clinical Pharmacology studies. 5/ Immunogenicity: The nature of the targeting moiety defines the need to characterize whether anti-drug antibodies could impact PK/safety/efficacy 6/ Dose optimization: in the context of Project Optimus, PK and dosimetry/biodistribution data are key to support dose selection. Population PK model and Exposure-Response analyses can be used to correlate exposure and organ absorbed doses to clinical efficacy endpoints or safety events to guide dose selection and therapeutic index definition. ***Conclusion:*** FIH studies for RLTs are key to guiding the clinical pharmacology strategy for later-phase trials and dose justification for labeling. ***References:*** Guideline on the non-clinical requirements for radiopharmaceuticals. Dynamic Total Body PET imaging unfolds [11C]-choline kinetics and dosimetry

G. Fuso[1], *I. Brusa*[2], *M. Santoro*[2], *D. Dall'Olio*[3], *F. Zagni*[2], *M. Assenza*[2], *E. Fortunati*[2], *E. Tabacchi*[2], *A. Farolfi*[2], *R. Mei*[2], *C. Nanni*[2], *P. Castellucci*[2], *L. Calderoni*[2], *L. Strigari*[2], *G. Castellani*[3], *S. Fanti*[1,2];
[1]*Policlinico Sant'Orsola-Malpighi, University of Bologna, Bologna, ITALY,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*University of Bologna, Bologna, ITALY.*

Aim/Introduction: Choline is a precursor of membrane phospholipids and preferentially accumulates in tissues with high coline-kinase activity, a hallmark of rapidly proliferating malignant cells. Compared to other PET radiotracers, [^{11}C]-choline has high sensitivity, low radiation dose and can detect small lesions. Yet, the physiology underlying [^{11}C]-choline uptake in reference organs remain unclear. Since static PET imaging snapshots the [^{11}C]-choline uptake within a limited-time window, dynamic PET (dPET) imaging can represent a solution over this limitation, as it can characterize the full tracer-uptake process. Here, we harness the Total Body (TB) PET/CT scanner to evaluate the biodistribution, dosimetry and kinetics of [11C]-choline in reference organs, which may provide a reference for future dPET imaging. ***Materials and Methods:*** A 50-min dPET scanning followed by a 20-min static TB PET/CT acquisition using a Long Axial Field of View scanner (LAFOV) at 100±10 min after injection was performed on 4 patients referred to our Centre for presurgical parathyroid adenoma detection. Whole body [^{11}C]-choline distribution and pharmacokinetics were evaluated by Standardized Uptake Value (SUV), tissue uptake, organ-absorbed doses and, finally, multi-time graphical analysis (MTGA) and kinetic modelling with compartment models (2TCM). ***Results:*** Rapid blood clearance was detected (<10 seconds) and only gallbladder, gluteus, liver, parotids and prostate showed a gradual rising uptake with no early uptake peak. Average uptake values after 50 minutes for liver (17.61±2.82%) and bowel (5.77±1.80%) compared to kidneys (2.77±0.24%) and urinary bladder (0.21±0.16%) suggested alternative excretion pathways for [11C]-choline other than renal clearance. Gallbladder (0.0192±0.0039 mGy/MBq), liver (0.0372±0.0084 mGy/MBq), pancreas (0.0222±0.0051 mGy/MBq), kidneys (0.0160±0.0048 mGy/MBq), and spleen (0.0229±0.0085 mGy/MBq) were the organs with the highest observed effective doses. These organs also showcased extreme values among K1, k2, k3 and k4, which provide them with the most distinctive kinetic patterns. ***Conclusion:*** Our study suggests that [11C]-choline is rapidly cleared from blood circulation and its biodistribution changes very slowly from 5 minutes onwards. The TB dynamic approach highlighted the pivotal role of liver metabolism, minimal renal excretion, and unique kinetic behaviors of gallbladder, pancreas, kidneys, and spleen. These data advance our understanding of [^{11}C]-choline's physiological uptake and support its continued use as a safe and highly informative tracer.

EP-0146

Design of Heterodimeric Radiopharmaceuticals Targeting FAP and SSTR2 Receptors Using Theoretical Affinity Profiling and Biodistribution Correlation

A. Abolhosseini Shahrnoy[1], *M. Pirdadeh*[1], *M. Safari*[1], *M. Dehghani*[1], *Z. Karimi*[1], *R. Salehi-Moratab*[1], *M. Nasiri*[2], *R. Nami*[1], *S. Mazidi*[1];
[1]*PARS ISOTOPE Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Cellular and Molecular Biology, School of Biology, Damghan University, Damghan, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Fibroblast activation protein (FAP) and somatostatin receptor subtype 2 (SSTR2) are widely expressed in various tumors and represent attractive targets for diagnostic and therapeutic radiopharmaceuticals. This study aimed to design novel heterodimeric compounds targeting both FAP and SSTR2 by analyzing the molecular characteristics of previously reported ligands and correlating them with their biodistribution profiles. ***Materials and Methods:*** A total of 125 radiopharmaceuticals, including 60 SSTR2-targeted and 65 FAP-targeted compounds, were selected from existing preclinical studies. Molecular structures were optimized, and their theoretical binding affinities to FAP and SSTR2 were evaluated using molecular docking and computational modeling. Key physicochemical parameters such as lipophilicity, molecular weight, and hydrogen bond donors/acceptors were calculated and correlated with reported biodistribution data to identify favorable traits. Based on these analyses, two dual-targeting heterodimers named PIC-6888 and PIC-2188 were designed to exhibit optimal binding and biodistribution characteristics. ***Results:*** Theoretical modeling identified specific structural motifs and physicochemical profiles that contributed to enhanced receptor affinity and favorable biodistribution. PIC-6888 and PIC-2188 were selected as lead compounds due to their predicted high affinity for both FAP and SSTR2 and favorable pharmacokinetic properties. These heterodimers are currently under synthesis for further in vitro and in vivo evaluation. ***Conclusion:*** This study demonstrates the utility of integrative computational approaches in designing heterodimeric radiopharmaceuticals with dual-target affinity. PIC-6888 and PIC-2188 are promising candidates for future preclinical studies and may offer improved tumor targeting in cancers co-expressing FAP and SSTR2.

EP-0147

Decoding Fluorine-18 PET Tracers: Integrated Pharmacokinetics and Molecular Design

V. Trusova*, U. Malovytsia, P. Kuznietsov, I. Yakymenko, G. Gorbenko;*
V.N. Karazin Kharkiv National University, Kharkiv, UKRAINE.

Aim/Introduction: Fluorine-18-labeled PET tracers are central to oncology imaging, yet their comparative evaluation across pharmacokinetic and molecular dimensions remains fragmented. Current studies often focus on isolated tracers or rely on modality-specific metrics. To address this gap, we aimed to develop a multidimensional in silico framework integrating kinetic simulation, ADME profiling, and clustering analysis to systematically characterize and stratify five widely used ^{18}F-labeled radiopharmaceuticals: [^{18}F]FDG, [^{18}F]FET, [^{18}F]DOPA, [^{18}F]FMISO, and [^{18}F]FLT. ***Materials and Methods:*** Each tracer was simulated in COPASI using a harmonized three-compartment model, capturing uptake under normal and pathological conditions. Pharmacokinetic metrics—area under the curve ($AUC_{0\text{-}60}$), tumor-to-normal ratios (TNR_{30}, TNR_{60}), and early-phase uptake slope (0-20 min)—were extracted. Sensitivity analysis was performed by perturbing kinetic rate constants (k_1, k_2, k_3) by ±20% to assess model robustness. In parallel, ADMETlab 3.0 was employed to predict structural descriptors, including lipophilicity (logP), topological polar surface area (TPSA), volume of distribution (VDss), plasma clearance, blood-brain barrier permeability, and CYP3A4 metabolism potential. Features were standardized and analyzed via principal component analysis (PCA) and hierarchical clustering to explore multidimensional tracer relationships. ***Results:*** Tracers clustered into two mechanistic groups: [^{18}F]FDG and [^{18}F]FLT exhibited irreversible trapping dominated by sensitivity to k_3, while [^{18}F]FET, [^{18}F]DOPA, and [^{18}F]FMISO demonstrated reversible transporter-mediated uptake with sensitivity to k_1 and k_2. [^{18}F]FET showed optimal early-phase performance (steep uptake slope and high TNR_{30}), whereas [^{18}F]FMISO provided superior tumor selectivity at delayed time points (highest TNR_{60}). ADME properties reinforced kinetic signatures, with lipophilic tracers correlating to higher permeability and trapping dynamics. The integrated PCA revealed that kinetic behavior and structural features jointly dictated tracer clustering, offering a mechanistically interpretable classification. ***Conclusion:*** This study demonstrates that a unified in silico framework integrating pharmacokinetics, molecular design, and clustering analysis can robustly stratify ^{18}F-labeled PET tracers by their diagnostic strengths. Such multidimensional profiling supports rational tracer selection, optimization of multitracer protocols, and preclinical prioritization strategies, advancing precision imaging in oncology.

Preclinical evaluation of radiolabelled desferrioxamine-B analogues for imaging bacterial infections

M. Petrik*[1,2,3], B. Neuzilova[1], K. Hrabakova[1], K. Krasulova[1], K. Dvorakova Bendova[1], R. Maradan[4,5,6], J. Kronberger[4,5,6], I. Feiner[4,7], X. Guarrochena[4,5], T. Mindt[4,6,8];*
[1]Institute of Molecular and Translational Medicine, Palacky University, Olomouc, CZECH REPUBLIC, [2]Czech Advanced Technology and Research Institute, Palacky University, Olomouc, CZECH REPUBLIC, [3]Institute of Molecular and Translational Medicine, University Hospital, Olomouc, CZECH REPUBLIC, [4]Bioorganic Radiochemistry, Institute of Inorganic Chemistry, University of Vienna, Vienna, AUSTRIA, [5]Vienna Doctoral School in Chemistry, University of Vienna, Vienna, AUSTRIA, [6]Joint Applied Medicinal Radiochemistry Facility, University of Vienna and Medical University of Vienna, Vienna, AUSTRIA, [7]Ludwig Boltzmann Institute Applied Diagnostic, AKH Wien c/o Sekretariat Nuklearmedizin, Vienna, AUSTRIA, [8]Department of Biomedical Imaging and Image Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Invasive microbial infections are a major cause of morbidity and mortality in immunocompromised patients. We have shown that a siderophore-based iron acquisition system could be an interesting target for molecular imaging, as radiolabelled siderophores appear to be promising agents for detection of various microbial infections (1). Recently, we have demonstrated that the siderophore deferrioxamine-B (DFO-B), which has been used as a chelator in nuclear medicine to label different biomolecules for decades, can be labelled with Ga-68 and used to detect variety of bacterial infections (2). Here, we report on the evaluation of synthetic DFO-B analogues and their potential for imaging bacterial infections. ***Materials and Methods:*** DFO-B analogues were labelled with Ga-68 in sodium acetate. In vitro characterization of ^{68}Ga-DFO-B analogues including the determination of partition coefficient, protein binding and stability in various media was performed. In vitro uptake of ^{68}Ga-DFO-B analogues was tested in selected microbial cultures under various culturing conditions. In vivo biodistribution was studied in healthy mice. PET/CT imaging of ^{68}Ga-DFO-B analogues was performed in a mouse model of microbial myositis. ***Results:*** All DFO-B analogues were radiolabelled with Ga-68 with high radiochemical purity. In vitro assays showed hydrophilic properties, relatively low protein binding and high stability in human serum and PBS for all ^{68}Ga-DFO-B analogues. The high in vitro uptake of tested ^{68}Ga-DFO-B analogues in selected strains of Pseudomonas aeruginosa (P.a.), Staphylococcus aureus (S.a.) and Streptococcus agalactiae (S.ag.) was completely inhibited in heat-inactivated microbial cultures. ^{68}Ga-DFO-B analogues showed high in vivo stability in blood and favourable pharmacokinetics with rapid renal elimination in mice. PET/CT images of animal infection model displayed high and specific accumulation of ^{68}Ga-DFO-B analogues in both P.a., S.a. and S.ag. infection with excellent image contrast. ***Conclusion:*** We have shown that all ^{68}Ga-DFO-B analogues exhibit promising in vitro properties and in vivo behaviour in mice. The high and specific uptake of ^{68}Ga-DFO-B analogues by selected bacteria was

confirmed both in vitro and in vivo, demonstrating that they can be used similarly to ^{68}Ga-DFO-B for imaging bacterial infections. ***References:*** 1. Petrik M et al. (2020) J Fungi 6: 73.; 2. EP-0149

Pharmacokinetics study of FT-FAPI, a novel multi-nuclide label-able FAP targeting tracer, in mice

X. Wang, *J. Ye, F. Kang, J. Wang;*
The First Affiliated Hospital of Air Force Medical University, Xi'an, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP) has become one of the most promising targets for integrated diagnosis and treatment. A class of radiopharmaceuticals has been designed based on quinoline-based FAP-specific inhibitors (FAPIs), but previous research data have shown that FAPI probes generally suffer from low tumor uptake and short retention time. FT-FAPI is a potential FAP-targeting probe that utilizes an organic trifluoroborate linker ($AMBF_3$) to enhance tumor targeting ability. In addition, $AMBF_3$ can be used to label a variety of diagnostic and treatment nuclides, such as ^{18}F, ^{68}Ga, and ^{177}Lu. ^{161}Tb is a new type of medical radionuclide. Compared with the widely used nuclide ^{177}Lu, ^{161}Tb can emit Auger electrons and convert electrons in addition to emitting β-rays and gamma rays of corresponding energy, and the dose absorbed by cells is three times higher than that of ^{177}Lu, which is expected to provide new therapeutic options. In this study, ^{161}Tb was synthesized to label FT-FAPI and imaging and pharmacokinetic performance in normal Kunming mouse models. ***Materials and Methods:*** The radiochemical synthesis of ^{161}Tb-FT-FAPI was performed using the traditional metal nuclide heating labeling method. Radio-HPLC was used to study the stability of ^{161}Tb-FT-FAPI. The lipid water partition coefficient LogP was determined by γ-counter. And ^{161}Tb-FT-FAPI pharmacokinetics, biodistribution and dosage studies were conducted on Kunming rats. ***Results:*** In this study, ^{161}Tb-FT-FAPI was successfully prepared, and the product was released and purified by more than 96%. The estimated specific activity was not less than 3.7×10^4 MBq/mmol, which could meet the requirements of subsequent experiments and clinical applications. Calculated based on the experimental results, the lipid-water partition coefficient of ^{161}Tb-FT-FAPI was -3.78 ± 0.03, which shows that 161Tb-FT-FAPI has good hydrophilicity. ^{161}Tb-labeled FT-FAPI showed higher safety and tolerance in mice. The pharmacokinetic characteristics of FT-FAPI in mice are most consistent with the three-compartment model. The biodistribution results showed that in mice, the distribution half-life ($T_{1/2\alpha}$) and clearance half-life ($T_{1/2\beta}$) of ^{161}Tb FT-FAPI was 0.68 h and 5.85 h, respectively. The effective dose equivalent (EDE) of ^{161}Tb-labeled FT-FAPI in an adult model was 16.30 μSv·MBq^{-1} and the effective dose (ED) was 8.14 μSv·MBq^{-1}. ***Conclusion:*** The image quality of ^{161}Tb-FT-FAPI in normal Kunming mice was good and the pharmacokinetic performance was excellent.

EP-0151

Using Modeling and Simulation to Assess the Impact of the Pharmacokinetics and Biodistribution on the Absorbed and Biologically Effective Dose for Radioligand Therapies

H. Stephens, *D.-C. Imbs, M. N. Trame, A. Manon;*
Certara, Radnor, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Radioligand therapies (RLT) are continuing to raise interest in the oncology space. Current standards are to adhere to dose-tolerance levels derived from external beam radiation therapy (EBRT). However, there are grounds to support that this is not appropriate for RLTs leaving risk to underdose tumors. Modeling and simulation can aid in dose optimization, addressing concerns for Project Optimus, on individual organ absorbed doses. We present how a population pharmacokinetic model can assess the impact of the biodistribution on the absorbed and biologically effective dose (BED) to aid in dose range finding decision making. ***Materials and Methods:*** Drug kinetics of a PSMA targeting radionuclide with Lu-177 was modelled in both the blood and organs of interest. Simulations on virtual subjects were performed at injected activities of 3.5, 7, and 10 GBq. Absorbed dose and BED were then calculated. The BED was also derived for the same absorbed dose received as a single fraction of EBRT. The ratio of the RLT BED and EBRT BED was calculated and used to analyze the disparity between RLT and EBRT BED and how dose rate impacts the BED ratio between differing dose-rate profiles. The analysis was performed using the kidneys, liver, and salivary glands. ***Results:*** The absorbed dose per injected activity did not vary linearly with injected activity. The BED ratio for the 7 and 10 GBq injected activity were not statistically different from each other for both the kidneys and salivary glands but were significantly different for the liver. The BED ratio for the 3.5 GBq injected activity was significantly different for the higher two injected activities for all three analyzed organs. The liver was not significantly different than EBRT for any of the tested injected activity levels. The BED for the kidneys and salivary glands was significantly different from the EBRT BED at all tested injected activity levels. ***Conclusion:*** From these results, the absorbed dose and BED do not increase proportionally with injected activity highlighting that simply scaling the absorbed dose by injected activity is not appropriate. The difference in the BED when comparing to EBRT is dependent on the biodistribution, as the organs with noticeable uptake phases had much more disparity compared to EBRT. This disparity seems to increase with injected activity but then saturate at some level. These differences highlight the importance of modeling and simulation to assess the impact of varying injected activity on organs at risk.

Single-cell RNA Sequencing Reveals Immune and Vascular Remodelling in Graves' Disease: Implications for Molecular Imaging and Targeted Therapy

S. Yang[1,2], *G. Zhu*[1];
[1]*Department of Nuclear Medicine, the First Affiliated Hospital of Kunming Medical University, Kunming City, Yunnan Province, CHINA,* [2]*Department of Nuclear Medicine, Yuxi People's Hospital of Yunnan Province/Department of Nuclear Medicine, the Sixth Affiliated Hospital of Kunming Medical University, Yuxi City, Yunnan Province, CHINA.*

Aim/Introduction: Graves' disease (GD) is a prevalent autoimmune disorder, the pathogenesis of which involves immune dysregulation and vascular abnormalities, but the dynamic changes at the single-cell level remain poorly characterised. This study used scRNA-seq in a non-human primate model to map the molecular features of GD and identify new cellular targets for molecular imaging and targeted therapies in nuclear medicine. ***Materials and Methods:*** A GD model was established in cynomolgus monkeys via an adenoviral vector encoding the TSHR A-subunit, with successful induction was confirmed by thyroid-specific SPECT/CT imaging

and serological evaluations. Thyroid tissues from GD monkeys (n=2) and HC (n=3), totalling 10 specimens, were analysed by scRNA-seq. The transcriptomic data were further validated using human samples (GD: n=6, HC: n=3). Cellular heterogeneity and gene expression patterns within the thyroid microenvironment were examined, with a particular focus on immune cell dysfunction and vascular remodelling in GD. ***Results:*** scRNA-seq analysis identified 9 cell types and 15 subtypes within the thyroid tissue. Key findings include: (1) A distinct subset of dysfunctional regulatory T cells (Tregs) in the GD, characterised by reduced FOXP3 expression and elevated levels of TNFRSF18, TNFRSF4, and TIGIT. This suggests a compensatory yet impaired immune regulatory response under inflammatory stress, with these cells potentially playing a pivotal role in the immune dysregulation seen in GD. (2) In thyroid follicular cells (TFCs), aberrant expression of MHC class II molecules was observed, potentially mediated by H2BC5, rather than the classical IFN-γ pathway. (3) Within the endothelial cell (EC) compartment, a paradoxical reduction in capillary endothelial cells (EC1) expressing COL8A1 was noted, despite evidence of active vascular proliferation. Conversely, increased proportions of arterial ECs (EC2), post-capillary venular ECs (EC3), and vascular smooth muscle cells (AC1) were observed, indicating a subtype-specific remodelling pattern of "vascular expansion with concurrent capillary loss."This phenomenon is hypothesised to be driven by COL8A1-mediated transdifferentiation or migration of capillary ECs, leading to endothelial heterogeneity and capillary depletion. We propose a novel mechanism, termed the "COL8A1-driven endothelial transdifferentiation/remodelling hypothesis," to explain these vascular alterations in GD. ***Conclusion:*** This study provides a comprehensive single-cell transcriptomic atlas of GD, highlighting the intricate interplay between immune dysregulation and vascular remodelling. The findings uncover novel cellular and molecular events underlying GD pathophysiology, offering potential targets for the development of radiolabelled tracers or ligand-based therapeutics in nuclear medicine. Future studies will focus on validating these targets for clinical translation and theranostic applications.

EP-0153

Impact of Isotope, Molar Activity, and Ligand Mass on the Biodistribution Profile of 212Pb-based Radioligand Therapies

F. Liu, *A. Prior, M. E. Monterosso, D. Boucher, S. Shakti, A. Horsfall, H. Green, S. Kumar, J. Koehbach, R. Huebner, K. Kuan, W. Tieu, S. Rose, A. Karmann, S. Puttick, G. Li, T. Kryza;*
AdvanCell Pty Ltd, Brisbane, AUSTRALIA.

Aim/Introduction: The theranostics paradigm consists in the utilization of the same targeting agent for both diagnosis and therapy. Lead-203/Lead-212 (^{203}Pb/^{212}Pb) forms one of the only element-equivalent theranostic isotope pairs. ^{203}Pb emits a 279 keV gamma-ray detectable by SPECT imaging, which makes it commonly used as a surrogate for ^{212}Pb. ^{212}Pb is a promising isotope for alpha therapy with high linear energy transfer, a short half-life, and simple decay scheme. Here we present the comparison of ^{203}Pb and ^{212}Pb in radiochemistry, cell binding potency, and in vivo biodistribution using different peptide radioligands. ***Materials and Methods:*** ^{203}Pb was sourced from U.S. Department of Energy (DoE) (Oak Ridge, USA) and ^{212}Pb was produced by AdvanCell (Brisbane, Australia). Two different peptide radioligands were used in this study: 1) a PSMA-ligand-DO3AM developed for prostate cancer, and 2) a melanoma-specific-ligand-DO3AM developed for melanoma. The labeling efficiency, stability and reproducibility of radiolabeling of these ligands labelled with ^{203}Pb and ^{212}Pb, respectively, were compared. The impact of isotope and molar activity were assessed by cell-binding assays, and in biodistribution studies using xenografted tumors with high and intermediate level of target expression. ***Results:*** Radiochemistry analyses showed that ^{203}Pb did not significantly differ from ^{212}Pb in radiolabeling efficiency of either peptide series and allows direct transfer of radiolabeling condition between ^{203}Pb and ^{212}Pb, including at high specific activity. ^{203}Pb- and ^{212}Pb-radiolabelled peptides were assessed by iTLC and rHPLC sequentially under identical analytical conditions, utilizing their gamma emissions. Stability studies showed that ^{212}Pb led to a higher radiolysis of the radioligand when used at high radioactivity concentration (>50 MBq/mL). In vitro binding assays showed comparable binding constants between ^{203}Pb and ^{212}Pb. In vivo biodistribution demonstrated both, molar activity and radioligand dose, affect the biodistribution of radioligands. ***Conclusion:*** Radiolabelling of ligands with ^{203}Pb or ^{212}Pb, and their subsequent analysis, can be translated between isotopes. Our findings demonstrate that the biodistribution profile of both ^{203}Pb- and ^{212}Pb-labeled radioligands is independently influenced by several factors including molar activity and administered dose. It remains unclear whether these differences are also related to the target or ligand type. Therefore, establishing equivalent conditions between ^{203}Pb and ^{212}Pb is essential before considering ^{203}Pb as a surrogate for ^{212}Pb.

EP-0154

Meeting Upcoming Clinical and Diagnostic Needs in oncological Imaging: A Structured Reporting System for Fibroblast-Activation-Protein-Targeted Imaging: FAP-RADS Version 1.0

E. Novruzov[1], *G. Sheikh*[2], *E. Mamlins*[1], *A. Holzgreve*[2], *Y. Mori*[1], *S. Ledderose*[2], *F. Klauschen*[2], *M. Gorin*[3], *M. G. Pomper*[4], *K. Herrmann*[5], *S. P. Rowe*[6], *R. A. Werner*[2], *F. L. Giesel*[1];
[1]*University Hospital Düsseldorf, Düsseldorf, GERMANY,* [2]*University Hospital München LMU, Munich, GERMANY,* [3]*Milton and Carroll Petrie Department of Urology, Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA,* [4]*Department of Radiology, University of Texas Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA,* [5]*University Hospital Essen, Essen, GERMANY,* [6]*Department of Radiology, University of North Carolina, Chapel Hill, NC, UNITED STATES OF AMERICA.*

Aim/Introduction: Fibroblast activation protein (FAP)-targeted imaging has emerged as a promising diagnostic tool for various oncologic and non-oncologic conditions. However, the increasing employment of FAP imaging with small-molecule radiotracers mandates a standardized reporting system to ensure consistent interpretation across various clinical scenarios, especially in oncological imaging. This study proposes FAP-reporting and data system (RADS) version 1.0 framework to address those needs, aiming to standardize FAP imaging reporting, improve clinical communication, and support multi-center research. ***Materials and Methods:*** We conducted a comprehensive literature review and combined it with expert consensus in nuclear medicine to design a new scoring system based on the principles of the molecular imaging (MI)-RADS framework. FAP-RADS version 1.0 system is intended for use across multiple tumor types with variable radiotracer uptake patterns and is non-specific to imaging modality (FAP-PET and FAP-SPECT) or radiotracer compound structure. We aimed to ensure that the system would be user-friendly and applicable to routine clinical practice. ***Results:*** FAP-RADS version 1.0 introduces a 5-point scale to assess the likelihood of malignancy in lesions based on the imaging characteristics of the lesions. The scoring system can be applied to different FAP ligands with varying pharmacokinetics. The framework does not rely on SUV thresholds, making it flexible and robust for clinical use. The implementation of this system aims to improve interdisciplinary communication, support longitudinal follow-up, and facilitate future multi-center trials. ***Conclusion:*** The proposed FAP-RADS version 1.0 reporting system is a comprehensive and flexible framework that has the potential to enhance the quality and consistency of FAP imaging interpretation in clinical practice.

Its application could lead to better research outcomes, broader acceptance within the oncological community, and streamlined regulatory processes related to FAP-based radiotracer approval.

EP-0155

Design and in vivo evaluation of a novel NIR-II/PET dual-modality probe

D. Fan[1], *L. Ai*[1], *K. Zhou*[2];
[1]*Department of Nuclear Medicine, Beijing Tiantan Hospital, Capital Medical University, Bejing, CHINA,* [2]*Center for Advanced Materials Research & Faculty of Arts and Sciences, Beijing Normal University, Zhuhai, CHINA.*

Aim/Introduction: Near-infrared-II (NIR-II, 1000-1700 nm) fluorescent dyes demonstrate exceptional advantages in biomedical applications due to their unique photophysical properties, particularly in deep-tissue imaging capability and ultrahigh-resolution imaging.NIR-II fluorescent dyes have emerged as powerful tools for real-time intraoperative navigation, offering significant advantages over conventional NIR-I imaging. PET(Positron Emission Tomography) imaging technology offers significant advantages for preoperative surgical localization, including ultrahigh-sensitivity detection, functional positioning, and multimodal integration capabilities. In this study, a novel NIR-II/PET dual-modality probe was designed and evaluated with both in vitro and in vivo studies, confirming its efficacy for preoperative tumor localization and real-time intraoperative guidance. ***Materials and Methods:*** The current clinical benchmark dye for NIR-II imaging is indocyanine green (ICG), which advantages are its excellent water solubility, low toxicity, and outstanding photophysical properties (particularly high brightness). While largely preserving ICG's molecular structure, we performed molecular engineering modifications to develop high-performance NIR-II probes for intraoperative navigation. The emission wavelength was determined through in vitro experiments and in vivo studies were conducted for NIR-II and microPET/CT imaging evaluation. ***Results:*** We propose a molecular asymmetrization strategy to reconstruct ICG's symmetric scaffold: transforming the original C_2-symmetric heptamethine cyanine structure into a D-π-A asymmetric system. Compared to ICG, this modification induces a bathochromic shift to 1021 nm, extending emission into the NIR-II window. And this structure permits conjugation with metal chelators for subsequent ^{68}Ga radiolabeling and PET applications. In vivo NIR-II and microPET/CT imaging evaluation studies showed that the probe demonstrates significant accumulation at the tumor site. ***Conclusion:*** A novel NIR-II/PET dual-modality probe was designed and evaluated, with both in vitro and in vivo studies confirming its efficacy for preoperative tumor localization and real-time intraoperative guidance, demonstrating significant clinical translation potential.

Toward Bacterial Vectors for Targeted Atherosclerosis Therapy: microSPECT/CT Biodistribution Studies of [^{111}In] In-Oxine-Labeled Mycoplasma pneumoniae in a murine model of Atheroma.

F. Pareja del Rio[1,2], *A. Fernández-González*[1,2], *A. Hendy-Pérez*[1,2], *J. Escola Gil*[3,4], *N. Rotllan Vila*[3,4], *I. Rodríguez-Arce*[5], *M. Collantes*[1,2,6], *G. Quincoces*[1,2], *I. Peñuelas*[1,2,6];
[1]*Radiopharmacy Unit. Nuclear Medicine Department. Clínica Universidad de Navarra, Pamplona, SPAIN,* [2]*Navarra Institute for Health Research (IdISNA), Pamplona, SPAIN,* [3]*Institut de Recerca de l´Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [4]*CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Madrid, SPAIN,* [5]*Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, SPAIN,* [6]*Translational Molecular Imaging Unit (UNIMTRA). Nuclear Medicine Department. Clínica Universidad de Navarra, Pamplona, SPAIN.*

Aim/Introduction: Atherosclerosis is a major contributor to the development of severe cardiovascular diseases such as acute myocardial infarction and stroke. Recent studies[1] have identified the presence of Mycoplasma pneumoniae within atheromatous plaques. This cell wall-less bacterium, the leading cause of atypical pneumonia, appears to exhibit a marked tropism for atheromatous plaques, likely due to its inability to synthesize essential membrane lipids, which it must scavenge from the host environment mediated by P1116 protein. If this affinity is further confirmed, genetically attenuated M. pneumoniae CV8 chassis could potentially serve as a novel therapeutic vector for targeted atherosclerosis treatment. To confirm in vivo the tropism of M. pneumoniae for atheromatous plaques, we radiolabeled the bacteria with [^{111}In]In-oxine and performed microSPECT/CT studies in a murine model of atherosclerosis, followed by ex vivo SPECT/CT imaging in explanted organs. ***Materials and Methods:*** The CV8 strain (10^7 CFU) was radiolabeled with 48.5 MBq of [^{111}In]In-oxine for 15´ at 37 ºC. Radiolabeled cells were purified by two steps of centrifugation and washing in PBS.Around 370 KBq of [^{111}In]In-oxine-CV8 were intravenously injected per mice: 3 atherosclerotic LDL receptor Knock-Out (LDLr KO) mice and 3 Wild-Type (WT) control mice, all of which had been fed a Estern diet for 10 weeks. MicroSPECT/CT imaging of the liver and heart was performed at 1 and 6 hours post-injection (hpi). At 6 hpi, mice were euthanized, hearts and aortas carefully extracted and ex vivo imaged by microSPECT/CT. ***Results:*** Radiolabeling efficiency was 10.5%, limited by the adsorption of [111In]In-oxine to preparation materials. In vivo imaging at 6 hours revealed prominent liver uptake, but no clear aortic signal was detected. However, ex vivo imaging showed the tropism of M. pneumoniae for atheromatous plaques, with positive signal detected in 2 of 3 LDLr KO mice and no signal in any of the WT animals. ***Conclusion:*** Radiolabeling and biodistribution studies support the affinity of M. pneumoniae for atheromatous plaques in this animal model. These findings suggest its potential as a novel vector for the targeted treatment of atherosclerotic lesions, although further research is needed to confirm and expand these promising results. ***References:*** 1. Neurofunctional changes over time after administration of Ibogaine and Noribogaine in Rats Assessed by [^{18}F]FDG PET Imaging

M. Bentura[1], *L. Reyes*[1], *A. Paolino*[1], *G. Falasco*[1], *L. Urrutia*[1], *B. Gonzalez*[2], *J. Mesa*[2], *F. Arredondo*[1], *I. Carrera*[2], *E. Savio*[1];
[1]*Departamento de Radiofarmacia, Centro Uruguayo de Imagenología Molecular (CUDIM), Montevideo, URUGUAY,* [2]*Departamento de Química Orgánica, Facultad de Química, UdelaR, Montevideo, URUGUAY.*

Aim/Introduction: Ibogaine is a psychedelic alkaloid derived from the root bark of Tabernanthe iboga, it has long-lasting anti-addictive effects demonstrated in both preclinical models and observational clinical studies. These effects include reduced drug cravings and alleviation of withdrawal symptoms. These effects persist beyond the pharmacokinetic elimination of ibogaine and its active metabolite, noribogaine. Although its mechanisms of action remain unclear, the prolonged effects point toward the involvement of neuroplasticity processes. Given the complex pharmacological profile and the diverse molecular targets associated with ibogaine and noribogaine, positron emission tomography (PET) imaging emerges as a valuable tool to explore the neurobiological substrates underlying their immediate and long-term central effects. The aim of this work is to further

investigate the metabolic changes in the brain induced by the administration of ibogaine and its active metabolite, noribogaine, through the use of PET combined with Computed Tomography (PET-CT), employing [^{18}F]Fluorodeoxyglucose ([^{18}F]FDG) as a radiotracer. ***Materials and Methods:*** This study was conducted on 24 male Wistar rats (3 months old). Animals received either ibogaine or noribogaine at different doses and via different routes of administration: intraperitoneal ibogaine (40 mg/kg), intravenous ibogaine (10 mg/kg), and intraperitoneal noribogaine (40 mg/kg). Image acquisition was performed using a nanoScan® PET/MRI 3T system (Mediso), at four time points: before treatment (control of each corresponding route of administration), during compound administration, one week post-treatment, and four weeks post-treatment. [^{18}F]FDG was administered following compound injection at time points corresponding to peak brain concentrations: 1 minute after intravenous ibogaine, 5 minutes after intraperitoneal ibogaine, and 20 minutes after intraperitoneal noribogaine. ***Results:*** Results showed significant differences compared to each control at all evaluated time points, including at one week and four weeks post-treatment, with intravenous ibogaine inducing the most pronounced metabolic changes. The brain regions affected varied depending on the compound and route of administration. Some of these effects were maintained over time, while others varied in intensity. Notably, alterations were observed in the motor and somatosensory cortices, hypothalamus, striatum, and parasubiculum—areas implicated in motor control, sensory processing, homeostatic regulation, reward-related functions, and cognition. ***Conclusion:*** These findings suggest that ibogaine and noribogaine induced distinct alterations in brain metabolism, which were maintained or varied over time, and are consistent with the previously described effects of both compounds. This supports the idea of distinct mechanisms of action between the parent drug and its metabolite, as well as potential neuroplasticity processes induced by the treatments.

EP-0158

Preclinical evaluation and first-in-human study of [68Ga]Ga/[177Lu]Lu-JH120061, novel CXCR4-targeting radiopharmaceuticals

J. Zang[1], *G. Wang*[1], *J. Zhan*[2], *E. Wang*[2], *J. He*[2], *H. Yu*[2], *W. Miao*[1];
[1]*The First Affiliated Hospital, Fujian Medical University, Fuzhou, Fujian, CHINA,* [2]*Bivision Pharmaceuticals, Inc., Shanghai, CHINA.*

Aim/Introduction: A novel CXCR4-targeting compound (designated JH120061) was developed through rational design and chemical synthesis. This study aimed to systematically assess its therapeutic potential through preclinical experiments and clinical studies using Pentixafor and Pentixather as references. ***Materials and Methods:*** JH120061 was synthesized and validated. Preclinical evaluation was performed by HT1080 hCXCR4 cells/tumor-bearing mice and compared with Pentixafor/Pentixather, respectively. Patients with several types of tumors were recruited for radiation dosimetry calculation of [^{68}Ga]Ga-JH120061 PET/CT and a head-to-head comparison between [^{68}Ga]Ga-JH120061 and [^{68}Ga]Ga-Pentixafor PET/CT. ***Results:*** JH120061 revealed a strong affinity for CXCR4 with an IC_{50} value of 7.52 ± 0.37 nM, likely outperforming Pentixafor and Pentixather (IC_{50} values: 217.13 ± 4.24 nM and 56.35 ± 7.33 nM, respectively). Preclinical evaluation demonstrated superior accumulation and prolonged retention of both [^{68}Ga]Ga-JH120061 and [^{177}Lu]Lu-JH120061 in CXCR4-positive models compared to their [68Ga]Ga-Pentixafor and [177Lu]Lu-Pentixather. The tumor uptake of [^{68}Ga]Ga-JH120061 and [^{177}Lu]Lu-JH120061 in HT1080 hCXCR4 tumor-bearing mice can be specifically blocked by excess unlabeled Pentixafor and Pentixather. Clinical PET/CT investigations revealed [68Ga]Ga-JH120061 maintained favorable biosafety, the effective dose of [^{68}Ga]Ga-JH120061 PET/CT was 2.01E-02 ± 6.66E-03 mSv/MBq, corresponding to 3.0 mSv for a target activity of 150 MBq.The tumor uptake of [^{68}Ga]Ga-JH120061 in patients with multiple myeloma and clear cell renal cell carcinoma was higher than that of [^{68}Ga]Ga-Pentixafor PET/CT (SUV_{max}: 24.3 ± 11.3 vs. 10.2 ± 6.7 at 60min, $P < 0.001$; 32.6 ± 11.2 vs. 6.7 ± 4.2 at 150min, $P < 0.001$). ***Conclusion:*** This study demonstrated that JH120061 may have excellent affinity for CXCR4, high tumor uptake, and prolonged retention in CXCR4-positive tumors. Further exploration of the application value of [^{68}Ga]Ga/[^{177}Lu]Lu-JH120061 in larger cohorts is needed in the future.

Intraoperative visualisation of tumor margins using FITC glucose as fluorescent probe

A. Aggarwal[1], *A. Sharma*[2], *S. Chopra*[1], *S. Pandey*[1], *D. Attri*[1], *A. Semwal*[1], *I. Laoriya*[1], *A. Aggarwal*[1], *B. R. Mittal*[1], *A. Bal*[1], *J. Shukla*[1];
[1]*Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA,* [2]*Amity University, Mohali, INDIA.*

Aim/Introduction: A fluorescent glucose probe (FITC-Glc) that targets GLUT transporters, mimicking ^{18}F-FDG was developed. This probe enables real-time visualisation of tumours during surgery, facilitating precision excision. ***Materials and Methods:*** Breast tumor models were developed in Wistar rats using a chemical carcinogen DMBA. Eighteen tumor models were administered FITC-Glc (10mg/kg) intravenously after a 4 h fasting and kept under isoflurane anesthesia for 1 hour at 37°C. Surgery was performed under both normal light and blue LED light, followed by ex-vivo tumor imaging using a gel doc system. Cryo-sectioning and histopathological analysis were conducted to validate tumor margins. Fluorescence quantification was performed in tumor and major organs using Fiji (ImageJ) software. The organs were mechanically homogenised with buffer for biodistribution studies and fluorescence intensities between FITC-Glc-administered rats and control rats administered with normal saline were compared by fluorescence spectrophotometer. Ex-vivo, patient derived breast tumor tissues were incubated with FITC-Glc and observed in confocal microscope. ***Results:*** In-vivo studies demonstrated selective uptake of FITC-Glc, with significantly higher fluorescence intensity in tumor analysed via gel doc. Using Fiji software, the mean fluorescence intensity of a 300 X 246 pixel area, yielded a value of 4919 and corresponding cyro-section analysis of the same region yielded a value of 22.8. Fluorescence intensity measurements in the tumor model at 515 nm (ex. 485 nm) showed varying levels across different tissues: kidneys exhibited the highest intensity at 668 a.u., followed by the stomach at 438 a.u., tumor at 309 a.u., and bladder at 231 a.u. Histopathological analysis confirmed tumor free margins, validating FITC-Glc for intraoperative tumor visualization and margin assessment. In patient derived tumor tissue, higher accumulation was observed, demonstrating its application in FGS. Due to sedation, reduced background uptake in brown adipose tissue and skeletal muscle. ***Conclusion:*** FITC-Glc exhibits favourable optical properties for blue light visualisation and excellent biocompatibility. The potential for intraoperative tumor visualization and margin assessment was validated through various studies supporting the clinical utility as a novel probe for FGS.

EP-0160

Evaluating 4-bed µPET/CT Imaging Performance using Mouse Phantoms.

I. Martin[1], *E. Jamieson*[1], *N. Colpo*[1], *J. Jeffry*[2], *B. Cox*[2], *F. Bénard*[1], *P. L. Esquinas*[1], *C. Uribe-Munoz*[1];
[1]*BC Cancer Research Centre, Vancouver, BC, CANADA,* [2]*Phantec LLC, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Quantitative µPET/CT provides an alternative method for pre-clinical biodistribution studies compared to traditional approaches requiring animal euthanasia. Modern pre-clinical PET systems allow multi-subject imaging, which increases

efficiency but may impact quantitative accuracy in small organs and tumours due to increased scatter and randoms in the field-of-view. The objective is to evaluate and optimize the quantitative accuracy of simultaneous multi-animal PET/CT imaging using mouse phantoms. ***Materials and Methods:*** The quantitative accuracy of ^{18}F activity measurements on a 4-bed Mediso NanoScan µPET/CT was investigated using BioMouse phantoms (Phantec LLC, USA). Each phantom was filled with three different activity concentrations: 9.0 MBq/mL (brain, kidneys, tumor, bladder), 6.3 MBq/mL (lungs, liver, heart, stomach, spleen), and 3.1 MBq/mL (background compartment). Experiment A: one phantom was imaged in each bed to evaluate consistency across bed positions. Experiment B: the number of phantoms imaged simultaneously was incrementally decreased from four to one to assess multi-bed imaging performance. Three images of the 4-phantom configuration were done to evaluate repeatability. Images were reconstructed using fine reconstruction resolution (8 iterations, 6 subsets, pixel size 0.30mm) and segmented using Mediso's Fusion software with volumes of interest positioned inside of each organ to reduce partial volume effects. Quantification accuracy was measured as percentage difference (%diff) between values obtained from images compared with true values administered. ***Results:*** Experiment A: average %diff in each compartment differed from true values by 11.1% in Bed 1, 2.27% in Bed 2, 7.85% in Bed 3, and 3.74% in Bed 4. Experiment B: average %diff in each compartment for the single phantom appearing in all four images were 5.4% for the 1-phantom scan, 6.8% for the 2-phantom scan, 12.2% for the 3-phantom scan, and 10.3% for the 4-phantom scan. Averaging across all phantom compartments in each image average %diff were: 5.4% for 1-phantom scan, 8.6% for 2-phantom scan, 17.3% for 3-phantom scan, and 25.7% for 4-phantom scan. When repeat scans of the 4-phantom set-up were done 3 and 3.5 hours later, average %diff dropped to 10.1% and 9.4%. Most measured values across repeated scans were consistent within 2% between the same compartments. ***Conclusion:*** Our results suggest that preclinical multi-bed µPET/CT images can provide accurate quantification of activity in mice. Although differences in phantom position and total activity within the field-of-view, we can estimate activity concentrations within 2-11%. We will continue investigating how different image reconstruction parameters can improve image accuracy.

EP-0161

Adjusting Relative Biological Effectiveness for Tumor Microdosimetric Heterogeneity in Radiopharmaceutical Therapy: A Theoretical Analysis

J. Hong[1], *S. Bae*[2,3], *H. Choi*[2,3,4], *M. Ryhiner*[1], *V. Morath*[5], *S. Kossatz*[5,6], *R. Seifert*[1], *W. Weber*[5,7], *A. Rominger*[1], *K. Shi*[1];
[1]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND,* [2]*Institute of Radiation Medicine, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [3]*Portrai, Inc., 78-18, Dongsulla-gil, Jongno-gu, Seoul, KOREA, REPUBLIC OF,* [4]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [5]*Department of Nuclear Medicine, TUM University Hospital, School of Medicine, Technical University of Munich, Munich, GERMANY,* [6]*Central Institute for Translational Cancer Research (TranslaTUM), School of Medicine and Health, Technical University Munich, Munich, GERMANY,* [7]*Bavarian Cancer Research Center (BZKF), TUM University Hospital, Munich, GERMANY.*

Aim/Introduction: Evidence has been reported unmatched effects to the accumulated dose in radiopharmaceutical therapy (RPT). Classical fixed value of relative biological effectiveness (RBE) may not be valid due to microdosimetric heterogeneity. This study aims to develop an adjustment coefficient of RBE based on in silico microenvironmental simulation [1]. For proof of concept, we focus on the adjustment of tumor RBE for prostate-specific membrane antigen (PSMA) RPT. ***Materials and Methods:*** We used publicly available Visium spatial transcriptomics (ST) datasets from primary prostate cancer tissue samples. Gene expression levels for FOLH1 (PSMA), GRPR, FAP, and Harris hypoxia signatures were extracted, and spot-level proportions of epithelial, endothelial, and prostate cancer (PC) cells were estimated. We focused on lutetium-labeled PSMA-RPT (Lu-PSMA-RPT) and actinium-labeled PSMA-RPT (Ac-PSMA-RPT). Radiopharmaceutical transport and retention were simulated using a convection-reaction-diffusion partial differential equation (PDE) model, and dose and survival probabilities were computed as described previously [1]. We investigated two levels of heterogeneity: (1) target heterogeneity via PSMA expression, and (2) TME heterogeneity via cell composition. For PSMA, local spatial heterogeneity was quantified using a moving kernel to compute the mean absolute deviation (MAD) of neighboring values, forming a heterogeneity index. Spots were classified into low, medium, or high heterogeneity based on 25th and 75th percentile thresholds. To assess TME heterogeneity, we computed an entropy-based index reflecting cell-type diversity at each spot. To simulate locally homogeneous conditions as a baseline, dose was averaged across neighboring spots within the kernel. We then compared dose-survival relationships under heterogeneous vs. homogeneous assumptions using the linear-quadratic (LQ) model for beta emitters and the exponential model for alpha emitters. We then compared the effective RBE at 10% survival (RBE_{10}) between PSMA-targeted RPT and external beam radiotherapy (EBRT). All parameters were extracted from the literature. ***Results:*** Spatial transcriptomics revealed heterogeneous distributions of PSMA and cell types in the TME. In Lu-PSMA-RPT, both PSMA and TME heterogeneity reduced RBE_{10}, with TME heterogeneity having a greater impact. High heterogeneity in either domain led to poor LQ model fits. In Ac-PSMA-RPT, heterogeneity also lowered RBE_{10}, though effects were less pronounced than those in Lu-PSMA-RPT. Here, PSMA heterogeneity had a stronger influence than TME composition. ***Conclusion:*** Our findings suggest that spatial heterogeneity in target and TME can impact apparent RBE in PSMA-RPT. Modeling approaches that incorporate microenvironmental variation may better predict therapeutic outcomes and guide personalized RPT planning. ***References:*** [1] Hong et al. Theranostics 2024 https://doi.org/10.7150/thno.99516.

EP-0162

Dosimetry-enabled Internal Hematopoietic Acute Radiation Syndrome Model Using the ^{86}Y/^{90}Y Isotopic Pair

L. Wehner*, O. Kwon, A. O. Adeniyi, H. Comas Rojas, M. Bio Idrissou, E. Aluicio-Sarduy, J. W. Engle, B. Bednarz, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Bone marrow toxicity is often the dose-limiting toxicity associated with radiopharmaceutical therapies. Current hematopoietic acute radiation syndrome models evaluate effects due to external exposure from gamma or x-ray sources and the limited number of internal ARS models have several limitations. Here, we aimed to develop a dosimetry-enabled, selective internal hematopoietic-ARS model based on ^{86}Y ($t_{1/2}$ = 14.7 h)/ ^{90}Y ($t_{1/2}$ = 64h) isotopic pair. ***Materials and Methods:*** The selectivity Yttrium for the bone was evaluated via serial PET/CT imaging at 3h, 24h, 47h, and 72h using an intravenous injection of 9.2 ± 0.4 MBq ^{86}Y and corroborated with ex vivo biodistribution following the 72h in vivo imaging timepoint. Absorbed dose rate estimates to the bone marrow were made for the ^{90}Y model using ^{86}Y PET/CT biodistribution. Male ICR mice (3-5-weeks) were administered ^{90}Y ranging from 376.5 - 779.6 MBq/kg and compared to cohorts receiving a uniform injection, irrespective of bodyweight, ranging from 11.1 - 16.7 MBq. Mice were periodically assigned a clinical score based on changes in bodyweight, posture, activity, skin, and fur texture with complete blood counts measured at baseline and days 7- and 28-post-injection (p.i.). Femur and soft-tissue organs

were collected in separate ^{90}Y bodyweight injected cohorts at days 7- and 31-p.i. with the contralateral femur processed for digital autoradiography on an ionizing-radiation Quantum Imaging Detector between days 8-13 p.i. ***Results:*** Osseous tissue selectivity was confirmed via femoral autoradiography demonstrating deposition at growth plate regions which corroborated with high uptake quantified via ^{86}Y PET/CT imaging and 72h biodistribution (26.8 %IA/g ± 3.5) compared to soft tissues (≤ 6%IA/g). Absorbed dose estimation of the femurs in the ^{90}Y model were quantified ranging from 20.6 - 60.9 Gy. Dose-dependent relationships between the bodyweight, clinical score, and survival were not observed in the model injected with uniform doses of ^{90}Y but were apparent in the bodyweight normalized model resulting in a significant effect of ^{90}Y dose on survival ($P < 0.0001$, logrank test for trend). Complete blood counts revealed severe thrombocytopenia and leukopenia at day 7 p.i. that resolved in surviving cohorts measured at day 28 p.i. in both models. Severe hypoplasia of the bone marrow was observed in several dose cohorts via histological examination. ***Conclusion:*** Herein, we present a robust and selective model H-ARS model characterized with ^{86}Y/^{90}Y that enables development of radiation countermeasure and mitigating intervention to address the bone marrow toxicities associated with RPT agents.

EP-0163

[^{18}F]-Pentixafor CXCR4-Targeted PET/CT for Osteogenesis Evaluation and Fracture Healing Monitoring

Z. Li, *D. Zhang, X. Su;*
First Affiliated Hospital of Zhejiang University, School of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Conventional skeletal imaging techniques primarily assess structural morphology without capturing cellular-level bone remodeling processes. The C-X-C chemokine receptor type 4 (CXCR4)/stromal cell-derived factor-1 (SDF-1) axis plays crucial regulatory roles in osteogenesis and fracture repair[1-3]. This study investigates the potential of [^{18}F]-Pentixafor PET/CT for non-invasive monitoring of CXCR4 expression dynamics during bone regeneration. ***Materials and Methods:*** Bulk RNA sequencing analysis (GSE230852) compared CXCR4 expression patterns in skeletal progenitor cells, with qPCR validation. Three murine age cohorts (postnatal: 4-6 weeks], adult: 3-4 months, and aged: >20 months) underwent serial [^{18}F]-Pentixafor PET/CT scans with concurrent micro-CT (µCT) bone volumetry. Standardized femoral fracture models received weekly PET/CT monitoring during healing phases (inflammatory through remodeling stages within 1 week after surgery). Immunohistochemical validation of CXCR4 expression patterns was performed in harvested callus specimens. ***Results:*** Transcriptomic analysis revealed significantly elevated CXCR4 expression in skeletal stem/progenitor cells (SSPCs) compared to mature osteoblasts ($p<0.05$). Physiological [^{18}F]-Pentixafor uptake demonstrated age-dependent variation: postnatal metaphysis SUVmax 0.58±0.06 vs. adult 0.40±0.02 vs. aged 0.28±0.05 ($p<0.05$). Fracture callus exhibited progressive tracer accumulation peaking at 2 weeks post-injury (SUVmax 2.00±0.51 vs. contralateral 0.03±0.01), positively correlated with SSPC enrichment. Age-stratified analysis showed differential healing responses: postnatal SUVmax 3.58±1.04 vs. adult 2.28±0.72 vs. aged 0.78±0.32 ($p<0.01$), paralleling µCT bone formation metrics and IHC staining. ***Conclusion:*** [^{18}F]-Pentixafor PET/CT enables quantitative, non-invasive monitoring of CXCR4-mediated osteogenic activity across developmental stages and fracture healing phases. The modality demonstrates significant predictive potential for bone regeneration capacity assessment, paving the way for clinical translation in personalized orthopedic management. ***References:*** [1]Kawakami Y, Ii M, Matsumoto T, et al. Supramolecular Chemistry Enables Radiolabelling of Antibodies under Mild Conditions

V. Goncalves[1], *R. Vizier*[1], *M. Moreau*[1], *J. Faivre*[1], *M. Carrierre*[1], *M. Cheveau*[1,2], *S. Poty*[1], *F. Denat*[1], *M. Boswinkel*[3], *S. van Lith*[3];
[1]*Université Bourgogne Europe, Dijon, FRANCE,* [2]*CheMatech, Dijon, FRANCE,* [3]*Radboud UMC, Nijmegen, NETHERLANDS.*

Aim/Introduction: One of the key challenges in using proteins as vectors in nuclear medicine is their limited thermal stability, which precludes the use of harsh radiolabelling conditions. To address this, we propose a two-step strategy for protein radiolabelling based on supramolecular chemistry. Specifically, we describe the synthesis of DOTA-cucurbit[7]uril (DOTA-CB[7]), a versatile precursor that can be efficiently radiolabelled with various radionuclides.[1] This compound was rapidly conjugated under mild, and biocompatible conditions to an adamantanamine-modified antibody. The resulting tracer was evaluated in vivo using SPECT/CT and biodistribution studies. Application of this platform to pre-targeted imaging is on-going. ***Materials and Methods:*** DOTA-CB[7] was synthesized starting from glycoluril and radiolabelled with ^{111}In, ^{89}Zr, ^{68}Ga, ^{177}Lu, ^{225}Ac, and ^{161}Tb at 90-95 °C. Adamantanamine was site-specifically conjugated to trastuzumab using transglutaminase. Supramolecular assembly between DOTA-CB[7] and trastuzumab-adamantanamine was achieved in PBS at 37 °C. Biolayer interferometry (BLI) measurements and cell binding assays were conducted to confirm the affinity of the immunoconjugate for HER2. In vivo experiments were performed on mice xenografted with SKOV3 cells. SPECT/CT images were recorded and ex vivo biodistribution was performed by gamma counting. ***Results:*** DOTA-CB[7] was synthesized in four steps. Adamantanamine was successfully conjugated to trastuzumab, achieving a degree of labelling of 2. The supramolecular conjugate was formed quantitatively after 1 minute of incubation at 37 °C in PBS. BLI showed that the binding affinity of the bioconjugate to HER2 was preserved, with a K_D of 0.11 +/- 0.02 nM. Radiolabeling of DOTA-CB[7] with ^{111}In, ^{89}Zr, ^{68}Ga, ^{177}Lu, ^{225}Ac, and ^{161}Tb succeeded with radiochemical yields >90%. All radioconjugates showed excellent stability in PBS and plasma. Upon administration of [^{111}In]In-DOTA-CB[7]⊂trastuzumab-adamantanamine, a significant accumulation of the tracer was observed in the tumor (40.5 +/- 2.4 %ID/g) at 72 h p.i. compared to the blocking group (14.2 +/- 1.4 %ID/g). This value was comparable to the one observed with the covalent conjugate (31.8 +/- 13.2 %ID/g). In contrast, [^{111}In]In-DOTA-CB[7] alone was rapidly cleared by renal elimination. ***Conclusion:*** DOTA-CB[7] represents a promising platform for the synthesis of radioimmunoconjugates. This robust, small molecule enables radiolabeling to be carried out under harsh conditions, achieving good radiochemical yields with a variety of radiometals. In vivo, the radioimmunoconjugate obtained by supramolecular assembly showed excellent stability over several days and a biodistribution profile comparable to that of the "conventional" covalent conjugate. The results of the application of this platform to a pretargeted approach will be disclosed. ***References:*** 1. WO2025003455A1.

EP-0165

Uridine-Based PET/NIRF Dual-Modality Imaging for Precision Tumor Diagnosis and Surgery

***L. Bian**;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Recent studies in Nature, Nature Metabolism, and Nature Cancer have revealed that uridine metabolism plays a crucial role in tumor survival under glucose deprivation, supporting glycolysis and redox homeostasis[1-3]. Building on these findings, we aimed to develop a novel dual-modality imaging platform that targets uridine metabolism to visualize tumor metabolic heterogeneity and guide intraoperative resection. ***Materials and Methods:*** We designed two uridine-based imaging probes: (1) [^{68}Ga]Ga-DOTA-FZUD for PET imaging and (2) ICG-FZUD for second near-infrared window (NIR-II) fluorescence imaging. The probes were evaluated for radiochemical purity, optical properties, pharmacokinetics, and in vivo stability. Tumor-bearing mice were used to assess biodistribution, imaging contrast, and tumor selectivity. Orthotopic and subcutaneous tumor models were employed to evaluate intraoperative fluorescence guidance. Ex vivo human gastric tumor specimens were imaged to explore translational potential. ***Results:*** [^{68}Ga]Ga-DOTA-FZUD showed high radiochemical stability and specific tumor uptake, enabling clear PET delineation of tumors with high tumor-to-background ratios. ICG-FZUD demonstrated excellent optical properties in the NIR-II window, allowing for precise visualization of tumor margins during surgery. The dual-modality approach improved diagnostic accuracy and facilitated complete resection. Fluorescence signal distribution correlated well with histopathology in both mouse and ex vivo human tumor tissues. ***Conclusion:*** This study introduces the first uridine-based PET/NIRF dual-modality imaging system targeting tumor metabolism. By leveraging the metabolic vulnerability of uridine utilization, our probes provide sensitive, noninvasive imaging and real-time surgical navigation. These findings offer a clinically translatable platform for precision diagnosis and treatment of metabolically heterogeneous tumors. ***References:*** 1. Aim/Introduction: Fibrosing mediastinitis (FM), a rare and life-threatening fibroproliferative disorder, lacks effective therapies. The novel radiopharmaceutical ^{177}Lu-FAPI-46, targeting fibroblast activation protein, shows preclinical promise but requires robust animal-to-human dosimetry translation for clinical trial design. This study evaluates five extrapolation methods to predict safe therapeutic dosing, focusing on dose-limiting organs. ***Materials and Methods:*** Five extrapolation methods were investigated: direct application of rat time-integrated activity coefficients (TIACs) to human organs (M1), relative mass scaling (M2), metabolic rate scaling (M3), combined mass and metabolic rate scaling (M4), and organ-specific allometric scaling (M5). The correlation between these methods and uterine uptake, as well as clinical imaging data, was further analyzed. ***Results:*** Method-dependent variability was observed in organ dose distributions. The uterus consistently emerged as the dose-limiting organ across all models. Physiological uptake was confirmed in uterus, ovaries, and small intestine. Maximum permissible administered activity was projected to be <2.78 GBq to avoid exceeding 16 Gy uterine dose. ***Conclusion:*** Uterine dose constraints necessitate limiting ^{177}Lu-FAPI-46 activity to <2.78 GBq, particularly for young females. These preclinical extrapolations provide critical guidance for first-in-human trials, though clinical validation remains essential.

EP-0167

Irisin as a Novel Therapeutic Agent for Glioblastoma: Targeting Ferroptosis via Specific Tumor Binding and AAV-Mediated Overexpression

***C. Chuang**[1], F. Huang[1], C. Huang[2];*
[1]National Taiwan University, Taipei City, TAIWAN, [2]Chang Gung Memorial Hospital, Taoyuan City, TAIWAN.

Aim/Introduction: Glioblastoma multiforme (GBM), a grade IV brain tumor with high aggressiveness, presents a median survival of 12-15 months. Emerging research indicates that exercise may lower cancer risk, including GBM, by modulating systemic and cellular pathways. This study aimed to investigate the biodistribution of irisin, a myokine induced by exercise and encoded by the FNDC5 gene, in a glioma xenograft mouse model using 68Ga-radiolabeled irisin for PET imaging, and to evaluate its therapeutic potential against GBM by exploring its ability to induce ferroptosis in glioma cells and validating its efficacy through adeno-associated virus (AAV)-mediated irisin overexpression. ***Materials and Methods:*** Irisin was radiolabeled with 68Ga and administered to mice bearing glioma xenografts for in vivo PET imaging to assess its biodistribution and tumor-specific binding. In vitro studies were conducted using glioma cell line (U-87 MG) to evaluate irisin's dose-dependent effects on cell viability and ferroptosis induction, confirmed by lipid peroxidation assays and ferroptosis markers. AAV vectors encoding irisin were constructed and administered to glioma cells and orthotopic tumor models to assess therapeutic effects on tumor growth as monitored by T2-weighted MRI and ferroptosis induction. To elucidate the underlying mechanisms, RNA sequencing (RNA-seq) analysis was conducted to identify differentially expressed genes and signaling pathways associated with irisin treatment. ***Results:*** PET imaging revealed specific binding of 68Ga-labeled irisin to glioma xenografts, with significant tumor uptake (SUVmean=1.56±0.35) compared to control tissues (muscle SUVmean=0.25±0.08). In vitro studies demonstrated that irisin triggered ferroptosis in glioma cells in a dose-dependent manner, evidenced by increased lipid peroxidation. Overexpression of irisin via AAV8 vectors reduced GBM cell viability and clonogenicity by approximately 50% at a titer of 1012 GC, compared to wild-type cells. AAV-mediated irisin overexpression reduced tumor growth in glioma xenografts (7.92 mm3 vs 99.6 mm3 at day 29), with prolonged survival in treated mice compared to controls. Transcriptomic analysis by RNA-seq revealed ferroptosis as a possible mechanism underlying irisin-mediated anti-tumor effects. ***Conclusion:*** These findings suggest that irisin demonstrates promise as a therapeutic candidate for glioblastoma given its ability to selectively target tumor cells. The possible involvement of ferroptosis-related pathways provides a mechanistic basis for its anti-tumor activity. Further investigation is required to elucidate these pathways in detail and to assess the potential for clinical application of irisin-based therapies.

Disrupted Synchronization of Organ Translocator Protein (TSPO) Expression in Glioblastoma Mice: Exploiting Total-Body TSPO-PET

G. Müller[1], *A. Zatcepin*[1,2], *L. Bartos*[1], *L. Hörmann*[1], *J. Thevis*[1], *L. Wesser*[1], *G. Palumbo*[1], *R. Oos*[1], *K. Wind-Mark*[1], *R. Werner*[1,3], *S. Ziegler*[1,4], *M. Brendel*[1,2,5];

[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY,* [3]*Russell H. Morgan Department of Radiology and Radiological Sciences, Johns Hopkins School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA,* [4]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY,* [5]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.*

Aim/Introduction: PET imaging of the 18 kDa translocator protein (TSPO) is increasingly used in preclinical research on neurological diseases and is expected to provide information about the immune response. TSPO is a biomarker for glial activity and is expressed in glioma cells and myeloid cells in the tumour microenvironment (1). In this study, associations between TSPO expression in glioblastoma and organ systems of the mouse were investigated. ***Materials and Methods:*** Static late-phase TSPO-PET images (40-60 min p. i.) with the tracer [^{18}F]GE-180 were used from a total of 67 C57Bl/6 mice, including sham-operated (n=18) and glioblastoma mice (syngeneic SB28 cell line) imaged at early (5-13 days, n=20) and late (18-19 days, n=29) time point after inoculation. The tumour and selected organs (healthy brain, heart, lung, skull, various bones) were segmented, and the average TSPO-PET activities were extracted to compare TSPO expression between groups of mice (sham, early- and late-stage glioblastoma). Pearson correlations between all organ regions were calculated to analyse connectivity patterns within the groups. To quantify deviations from normal connectivity patterns, the correlation abnormality score (CAS) was introduced at both cohort and individual level. ***Results:*** Comparing late-stage glioblastoma mice with sham-operated mice, mean TSPO expression was significantly increased in the tumour region ($p<0.0001$) and the skull ($p<0.002$). We also observed a significant increase of the TSPO heart-to-lung ratio ($p=0.0075$). In late-stage glioblastoma mice, the heart-lung correlation was impaired (late-stage glioblastoma: $R=0.15$, $p=0.636$; sham: $R=0.56$, $p=0.050$), while bones and lungs developed a negative correlation (vertebra: late-stage glioblastoma: $R=-0.46$, $p=0.038$; sham: $R=0.07$, $p=0.782$). Additionally, late-stage glioblastoma mice demonstrated a significant increase in individual CAS compared to sham-operated mice, particularly in the tumour region ($p=0.0003$) and lung ($p=0.0175$). When comparing the cohort-level CAS, the most significant abnormality was observed in the tumour-vertebra CAS ($p<0.0001$). ***Conclusion:*** Our analysis of total-body TSPO connectivity revealed distinct stage-dependent changes in TSPO expression in organs that relate to immune response, which may suggest increased migration of myeloid cells. These results highlight the effects of inflammatory responses on TSPO expression and could provide important insights into tumour-associated immune processes. ***References:*** 1.B. Zinnhardt, F. Computational Design of Chelators for Actinium-225 and Its Decay Daughters: Toward Optimized Alpha-Emitter Theranostics

D. Lee[1], *J. Kim*[2], *K. Kang*[3], *J. Yoo*[3], *W. Lee*[2], *M. K. Schultz*[4];
[1]*Department of Physics and Chemistry, Korea Military Academy, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Chemical and Biological Engineering, Seoul National University, Seoul, KOREA, REPUBLIC OF,* [3]*Chemical, Biological, Radiological Defense Research Institute, Seoul, KOREA, REPUBLIC OF,* [4]*Perspective Therapeutics, Inc., Coralville, IA, UNITED STATES OF AMERICA.*

Aim/Introduction: Actinium-225 (^{225}Ac) is a potent alpha emitter used in targeted radionuclide therapy (TRT). Its relatively long half-life (~10 days) allows for extended therapeutic action but also imposes a stringent requirement for prolonged in vivo chelation stability. Clinical application is further complicated by the complex decay cascade of ^{225}Ac, which produces daughter radionuclides (e.g., Fr-221, At-217, Bi-213) with distinct chemical properties and substantial recoil energies. While existing chelators such as DOTA, macropa, and crown ether derivatives show moderate success in coordinating Ac^{3+}, their capacity to retain both parent and daughter radionuclides under sustained alpha flux remains poorly understood. This study aims to explore and rationally design chelators that provide thermodynamic and structural stability across the full decay profile of ^{225}Ac. ***Materials and Methods:*** Density Functional Theory (DFT) calculations were performed using the ORCA package to evaluate the interaction energies, coordination geometries, and charge distributions of chelator-metal complexes. Multiple trivalent chelator scaffolds, including DOTA, macropa, and crown-based ligands, were modeled in conjugation-ready forms (linked via ethylamine), with plans to expand the library to structures capable of dual-size accommodation. While experimental data on Fr, At, and Bi chelation is limited, their ionic radii and potential coordination preferences were inferred from known analogs and will be addressed in future modeling. ***Results:*** Initial computational stabilization of Ac-chelator complexes confirmed trends seen with other trivalent radionuclides: DOTA adopts 8-coordinate geometries, while macropa and crown-based ligands provide more flexible coordination spaces. Chelation energy analysis indicated that macropa-type structures offer lower interaction energies than DOTA for Ac^{3+}, suggesting improved thermodynamic stability. However, current models do not yet account for daughter isotope retention or recoil effects. Structural expansion toward bifunctional or adaptive cavity chelators is underway to address the distinct ionic sizes and coordination tendencies of ^{221}Fr (monovalent, alkali-like), ^{217}At (multiple oxidation states, borderline halogen), ^{213}Bi (trivalent, borderline-soft). These designs are being developed using stepwise DFT-based screening and constrained geometry optimization. ***Conclusion:*** This work presents a rational computational approach to identifying chelator structures suitable for ^{225}Ac and potentially its decay daughters. While no single chelator is currently known to retain all progeny, our modeling platform enables systematic design and assessment of chelators with cavity flexibility and charge-balancing features. Future directions include modeling daughter-specific chelation, with the goal of guiding the synthesis of next-generation chelators optimized for complete alpha-emitter retention and safety in clinical TRT.

Dimorphism of whole body Crayfish by [^{18}F]FDG uptake

A. Avendaño-Estrada[1,2], *K. Mendoza-Ángeles*[1], *J. Hernandez-Falcón*[1], *M. Ávila-Rodríguez*[1,2];
[1]*School of Medicine, UNAM, Mexico, MEXICO,* [2]*Centro de Investigación sobre el Envejecimiento, Centro de Investigación y de Estudios Avanzados Sede Sur, Mexico City, MEXICO.*

Aim/Introduction: Crustaceans are used in biomedical research due to their accessibility, adaptability, and resistance. Crayfish (Procambarus clarkii) has been evaluated by genetics, molecular biology, behavior assessments, electrophysiology, and microscopy techniques; nevertheless, in vivo evaluation by micro positron emission tomography (MicroPET) has not been assessed in this specie. MicroPET imaging in crustacean models represents a novel approach in evaluating metabolic processes in these organisms. This work aimed to assess the uptake in different organs (brain, green gland, heart, gonads, and ganglia) of [^{18}F]FDG in male and female crayfish using MicroPET imaging and to find the optimal

scan acquisition time. ***Materials and Methods:*** Adult male and female crayfish (n=6/sex, 30-40 g, 6-8 cm length) underwent 1 hour MicroPET scans (6 frames of 10 minutes) after administration of [^{18}F]FDG (7.4 ± 10 MBq). Animals were fasted for one week before imaging acquisition. Standardized uptake values (SUV) were calculated for the brain, gonads, green gland, heart, and ganglia of the ventral nerve cord. ***Results:*** Green gland, brain, and, subesophageal ganglion showed the highest [^{18}F]FDG uptake. Significant differences in the SUV associated to sex were observed only in the gonads (females showed highest uptake). No significant differences were found in other structures, nevertheless, male crayfish showed a higher coefficient of variation (0.7-1.2) than females (0.1-0.6). All the evaluated regions reach a maximum and constant SUV between 40 and 50 minutes after [^{18}F]FDG administration. ***Conclusion:*** MicroPET imaging is useful to assess metabolic activity and sexual dimorphisms in crayfish in a single 10-minute scan (e.g. from minute 40-50).

EP-0171

PET-Based Assessment of Tumour Heterogeneous Uptake in Response to Doxorubicin/Andiroba Oil Nanoemulsion Therapy in a 4T1 Murine Breast Cancer Model

M. B. Silveira[1], *S. E. M. Miranda*[1], *A. L. P. Magalhães*[2], *A. E. M. M. Oliveira*[2], *J. O. Silva*[2], *A. L. B. Barros*[2];
[1]*Center for the Development of Nuclear Technology (CDTN/CNEN), Belo Horizonte, BRAZIL,* [2]*Federal University of Minas Gerais (UFMG), Belo Horizonte, BRAZIL.*

Aim/Introduction: Positron emission tomography (PET) is a valuable tool for developing novel therapeutics in preclinical cancer models. Earlier, we have investigated therapeutic efficacy using an Andiroba oil-based nanoemulsion loading Doxorubicin (unpublished data), which demonstrated in vitro antitumoral activity. In this study, we aimed to quantitatively assess both low- and high-uptake regions within necrotic large-volume tumors using [^{18}F]FDG PET imaging, correlating PET-derived parameters with caliper-derived volumetric measurements to enhance the understanding of treatment response dynamics. ***Materials and Methods:*** The study evaluated 4T1 tumor-bearing BALB/c mice (n=4-8), divided into control (C), free doxorubicin (Doxo), and nanoemulsion-loaded doxorubicin (NE) groups. On day 18 post-treatment, mice received 20-30 MBq [^{18}F]FDG IV. Software measurements were taken using AMIDE®. Total and corrected volumes (excluding regions of hypocaptation) were analyzed. Imaging data were statistically compared (ANOVA) with caliper-based assessments using the ellipsoid formula [$V = 0.5 \times (d1)^2 \times d2$] (d1 = shortest and d2 = longest diameter). ***Results:*** Quantitative analysis revealed significant volumetric differences between measurement modalities. Caliper measurements showed tumor volumes of 872.7 ± 196.3 mm^3 (C), 471.9± 277.1 mm^3 (Doxo), and 330.2 ± 110.6 mm^3 (NE), while PET-derived volumes were consistently larger (1688.9 ± 412.3 mm^3 control, 1019.4 ± 387.0 mm^3 Doxo, 807.1 ± 158.3 mm^3 NE; p=0.0002 for all inter-method comparisons). The corrected volumes (excluding regions of hypocaptation) were 1427.2 ± 390.4 mm^3 (C), 776.4 ± 372.4 mm^3 (Doxo) and 656.8 ± 188.8 mm^3 (NE). There was a statistical difference when comparing the volumes obtained between the ways of analysing, all with a p-value of 0.0002, but no difference was observed between both treated groups. When comparing the results between the groups, the volumes and caliper measurements gave differences of p-value=0.0081 between Doxo and C, and p-value=0.0002 when comparing NE with C. Correlation analysis revealed parallel response curves across methodologies (p>0.05). Hypermetabolic region analysis showed treatment-specific differences (Doxo p=0.0312, NE p=0.0002 vs control), while hypometabolic areas exhibited >85% correlation with total tumor volume across all groups, indicating their significant contribution to tumor progression. ***Conclusion:*** [^{18}F]FDG uptake heterogeneity predicts therapy response in preclinical models, especially for necrotic/large tumors. Our data show hypometabolic expansion correlates with tumor volume. PET surpasses conventional methods, providing crucial data for drug development and personalized chemotherapy. These findings support incorporating PET-based volumetric analysis as a mandatory component in antitumor drug development pipelines to improve clinical translation.

Glioma and brain blood flow quantification using dynamic [^{18}F]FET PET/CT and Tikhonov model-free deconvolution

C. Engkebølle[1], *U. Lindberg*[2], *O. M. Henriksen*[1], *K. Madsen*[3], *T. L. Andersen*[1], *T. Urup*[4], *R. Rasmussen*[5], *H. B. W. Larsson*[2], ***I. Law***[1];
[1]*Department of Clinical Physiology & Nuclear Medicine, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [2]*Functional Imaging Unit, Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital Rigshospitalet, Glostrup, DENMARK,* [3]*Department of Clinical Physiology & Nuclear Medicine, Rigshospitalet, Copenhagen, DENMARK,* [4]*Department of Oncology, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [5]*Department of Neurosurgery, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: The advent of long axial field-of-view (LAFOV) PET/CT enables whole-brain dynamic imaging with high spatiotemporal resolution and novel kinetic modelling strategies. We have evaluated the [^{18}F]FET-derived quantitative estimates of cerebral blood flow (CBF) and blood-brain barrier extraction fraction (E) using Tikhonov-regularised model-free deconvolution in brain tumours and healthy-appearing grey (GM) and white matter (WM). ***Materials and Methods:*** In 12 patients (median age 48, range 22-70, 4M/8F), referred for suspected or confirmed brain tumours or epilepsy, a 40-minute dynamic [^{18}F]FET PET/CT was performed on a Siemens Biograph Vision Quadra. Images were reconstructed with 2-second frames across the bolus injection and modelled using an image-derived input function (1) and Tikhonov model-free deconvolution to derive CBF and E from the residue impulse response function (2). Tumour modelling was performed in patients with metabolic tumour volume (MTV) >10 ml using a tumour-to-background ratio threshold of 1.6. ***Results:*** Perfusion quantification in GM showed an E of 2.54 ± 1.03 % (range: 1.10-4.90), with CBF of 63.6 ± 14.8 ml/100 ml/min. The unidirectional influx constant (K_1) was 1.43 ± 0.30 ml/100 ml/min and mean transit time (MTT) was 32.7 ± 11.5 s. In WM the E was higher at 4.45 ± 1.5 % (2.80-8.60) while CBF and K_1 were lower at 23.1 ± 5.14 ml/100 ml/min and 0.99 ± 0.22 ml/100 ml/min, respectively. MTT was higher at 60.3 ± 21.1 s. In the 6 patients with MTV > 10 ml (range 14 to 123 ml) E was elevated compared to GM, ranging from 4.50 to 11.60 %. CBF ranged from 31.7 to 65.4 ml/100 ml/min, K1 from 2.4 to 6.0 ml/100 ml/min, and MTT from 52.7 to 118.9 s. ***Conclusion:*** Tikhonov-regularised model-free deconvolution using [^{18}F]FET LAFOV PET/CT enables physiologically plausible and consistent quantification of CBF and E in healthy-appearing brain tissue, with clear distinction between GM and WM. The method also permits parameter estimation in metabolically active tumours. While MTT can be derived, it remains an approximation—progressively underestimated at higher extraction due to tracer

retention during acquisition. These findings encourage further evaluation of kinetic parameters beyond standard uptake metrics in dynamic amino acid PET. This approach may also be applied to a wider range of PET tracers to characterise blood-brain barrier transport, CBF and E, thereby increasing the probability of clinical translation. ***References:*** (1) Andersen, T. L., et al Diagnostics (2024). 14(15), Article 1590. (2) Larsson, H. B. W., et al EJNMMI.,(2024). 51(3), 707-720.

EP-0173

Features of PET/CT with fluoroethyltyrosine interpretation after proton radiation therapy of patients with IDH wildtype glioblastoma

E. Gromova, *N. Kataev, D. Susin, Nikolay Vorobyov, Marina Linnik, Natalia Berezina;*
LDC MIBS, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: To identify the features of PET/CT with fluoroethyltyrosine in patients with IDH wildtype glioblastoma who received proton therapy as part of adjuvant chemoradiation treatment. ***Materials and Methods:*** We evaluated 17 PET/CT c FET studies in 13 patients 3-18 (median 5.5, SD 12) months after proton therapy. PET/CT was performed at the decision of the neuro-oncologist for differential diagnosis of radionecrosis and tumor progression. PET-CT was performed according to the standard protocol: scanning 20 min after RFP injection, scanning time 20 min. The evaluation was performed by semi-quantitative method, with TBTmax calculation, as well as with comparison with MRI data and irradiation plans. Radiation therapy was delivered to all patients with a scanning pencil beam using 2 5/13 (38%) or 3 8/13 (62%) fields. In 10/13 (76.9%) cases, at least one of the fields was not coplanar. Two radiation therapy regimens were used: 45 Gray for 15 fractions and 60 Gray for 30 fractions (112.5-120.0 BED) Cases of RFP hyperfixation foci outside the initial volume of high (D95%) dose were considered separately - the zones of their occurrence, correlations between the necrosis site and the direction of proton therapy fields were determined separately. ***Results:*** In total, in 13 primary studies, 6 studies were interpreted as radionecrosis (TBRmax up to 2.4), 2 as disease progression (TBRmax 3.2) , 5 could not be interpreted unambiguously according to current guidelines and required dynamic follow-up. In two cases, we encountered cases of necrosis outside the original high volume (D95%). In both cases two fields were used, in one case coplanar. In both cases, radionecrosis occurred in the paraventricular regions of the lobar lobes (TBRmax 2.3). ***Conclusion:*** 1. TBRmax in cases diagnosed as radionecrosis is higher than in guidelines 2. Comparison with the radiation plan is important. 3. PET/CT before treatment to assess tumor metabolic activity - highly desirable.

EP-0174

Integrated ^{18}F-FET PET/MR-Based Multi-parametric Imaging for Predicting IDH Mutation and MGMT Promoter Methylation in Adult Gliomas

Q. Han[1], *J. Liu*[2], *T. Li*[1], *E. Li*[3], *Z. Lin*[4], *Y. Yang*[3], *X. Guo*[2], *Y. Wang*[2], *H. Xing*[2], *W. Ma*[2], *Y. Wang*[2], *X. Cheng*[1], *L. Huo*[1];
[1]Nuclear Medicine Department, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, CHINA, [2]Department of Neurosurgery, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [3]Beijing United Imaging Healthcare Co., Ltd, Beijing, CHINA, [4]United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA.

Aim/Introduction: Gliomas are among the most common primary tumors of central nervous system (CNS), with high-grade subtypes showing poor prognosis despite standard treatment. The WHO classification of CNS tumors emphasizes molecular profiling, notably isocitrate dehydrogenase (IDH) mutation and O6-Methylguanine-DNA-methyltransferase (MGMT) promoter methylation, for prognostication and therapy guidance. As noninvasive tools for molecular stratification are needed, ^{18}F-FET PET and intravoxel incoherent motion (IVIM) MRI have shown promise in capturing tumor metabolism and heterogeneity. However, the influence of different volume-of-interest (VOI) delineation strategies on biomarkers performance remains unclear. This study aimed to investigate the diagnostic performance of integrated ^{18}F-FET PET/MR for predicting IDH and MGMT status using multi-parametric modeling across various VOI delineation strategies. ***Materials and Methods:*** This retrospective study included 45 patients with histopathologically confirmed gliomas who underwent preoperative integrated ^{18}F-FET PET/MR. Tumor VOIs were semi-automatically delineated from PET (biological tumor volume: BTV; metabolic tumor volumes at 60% and 80% of maximum standardized uptake value: MTV60, MTV80) and MRI (contrast-enhanced T1-weighted imaging: VOI-T1CE; T2 fluid-attenuated inversion recovery: VOI-T2F). PET parameters included maximum and mean tumor-to-background ratio (TBR_{max}, TBR_{mean}), and compartmental uptake ratio ($CU_{60/1.6}$, $CU_{80/1.6}$). A total of 126 IVIM-derived radiomic features were extracted from seven parametric maps: apparent diffusion coefficient (ADC), true diffusion coefficient (D), pseudo diffusion coefficient (D*), perfusion fraction (f), relative blood flow (rBF), distributed diffusion coefficient (DDC), and heterogeneity index (α). Logistic regression models were constructed using both single PET parameter and multi-parametric combinations, with LASSO-based feature selection via LASSO and ROC-based performance evaluation. ***Results:*** Different VOIs significantly affected tumor volume and spatial overlap ($P < 0.001$), with VOI-T2F exceeding BTV in 86.7% of cases. These differences influenced IVIM-derived features distributions. For IDH mutation, the MTV80-based IVIM multi-parametric model achieved the highest diagnostic performance (AUC = 0.937), further improved to 0.962 by adding PET parameters. For MGMT promoter methylation, the best performance was observed in BTV-based IVIM features model (AUC = 0.909), also enhanced with PET parameters integration (AUC = 0.928). TBR_{max} and IVIM-derived diffusion heterogeneity features (e.g., DDC minimum, DDC median) were key discriminative predictors. Univariate analyses confirmed significant groupwise differences in PET and diffusion metrics across molecular subgroups ($P < 0.05$). ***Conclusion:*** Integrated ^{18}F-FET PET/MR with VOI-specific IVIM features enables accurate noninvasive prediction of IDH mutation and MGMT promoter methylation. These findings highlight the clinical utility of integrated PET/MR multi-parametric modeling for molecular stratification and personalized treatment guidance in adult glioma.

Prognostic role of [^{18}F]FET PET/CT: integrating metabolic and molecular data in the management of gliomas

A. Castello[1], *G. A. Zuccotti*[2], *G. Lopez*[3], *G. Fiore*[4], *M. Schiavini*[1], *E. Galli*[1], *M. Arnaboldi*[1], *F. Buffoni*[1], *C. Pettinato*[5], *L. Savio*[6], *M. Locatelli*[4], *M. Caroli*[7], *M. Castellani*[1], *L. Florimonte*[1];
[1]Department of Nuclear Medicine, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, ITALY, [2]Unit of Nuclear Medicine, Aosta Regional Hospital, Aosta, Italy, Aosta, ITALY, [3]Division of Pathology, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, ITALY, [4]Unit of Neurosurgery, IRCCS Ca' Granda Foundation Ospedale Maggiore Policlinico, Milan, ITALY, [5]Medical Physics Unit, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milan, ITALY, [6]Department of Physics "Aldo Pontremoli", University of Milan, Milan, ITALY, [7]Unit of Neurosurgery, IRCCS Ca' Granda Foundation Ospedale Maggiore Policlinico, Milan, ITALY.

Aim/Introduction: Our study aimed to investigate the prognostic role of [^{18}F]FET PET/CT, analyzing metabolic parameters and molecular data in patients with gliomas. ***Materials and Methods:*** This prospective, single-center study included 98 patients

who underwent [18F]FET PET/CT imaging between September 2020 and November 2024. Metabolic parameters, including SUVmax, SUVmean, metabolic tumor volume (MTV), total tumor metabolism (TTM), tumor-to-brain ratio (TBR)max, and TBRmean, were assessed alongside molecular markers, such as IDH mutation, MGMT methylation, and TERTp mutation. Progression-Free Survival (PFS) and Overall Survival (OS) were evaluated using Kaplan-Meier survival analysis, and statistical significance was determined with log-rank tests over a mean follow-up of 15.1±13.7 months. ***Results:*** Patients with IDH wild-type gliomas exhibited higher SUVmax (4.42 vs. 3.32, p=0.019), SUVmean (2.39 vs. 1.82, p=0.014), TTM (25.14 vs. 14.13, p = 0.041) and TBRmax (4.21 vs. 3.22, p=0.046) compared to IDH-mutated gliomas. Moreover, IDH status was significantly associated with OS (14.97 months for IDH wild-type vs 43.86 months for IDH-mutated, p<0.001). in non-methylated MGMT promoter gliomas, metabolic parameters were significantly higher (SUVmax 6.06 vs. 3.51, p=0.008; TBRmean 3.07 vs. 1.97, p=0.018). Astrocytomas IDH-mutated with SUVmax (13.67 months vs 7.57 months, p=0.055), SUVmean (13.67 months vs 7.57 months, p=0.055), TBRmax (13.67 monthsvs 7.57 months, p=0.061), and TBRmean (18.7 months vs 7.97 months, p=0.026) above the median had a shorter PFS. On the other hand, in high-grade astrocytomas SUVmax, SUVmean, TBRmax and TBRmean below the median values were significantly associated with longer PFS. In patients with oligodendroglioma, TBRmax and TBRmean below the median value were associated with longer PFS (medianPFS 27.87 vs 10.88, p=0.024), Finally, glioblastomas with MGMT promoter methylation and TBRmax above the median exhibited shorter PFS (22.43 vs. 11.67 months, p=0.038). In this last group, TERTp mutation was associated with poorer PFS (11.67 vs. 31.77 months, p=0.035) and OS (14.9 vs. 19.9 months, p=0.043). ***Conclusion:*** [18F]FET PET parameters were associated with tumor grading and molecular profile, expressed by IDH status and MGMT methylation. In addition, SUVmax, SUVmean, TBRmax, TBRmean were prognostic factors for PFS both in astrocytomas IDH-mutated and high grade gliomas, whereas only TBRmean was prognostic in glioblastoma with MGMT promoter methylation. [18F]FET PET seems to offer valuable insights for glioma patients and whether integrated into clinical routine could aid clinicians for a better individualized glioma management. ***References:*** doi: 10.1016/j.radonc.2024.110386. doi: 10.1093/neuonc/noae208.

EP-0176

Improved AI Reporting of Amyloid PET with Location-Based Centiloids

B. Schemmer*;*
Katholisches Klinikum Bochum, Bochum, GERMANY.

Aim/Introduction: Quantification is an important part of assessment of Amyloid PET for the diagnosis of Alzheimers. However in general a global Centiloid value for the whole brain and corresponding reference regions is used. It is known that acquisition time and other parameters influence uptake in the reference regions as well as the brain structures themselves in a location specific manner. ***Materials and Methods:*** We developed a small AI based system that can segment the different brain regions using the CerebrA template and consider regional as well as acquisition based differences for each participant. ***Results:*** We found that a small system of interconnected AIs with at most 3-level deep binary classifiers was sufficiently complex to accommodate our problem. The AIs were trained independently on a standard thin client within minutes without the use or necessity for GPUs. We trained with a small collective of 20 patients from AMYPAD consortiums amyloid PET database limiting ourselves to patients that were sufficiently distinct when using the global Centiloid score (0-100 in steps of 5) with a total of 20 image slices per patient as well as 20 patients for which acquisition parameters are known precisely from our previous AI. An additional AI system was trained to localize brain regions according to the CerebrA atlas. ***Conclusion:*** The current system can classify the regions of amyloid deposition correctly and provide regional Centiloid values. In comparison to our previous fast AI classification system for automated Amyloid PET reporting, this current version can consider acquisition parameters, reducing uncertainty and improving comparability between sites and follow-up examinations. The speed of the system is slightly lower due to the increased number of AIs working in unison, however there is still no need for sophisticated hardware and reporting per patient can be finished in less than 100 ms per patient. ***References:*** Collij et. al.: Quantification Supports Amyloid PET Visual Assessment of Challenging Cases: Results from the AMYPAD Diagnostic and Patient Management Study. EP-0177

Ga-68 PSMA-11 PET/CT in High-Grade Glioma Recurrence: Imaging, Prognosis, and Theranostic Implications

V. Arunachalam Ragupathi*, N. Damle, M. Tripathi, S. Shamim, V. Tandon, K. Haresh, S. Bharati, A. Kumar, S. Gupta, A. Singhal, S. Rastogi, A. Mohan;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: High-grade gliomas (HGG) are aggressive primary brain tumors with a high propensity for recurrence despite multimodal treatment. Prostate-specific membrane antigen (PSMA) has shown promising results in glioma imaging. This study aimed to assess Ga-68 PSMA-11 uptake in patients with suspected recurrent HGG using PET/CT imaging, with a view toward its potential application in PSMA-targeted theranostics. ***Materials and Methods:*** Patients with clinically and radiologically suspected recurrent HGG following surgery and chemoradiotherapy were prospectively enrolled. All participants underwent Ga-68 PSMA-11 PET/CT imaging 45-60 minutes after tracer injection, including whole-body and dedicated brain acquisitions. Lesion uptake was evaluated visually and semiquantitatively using a five-point Likert scale relative to liver and parotid gland uptake: 1 = no uptake, 2 = less than liver, 3 = equal to liver, 4 = greater than liver but less than parotid, and 5 = equal to or greater than parotid. Lesions with uptake more than or equal to liver were considered potentially suitable for PSMA-targeted therapy. Survival analysis stratified based on the lesion uptake (SUVmax). ***Results:*** Of the 24 enrolled patients (14 males, 10 females; median age 43 years, range 28-69), PSMA-avid lesions were identified in 21 patients (87.5%). Among these, 18 patients (85.7%) exhibited high PSMA expression (Likert score 4), while 3 demonstrated moderate uptake (Likert score 3). The median SUVmax and SUVmean for tumor lesions were 2.65 (IQR: 1.57-3.50) and 1.6 (IQR: 0.4-4.7), respectively. Five patients were lost to follow-up. Among the 19 remaining patients, the median survival was 4 months, and SUVmax >3.5 was significantly associated with poorer survival. Additionally, PSMA uptake correlated with regions of suspected recurrence on MRI, enhancing lesion visibility. ***Conclusion:*** Ga-68 PSMA-11 PET/CT reliably identifies PSMA expression in recurrent HGG, may help differentiate true tumor recurrence from post-treatment changes and predicts survival with higher SUVmax portends poorer prognosis, while targetable uptake supports PSMA-directed theranostics, offering a dual diagnostic-therapeutic strategy for this challenging disease context.

EP-0178

Amino Acid PET/CT in Assessing EGFR Gene Expression in CNS Gliomas

N. Vikhrova[1], *D. Kalaeva*[1,2], *S. Drozd*[1], *O. Kalennik*[1], *G. Pavlova*[1,3], *I. Pronin*[1];
[1]*National Medical Research Center for Neurosurgery named after N.N. Burdenko, Moscow, RUSSIAN FEDERATION,* [2]*National Research Nuclear University MEPhI, Moscow, RUSSIAN FEDERATION,* [3]*Institute of Higher Nervous Activity and Neurophysiology, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: The molecular and genetic features of CNS gliomas, as outlined in the 2021 WHO classification, present a significant challenge for radiologists - the non-invasive prediction of tumor biological behavior on primary amino acid PET/CT data. Epidermal growth factor receptor (EGFR) is one of the significant prognostic factor in guiding treatment decisions in glioma patients, after IDH-mutation. That prompted us to compare the data of morphological characteristics EGFRwt gene expression with CNS tumor metabolic characteristics. ***Materials and Methods:*** 71 adult patients with glial tumors (WHO 2021): glioblastoma (n=52), astrocytoma Grade3 (n=11) and oligodendroglioma Grade3 (n=8) were underwent static ^{11}C-methionine (n=41) and ^{18}F-FET (n=30) PET/CT. Tumor-to-brain ratio (TBR), metabolic tumor volume (MTV) were estimated in a standard way. MTV segmentation reference for both tracers was TBR=1,6. Metabolic data were compared with EGFRwt/EGFRvIII gene expression determined by PCR. ***Results:*** According to our data comparative analysis of EGFRwt gene expression in glioma with control group revealed significantly higher levels in glioblastomas with lower expression observed in oligodendrogliomas and astrocytomas. Significant positive correlation was found between level of EGFRwt gene expression and MTV (Rs=0.44, p=0.02). Moderate negative correlation between metabolic activity (TBR) and EGFRwt gene expression levels was detected in small astrocytoma group (n=11, Rs = -0,64, p=0,04). While there were no significant correlations in glioblastomas or oligodendrogliomas, this is likely due to high EGFRwt variability. EGFRvIII gene expression was detected in 25% gliomas (n=13, all glioblastomas), however, contrary to expectations, it doesn't show an association with metabolic parameters, possibly due to the small number of patients. ***Conclusion:*** High EGFR expression is generally associated with poor prognosis. Our findings demonstrate distinct EGFRwt gene expression patterns across glioma subtypes. The correlation between the level of EGFRwt gene expression and MTV indicating potential role of metabolic parameters on PET/CT as a prognostic markers, but further data collection and survival analysis are needed. The clinical implementation of EGFR blockade therapies has become a hallmark example of personalized targeted treatment and serving as a model for developing similar strategies in neuro-oncology. ***References:*** Oprita, A. et al. Updated Insights on EGFR Signaling Pathways in Glioma. Int. J. Mol. Sci. 2021,22(2):587.

EP-0179

Amino-acid PET imaging to monitor mIDH inhibitors treatments in patients with refractory IDH-mutant gliomas

G. Stien[1], *T. Obara*[2,3], *M. Blonski*[2,3], *L. Taillandier*[2,3], *A. Verger*[1,4,5];
[1]*Department of Nuclear Medicine, CHRU of Nancy, Nancy, FRANCE,* [2]*Department of Neurology, Neurooncology Unit, CHRU Nancy, Nancy, FRANCE,* [3]*Centre de Recherche en Automatique de Nancy CRAN, UMR 7039, Université de Lorraine, CNRS, Nancy, FRANCE,* [4]*IADI, U1254, Inserm, Université de Lorraine, Nancy, FRANCE,* [5]*Nancyclotep Imaging Platform, Université de Lorraine, Nancy, FRANCE.*

Aim/Introduction: Mutant IDH (mIDH) inhibitors represent a novel therapeutic approach for IDH-mutant gliomas. This study aims to evaluate the role of amino acid PET imaging in monitoring the response to mIDH inhibitor treatment in patients with refractory IDH-mutant gliomas, in comparison to conventional MRI. ***Materials and Methods:*** Patients with confirmed IDH-mutant gliomas who received ivosidenib or vorasidenib between February 2022 and November 2024, and who had a baseline ^{18}F-FDOPA PET scan available, were included in this study. All patients had received at least one prior line of systemic therapy. Lesions were assessed using RANO 2.0 and PET RANO criteria to determine measurability and, in patients with early follow-up imaging, to predict 6-month progression-free survival (PFS-6). ***Results:*** Twenty-two patients were included (mean age: 42.1 ± 10.5 years; 8 women; 14 with IDH-mutant astrocytomas). Among them, 11 underwent early follow-up imaging with both MRI and PET within the first 100 days of treatment. At baseline, MRI identified measurable lesions in 10 of 22 patients (45%), while amino acid PET identified lesions in 20 of 22 patients (91%) ($p < 0.01$). In patients with early follow-up, RANO 2.0 criteria predicted PFS-6 with 91% accuracy (10/11), compared to 82% accuracy (9/11) with PET RANO (not statistically significant). The only discordant case showed progression on PET but stability on MRI, with confirmed clinical progression at 10 months post-treatment initiation. ***Conclusion:*** Amino acid PET is a valuable tool for monitoring treatment with mIDH inhibitors in patients with refractory IDH-mutant gliomas, demonstrating performance at least comparable to that of MRI. Additionally, amino acid PET detects a greater number of measurable lesions than MRI, highlighting its complementary role in the treatment monitoring of IDH-mutant gliomas. ***References:*** 1. Mulit-Pinhole SPECT/CT in Meningioma Imaging: A New Diagnostic Perspective

G. Sipka[1], *K. Apro*[1], *A. Dobi*[2], *K. Hideghety*[2], *M. Balazsfi*[3], *P. Barzo*[3], *M. Szolikova*[4], *L. Pavics*[1], *Z. Besenyi*[1];
[1]*University of Szeged, Department of Nuclear Medicine, Szeged, HUNGARY,* [2]*University of Szeged, Department of Oncotherapy, Szeged, HUNGARY,* [3]*University of Szeged, Department of Neurosurgery, Szeged, HUNGARY,* [4]*Mediso Medical Imaging Ltd., Budapest, HUNGARY.*

Aim/Introduction: Meningiomas represent the most prevalent type of adult brain tumors. Despite their frequently benign nature and slow growth rate, these tumors exhibit a high rate of recurrence. The increased expression of the somatostatin receptor type 2 (SSTR 2) has led to the development of somatostatin analogues as targeted diagnostic and therapeutic modalities. This prospective study aims to evaluate and compare the diagnostic performance of SSTR SPECT/CT using both parallel-hole (PH) and multi-pinhole (MPH) collimators against the current gold standard MRI in patients with clinically progressive, histologically confirmed Grade I-III meningiomas. ***Materials and Methods:*** A total of 13 patients underwent SSTR-targeted SPECT/CT imaging with 99mTc-EDDA-HYNIC-TOC, utilizing a multi-pinhole collimator followed consecutively by a parallel-hole collimator acquisition. The resulting SPECT/CT scans were co-registered with contrast-enhanced T1-weighted MRI, with tumor delineation based on the MR images. A comparative analysis was conducted among the three imaging modalities in terms of lesion number, extent, and bone involvement. Semi-quantitative analysis was also performed, including assessment of lesion uptake (SUVmax, SUVmean) and tumor-to-background ratios (TBR). ***Results:*** MPH-SPECT/CT identified a total of 22 lesions, compared to 19 foci detected by contrast-enhanced MRI (86%) and only 16 lesions by parallel-hole

SPECT/CT (73%). The pathological confirmation of all 22 lesions was attained during the follow-up period (minimum 6 months) through the use of subsequent MRI or histological analysis. The use of MRI revealed the presence of multinodular meningiomas in three patients, while MPH-SPECT/CT led to the detection of two additional cases. Furthermore, MPH-SPECT/CT exhibited a marked increase in the extent of osseous involvement, identifying bone infiltration in nine lesions, in contrast to the four detected by MRI. Semi-quantitative analysis revealed significantly higher tracer uptake and tumour-to-background ratios in MPH studies relative to parallel-hole acquisitions (SUVmean: p = 0.001; SUVmax: p = 0.002; paired t-test). ***Conclusion:*** Our findings suggest that MPH-SSTR-SPECT/CT not only offers high diagnostic accuracy in the detection of meningiomas, but may also outperform contrast-enhanced MRI in evaluating lesion multiplicity and bone involvement. These results underscore the potential of advanced SPECT techniques to bridge the diagnostic gap between conventional SPECT and PET imaging. MPH-SPECT/CT may represent a viable alternative to PET in specific clinical scenarios, warranting further comparative studies.

EP-0181

Utility of Dynamic [^{68}Ga]Ga-PSMA PET/CT in post-surgical high-grade gliomas: An insight on preliminary Analysis

M. Usmani, *K. al Riyami, S. Hashmi, A. Jain, S. Kheruka, V. Jayakrishnan, A. al busaidi, Z. Al-Mandhari;*
Sultan Qaboos Comprehensive Cancer Care and Research Center (SQCCCRC), University Medical City, Muscat, OMAN.

Aim/Introduction: High-grade gliomas (HGG) are aggressive brain tumors that arise from the glial cells in the brain. Accurate post-surgery detection of residual gliomas is vital for managing HGG and guiding treatment, including radiotherapy. Previous research demonstrates PSMA expression in neovascularization related to these tumors. The aim of this study is to assess the feasibility of early dynamic [^{68}Ga]Ga-PSMA PET/CT in detecting residual gliomas. ***Materials and Methods:*** A total 9 patients (mean age, 46±9.7 years) with HGG post resection underwent dynamic [^{68}Ga]Ga-PSMA PET/CT with an activity of 2.2MBq/kg. Dynamic images were acquired over the skull with a frame time of 20 sec for 10 min for extraction of time-activity curves (TACs) within selected volumes of interest. Static images of 10 min per bed position were acquired at 60 min post injection. ***Results:*** All patients showed high target to non-target ratio in the early dynamic images comparable to that seen on the delayed images. SUVmax of the glioma lesion was significantly higher than that of background throughout the dynamic study at all time points (P <0.001). In dynamic images the glioma lesions have radioactive concentration of 4.06±1.43 KBq/ml and SUV max 3.21±0.97 in comparison with contralateral brain parenchyma 0.40±0.49 KBq/ml and SUV max 0.16±0.22. Static images showed more tracer accumulation than dynamic images in the residual tumor. On delayed static images glioma lesions showed SUVmax 5.65±1.5 and SUV mean 3.08±0.85. The tumor to background brain ratio was 58.8±15.23. Semi-quantitative analyses show PSMA-tumor volume (TV)= 19.1±15.0cm^3 and total tumor burden (T PSMA burden)= 52.63±44.6. Preliminary findings suggest that dynamic [^{68}Ga]Ga-PSMA PET show excellent visualization of glioma lesions and provides valuable complementary information in the imaging of residual high-grade gliomas. ***Conclusion:*** Our initial experience suggests that dynamic [^{68}Ga]Ga-PSMA PET offer additional characterizing of tumor angiogenesis. Moreover, it allows quantitative assessment of perfusion and PSMA expression in high grade glioma. Early dynamic images may be conducted in combination with the routine 60 min static acquisition in patients with high grade gliomas. Further investigation with larger cohorts and correlation with clinical outcomes is warranted to validate these initial findings.

EP-0182

Meningioma Risk Stratification: Association Between Molecular-Morphologic Score and Somatostatin Receptor Expression on PET Imaging.

A. Chaban[1], *O. Kertels*[2], *C. Ertelt-Delbridge*[3], *D. Bernhardt*[4], *F. Schmidt-Graf*[5], *B. Wiestler*[2], *C. Negwer*[6], *I. Yakushev*[1];

Aim/Introduction: The recently proposed integrated molecular-morphologic meningioma score (MMS) has demonstrated superior predictive value for tumor recurrence compared to conventional WHO grading. This study investigates, for the first time, the association between MMS and somatostatin receptor (SSR) expression as quantified by PET imaging. ***Materials and Methods:*** Our institutional database was searched for patients who underwent postoperative SSR-PET imaging for residual meningioma assessment and for whom MMS data were available. Only patients with measurable residual tumor as defined by established routines - isocontour volume-of-interest (40% SUVmax threshold) with a minimum volume of 0.5 ml - were included. PET-derived parameters included unscaled SUVmax, SUVmean as well as their ratios scaled to the superior sagittal sinus and contralateral meninges. ***Results:*** Thirty patients were included, all diagnosed with WHO grade 2 meningioma. Based on MMS, patients were stratified into low- (n=4), intermediate- (n=19), and high-risk (n=7) groups. Most PET parameters were non-normally distributed (Kolmogorov-Smirnov test, p<0.05). All PET parameters showed a positive correlation with MMS (p<0.05), with the strongest association observed for unscaled SUVmax of meningiomas (Spearman's r = 0.64, p<0.001). ***Conclusion:*** Our findings reveal a significant, positive associationbetween the molecular-morphologic properties and SSR expression on PET imaging. These results support the potential of PET-based biomarkers to improve risk stratification and guide personalized treatment strategies. Further data collection is ongoing to define clinically meaningful PET-based thresholds.

Aim/Introduction: Few systematic data exist on the use of positron emission tomography (PET) among brain tumour centers in Europe. ***Materials and Methods:*** From June 2024 to August 2024, a cross-sectional survey was conducted among European Organisation for Research and Treatment of Cancer - Brain Tumour Group (EORTC-BTG) sites to gain insights into the availability and use of PET across brain tumor centers in Europe. ***Results:*** Out of the 312 invited sites, 103 replies were received from 20 countries. PET was available at 96/103 (93.2%) sites, and 74 of these reported PET use in patients with brain tumours. Glioma was the entity in which PET was most frequently performed (69/74, 93.2%), followed by brain metastasis (58/74, 78.4%), meningioma (52/74, 70.3%), and CNS lymphoma (46/74, 62.2%). Amino acid PET was used at 62/71 sites (87.3%), predominantly in glioma (58/59, 98.3%) and for differentiating treatment-related changes from tumor progression (58/59, 98.3%). Use of dynamic acquisition protocols was reported by 35/59 (59.3%) centres, and most sites reported use of [^{18}F]FET as amino acid tracer (45/59, 76.3%), followed by [^{18}F]FDOPA (22/59, 37.3%) and [^{11}C]methionine (15/59, 25.4%). Somatostatin receptor (SSTR) PET was applied at 50/68 sites (73.5%), predominantly in meningioma (48/49, 98.0%), and mainly for patient selection before radioligand therapy (41/49, 83.7%) as well as for target volume definition in radiotherapy (33/49, 67.3%). According to self-reported information, PET was covered by statutory health insurance at 46/59 (78.0%) centers for amino acid PET and 33/49 (67.3%) for SSTR PET. Reasons for not using PET in clinical routine included limited availability of tracers (14/29, 48.3%), high cost (11/29, 37.9%), and a perceived lack of added value (8/29, 27.6%). ***Conclusion:*** Overall, PET is already widely used among EORTC BTG sites, although non-response and selection biases must be considered in the interpretation of survey results. While these findings support the implementation of PET-based endpoints in clinical trials, comprehensive surveys also covering non-academic centers would be needed to guide further implementation in clinical routine.

EP-0184

Diagnostic accuracy of FET-PET/CT for the differential diagnosis of recurrent brain metastases versus radionecrosis

N. Testart Dardel, *N. Schilliger, K. Auf Der Springe, M. Nicod-Lalonde, N. Schaefer, J. Prior, M. Jreige;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: O-(2-18F-fluoroethyl)-L-tyrosine (FET) PET/CT is a well-known complementary tool for the follow-up of brain gliomas. However, less evidence exists for irradiated brain metastases with doubtful MRI. We aimed to review our center's experience with digital FET PET/CT as an additional tool in the follow-up of brain metastases for differentiating between tumor recurrence and radiation necrosis (RN), and to determine its diagnostic accuracy. ***Materials and Methods:*** Retrospective analysis of consecutive n=29 patients with previously irradiated brain metastases in the last 5 years and who underwent a FET-PET/CT in a digital device, with subsequent MRI and follow-up at CHUV. We performed semiquantitative measurements at the lesion-level (SUVmax, SUVmean, tumor-to brain ratios TBRmax, TBRmean using contralateral normal brain's SUVmean). Diagnostic accuracy was determined using the literature's TBRmax cutoff of 3.11*. Receiver operating characteristic (ROC) curves were analyzed to derive the optimal TBRmax threshold in our population. The final diagnosis was determined on a per lesion basis using either biopsy or >3-month imaging follow-up. ***Results:*** We performed a per-lesion analysis (n=74) with a final diagnosis of 29 metastases and 45 RN, established by histology (n=13) or by MRI (6-month median follow-up, n=61). Metastases demonstrated significantly higher values than RN for SUVmax (5.3±1.0 vs. 3.7±1.0), SUVmean (2.8±0.8 vs. 2.2±0.6), TBRmax (3.8±0.9 vs. 2.5±0.7), and TBRmean (2.0±0.5 vs. 1.5±0.4) (all p<0.001). The previously reported TBRmax=3.11 cutoff value was confirmed as optimal in our study population, achieving a 81% [95%CI 58-93] sensitivity, 89% [71-97] specificity, and area under the curve (AUC) 0.89 [0.78-0.96] for distinguishing metastases from RN. ***Conclusion:*** We achieved high accuracy of FET-PET/CT in the follow-up of patients with irradiated brain metastases with an optimal cutoff value of TBRmax = 3.11 in our digital PET/CT device. ***References:*** Lohmann et al. Radiation injury vs. recurrent brain metastasis: combining textural feature radiomics analysis and standard parameters may increase 18F-FET PET accuracy without dynamic scans. ^{68}Ga-FAPI-04 PET/CT For Predicting Pathological Response of Cervical Lymph Node Metastases to Neoadjuvant Chemoimmunotherapy in Locally Advanced Oral Squamous Cell Carcinoma

Y. Jiang[1], *Z. Yu*[2], *Y. Sun*[3], *L. Wang*[3], *J. Jia*[2], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Oral and Maxillofacial Surgery, School and Hospital of Stomatology, Wuhan University, Wuhan, CHINA,* [3]*Department of Pathology, School and Hospital of Stomatology, Wuhan University, Wuhan, CHINA.*

Aim/Introduction: Nonspecific lymph node uptake on ^{18}F-FDG PET/CT following immunotherapy has emerged as a diagnostic

challenge in nodal restaging. FAPI-based radiotracers have shown excellent diagnostic specificity for lymph node metastasis in head and neck cancer. This study aimed to investigate the performance of ^{68}Ga-FAPI-04 PET/CT in restaging cervical lymph nodes after neoadjuvant chemoimmunotherapy (NACI) in patients with locally advanced oral squamous cell carcinoma (LAOSCC). ***Materials and Methods:*** Twenty treatment-naïve patients with LAOSCC (clinical stage III-IVA) underwent two cycles of NACI followed by radical surgery. ^{68}Ga-FAPI-04 PET/CT was performed at baseline and after the second cycle of NACI, prior to surgery. Cervical lymph nodes were categorized as pathologic complete response (pCR) and non-pCR based on postoperative histopathology. The maximum standardized uptake value (SUVmax) of visually identified FAPI-avid cervical lymph nodes was measured, and the percentage change (ΔSUVmax, %) between baseline and post-NACI scans was calculated. PET parameters were compared between the pCR and non-pCR groups and further analyzed to assess their correlation with pathologic response. FAPI PET-based nodal restaging was also evaluated, with pathologic findings as the reference standard. ***Results:*** A total of 789 lymph nodes were resected from the 20 enrolled patients, with 53 histologically confirmed as metastatic lymph nodes. In lesion-based analysis, 13 lymph nodes from 9 patients demonstrated pCR. These lymph nodes demonstrated a significantly lower post-NACI SUVmax (2.78 ± 1.81) compared with baseline values (10.12 ± 5.99, P = 0.001). In contrast, non-pCR lymph nodes showed no significant difference between baseline and post-NACI SUVmax (8.61 ± 4.91 vs 9.10 ± 4.15, P = 0.462). The absolute ΔSUVmax was significantly greater in pCR nodes than showed in non-pCR nodes (-70.53% ± 10.77 vs 3.99%, [−50.23%, 418.67%]; P < 0.001). Baseline SUVmax showed no significant correlation with pathologic response (r = 0.133, P = 0.390). In contrast, both post-NACI SUVmax (r = −0.630, P < 0.001) and ΔSUVmax (r = −0.468, P = 0.001) demonstrated significant negative correlations with pathologic response. In the 20 enrolled patients, FAPI PET-based restaging of cervical lymph nodes demonstrated histopathologic concordance in 16 cases (80%). Notably, post-NACI PET revealed no new ipsilateral FAPI-avid lymph node, unlike FDG, which often shows such findings that are rarely indicative of disease progression or metastasis. ***Conclusion:*** ^{68}Ga-FAPI-04 PET/CT demonstrated high diagnostic accuracy in nodal restaging after NACI and showed potential for evaluating the therapeutic response of cervical lymph nodes in LAOSCC patients.

EP-0187

Predictive value of ^{68}Ga-FAPI-04 PET/CT for assessing pathologic response to neoadjuvant chemoimmunotherapy in locally advanced resectable oral squamous cell carcinoma

Y. Jiang[1], *J. Jia*[2], *Z. Yu*[2], *Y. Sun*[3], *Y. Tian*[1], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Oral and Maxillofacial Surgery, School and Hospital of Stomatology, Wuhan University, Wuhan, CHINA,* [3]*Department of Pathology, School and Hospital of Stomatology, Wuhan University, Wuhan, CHINA.*

Aim/Introduction: This study aimed to investigate the predictive value of ^{68}Ga-FAPI-04 PET/CT for assessing pathologic response to neoadjuvant chemoimmunotherapy (NACI) in patients with resectable locally advanced oral squamous cell carcinoma (LAOSCC). ***Materials and Methods:*** Thirty-one treatment-naïve patients with pathologically confirmed OSCC and clinically staged locally advanced disease (stage III-IVA) were prospectively enrolled. Among them, twenty patients completed two cycles of NACI, consisting of anti-PD-1 antibody combined with albumin paclitaxel and cisplatin, followed by radical surgery. ^{68}Ga-FAPI-04 PET/CT was performed at baseline and after the second cycle of NACI, immediately prior to surgery, to assess treatment response. Patients were categorized into major pathological response (MPR) and non-MPR groups based on postoperative histopathological results. Semiquantitative PET parameters for the primary tumour, SUVmax, SUVmean, SUVpeak, and their percentage changes (ΔSUVs, %) were recorded. These parameters were compared between the two groups, and their correlation with pathologic response, PD-L1, fibroblast activation protein (FAP), granzyme B (GZMB) expression, and CD8+ T cells infiltration in the tumour tissues was also analyzed. ***Results:*** Twenty patients were included in the final analysis. Eight patients (40.0%) achieved MPR, including 6 with pathologic complete response (pCR), while 12 patients (60.0%) were categorized as non-MPR. The average preoperative SUVmax was significantly lower in the MPR group (9.38 ± 2.60) compared with that in the non-MPR group (16.20 ± 5.23; P = 0.003), while baseline SUVmax was not significantly different (P = 0.053). The absolute ΔSUVmax value in the MPR group (−59.10% ± 13.33) was notably higher than that in the non-MPR group (−15.96%, [−52.56%, 66.33%]; P = 0.002). Preoperative SUVs and ΔSUVs were significantly associated with pathologic response. FAP expression positively correlated with preoperative SUVs, and the MPR group demonstrated higher expression of CD8 and GZMB compared to the non-MPR group. ***Conclusion:*** ^{68}Ga-FAPI-04 PET/CT parameters are able to well predict the achievement of MPR following NACI in patients with LAOSCC. ΔSUVs are identified as significant predictors of MPR. These findings warrant validation in larger cohorts.

Imaging-Detected Lymph Node Metastases (iLNM) and Extranodal Extension (iENE) as Prognostic Factors in HPV-Related Oropharyngeal Squamous Cell Carcinoma: FDG-PET/CT and Node-RADS-Based Evaluation

S. Tsukamoto*, S. Koyasu, C. Suzuki, K. Nakatani, Y. Kishimoto, Y. Nakamoto;*
Kyoto University Hospital, Kyoto, JAPAN.

Aim/Introduction: Human papillomavirus (HPV)-positive oropharyngeal squamous cell carcinoma (OPSCC) is established as a distinct entity in the 8th edition of the UICC TNM classification. While extranodal extension is an adverse prognostic factor in HPV-negative (p16-negative) OPSCC, it is not incorporated in the HPV-positive (p16-positive) OPSCC staging system. Furthermore, there is a discrepancy between pathological and clinical N staging in p16-positive OPSCC: pathology is based merely on the number of lymph node metastases (0, 1-4, or 5-), while clinical staging is mainly based on laterality and size. This study aimed to investigate the prognostic value of the imaging-detected lymph node metastases (iLNM), which we defined by the combination of FDG-PET/CT and Node-RADS (1), and extranodal extension (iENE) in patients with HPV-positive OPSCC. ***Materials and Methods:*** We retrospectively included consecutive patients with p16-positive OPSCC treated at Kyoto University Hospital between January 2014 and December 2024. Patients with recurrent disease or without pre-treatment FDG-PET/CT were excluded. Two readers evaluated images and measured SUVmax of each suspicious lymph node. iLNM was defined as the number of lymph nodes with SUVmax ≥3.5 (2) or Node-RADS score ≥3. iENE was assessed according to Head and Neck Cancer International Group criteria (3). Cox proportional hazards regression was used for univariable and multivariable analyses of overall survival (OS) and event-free survival (EFS: recurrence or death from the index cancer). Additionally, each case was dichotomized based on the highest SUV value (cutoff: 10.2) among the lesions. ***Results:*** Sixty-nine patients were analyzed. The OS and EFS rates were 84.0% and 81.2%, respectively. SUVmax ≥10.2 (HR 1.6; 95%CI: 0.5-5.5; p=0.45) did not show statistical significance in OS and EFS. In univariable analysis, iLNM ≥5 (HR 6.7; 95%CI: 1.8-24.6; p=0.004) and higher cStage (II or III, HR 3.8; 95%CI: 1.1-13.3; p=0.03) were significantly associated with worse OS. In multivariable analysis, iLNM ≥5 remained an independent prognostic factor in OS (HR 4.7; 95%CI: 1.2-18.3; p=0.02). Regarding EFS, iLNM ≥5 (HR 4.5; 95%CI: 1.4-14.8; p=0.01) and iENE grade ≥2 (HR 3.5; 95%CI: 1.1-11.5; p=0.04) were significant in univariable analysis, but not in multivariable analysis. ***Conclusion:*** The imaging parameter iLNM, defined by FDG-PET/CT and Node-RADS, was an independent predictor of

OS in patients with p16-positive OPSCC. iLNM ≥5 and iENE grade ≥2 were also poor prognostic factor in EFS in univariable analysis. ***References:*** 1. Elsholtz FHJ, et al. Eur Radiol. 2021;31:6116.2. Subramaniam RM, et al. J Nucl Med. 2022;63:1887.3. Henson C, et al. Lancet Oncol. 2024;25:e297.

^{18}F-PSMA and ^{18}F-FDG PET/CT in Head and Neck Squamous Cell Carcinoma: A comparative Analysis

V. Heringer, *H. S. V. Sousa, L. T. Macedo, N. A. A. Silveira, S. Kuba, C. S. P. Lima, C. D. Ramos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: ^{18}F-fluorodeoxyglucose PET/CT is widely used for staging and monitoring Head and Neck Squamous Cell Carcinoma (HNSCC). However, its specificity is limited due to false-positive findings from inflammatory processes. PET/CT with Prostate-Specific Membrane Antigen (PSMA) has been investigated as an alternative to ^{18}F-FDG PET/CT due to its expression in tumor neovasculature; however, its role in HNSCC remains unclear. This study aimed to evaluate ^{18}F-PSMA-1007 PET/CT uptake patterns in HNSCC in comparison to ^{18}F-FDG PET/CT, exploring their potential for tumor characterization, staging, and monitoring. ***Materials and Methods:*** Patients with locally advanced HNSCC, either at initial diagnosis or with recurrent disease, were included. Individuals who had undergone surgical tumor resection or received chemotherapy and/or radiotherapy within the previous six months were excluded. All participants underwent both ^{18}F-FDG PET/CT and ^{18}F-PSMA-1007 PET/CT imaging, with a 24-hour interval between scans. Image interpretation was independently performed by two nuclear medicine physicians and one radiologist. ***Results:*** Fourteen patients (11 male) with a median age of 61 (49-81) years were studied. Most patients were current or former smokers and alcohol consumers, had good performance status (ECOG 0), and presented with stage IV tumors. The primary tumors were located in the oropharynx, larynx, and oral cavity, with one sinonasal tumor. Recurrences were observed in locoregional lymph nodes, lungs, and bones. HNSCC lesions were typically characterized by FDG uptake, although most lesions also exhibited varying degrees of PSMA uptake. In primary tumors and nodal disease, the mean ± SD and median (range) SUV values obtained with FDG PET/CT at 1 hour were 25.6 ± 16.4 and 21.0 (10.7-59.8), and 11.7 ± 7.7 and 8.6 (2.7-26.4), respectively. For PSMA PET/CT, the mean ± SD and median (range) SUV values at 1 hour in primary tumors and nodal disease were 4.5 ± 1.3 and 4.3 (2.9-6.3), and 4.9 ± 2.6 and 3.9 (2.8-10.2), respectively. FDG uptake values were higher than PSMA uptake values in primary tumors ($P < 0.001$) and lymph nodes ($P = 0.01$). ***Conclusion:*** ^{18}F-FDG demonstrates superior sensitivity in detecting HNSCC tumor activity. However, frequent ^{18}F-PSMA uptake indicates concurrent glycolytic metabolism and neoangiogenesis, supporting a possible complementary role of integrating ^{18}F-FDG and ^{18}F-PSMA PET in tumor assessment. More pronounced PSMA expression in select cases suggests potential use of PSMA-targeted theranostics and anti-angiogenic therapies. Further studies are needed to clarify the clinical significance of PSMA expression and angiogenesis in HNSCC biology.

Prognostic Assessment in Nasopharyngeal Carcinoma Patients without distant metastases: Development and Validation of a Multidimensional Prognostic Nomogram integrating ^{18}F-FDG PET/CT Parameters, Inflammation Markers, and Clinical Characteristics

Y. Lv[1,2,3], *D. Zheng*[1,2,3], *R. Wang*[4], *Z. Zhou*[1,2,3], *Z. Dai*[1,2,3], *S. Wei*[1,2,3], *Z. Gao*[1,2,3], *X. Lan*[1,2,3], *C. Qin*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA,* [4]*Department of Radiology, The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, CHINA.*

Aim/Introduction: To investigate and compare the prognostic significance of ^{18}F-FDG PET/CT quantitative parameters and develop a comprehensive nomogram prediction model by integrating blood inflammatory markers and clinicopathological characteristics in stage I-IVa nasopharyngeal carcinoma (NPC) patients. ***Materials and Methods:*** Data of 86 stage I-IVa NPC patients who underwent ^{18}F-FDG PET/CT before treatment between 2018 and 2019 were retrospectively collected. We analyzed ^{18}F-FDG PET parameters of the primary tumor and clinicopathologic parameters, including traditional PET parameters (SUVmax, SUVmean, SUVpeak, MTV, and TLG), heterogeneity indices (CV40% = SD of SUV/SUVmean; HI = SUVmax/SUVmean; and HF, calculated as the derivative of the volume-threshold function from 30% to 50%), blood inflammatory markers (systemic immune-inflammation index SII, systemic inflammation response index SIRI, and neutrophil-to-lymphocyte ratio NLR), and clinical characteristics (age, gender, TNM staging, and treatment strategy). The correlation among PET parameters was evaluated with Spearman's rho test. ROC curve was used to evaluate the predictive performance and calculate the best cut-off values. Survival analyses used the Kaplan-Meier analysis and log-rank test. Univariate and multivariate COX regression analyses screened independent PFS correlated prognostic factors. Subsequently, a prognostic nomogram model was developed and internally validated. ***Results:*** HF correlated highly with MTV ($r = 0.88$, $P < 0.01$), while other PET heterogeneity indices had weak to mild or no correlations with traditional parameters. HF and MTV exhibited good predictive value for 1-year, 3-year, and 5-year PFS (HF: AUC = 0.817, 0.678, and 0.672; MTV: AUC = 0.866, 0.685, and 0.670), with the best prognostic efficacy for 1-year PFS. HF, MTV, TLG, SII, SIRI, NLR, overall stage, and whether concurrent chemoradiotherapy were significantly associated with 5-year PFS. HF (HR=2.70, 95%CI: 1.05-6.95), SII (HR=2.60, 95%CI: 1.02-6.61), overall stage (HR=2.70, 95%CI: 1.06-6.81), and concurrent chemoradiotherapy (HR=0.69, 95%CI: 0.11-0.80) were independent prognostic factors for 5-year PFS, respectively, with all P values < 0.05. The nomogram showed that the prognostic model had high 5-year PFS predictive ability, with an AUC of 0.827 and a C-index of 0.776. In addition, the calibration curves showed good agreement between the predicted probabilities and actual observations and decision curve analysis (DCA) suggested that the nomogram was useful for clinical decision-making. ***Conclusion:*** HF strongly correlates with MTV and has prognostic value for PFS, especially for 1-year PFS. A novel multifactor nomogram integrating HF, SII, overall stage, and concurrent chemoradiotherapy shows superior prognostic predictive performance, improving accuracy and enabling personalized assessment in managing I-IVa stage NPC patients.

"Ultra-Low-Dose ^{18}F-FDG PET With Ultra-Low-Dose CT" Based Radiomic Features And Machine Learning In Non-Invasive Characterization Of Suspicious Lung Lesions

P. Singh, *T. Singhal, S. K. Gupta, R. Kumar, N. Singh, H. Singh, B. R. Mittal;*
PGIMER, Chandigarh, INDIA.

Aim/Introduction: Lung cancer (LCa) is second most prevalent malignancy and most common cause of cancer-related death world-wide. However, lung nodules seen on CT are commonly benign (88-99%). even in high-risk patients. Thus, we here-by tried to evaluate the role of "ultra-low-dose ^{18}F-FDG PET with ultra-low-dose CT" derived radiomic features(RFs) and machine learning models(MLMs) to accurately characterise suspicious lung lesions delivering overall similar/lesser radiation dose as compared to LCa screening CT. ***Materials and Methods:*** Patients with suspicious lung lesions who underwent Ultra-low-dose ^{18}F-FDG PET with Ultra-low-dose CT were included in the study. Experienced Nuclear Medicine physicians manually delineated regions of interest(ROIs),

and intensity-threshold restrictions of 25% and 35% were applied to create three distinct sets of ROIs and high-dimensional RF were extracted using LIFEx(v7.8).Univariate analysis was applied to each RF, using area-under-curve(AUC) of receiver-operator-curve(ROC) and p-value computed by Mann-Whitney-U test. p-value <0.05 was considered significant. PET/CT guided biopsy delivered Histopathological examination(HPE) was taken as the gold standard. RFs with an AUC >0.7 were further refined using a total of 5 feature selection methods: random forest(RF), distance correlation(DC), eXtreme gradient boosting(Xgboost), gradient boosting decision tree(GBDT) and least absolute shrinkage and selection operator(LASSO).Nine MLMs were applied: support vector machine(SVM), linear discriminant analysis(LDA), decision tree(DT), RF, K-nearest neighbourhood(KNN), GBDT, adaptive boosting(AdaBoost), logistic regression(LR) and Gaussian Naïve-Bayes(GaussianNB) were developed using Python-3. 75% of data was used for training and 25% for validation. Model's performance was assessed using ROC curves. ***Results:*** The study included 443 patients(302 males, median-age:60, range: 17-90years). Among these, 311 were neoplastic while 132 had infection/inflammation on final HPE. A total of 166-RFs were extracted from each 18-F FDG PET-CT image at three intensity thresholds. Based on the combination of appropriate feature selection methods with different MLMs, forty-five discriminative models were established for each threshold. Most classifiers demonstrated acceptable discriminative ability with AUCs >0.7.Univariate-analysis revealed that 125 RFs were statistically significant predictors of outcome. LR-MLM with GBDT classifier at 25% threshold achieved best discriminative performance (AUC-.779) with a sensitivity, specificity and accuracy of 83.7, 72.0% & 81.1% respectively. ***Conclusion:*** RFs derived from Ultra-low-dose ^{18}F-FDG PET with Ultra-low-dose CT, when combined with MLMs, can effectively characterise lung lesions while delivering similar if not less radiation dose as compared to LCa screening CT. In this analysis, LR-MLM with GBDT classifier at 25% threshold performed best for characterisation of suspicious Lung lesions.

EP-0192

Prognostic Value of Pre-Treatment F-18 FDG PET/CT Volumetric Parameters in Patients Diagnosed with Laryngeal Squamous Cell Carcinoma

I. Ak Sivrikoz[1], *E. Ilhan*[1], *M. F. Acikalin*[2], *S. Aslan*[1], *I. Uslu Biner*[1]; *[1]ESOGU School of Medicine Department of Nuclear Medicine, Eskisehir, TÜRKIYE, [2]ESOGU School of Medicine Department of Pathology, Eskisehir, TÜRKIYE.*

Aim/Introduction: Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) derived from FDG PET/CT have been proposed as prognostic biomarkers in various solid malignancies; however, their prognostic value in laryngeal cancer remains unclear. In this study, we aimed to investigate the relationship between volumetric parameters based on standardized uptake values obtained from FDG PET/CT and progression-free survival (PFS) and overall survival (OS) in newly diagnosed laryngeal cancer patients. ***Materials and Methods:*** Patients diagnosed with laryngeal cancer and who underwent FDG PET/CT for pre-treatment staging at our department between 2012 and 2020 were retrospectively evaluated. Patients who had not received prior surgery or chemotherapy/radiotherapy and had no additional malignancy were included. SUVmax, SUVmean, MTV, and TLG values of the primary laryngeal lesion were calculated from PET/CT images, and lymphatic and distant metastases were assessed. Clinical, pathological, and demographic data as well as dates of radiological progression and death were obtained from the hospital information system. OS/PFS was analyzed with a 60-month evaluation period. ***Results:*** A total of 62 patients (58 males, 4 females), aged between 45 and 87 years (mean: 64.75), were included in the study. At the time of analysis, 36 patients had died and 26 were still alive. The mean SUVmax of the laryngeal tumors was 11.22±6.03 (range: 2.99-29.43), mean SUVmean was 6.86±3.74 (range: 2.95-19.12), mean MTV was 6.35±8.34 (range: 0.04-37.55), and mean TLG was 39.62±99.32 (range: 0.12-494.58). Median OS was 57.50 months [95% confidence interval (CI): 44.15-61.53]; no significant association was found between OS and SUVmax (p=0.43), SUVmean (p=0.36), or TLG (p=0.16). However, a significant association was observed between OS and MTV (p=0.03). OS was not associated with tumor location within the larynx (glottic/supraglottic/subglottic/transglottic), tumor differentiation (poor, moderate, well, unspecified), gender, smoking status, or lymph node metastasis. Nevertheless, OS was significantly associated with age (p=0.00). Median PFS was 25 months (95% CI: 30.55-48.69). No significant association was found between PFS and SUVmax (p=0.17), SUVmean (p=0.13), or TLG (p=0.14). Similar to OS, a significant association was found between PFS and MTV (p=0.04). PFS was significantly associated with age (p=0.02) and presence of lymph node metastasis (p=0.006). ***Conclusion:*** In patients diagnosed with laryngeal SCC, tumor MTV appears to be an independent prognostic marker for OS. In addition, the presence of lymph node metastasis may serve as a prognostic marker for PFS, and older age may be a prognostic factor for both OS and PFS.

EP-0194

Prognostic Utility of ^{18}F-FDG PET/MRI with Intravoxel Incoherent Motion Imaging in Nasopharyngeal Carcinoma

S.-C. Chan[1], *S.-H. Ng*[2], *C.-H. Yeh*[2]; *[1]Hualien Tzu Chi Hospital, Hualien, Taiwan, [2]Linkou Chang Gung Memorial Hospital, Taoyuan, TAIWAN.*

Aim/Introduction: Intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI) enhances tissue diffusion assessment by differentiating true molecular diffusion from microvascular perfusion, surpassing conventional DWI. This prospective study assessed the prognostic utility of ^{18}F-FDG PET/MRI with IVIM imaging in patients with primary nasopharyngeal carcinoma (NPC). ***Materials and Methods:*** Quantitative parameters derived from IVIM-DWI, dynamic contrast-enhanced MRI (DCE-MRI), and ^{18}F-FDG PET were analyzed for their associations with overall survival (OS) and recurrence-free survival (RFS). ***Results:*** The IVIM-derived minimal true diffusion coefficient (Dmin) and perfusion-related diffusion coefficient (D*) were significantly correlated with RFS (p = 0.018 and 0.043, respectively), outperforming the apparent diffusion coefficient (ADC; p = 0.946). Univariate analysis identified age, tumour stage, T classification, primary tumour standardized uptake value (SUVt), nodal SUV (SUVn), and total lesion glycolysis (TLG) as significant OS predictors. Significant predictors of RFS included Epstein-Barr virus DNA titre, SUVn, DCE-MRI parameters (Kep and Ve), and IVIM parameters (D* and Dmin). In multivariate analysis, age, SUVt, and TLG were independent OS prognostic factors, whereas SUVn, Kep, Dmin (p = 0.009), and Ve (p = 0.012) independently predicted RFS. Prognostic models incorporating the PET/MRI imaging biomarkers showed a significantly higher integrated AUC and Harrell's C-index than the TNM staging system alone (p = 0.013 and 0.003, respectively). ***Conclusion:*** Integrated PET/MRI with IVIM imaging enables simultaneous quantification of water molecule diffusion, tumor microvascular perfusion, and glucose metabolism in NPC, yielding complementary imaging biomarkers that demonstrate superior prognostic value compared to conventional TNM staging. ***References:*** 1. C-X-C motif chemokine receptor 4-directed PET/CT in newly diagnosed squamous cell carcinoma of the oral cavity - initial experience and comparison to [^{18}F]FDG PET/CT

S. Serfling[1], *Y. Zhi*[2], *P. E. Hartrampf*[1], *H. Takahiro*[1], *A. Kübler*[3], *A. K. Buck*[1], *R. A. Werner*[4], *S. Hartmann*[3];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Department of Otorhinolaryngology, Plastic, Aesthetic and Reconstructive Head and Neck Surgery, University Hospital Würzburg, Würzburg, GERMANY,* [3]*Department of Oral and Maxillofacial Plastic Surgery of the University Hospital Würzburg, Würzburg, GERMANY,* [4]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Inflammatory processes in the oral cavity and the resulting reactive, loco-regional cervical lymph nodes pose a challenge for the routinely used radiotracer [^{18}F]FDG. We aimed to compare [^{18}F]FDG PET/CT relative to the inflammatory-specific C-X-C motif chemokine receptor 4-directed [^{68}Ga]PentixaFor in patients affected with newly diagnosed oral squamous cell carcinoma (OSCC). ***Materials and Methods:*** 10 newly diagnosed untreated patients with a histologically confirmed OSCC underwent CXCR4-PET/CT using [^{68}Ga]PentixaFor and [^{18}F]FDG PET/CT to determine disease extent within 2 days. We also quantified tumor volume (TV), maximum SUV (SUV_{max}) and target-to-background ratio (TBR, with healthy liver parenchyma serving as reference organ) thereby providing information on image contrast. We compared the results with pathological findings in resected lymph nodes. ***Results:*** On a lesion-based level, the primary was detected for both tracers in 8 out of 10 patients. In two cases the primary was not detected (both T1 stage). Median tumor TV was 7.61±6.0 for [^{18}F]FDG and 3.83±6.82 for [^{68}Ga]PentixaFor ($P<0.03$). Comparable results were recorded for SUV_{max} ([^{18}F]FDG, 21.31±4.92 vs. [^{68}Ga]PentixaFor, 6.5±2.34; $P<0.4$), with respective TBR of 8.86±2.64 for [^{18}F]FDG ([^{68}Ga]PentixaFor, 4.3±1.4; $P<0.18$). 159 lymph nodes were resected at all. Only two of the suspected lymph nodes were histologically confirmed metastases, which were detected by both tracers. ***Conclusion:*** In patients with OSCC, both tracers can detect the primary tumor (minimum T2 stage) with [^{18}F]FDG showing a higher image contrast. Neither tracer was able to adequately identify lymph node involvement.

EP-0196

Prognostic value of volumetric ^{18}F-FDG PET in head and neck cancer

A. Doma[1,2], *T. Škerl*[1], *A. Studen*[3,4], *P. Strojan*[1,2];
[1]*Oncology institute, Ljubljana, SLOVENIA,* [2]*Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA,* [3]*Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA,* [4]*Experimental Particle Physics Department, Jožef Stefan Institute, Ljubljana, SLOVENIA.*

Aim/Introduction: Head and neck cancer (HNC) is the 7th most common type of cancer, representing a heterogeneous group of malignancies with variable prognosis, influenced by tumor site, stage, and patient-related factors. ^{18}F-FDG PET/CT (PET/CT) is effective for staging and prognostication of HNC. Recently, focus of PET/CT shifted from conventional standardized uptake value (SUV) to volumetric parameters, e.g. metabolic tumor volume (MTV) and total lesion glycolysis (TLG) as potential prognostic markers. The present study aimed to evaluate the prognostic value of several clinical and PET based parameters for prediction of overall survival (OS) in patients with HNC undergoing radiotherapy. ***Materials and Methods:*** 28 patients with histologically confirmed HNC of M0 stage and baseline PET/CT prior to curative-intent radiotherapy, with or without concomitant chemotherapy were included. Clinical variables included age, gender, smoking history, World Health Organization performance status (WHO), tumor (T), and nodal (N) stage. PET derived variables analyzed were maximum standardized uptake value (SUVmax) and metabolic tumor volume using a 41% SUVmax threshold (MTV41) for primary tumors, regional metastases, and total disease. Statistic analyses included descriptive statistics, ROC analysis (AUC, cut-offs) and univariate Kaplan-Meier survival estimates with log-rank tests, with $p < 0.05$ considered significant. ***Results:*** 22 men and 6 women of a median age 55 years (range: 32,8-75,9) were analyzed. The most frequent primary sites were the nasopharynx (n=15) and oropharynx (n=10). 10 patients were former and 11 were current smokers. All patients recived 70 Gy and 24 of them had concurrent chemotherapy. After a median follow-up of 38 months (range: 5-98), ROC analysis demonstrated that total MTV41 was the strongest predictor of OS (AUC 0,85; p=0,0034), yielding high sensitivity (0,88) and specificity (0,78). Additional significant variables were metastases SUVmax (AUC 0,80; p=0,03), and tumor MTV41 (AUC 0,76; p=0,04). T stage (AUC 0,66), N stage (AUC 0,69), age (AUC 0,67), and smoking history (AUC 0,47) were found non-significant.Kaplan-Meier analysis confirmed significantly worse OS in patients with total MTV41>13,96 ml, metastases MTV41>6,51 ml, tumor MTV41>16,13 ml and metastases SUVmax>14,32. Notably, tumor SUVmax, as well as traditional patient- and tumor-related prognosticators were not significantly associated with OS. ***Conclusion:*** In the present study, total MTV41 emerged as the most powerful predictor of OS in locoregionally advanced HNC treated with definitive (chemo)radiotherapy, outperforming conventional clinical staging and tumor SUVmax metrics. Baseline MTV tumor burden may help identify high-risk patients, benefiting from intensified treatment regimens.

EP-0197

Comparison of the Diagnostic Value of FDG PET/MRI and MRI Imaging in Nodal Staging of Laryngeal Cancer and Predictive Parameters of Lymph Node Metastasis

E. Erbil Capci*, U. Aydos, S. Gülbahar Ateş, E. Balcı, M. Yılmaz, M. Uçar, L. Atay;*
Gazi University Faculty of Medicine, Ankara, TÜRKIYE.

Aim/Introduction: This study aimed to compare the diagnostic performance of FDG PET/MRI and MRI modalities in detecting lymph node(LN) metastasis and to determine the predictive parameters of LN metastasis. ***Materials and Methods:*** 39 patients who underwent whole-body PET/MRI and head-neck MRI for primary staging, followed by subsequent surgical resection were included. PET/MRI images were retrospectively reviewed by a nuclear medicine physician, and MRI images by a radiologist. In PET/MRI visual assessment, three N stages were determined using thresholds of background(BG), mediastinal blood pool(ME), and liver(LI) activity. SUVmax, SUVmean, SUVpeak, MTV and TLG values of the primary tumor were calculated. The T stage, local spread characteristics (paraglottic space involvement, anterior commissure involvement, cartilage invasion and extralaryngeal extension), ADCmin value and N stage were determined from MRI images. Histopathology was used as the reference standard. Diagnostic performances of imaging modalities in N staging were evaluated with chi-square test. Statistical analyses were conducted using SPSS 25.0. The role of imaging parameters of the primary tumor in predicting the presence of LN metastasis was evaluated by logistic regression analysis. A nomogram model was developed using regression coefficients with the lrm() and nom()

functions in the [1]rms[2] package with R software. ***Results:*** The accuracy of PET/MR BG, ME, LI and MRI N stage were calculated as 30.8%, 46.2%, 69.2%, and 59%, respectively. In univariate logistic regression analyses, MTV and ADCmin value of primary tumor and the presence of paraglottic space involvement were identified as predictive factors for LN metastasis. In the nomogram developed to predict LN metastasis, the variables used were MTV (0.43-35 scored 0-92.5), paraglottic space involvement ("absent"-"present" scored 0-43.75) and ADCmin (200-20 scored 0-100), which are scored on a 0-100 scale, and the probability of LN metastasis is obtained according to the total score. The optimal probability threshold was calculated as 27%, with a sensitivity of 93%, specificity of 60% and accuracy of 81% for predicting LN metastasis. To reduce the false positive rate, PET/MRI-LI was applied to assess LN metastasis in 23 patients with scores above the cut-off value; this raised the model's specificity to 92% and accuracy to 90%. ***Conclusion:*** A model incorporating MTV and ADCmin value of primary tumor and paraglottic space involvement obtained from PET/MRI imaging in laryngeal cancer provides high sensitivity in predicting LN metastasis. Using the liver threshold in PET/MRI for N staging and predicting LN metastasis significantly improves the diagnostic performance of the modality.

Habitat-Based Radiomic Features from ^{18}F-FDG PET/MR for Recurrence Prediction in Head and Neck Oral Carcinoma

W. Zhou[1], *C. Jiang*[1], *J. Yang*[1], *X. Peng*[1], *K. Zheng*[1], *Y. Guo*[2], *H. Ye*[1]; *[1]Department of PET-CT Center, The Affiliated Cancer Hospital of Xiangya School of Medicine/Hunan Cancer Hospital, Central South University, Changsha, CHINA, [2]Shenzhen United Imaging Healthcare Co., Ltd., Shenzhen, CHINA.*

Aim/Introduction: Recurrence prediction in head and neck oral carcinoma remains at an early research stage, particularly when accounting for tumor heterogeneity. This study evaluates the predictive value of habitat-derived radiomic features extracted from ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET/MR and diffusion-weighted imaging (DWI) for recurrence risk stratification. ***Materials and Methods:*** We retrospectively analyzed 21 patients (13 with recurrence, 8 without) who underwent pretreatment ^{18}F-FDG PET/MR scans including DWI sequences. Tumor habitats were delineated on PET images using Otsu's thresholding method, separating high- and low-metabolism subregions. Radiomic features—including shape, first-order, and texture features (GLCM, GLSZM, GLRLM, NGTDM, GLDM)—as well as quantitative metabolic and diffusion parameters were extracted from these habitats and the peritumoral regions. Feature selection was performed using the least absolute shrinkage and selection operator (LASSO) regression, and a support vector machine (SVM) classifier was trained and evaluated via fivefold cross-validation. ***Results:*** A total of 214 radiomic features per PET and ADC modality were initially extracted across three distinct tumor regions, resulting in 657 features. After excluding features with poor reproducibility (intraclass correlation coefficient < 0.75), 611 robust features remained for analysis. Six key features were ultimately selected via LASSO regression, predominantly originating from low-metabolism PET and peritumoral regions, as well as high-metabolism and diffusion-related zones on DWI, reflecting the inherent spatial metabolic and microstructural heterogeneity of buccal carcinoma. The SVM classification model achieved a cross-validated area under the ROC curve (AUC) of 0.805 (95% CI: 0.665-1.000). At the optimal threshold of 0.597, determined by maximizing Youden's index using ROC analysis, the model achieved an accuracy of 83.3%, sensitivity of 81.8%, and specificity of 85.7%. This integrative approach highlights the significant contribution of habitat-specific radiomic features in predicting recurrence risk and underscores the importance of capturing tumor heterogeneity via multi-modal imaging. ***Conclusion:*** PET/MR habitat-based radiomic features capturing metabolic and diffusion heterogeneity show promise for noninvasive prediction of recurrence risk in oral carcinoma. Notably, several selected features originate from low-metabolism and peritumoral PET regions, suggesting that metabolic heterogeneity—beyond simple uptake intensity—may be critical for identifying tumors with higher recurrence potential. These findings emphasize the value of quantitative imaging biomarkers in assessing tumor heterogeneity and support personalized patient management. Further validation in larger, multi-center cohorts is currently underway.

EP-0199

[^{18}F]FDG PET/CT in Post-Treatment Assessment of Head and Neck Cancer: Exploring the Diagnostic Role of SUVmax and Uptake Pattern

D. Silva*, I. Miguel, D. Barbosa, N. Vasconcelos, R. Marão, P. Silva, J. Ferro, S. Fontão de Castro, L. Violante, J. Teixeira, A. Soares, H. Duarte, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL

Aim/Introduction: [^{18}F]fluorodeoxyglucose positron emission tomography/computed tomography ([^{18}F]FDG PET/CT) plays a central role in the post-treatment evaluation of head and neck cancer (HNC). To enhance objectivity in response assessment, structured scoring systems have been developed, such as Christie Score, a simple and effective three-tier system (based on the lesion and blood pool SUVmax). Our aim was to assess the diagnostic performance of Christie Score in our population, and to investigate the prognostic value of quantitative PET metrics. We also assessed the feasibility of incorporating uptake patterns (focal vs diffuse) into a semiquantitative scoring approach. ***Materials and Methods:*** We retrospectively reviewed data from 131 patients with HNC treated with radical radiotherapy (with or without chemotherapy) at our institution between January 2020 and December 2022. Pre- and post-treatment FDG-PET scans were reviewed to extract relevant variables. All patients underwent response-assessment PET/CT at or beyond 12 weeks post-treatment, with uniform timing. These studies were classified using the Christie Score, and the original report conclusions were mapped to the equivalent Christie Score categories (complete metabolic response, likely post-treatment inflammation, or residual/recurrent disease) to enable statistical analysis. Clinical and imaging follow-up served as reference standard. ***Results:*** The Christie Score showed good diagnostic accuracy (AUC 0.835, p<0.001), with 89.5% sensitivity, 76.8% specificity, high negative predictive value (97.7%), although lower positive predictive value (PPV) (39.5%). FDG-PET reports showed higher predictive performance, with an improved of PPV 76% (p<0.001), likely reflecting the benefit of combining visual interpretation and clinical expertise. Post-treatment SUVmax alone yielded excellent diagnostic accuracy (AUC 0.965), accounting for 75.8% of outcome variation (R^2=0.758), with an optimal cut-off of 4.82 for predicting disease persistence. Incorporating uptake patterns into the model further increased explanatory power (R^2=0.837), indicating potential added value. Baseline SUVmax was not significantly associated with outcomes. ***Conclusion:*** Structured tools like the Christie Score can support standardized assessment, but expert clinical interpretation outperformed purely quantitative approaches in our cohort. Our findings highlight the potential utility of a semiquantitative scoring model that integrates SUV metrics with uptake pattern analysis to enhance diagnostic confidence when differentiating residual disease from post-treatment changes in HNC. This aligns with emerging evidence supporting hybrid models that combine

objective data with visual assessment. Prospective validation in larger cohorts is warranted to confirm reproducibility and clinical utility. ***References:*** DOI:10.1186/s41824-024-00230-8.

Machine learning for the prediction of synchronous second primary tumours in head and neck cancer assessed by ^{18}F-FDG PET/CT

F. Gomez-Caminero Lopez[1], *E. Campaña Diaz*[1], *S. Rama Alonso*[1], *J. Cañadas Salazar*[1], *F. Caltagirone Rodriguez*[1], *L. Diaz Gonzalez*[1], *J. Villanueva Curto*[1], *J. Badell Martinez*[1], *M. Sanchez Barba*[2], *P. Garcia-Talavera San Miguel*[1];
[1]*Nuclear Medicine. University Health Complex of Salamanca, Salamanca, SPAIN,* [2]*Department of Statistics, University of Salamanca, Salamanca, SPAIN.*

Aim/Introduction: Patients with head and neck cancer (HNCC) are at increased risk of developing synchronous second primary tumours (SPTs), which may influence both staging and treatment strategy. This study aims to assess the predictive value of ^{18}F-FDG-PET/CT metabolic parameters and demographic variables for SPT detection using machine learning (ML) algorithms. ***Materials and Methods:*** A retrospective analysis was conducted on 2,081 patients who underwent 18F-FDG-PET/CT for staging of HNCC between Oct´2014-Dec´2022. Data included demographic variables (age, sex) and metabolic parameters of the index tumour: maximum standardised uptake value (SUVmax), metabolic tumour volume (MTV) and total lesion glycolysis (TLG). ML modelling was applied to estimate the probability of SPT presence. Lesions suspicious for SPT were histopathologically verified whenever possible. ***Results:*** 285 suspicious lesions were initially identified. 203 were included in the final analysis. Among these, 133 were confirmed as true SPTs (6,8%). Feature selection identified age, SUVmax, MTV, and TLG as the most relevant predictors of SPT. A random forest classifier achieved 100% sensitivity in detecting confirmed SPTs. The most frequent SPT sites were the lungs and gastrointestinal tract. The majority of STP were diagnosed at an early stage. ***Conclusion:*** ^{18}F-FDG-PET/CT is an effective imaging modality for early detection of SPT in patients with HNCC. ML techniques, particularly random forest algorithms, can enhance predictive performance by integrating metabolic imaging and clinical variables. These results highlight the potential role of AI-supported models in clinical decision-making and personalised oncology. ***References:*** Strobel K, Haerle SK, Stoeckli SJ, et al. Leveraging ^{18}F-FDG PET/CT to investigate the biology of circulating cell-free tumor DNA (ctDNA): an exploratory study in metastatic breast cancer (MBC) patients

M. de Oliveira Taveira[1], *L. Cabel*[1], *J. Das*[1], *J. Teysir*[1], *C. White*[1], *Y. Chen*[1], *P. Razavi*[1], *R. Yeh*[2];
[1]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*Mount Sinai Health System, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: ctDNA levels in blood are strongly correlated with disease burden and tumor type and biological features such as proliferation and apoptosis rates, but there is incomplete understanding of the biology of ctDNA shedding in metastatic patients, as different metastatic sites may shed ctDNA differently. As a whole-body functional and anatomical imaging modality, FDG PET/CT is an ideal tool to investigate ctDNA biology in metastatic patients. ***Materials and Methods:*** HR+/HER2- MBC patients with MSK-ACCESS ctDNA assay collected within 7 days of the initiation of 1st line therapy for MBC and with PET/CT done within 60 days of ctDNA collection were included. Semi-automated segmentation of all tumor sites was done by 3 radiologists specialized in oncological imaging using a combination of threshold and manual segmentation. Lesion site, SUVmax, SUVmean, and Metabolic Tumor Volume (MTV) with a relative threshold of 40% of SUVmax were annotated. Total Lesion Glycolysis (TLG) was calculated multiplying weighted SUVmean by MTV. All variables were analyzed at lesional, organ and patient level. Variant Allele Frequency (VAF) in ctDNA was calculated using the number of mutant DNA molecules divided by the total number of DNA molecules (mutant plus wild type) at that specific genetic locus. Kendall's Tau was used to evaluate the correlation between PET and ctDNA. ***Results:*** Out of 766 patients with MSK-ACCESS, 78 patients had concurrent FDG PET/CT. 77/78 had measurable disease on PET/CT with 1392 lesions measured and 58/78 had positive ctDNA at that time point. Most common metastatic sites were bone (60/78), lymph node (47/78), liver (25/78) and lung (21/78). PET-derived variables most correlated to VAF ctDNA according to Kendall's tau score were: Global TLG, 0.42 ($p<0.001$); Global MTV, 0.40 ($p<0.001$); Liver metastasis weighted SUVmean, 0.38 ($p=0.008$), Liver metastasis highest SUVmax, 0.34 ($p=0.018$), and single metastasis with the highest SUVmax, 0.32 ($p<0.001$). ***Conclusion:*** There is moderate correlation between ctDNA VAF and MTV, TLG, highest SUVmax, liver metastasis weighted SUVmean and highest liver metastasis SUVmax in MBC patients. Liver-specific PET biomarkers are more closely associated with ctDNA than other organ-based variables, potentially implying higher shedding from these metastases. The imperfect correlation between PET and ctDNA points towards added value of combining both evaluations that could inform clinical trials attempting to incorporate ctDNA as a biomarker in addition to standard imaging-derived surrogate endpoints. Incorporating both PET/CT and ctDNA variables into clinical models may improve tumor response evaluation and personalized treatment strategies in metastatic breast cancer.

EP-0202

Predictive value of 18F-FES PET/CT on the efficacy of late rechallenge of hormone therapy in metastatic breast cancer

***M. Masse**, C. Bailleux, J.-M. Ferrero, A. Creisson, O. Humbert;*
Centre Antoine Lacassagne, Nice, FRANCE.

Aim/Introduction: Hormone-dependent breast cancer (HR+), accounting for over two-thirds of breast cancers, are initially treated with hormone therapy (HT). After progression on initial HT and chemotherapy, late rechallenge with other hormonal agents is a therapeutic option. Tumor hormone sensitivity is usually determined by immunohistochemical analysis of a single biopsied lesion. However, 18F-FES PET/CT, a functional imaging targeting estrogen receptors, could be used to assess the residual expression of estrogen receptors of tumor lesions, on a whole-body scale.The aim of this study is to determine the predictive value of 18F-FES PET/CT for the efficacy of late hormone therapy rechallenge in patients with HR+ metastatic breast cancer who have already received multiple prior lines of hormone therapy and chemotherapy. ***Materials and Methods:*** This retrospective study included all patients with metastatic breast cancer, initially HR+, who had received at least one line of hormonal therapy and one line of chemotherapy and were progressing on chemotherapy. Consecutive ^{18}F-FDG and 18F-FES-PET/CT scans were performed between March 2022 and September 2023 to evaluate residual hormone receptor expression. The analysis was qualitative: a lesion was considered FDG+ if the uptake was higher than the hepatic background noise, and an FES-PET/CT was considered positive if all FDG+ lesions showed visual FES uptake (higher than the local background noise). All other 18F-FES PET/CT exams (heterogeneous or negative FES fixation) were considered negative (1). The primary endpoint was progression free survival (PFS), and the secondary endpoint was overall survival (OS). ***Results:*** Thirty-six patients were included: 13 had a positive FES-PET/CT and 23 had a negative FES-PE/CT. Patients with positive FES-PET/CT underwent hormone therapy rechallenge, achieving significantly longer median PFS than negative FES-PET/CT patients (medPFS: 6 vs. 3 months, p = 0.042). Negative FES-PET/CT patients mostly received chemotherapy. There was also a trend towards better overall survival in patients with positive 18F-FES PET scans, although these results were not significant in our sample of patients (medOS: 22 vs. 19 months, p = 0.32). ***Conclusion:*** Persistence of 18F-FES uptake across all metastatic lesions can predict the effectiveness of an additional line of hormone therapy in patients with HR+ metastatic breast cancer who have already received multiple prior lines of hormone therapy and chemotherapy. Prospective studies with larger cohorts are needed to validate these results and to optimize therapeutic strategies. ***References:*** (1) Mankoff et al. SNMMI/EANM Practice Guideline for Estrogen Receptor Imaging of Patients with Breast Cancer Using 16α-[18F]Fluoro-17β-Estradiol PET. JNuclMed. 2024 doi:10.2967/jnumed.123.266938.

EP-0203

The Potential Of 18F-Fluorocholine Computed Tomography (18F-FCH PET CT) As Predictor For Breast Cancer Immunophenotyping And Genetic Profiling Heterogenicity.

***M. Zakaria**[1], S. Shaharuddin[2], S. Abdullah Suhaimi[3], F. Ahmad Saad[1];*
[1]Universiti Putra Malaysia, Serdang, MALAYSIA, [2]Universiti Pertahanan Nasional Malaysia, Kuala Lumpur, MALAYSIA, [3]Universiti Kebangsaan Malaysia, Cheras, MALAYSIA.

Aim/Introduction: To determine the potential of 18-FCH PETCT as a predictor for breast cancer immunophenotyping and genetic profiling heterogenicity. ***Materials and Methods:*** This study used the hospital information system retrospectively. 21 patients with primary or recurrent breast carcinoma who underwent 18F- FCH PET-CT imaging prior to biopsy. All patients had Birads 4/5 breast lesions on the mammogram. Histopathological examination (HPE) were recorded; benign and malignant. The patients were dichotomized into different immunophenotyping profiling : HER-ve and HER +ve immunophenotyping. Semiquantitative analysis utilizing the standardized uptake value (SUVmax (g/dl)/g/dl) was used to predict the two groups of different immunotyping. ***Results:*** 21 females with mean age of 52.82 ± 10.71 years. Eighteen patients had malignant disease (18/21; 85.8%) on histology with eleven (52.4%) with HER -ve immunophenotype. There is a significant difference between 18F-FCH SUVmax (g/dl) of the HER-ve and the HER +ve immunophenotyping group (1.99 g/dl vs 0.2g/dl; p<0.05). The malignant group has higher SUVmax (g/dl) value as compared to the benign group (1.36 ± 0.13; p<0.05). High SUVmax (g/dl) FCH predicted malignant breast lesion for the malignant histological subtype and HER-ve protein overexpression genotype at the cut-off value of 0.75 (p<0.05), predicting the aggressiveness of breast carcinoma. The SUVmax (g/dl) FCH PET-CT of > 0.75 was a good predictor to signal aggressive breast carcinoma cellular gene reprogramming. ***Conclusion:*** There is good potential of 18F-Fluorocholine Computed Tomography (18F-FCH PET CT) as potent predictor for breast cancer immunophenotyping determination and genetic profiling hence improve the diagnostic accuracy and disease progression monitoring for enhancing disease`s survival rate. ***References:*** Zhang, H. et al. MAMMI PET-based Habitat-radiomics for Measuring Intratumoral-heterogeneity and Predicting Neoadjuvant Chemotherapy Response in HER2-positive Breast Cancer

***C. Ren**;*
Shanghai Proton and Heavy Ion Center, Shanghai, CHINA.

Aim/Introduction: Intratumoral heterogeneity (ITH) of human epidermal growth factor receptor 2-positive (HER2+) breast cancer (BC) results in different responses to neoadjuvant chemotherapy (NAC), which cannot be non-invasively evaluated before treatment. The aim of this study was to develop the habitat radiomics models for measuring ITH based on pretreatment high-resolution dedicated breast PET (MAMMI PET) and predicting pathologic complete response (pCR) after NAC in HER2+ BC patients. ***Materials and Methods:*** This retrospective single-center study included HER2+ BC patients who underwent preoperative dbPET and received NAC followed by surgery from June 2021 to July 2023. Habitat radiomics features (RFs) were extracted from different metabolic subregions (VOI_{high}, VOI_{low}, etc.), and selected to develop models for NAC response prediction by machine-learning algorithms. The correlation between habitat RFs with ITH (Ki-67 expression) was measured by Pearson test. The performance of prediction models was evaluated and compared by the area under the receiver operating characteristic curve (AUC) and DeLong test. The optimal model was expressed as nomogram, together with significantly clinical-image risk factors. ***Results:*** This study included 140 female patients (median age, 51 years [IQR, 44-

57 years])), 98 patients (median age, 51 years [IQR, 46-58 years]) from the training set, of which 60 patients (61.2%) were pCR, and 42 patients (median age, 52 years [IQR, 43-56 years]) from the validation set, of which 24 patients (57.1%) were pCR, respectively. Habitat radiomics matrix extracted from VOI_{low} was significantly associated with Ki-67 expression (r: 0.44, $p < 0.05$). The nomogram constructing with Ki-67 expression, SUVmax and ITH Model, which developed by VOI_{high}/VOI_{low} habitat RFs, showed the optimal performance for predicting pCR to NAC in both the training and validation sets (AUCs of 0.88 and 0.94, respectively). ***Conclusion:*** Habitat radiomics analysis based on dbPET had great potential in non-invasively measuring ITH and enabled identification of HER2+ BC patients who are unlikely to benefit from NAC.

EP-0205

^{18}F-fluoroestradiol (^{18}F-FES) PET/CT guided first-line treatment for HR+/HER2- metastatic breast cancer patients: experience from real-world

C. Liu[1], *Y. Xie*[2], *Y. Chen*[2], *S. Song*[1], *B. Wang*[2], *Z. Yang*[1]; *[1]Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA, [2]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, CHINA.*

Aim/Introduction: In the past decade, the combination of CDK4/6 inhibitors and endocrine therapy has significantly extended the survival of patients with hormone receptor (HR) positive and human epidermal growth factor receptor 2 (HER2) negative metastatic breast cancer (MBC). However, a minority of patients might have difficulty in benefiting from this combination therapy because of estrogen receptor (ER) heterogeneity between lesions. ^{18}F-fluoroestradiol (^{18}F-FES) positron emission tomography (PET)/computed tomography (CT) is recognized as a potent tool for assessing ER expression in patients with HR+/HER2- MBC on a comprehensive, whole-body level. Nevertheless, it remains unknown whether ER status screened by ^{18}F-FES-PET could identify patients who benefit more from CDK4/6i plus ET or chemotherapy (CT) compared to unscreened controls. ***Materials and Methods:*** The medical records of patients diagnosed with HR+/HER2- MBC from 2020 to 2024 in Fudan University Shanghai Cancer Center were retrospectively evaluated. Patients screened or unscreened by ^{18}F-FES-PET before first-line CDK4/6i plus ET or CT were included in this study. ***Results:*** A total of 473 patients were included in the study. 156(33.0%) and 317 (67.0%) patients were screened or unscreened by ^{18}F-FES-PET before first-line treatment. 111 patients with all-FES positive metastatic lesions and 17 patients with FES heterogeneity received CDK4/6i plus ET. 21 patients with all-FES negative metastatic lesions and 7 patients with FES heterogeneity received CT. As for the unscreened group, 236 received CDK4/6i plus ET and 81 received CT. In CDK4/6 plus ET cohort, FES-screened group showed a significantly prolonged progression-free survival (PFS) compared with unscreened group (mPFS 32.4 months versus 17.3 months, Hazard Ratio = 0.49; 95% CI, 0.34 to 0.69; $P < 0.0001$). And CT cohort showed superior PFS for screened patients as well (mPFS 11.38 months versus 8.91 months, Hazard Ratio = 0.56; 95% CI, 0.33 to 0.94; $P = 0.026$). ***Conclusion:*** HR+/HER2- MBC patients with FES-guided initial treatment showed significantly better efficacy than those who had not been assessed by ^{18}F-FES-PET/CT in real world. This study highlights the crucial instructive role of FES assessment in evaluating ER expression in patients prior to administering first-line treatment.

Aim/Introduction: although triple-negative breast cancer (TNBC) is a recognized [18F]-FDG-avid tumor, there is still limited robust evidence in the literature regarding the prognostic value of this imaging modality. TRINE-PET is a large, retrospective, real-world, multicenter Italian study designed to evaluate the correlation between [18F]-FDG PET/CT findings and survival outcomes in TNBC patients across various clinical settings. ***Materials and Methods:*** data on [18F]-FDG PET/CT in TNBC patients were retrospectively collected from 24 Italian centers. Scans were categorized according to four clinical settings: (a) baseline, (b) post-neoadjuvant chemotherapy (NAC), (c) suspected disease recurrence and (d) patients undergoing systemic therapies. Only patients with a minimum of two years of follow-up were eligible. A per-site PET-based analysis was performed, and survival outcomes (progression and death) were compared across the clinical settings using the log-rank test. Associations between categorical variables were analyzed using the chi-squared test. ***Results:*** a total of 707 [18F]-FDG PET/CT scans from 389 TNBC patients (mean age = 54±13 years) were analyzed. The distribution of scans across the four clinical settings was as follows: baseline = 257, post-NAC = 111, suspected recurrence = 144, and systemic therapy = 195. At baseline, [18F]-FDG PET/CT detected the primary tumor in 234 patients (91.1%). Lymph node and distant metastases were identified in 284 (40.2%) and 181 (25.6%) patients, respectively. During a median follow-up of 3 years, 278 patients (39.3%) experienced disease progression, and 200 (28.3%) died. The presence of an [18F]-FDG-avid primary tumor at baseline was significantly associated with shorter survival (p=0.0001). Additionally, detection of nodal (N+) or distant (M+) metastases on PET/CT correlated strongly with a higher risk of disease progression in all four clinical settings (all p<0.001). Presence of distant metastases (M+) was also significantly associated with increased mortality in the suspected recurrence and systemic therapy settings (p=0.018 and p<0.0001, respectively). ***Conclusion:*** the presence of an [18F]-FDG-avid primary TNBC tumor on baseline PET/CT is associated with a higher risk of death. Furthermore, a strong correlation was observed between nodal or distant metastatic disease at [18F]-FDG PET/CT and worse survival outcomes. Specifically, detection of lymph nodes or distant metastases at early disease stages (baseline and post-NAC) was prognostic for shorter progression-free survival. In contrast, the presence of distant metastases in PET/CT scans performed

for suspected recurrence or during systemic treatment predicted both shorter progression-free and overall survival. ***References:*** DOI: 10.1007/s00259-024-06866-9Acknowledgements: De Rimini M.L., Frega N., Filippi L. and Travascio L.

EP-0207

Visualising HER2 Heterogeneity in Advanced Breast Cancer using [^{68}Ga]Ga-ABY-025 PET - a SingleCentre Polish Experience

G. Kramer-Marek[1,2], *A. Kastelik-Hryniewiecka*[2], *M. Kubeczko*[2], *I. Gorczewska*[2], *A. d'Amico*[2], *J. Feldwisch*[3], *F. Y. Frejd*[3,4], *K. Daszewska*[2], *M. Jarzab*[2];
[1]*The Institute of Cancer Research, London, UNITED KINGDOM,* [2]*Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice, POLAND,* [3]*Affibody AB, Solna, SWEDEN,* [4]*Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Molecular heterogeneity and the distinct characteristics of HER2-positive metastatic breast cancer (MBC) constrain precise patient management in the era of antibody-drug conjugates. Moreover, the limitations of repeated biopsies and immunohistochemistry (IHC), which fail to capture the full tumour burden, highlight the need for superior biomarkers to identify patients most likely to benefit from these therapies. Here, we evaluated the use of [^{68}Ga]Ga-ABY-025 HER2-targeted positron emission tomography (PET) in detecting tumour lesions that overexpress HER2 in patients with HER2-positive MBC. ***Materials and Methods:*** The GMP-grade Affibody molecule (ABY-025) for clinical use was provided by Affibody AB, Sweden. Radiolabelling was performed manually for 25 minutes, followed by 40 minutes of pre-release quality control (including radiochemical, chemical, and radionuclide purity, ethanol content, half-life, bacterial endotoxin, pH, sterility, and bubble point tests). All methods were validated under GMP-compliant conditions. The clinical study was approved by the Local Bioethical Committee (#KB/430-51/23). Seven female patients with pre-diagnosed metastatic HER2-positive breast cancer received [^{68}Ga]Ga-ABY-025 (400-600 µg peptide, 100-250 MBq, 8 mL) in saline. PET/CT images were acquired 3 hours post-administration using a Biograph Vision 600 Edge scanner (Siemens Healthineers). Uptake was measured in the largest lesions selected on baseline CT. 33 lesions were included in the analysis. Images were compared to [^{18}F]FDG PET scans obtained 2 or 3 days earlier. ***Results:*** The manual radiolabelling process was rapid, yielding a final product with high radiochemical yield (RCY>80%) and purity (RCP>99%). No adverse events related to HER2 PET radiotracer injection were observed. The biodistribution of [^{68}Ga]Ga-ABY-025 agreed with a previously conducted phase II study[1]. Physiological uptake appeared in the salivary glands, liver, kidneys, and intestines. Across 33 baseline CT defined tumour lesions, 4/33 (12%) had negligible [^{18}F]FDG avidity (SUV_{max} equal to or less than the mediastinal blood pool) yet were clearly HER2-positive (SUV_{max} 9-20) in the HER2 PET. Conversely, one lesion was [^{18}F]FDG positive (SUV_{max} 7.35) but HER2-negative. In addition, there were [^{68}Ga]Ga-ABY-025 SUV_{max} variations at the intra-patient level, ranging from 3 to 20 across different lesions. Importantly, [^{68}Ga]Ga-ABY-025 uptake enabled clear visualisation of brain metastases, while [^{18}F]FDG demonstrated poor sensitivity in this region due to intense physiological accumulation in the grey matter. ***Conclusion:*** This study demonstrates that [^{68}Ga]Ga-ABY-025 PET can capture total disease burden and reveal intra-patient HER2 heterogeneity in HER2 positive breast cancer, providing crucial information that can guide clinicians toward more precise, individualised therapy. ***References:*** [1] Alhuseinalkhudhur et al., J Nucl Med (2023); 64:1364-1370.

Aim/Introduction: Estrogen receptor (ER) expression imaging with 16α-[^{18}F]fluoro-17β-estradiol ([^{18}F]FES) positron emission tomography/computed tomography (PET/CT) was approved by the United States Food and Drug Administration in 2020 to identify ER-expressing lesions in recurrent or metastatic breast cancer. The prognostic value of [^{18}F]FES PET/CT remains undetermined. Our aim was to evaluate the prognostic value of [^{18}F]FES PET-based molecular imaging tumour-node-metastasis (miTNM) staging and [^{18}F]FES PET whole-body (WB) quantitative parameters. ***Materials and Methods:*** This was a single-centre retrospective analysis of patients who underwent [^{18}F]FES PET/CT between December 2021 and March 2024. We created a [^{18}F]FES PET miTNM system, based on the Union for International Cancer Control TNM 8th edition, to describe ER-positive lesion distribution at the patient level. The evaluators, blinded to outcomes, reviewed each scan to apply the miTNM classification. WB quantitative parameters—total tumour volume (TV), maximum standardised uptake value (SUV_{max}), mean SUV (SUV_{mean}), and total lesion uptake (TLU = TV × SUV_{mean})—were also calculated. Outcome measures were progression-free survival (PFS), defined as PET/CT to clinically documented disease progression by imaging, biomarkers, pathology, or physician judgement, and overall survival (OS). Associations were analysed using Kaplan-Meier and Cox regression models. ***Results:*** Sixty-nine patients were included: median age 65 years (interquartile range [IQR]: 57-74); 36 (52%) had invasive lobular carcinoma, 25 (36%) invasive ductal carcinoma. [^{18}F]FES PET/CT was performed for initial staging in 11 (16%) and restaging in 58 (84%). Based on miTNM, 38 (55%) were miT0N0M0, 9 (13%) miT+, 11 (16%) miN+, and 22 (32%) miM+. Median TV, SUV_{max}, SUV_{mean}, and TLU were 6.48 mL (IQR: 1.45-46.2), 4.32 (IQR: 2.85-7.76), 2.59 (IQR: 2.23-2.96), and 20.0 (IQR: 3.36-119.7), respectively. Median follow-up was 24 months (95% confidence interval [CI]: 20-28). Median PFS was not reached (NR) (95% CI: 15.8-NR); 2-year PFS was 58% (95% CI: 47-72). Median OS was NR (95% CI: NR-NR); 2-year OS was 87% (95% CI: 81-97). PFS was significantly shorter in miN+ vs. N0 (hazard ratio [HR] = 2.97; 95% CI: 1.24-7.11; p = 0.014) and in miM+ vs. M0 (HR = 2.92; 95% CI: 1.34-6.33; p = 0.0068). WB parameters showed no significant association. ***Conclusion:*** In this cohort, the [^{18}F]FES PET miTNM staging demonstrated prognostic value for PFS, whereas [^{18}F]FES PET WB quantitative parameters did not. The proposed miTNM framework may support standardised evaluation and broader clinical implementation of [^{18}F]FES PET/CT.

EP-0209

[^{68}Ga]Ga-NOTA-T4 PET/CT Imaging of Trop2 Expression in Patients with Metastatic Breast Cancer

L. Yao[1], *Z. Chu*[2], *Y. Wu*[1], *D. Jiang*[1], *Y. Gu*[3], *Q. Ge*[4], *Y. Guan*[1], *W. Wei*[5], *F. Xie*[1];
[1]*Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*Department of Oncology, Huashan Hospital, Fudan University, Shanghai, CHINA,* [3]*Central Research Institute United Imaging Healthcare Group Co, Ltd, Shanghai, CHINA,* [4]*Central Research Institute United Imaging Healthcare Group Co, Ltd, Shanghai, CHINA,* [5]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: Gallium-68([^{68}Ga])-labeled Ga-NOTA-T4 PET/CT is a promising noninvasive imaging tool for visualizing trophoblast cell-surface antigen 2 (Trop2) expression, which could aid clinical decisions regarding Trop2-targeted therapies. This study aims to evaluate the diagnostic performance of [^{68}Ga]Ga-NOTA-T4 PET/CT, a novel Trop2-targeting tracer, for detecting Trop2 expression in metastatic breast cancer and to compare its efficacy with conventional fluorine-18 labeled fluorodeoxyglucose ([^{18}F]FDG) PET/CT. ***Materials and Methods:*** From September 2023 to October 2024, patients with metastatic breast cancer were prospectively enrolled. All participants underwent [^{68}Ga]Ga-NOTA-T4 PET/CT, with or without additional [^{18}F]FDG PET/CT. Tracer uptake in detected lesions was quantified using the maximum standardized uptake value (SUVmax) and the target-to-background ratio (TBR). Quantitative differences between groups were analyzed using the t-test. ***Results:*** A total of 23 patients (mean age: 54 ± 13 years; all female) were included in the study, with 9 undergoing both [^{68}Ga]Ga-NOTA-T4 and [^{18}F]FDG PET/CT. [^{68}Ga]Ga-NOTA-T4 successfully detected lesions in 82.6% (19/23) of patients. Compared with [^{18}F]FDG PET/CT, [^{68}Ga]Ga-NOTA-T4 PET/CT identified the same number of patients (9 vs. 9) but a slightly lower number of lesions, with metastatic lesions showing lower SUV_{max} and TBR values. Notably, [^{68}Ga]Ga-NOTA-T4 imaging showed no uptake in an inflammatory nodule identified by [^{18}F]FDG PET/CT, suggesting its potential for distinguishing malignant from inflammatory lesions . ***Conclusion:*** [^{68}Ga]Ga-NOTA-T4 PET/CT is a promising tool for visualizing Trop2 expression in metastatic breast cancer, with potential applications for patient stratification and precision therapy. While its diagnostic performance is comparable to [^{18}F]FDG PET/CT, it offers additional advantages in reducing false positives from inflammatory lesions.

EP-0210

The Predictive Role of Pre-Treatment PET/CT-Derived Quantitative Parameters in Disease Progression of Triple-Negative Breast Cancer

N. Ünsal[1], *S. Karabulut*[1], *A. Aksu*[2], *G. Capa Kaya*[1];
[1]*Dokuz Eylul University Medical Faculty Hospital, Departmant of Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Izmir Katip Celebi University Medical Faculty Hospital, Departmant of Nuclear Medicine, Izmir, TÜRKIYE.*

Aim/Introduction: The aim of this study is to evaluate the role of quantitative parameters obtained from pre-treatment 18-fluorodeoxyglucose positron emission tomography/computed tomography (F-18 FDG PET/CT) in predicting progression in patients diagnosed with triple-negative breast cancer (TNBC). ***Materials and Methods:*** Pre-treatment PET/CT images of patients with at least 2 years of follow-up were analyzed using LIFEx software. The primary tumor's volume of interest (VOI) was manually segmented. From these VOIs, morphological, density-based and histogram parameters were obtained. The presence of lymph node and distant metastasis on staging PET, as well as progression during follow-up, were recorded. The relationship between progression and non-progression patients was evaluated statistically. ***Results:*** Thirty-eight patients with a mean age of 61±14 (range 40-94) years were included in the study. Thirty patients (78.9%) had unifocal tumors, and 18 (47.4%) had multifocal tumors. Lymph node metastasis was present in 27 (71.7%) patients, and distant metastasis was present in 9 (23.7%). The median progression-free survival (PFS) was 72.8±7.9 (range 57.2-88.4) months. Progression was detected in 14 patients (36.8%) during follow-up. In patients with progression, the rates of lymph node and distant metastasis were higher than in those without progression (p: 0.030 and 0.006, respectively). Significant differences were observed between progression and non-progression patients in 15 morphological, 2 density-based, and 3 histogram parameters derived from the primary tumor. No correlation was observed between morphological_surface_area and intensity_based_skewness parameters. In logistic regression analysis, morphological_surface_area (p: 0.008, OR: 24.143, 95% CI: 2.277-256.043) and intensity_based_skewness (p: 0.018, OR: 11.021, 95% CI: 1.518-80.003) were identified as prognostic factors for predicting progression. The model derived from these parameters was able to accurately classify 32 patients (p<0.001, AUC: 0.887, 78.6% sensitivity, 87.5% specificity). ***Conclusion:*** Morphological and density-based parameters obtained from the primary tumor can serve as predictive factors for identifying TNBC patients who may progress during follow-up.

EP-0211

Accuracy of [^{68}Ga]Ga-FAPI PET/CT in Evaluating Axillary Lymph Node Status After Neoadjuvant Therapy in Clinically Node-Positive Breast Cancer Patients

Y. Fan[1], *J. Hu*[1], *C. Hu*[2], *S. Zhu*[2], *Y. Lu*[2], *Y. Peng*[1], *Q. Hu*[1], *P. Ju*[1], *B. Li*[1], *Y. Yuan*[3], *K. Shen*[2], *X. Chen*[2];
[1]*Department of Nuclear Medicine, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Department of General Surgery, Comprehensive Breast Health Center, Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [3]*Department of Radiology, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: Accurate diagnosis of axillary lymph node (ALN) status after neoadjuvant therapy (NAT) can guide de-escalation surgery in breast cancer. Given the lack of accurate imaging methods for assessing residual ALN status, we investigated the accuracy of [^{68}Ga]Ga-FAPI PET/CT in evaluating ALN after NAT in clinical ALN positive breast cancer patients. ***Materials and Methods:*** In this prospective phase II study, breast cancer patients with clinical lymph node positive (cN+) who underwent NAT receiving pre-operative assessed with ALN ultrasound (US) and [^{68}Ga]Ga-FAPI PET/CT after NAT were enrolled between August 2024 and February 2025. PET parameters were measured on PET/CT images for ALN, mediastinal blood pool, and hepatic blood pool. Imaging findings were subsequently compared with histopathological results from surgical specimens of the ALN. ***Results:*** A total of 48 patients were included, of whom 22 (45.8%) achieved ypN0 status. The mean ALN SUVmax value on [^{68}Ga]Ga-FAPI PET/CT was significantly lower in the ypN0 group (3.04 ± 3.78) compared to the ypN+ group (8.75 ± 8.98, P = 0.006). Based on AUC analysis and Youden's index, an SUVmax cutoff value of 3.19 was identified as optimal for distinguishing lymph node status. When compared to ultrasound (specificity: 0.46, 95% CI: 0.27-0.68; positive predictive value [PPV]: 0.60, 95% CI: 0.49-0.71), [^{68}Ga]Ga-FAPI PET/CT demonstrated superior diagnostic performance, with a specificity of 0.96 (95% CI: 0.86-1.00, P < 0.001) and a PPV of 0.94 (95% CI: 0.81-1.00, P < 0.001). Furthermore, the negative predictive value (NPV) was significantly higher in patients with triple-negative or HER2-positive breast cancer compared with ultrasound (1.00 vs. 0.56, P < 0.001). Additional PET parameters, including the SUVmax ratio of ALN-to-aortic arch blood pool (TBRAmax) and the SUVmean ratio of ALN-to-liver blood pool (TBRLmean), also exhibited strong diagnostic efficacy. With thresholds of 0.841 and 2.517, respectively, these parameters demonstrated sensitivities of 0.92 (95% CI: 0.81-1.00) and 0.81 (95% CI: 0.65-0.96), as well as NPVs of 0.88 (95% CI: 0.72-1.00) and 0.76 (95% CI: 0.63-0.92). ***Conclusion:*** Our study demonstrated that [^{68}Ga]Ga-FAPI PET/CT had superior diagnostic accuracy in assessing ALN status after NAT compared to ultrasound, which could potential guide further de-escalation surgery of ALN in these breast cancer patients.

EP-0212

Trop2-targeted [18F]AIF-RESCA-T4 Immuno-PET/CT in Breast Cancers: Evaluation Across Different Molecular Subtypes

***W. Jia**, G. Huang, J. Liu, W. Wei;*
Department of Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: The study aimed to evaluate Trop2 expression in different molecular subtypes of breast cancer and explore the potential of [^{18}F]AIF-RESCA-T4 immuno-PET/CT imaging in diagnosing primary lesions and lymph node metastases. ***Materials and Methods:*** Trop2 expression was detected using immunohistochemistry (IHC) on tissue microarrays (TMA) and quantified using the H-score (0–300). Seventeen breast cancer patients underwent [^{18}F]AIF-RESCA-T4 immuno-PET/CT imaging to detect primary lesions and potential metastases. Pathology specimens from all patients were used for Trop2 staining. Receiver Operating Characteristic (ROC) curves were used to calculate the diagnostic cutoff values of the tracer. ***Results:*** Trop2 expression was significantly higher in breast tumor tissues than adjacent normal tissues, with no significant correlation to clinicopathological features. [^{18}F]AIF-RESCA-T4 uptake strongly correlated with Trop2 expression in the primary and metastatic tumors (R^2 = 0.7339, P < 0.001). Diagnostic cutoff values for the primary tumors (SUVmax = 3.125) and lymph node metastases (SUVmax = 2.12) showed high sensitivity and specificity, with 97.2% and 94.4% for primary tumors and 95% and 98.6% for lymph node metastases, respectively. [^{18}F]AIF-RESCA-T4 immuno-PET/CT imaging demonstrated good diagnostic value for most invasive cancer types, except neuroendocrine tumors, and effectively differentiated tumors from inflammatory diseases. ***Conclusion:*** Trop2 is highly expressed across all breast cancer molecular subtypes and is unrelated to clinicopathological features. [^{18}F]AIF-RESCA-T4 immuno-PET/CT imaging shows potential for assessing tumor burden, detecting lymph node metastases, and guiding therapeutic decisions in breast cancer.

EP-0213

Response Assessment with ^{18}F-FDG PET/CT in Tripple Negative Breast Cancer Patients Undergoing Combined Immunochemotherapy: A Retrospective Analysis

***E. Popova**[1], Z. Zhelyazkova[2], S. Sergieva[1], R. Krasteva[2];*
[1]Acibadem City Clinic Tokuda Hospital, Sofia, BULGARIA, [2]Unihospital, Panagyurishte, BULGARIA.

Aim/Introduction: The integration of immunotherapy into chemotherapy regimens is expanding therapeutic strategies for triple negative breast cancer (TNBC), both in early-stage or metastatic disease [1]. Accurate assessment of treatment response is essential for tailoring clinical management. ^{18}F-FDG PET/CT combines anatomical and metabolic information, offering a comprehensive tool for evaluating disease status beyond conventional imaging alone [2]. This retrospective study assesses therapy response in triple negative breast cancer patients receiving combined immunochemotherapy in a clinical practice setting. ***Materials and Methods:*** We retrospectively included all patients diagnosed with triple negative breast cancer and treated with Immune Checkpoint Inhibitors (ICIs) between March 2023 and February 2024 at our center. Of the 19 initially identified patients, 3 were excluded due to insufficient follow-up data, resulting in a final cohort of 16 patients. Data included ICD-10 diagnosis, TNM staging (with post-surgical staging in neoadjuvant cases), histopathological results, PET/CT findings at baseline and up to three follow-up timepoints, treatment regimens, and any therapy modifications. Ten patients received neoadjuvant therapy and six received adjuvant therapy. ***Results:*** In the neoadjuvant group, 6 of 10 patients (60%) showed complete response (CR) on PET/CT, all of whom also achieved pathological complete response (pCR), demonstrating full concordance between PET/CT imaging and histology. Four of the ten patients showed partial response (PR). In the adjuvant group, 4 of 6 patients (67%) achieved complete response (CR), one had progressive disease (PD), and one achieved stable disease (SD). The overall complete response rate in the cohort of 16 patients was 63% (10 out of 16 patients). ***Conclusion:*** Combined immunochemotherapy demonstrated high efficacy in this cohort, with a substantial proportion of patients achieving complete response in both neoadjuvant and adjuvant settings. PET/CT served as a valuable tool for response assessment, offering combined anatomical and metabolic insights. In the neoadjuvant group, PET/CT complete response correlated strongly with pathological complete response, supporting its role in guiding treatment decisions. Further prospective studies with larger cohorts are needed to confirm these findings. ***References:*** 1. Javier Cortes, Hope S. Rugo, David W. Cescon et al. Influence of Plasma Estradiol Levels on ^{18}F-FES Uptake in ER-Positive Breast Cancer

***K. Miyake**[1], Y. Shimizu[1], M. Kawashima[1], S. Yuge[2], Y. Kitano[1], S. Yasumura[1], Y. Kitai[3], T. Oishi[3], K. Itagaki[3], M. Kataoka[1], N. Masuda[1], K. Nakatani[1], Y. Nakamoto[1];*
[1]Kyoto University Graduate School of Medicine, Kyoto, JAPAN, [2]Tenri Hospital, Nara, JAPAN, [3]Kyoto University Hospital, Kyoto, JAPAN.

Aim/Introduction: The estrogen receptor (ER) is a crucial biomarker in breast oncology, and ^{18}F-fluoro-17β-estradiol (FES) PET is increasingly utilized as a noninvasive tool to assess ER expression. While several factors such as SERDs and SERMs are known to affect FES uptake, the impact of menopausal status or plasma estradiol (E2) levels remains controversial [1]. This study aimed (1) to investigate the association between tumor FES uptake and endogenous plasma E2 levels in breast cancers with high ER expression, and (2) to explore whether physiological uterine uptake could serve as a surrogate marker to predict the influence of E2 on tumor uptake. ***Materials and Methods:*** Female patients with ER-positive breast cancer who underwent FES PET/CT at initial staging and had no prior exposure to selective estrogen receptor modulators or selective estrogen receptor downregulators were included. SUVmax was measured for histologically confirmed primary invasive breast cancers with high ER expression (>70% IHC staining), as well as for the uterus. Plasma estradiol levels were measured at the time of FES injection and categorized as low (<20 pg/mL), mild (20-100 pg/mL), moderate (100-200 pg/mL), or high (≥200 pg/mL). Statistical analyses were conducted using the Wilcoxon/Kruskal-Wallis test and Spearman's rank correlation coefficient. ***Results:*** A total of 61 female patients (age range: 27-90 years; 25 premenopausal, 36 postmenopausal) were included. Among 67 tumors (56 NOS, 7 ILC, 4 others), the median tumor SUVmax was 3.2 (range: 0.5-22). Tumor SUVmax was significantly lower in premenopausal patients (median: 4.0, range: 0.5-9.1) compared to postmenopausal patients (median: 4.4, range: 0.9-22). There was a mild but significant positive correlation between tumor SUVmax and age (ρ = 0.32, p < 0.01). Tumor SUVmax differed significantly across E2 categories (p = 0.035) and showed an inverse correlation with E2 levels (ρ = -0.32, p < 0.01). No association was found between tumor size and SUVmax. Uterine SUVmax (median: 6.0, range: 1.5-14.6) was observed regardless of menopausal status. Uterine SUVmax did not significantly correlate with menopausal status or E2 levels. No significant association was found between tumor SUVmax

and uterine SUVmax. ***Conclusion:*** In breast cancers with high ER expression, tumor FES uptake appears to be influenced by plasma E2 levels. However, physiological uterine uptake does not reliably predict the E2-related decrease in tumor FES uptake. ***References:*** 1) Peterson LM, et al. Factors influencing the uptake of 18F-fluoroestradiol in patients with estrogen receptor positive breast cancer. Nucl Med Biol. 2011;38:969-978.

EP-0215

Toward 'Less is More': ^{68}Ga-FAPI PET/CT Optimizes Axillary Management in Invasive Breast Cancer

J. Li, *W. Mu, Y. Tang, K. Zhang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: The shift toward "less is more" in axillary management of breast cancer (BC) necessitates accurate nodal staging to minimize overtreatment. Although sentinel lymph node biopsy (SLNB) and axillary lymph node dissection (ALND) remain standards for clinically node-negative (cN0) patients, their procedural morbidity (e.g., lymphedema) drives demand for non-invasive alternatives. Conventional imaging often fails to accurately stratify nodal tumor burden, leading to unnecessary interventions. We prospectively evaluated ^{68}Ga-FAPI PET/CT for preoperative axillary metastasis detection and surgical de-escalation guidance, aligning with modern de-escalation paradigms (e.g., Z0011, AMAROS). ***Materials and Methods:*** Seventy treatment-naive cT1-3N0M0 invasive BC patients (females; mean age 53 years) underwent preoperative ^{68}Ga-FAPI PET/CT and MRI, followed by SLNB/ALND. Visual and quantitative analyses of PET/CT images were performed using pathology (macro-metastasis >2 mm) as the reference standard. Diagnostic performance for nodal metastasis (binary detection and burden stratification: N-low [0-2 nodes] vs. N-high [≥3 nodes]) was assessed. Optimal SUVmax thresholds were derived. Statistical analyses used SPSS 27 and R 4.4.2. ***Results:*** For binary ALN metastasis detection, ^{68}Ga-FAPI PET/CT visual analysis outperformed MRI (AUC: 91.4% vs. 72.9%; p<0.001), with 66.7% sensitivity, 100% specificity, 100% PPV, and 89.7% NPV. Quantitative analysis further improved performance (SUVmax cutoff 1.25: 94.9% accuracy, 80% sensitivity, 100% specificity, 100% PPV, 93.6% NPV). Crucially, ^{68}Ga-FAPI PET/CT achieved 100% accuracy, specificity, and NPV in nodal burden stratification, correctly identifying all N-low cases (enabling potential ALND avoidance) and distinguishing N-high disease. ***Conclusion:*** ^{68}Ga-FAPI Ga-FAPI PET/CT offers a highly specific, non-invasive tool for preoperative ALN assessment in invasive cT1-3N0M0 BC, facilitating precision axillary management. Its superior diagnostic performance over MRI supports its integration into de-escalation protocols to reduce unnecessary surgeries.

EP-0216

Radiological indicators of peritumoural and whole-breast vascularity and their association with [^{18}F]-FMISO PET/MRI parameters of hypoxia and vascular function in breast cancer

R. Manavaki[1], *J. C. Carmona-Bozo[1], S. Carriero[1], N. Stranz[1], J. L. Miller[2], C. Brodie[2], C. Caracò[1], M. J. Graves[1], A. J. Patterson[1], T. D. Fryer[1], E. Provenzano[3], F. J. Gilbert[1];*
[1]University of Cambridge, Cambridge, UNITED KINGDOM, [2]Cancer Research UK - Cambridge Institute, Cambridge, UNITED KINGDOM, [3]Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM.

Aim/Introduction: Breast cancers, like other solid tumours, exhibit vascular abnormalities, leading to irregular blood flow and heterogeneous states of hypoxia within the lesion. This study assessed the relationship between radiological markers of whole-breast and peritumoral vascularity and parameters of tumour hypoxia and vascular function derived from PET/MR imaging with [^{18}F]-fluoromisonidazole ([^{18}F]-FMISO). ***Materials and Methods:*** Women aged >18 years with treatment-naïve, biopsy-confirmed breast cancer underwent a 60-min PET/MR scan two hours after injection of 300 MBq [^{18}F]-FMISO. Parameters of vascular function (K^{trans}, k_{ep}, v_e, v_p) were derived from DCE-MRI using the extended Tofts' model. Tumour hypoxia was assessed using the influx rate constant K_i for [^{18}F]-FMISO determined by Patlak-plot analysis. Hotspot (hs)-K^{trans} was also calculated. Peritumoural vascularity was analysed by counting adjacent feeding vessels (AFV) in contact with or penetrating the lesion. Whole-breast vascularity was quantified by counting the number of significant vessels (i.e., ≥3 cm long, and ≥2 mm in transverse diameter) in the ipsilateral breast. Post-surgical tumour sections were stained for CD31, hypoxia-inducible factor (HIF)-1α and carbonic anhydrase IX (CAIX). Microvessel density (MVD) and median vessel diameter were obtained from CD31 microarrays via computer-assisted analysis. HIF-1α and CAIX expression were scored by the percentage of positively stained cells. Pathological correlates included tumour type, grade, and molecular subtype. Associations between variables of interest were analysed using linear models or Spearman's ρ. ***Results:*** 31 tumours were analysed with the majority being ductal cancers (20/31; 64.5%), grade 2 or 3 (28/31; 90%) and hormone receptor-positive (30/31; 97%). A negative association was found between AFV number and [^{18}F]-FMISO K_i (ε^2=0.07, p=0.048), while a positive association was observed with hs-K^{trans} (ε^2=0.27, p=0.002). Similarly, a negative relationship was observed between the number of significant vessels in the ipsilateral breast and tumour [^{18}F]-FMISO K_i (ε^2=0.11, p=0.04). In contrast, significant vessel number was positively related with mean tumour K^{trans} (ε^2=0.21, p=0.006), v_e (ε^2=0.11, p=0.04) and v_p (ε^2=0.21, p=0.006). No significant association was observed between measures of peritumoural or whole-breast vascularity and tumour histology, grade or molecular subtype. In a subset of 24 cancers for which immunohistochemistry was available, AFV was negatively correlated with vessel diameter (ρ=-0.49, p=0.03). In contrast, no significant correlations were found between AFV or significant vessel number with MVD, CAIX or HIF-1α expression. ***Conclusion:*** Poor peritumoural and whole-breast vascularity are associated with hypoxia and inadequate vascular function as measured by [^{18}F]-FMISO-PET/MRI, suggesting potential use of these radiological descriptors in characterising breast cancer.

EP-0217

[18F]FDG and [68Ga]FAPI PET/CT for lesion detection and characterization in Triple Negative Breast Cancer patients

N. Hovhannisyan-Baghdasarian[1], *L. Champion[2], N. Jehanno[3], R.-D. Seban[2], H. Tissot[3], J. Fouque[4], F. Coussy[5], D. Bello Roufai[5], D. Loirat[6], S. Rafie[7], F.-C. Bidard[5], F. Mechta-Grigoriou[7], I. Buvat[1];*
[1]Institut Curie, Inserm, Orsay, FRANCE, [2]Dpt of Nuclear Medicine, Institut Curie, Saint Cloud, FRANCE, [3]Dpt of Nuclear Medicine, Institut Curie, Paris, FRANCE, [4]Dpt of Pharmacy, Institut Curie, Saint-Cloud, FRANCE, [5]Dpt of Medical Oncology, Institut Curie, Saint-Cloud, FRANCE, [6]Dpt of Medical Oncology, Institut Curie, Paris, FRANCE, [7]Unité Chimie Biologie des Cancers, Institut Curie, Inserm, CNRS, Paris, FRANCE.

Aim/Introduction: The usefulness of [68Ga]FAPI PET/CT for triple negative breast cancer (TNBC) patient management has not been studied much, while Fibroblast Activation Proteins (FAP) are significantly expressed in the TNBC tumor microenvironment. As part of the Skyline trial (NCT06175390), we investigate the complementarity between [18F]FDG and [68Ga]FAPI PET/CT for lesion detection and characterization in early and advanced TNBC patients. ***Materials and Methods:*** Skyline is an ongoing phase 2 trial prospectively enrolling 160 patients with TNBC to explore the use of an anti-TIGIT therapy combined with anti PD-L1 and chemotherapy in 2 cohorts: neoadjuvant (cohort A) or first line therapy (cohort B). All patients undergo [18F]FDG and [68Ga]FAPI-46 PET/CT before treatment and after 2 cycles. All tumor lesions were segmented by an expert using a threshold of SUV≥2.5 in the

[18F]FDG and [68Ga]FAPI PET images independently. SUVmax and Total Tumor Signal (TTS) defined as mean SUV multiplied by the tumor volume on the corresponding PET images were calculated. Patient response is not disclosed as patient recruitment is ongoing. ***Results:*** 50 patients have already been enrolled: 38 in cohort A, 12 in cohort Images of 33 patients who had their baseline and 2-cycle scans performed have been analyzed (26 from cohort A and 7 from cohort B), corresponding to 91 lesions (primary, nodes and metastases) in total. In those 91 lesions, 83 were seen on the FDG and FAPI scans, 7 were seen on the FDG scan only, and 1 was seen on the FAPI scan only. At baseline, SUVmax in the primary tumors (n=33) was significantly lower in the FAPI scan (15.2±4.8) compared to the FDG scan (18.2±7.6, paired t-test p<0.05). Yet, the primary tumor volume tended to be higher in the FAPI images (27±23 mL) compared to the FDG images (22±35 mL, p=0.125). This resulted in a TTS non-significantly different in FDG and FAPI scans (p=0.5). Similarly, in nodes (n=20), the average SUVmax_FAPI was significantly lower than SUVmax_FDG (p=0.04), while TTS was not significantly different in FDG and FAPI scans. ***Conclusion:*** In these two cohorts, 91% of the lesions seen on the FDG scans expressed FAP as revealed by [68Ga]FAPI PET. Although the baseline SUVmax was significantly lower in the FAPI scans compared to the FDG scans, the volume of [68Ga]FAPI expression tended to be larger than the FDG positive volume, suggesting that both SUVmax and TTS should be later correlated with the treatment response and patient outcome.

Exploring Brain Metabolic and Functional Changes in Solitary Pulmonary Lesions: A ^{18}F-FDG PET/MR Study Comparing Malignant and Benign Cohorts

N. Meng[1], *Q. Ji*[2], *J. Pan*[1], *Q. Chen*[1], *Y. Yang*[3], *Z. Wang*[2], *M. Wang*[1];
[1]*Henan Provincial People's Hospital, Zhengzhou, CHINA,* [2]*United Imaging Healthcare Advanced Technology Research Institute Co., Ltd., Shanghai, CHINA,* [3]*United Imaging Healthcare Co., Ltd., Beijing, CHINA.*

Aim/Introduction: The brain is the most important organ in the human body, and the lungs are the primary respiratory organ, and previous studies have shown that there is an important interaction between the lungs and the brain. This study aims to investigate differences in brain metabolic and functional alternations between patients with benign and malignant solitary pulmonary lesions (SPL) using multimodal ^{18}F-FDG PET/MR imaging. ***Materials and Methods:*** A total of 124 SPL patients were enrolled in this study, including 24 with benign lesions and 100 with malignant lesions. Cognitive status of each subject was evaluted using the Mini-Mental State Examination (MMSE). All patients underwent integrated ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET/MR examinations, with acquisition of high-resolution T1-weighted structural images, resting-state functional fMRI (rs-fMRI) and ^{18}F-FDG images. Normalized standardized uptake value ratio (SUVR) maps were calculated from ^{18}F-FDG images using pons as the reference region to quantify metabolic changes. For functional characterization, regional homogeneity (ReHo), amplitude of low-frequency fluctuation (ALFF), and fractional ALFF (fALFF) maps were computed from rs-fMRI data to investigate intrinsic brain functional alterations. Whole-brain voxel-wise group comparisons between malignant and benign group were performed using two-sample t-tests. ***Results:*** Patients with malignant SPL exhibited significantly lower MMSE scores compared to those with benign SPL (27.1 ± 3.5 vs. 29.4 ± 1.2, $p < 0.01$). Metabolic analysis found significantly reduced SUVR in malignant group in posterior cingulate (peak MNI: [4 -62 6]), with additional reductions observed in occipital lobe (two-tailed, voxel $p < 0.01$, cluster $p < 0.05$, GRF-corrected). In contrast, all functional metrics, including ReHo, ALFF, and fALFF showed no significant between-group differences across all brain regions. ***Conclusion:*** The results revealed that malignant SPL is associated with a marked reduction in cognitive performance relative to benign SPL. Significant metabolic reductions were found in posterior cingulate and other specific brain regions. These results provide evidence for lung cancer-induced brain alterations, suggesting that tumor-related metabolic dysfunction in specific neural circuits may underlie cognitive impairment observed in cancer patients.

Long-Axial-Field-Of-View PET/CT in Deep-Inspiration-Breath-Hold for radiation therapy planning of mediastinal lymphoma

S. Honoré d'Este[1], *O. E. Wagner*[1], *P. A. Andersen*[2], *D. Dejanovic*[1], *A. Loft*[1], *M. G. Askløf*[1], *E. Albrecht-Beste*[1,3], *I. R. Vogelius*[2,3], *L. Specht*[2,3], *F. L. Andersen*[1,3];
[1]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Copenhagen, DENMARK,* [2]*Department of Oncology, Copenhagen University Hospital, Copenhagen, DENMARK,* [3]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: Initial staging Positron Emission Tomography / Computed Tomography (PET/CT) of mediastinal lymphoma patients was shifted from conventional to the 106cm Long-Axial-Field-Of-View (LAFOV) PET/CT upon installation in 2021. The increased FOV allowed for inclusion of the neck, chest and upper abdomen in a single bed position during Deep-Inspiration-Breath-Hold (DIBH). This allowed optimal image fusion with later radiotherapy planning CT in DIBH following chemotherapy. This enabled a reduction in radiation exposure to nearby Organs-At-Risk (OAR) such as the heart and lungs [1]. ***Materials and Methods:*** 37 adult patients (20y-95y) with mediastinal lymphoma were included. Initial staging was performed using a LAFOV PET/CT standard protocol of 3 MBq/kg [18F]FDG, administered 60min prior to scanning. A custom made mount platform was developed to mount the Respiratory-Gating-for-Scanners (RGSC) system to the standard flat table-top for correct positioning in potential RT. The initial protocol included a Whole-Body DIBH CT with intravenous contrast and 4x18sec DIBH PET acquisitions, which were decay corrected and averaged to a final 72sec PET image. Thoracic wall movement of ±1.5mm was tolerated during DIBH. The staging protocol was finalized with a 300sec Free Breathing (FB) PET using a Low-Dose CT for attenuation correction. 10/37 patients received additional RT following chemotherapy. These patients underwent a DIBH planning CT post-treatment, which was fused with the initial staging DIBH PET/CT and used for delineation of the initial Gross-Lymphoma-Volume, the Clinical-Target-Volume (CTV, i.e., the initially involved lymphoma volume modified for anatomical changes during chemotherapy), and OAR. RT planning was done in accordance with national and international guidelines. ***Results:*** 35/37 patients tolerated all 4x18sec WB DIBH PET scans, while the remaining 2/37 only accomplished 2x18sec DIBH. 37/37 patients achieved DIBH images of satisfactory quality for RT planning with a mean liver Coefficient-Of-Variance of 14.3% ±2.00. The fusion of the initial staging and post-chemo imaging allowed optimal conditions for later CTV delineation which enabled us to keep the mean dose to the heart at a median of 4.37Gy (range [1.68Gy;7.24Gy]) and to the lungs at a median of 7.81Gy (range [4.43Gy;14.2Gy]). ***Conclusion:*** DIBH PET images of satisfactory clinical quality can be obtained in 4x18sec on LAFOV PET/CT and

are well tolerated by patients. Fusion of initial staging DIBH PET/CT with DIBH planning CT performed post-chemotherapy allows for higher precision in target definition and reduction in mean dose of surrounding OAR during RT. ***References:*** [1] doi:10.1102/1470-7330.2011.9063.

EP-0220

Multicenter Evalution of Predictive Clinical and Radiological markers for Pathological Complete Response and Major Pathological Response in NSCLC Patients Undergoing Neoadjuvant Chemoimmunotherapy

M. Zhang[1], *M. Yan*[2], *Z. Zhang*[1];
[1]*Department of Lung Cancer Surgery, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin Lung Cancer, Tianjin, CHINA,* [2]*Department of Radiology, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin Lung Cancer Center, 30, Tianjin, CHINA.*

Aim/Introduction: This study aimed to identify clinical factors and develop a predictive model for pathologic complete response (pCR) and major pathologic response (MPR) in non-small cell lung cancer (NSCLC) patients receiving neoadjuvant chemotherapy combined with immune checkpoint inhibitors (ICIs). ***Materials and Methods:*** Cases meeting inclusion criteria were divided into high- and low-risk groups according to 75 clinical indicators based on 10-fold LASSO selection. Logistic regression was employed to analyze both pCR and MPR. The accuracy of the nomograms was assessed using the time-dependent area under the curve (AUC). ***Results:*** A total of 883 patients from four multiple centers were included in the study, with 526 assigned to the training set and 357 to the testing set. The AUC was determined for the prediction of pCR (training: 0.97; testing: 0.87) and MPR (training: 0.94; testing: 0.85). Significant associations were observed between the preoperative tumor maximum diameter, preoperative tumor maximum standardized uptake value (SUV_{max}), changes in tumor SUV_{max}, percentage of tumor reduction, baseline total CYFRA21-1 and pathological response ($P < 0.001$). ***Conclusion:*** The combined application of clinical indicators including non-invasive tumor imaging and hematology can help clinicians to obtain a higher ability to predict NSCLC patient's pathological remission, and the effect is better than that of clinical factors alone. These findings could help guide personalized treatment strategies in this patient population.

EP-0221

Performance pulmonary nodules detection using Deep Learning motion correction techniques in 18-FDG PET/CT protocols.

M. Giménez Aranda[1,2], *E. Marino*[1,3], *G. Peña*[1];
[1]*FUESMEN (Fundación Escuela de Medicina Nuclear), Mendoza, ARGENTINA,* [2]*Universidad de Mendoza, Mendoza, ARGENTINA,* [3]*CNEA (Comisión Nacional de Energía Atómica), Buenos Aires, ARGENTINA.*

Aim/Introduction: Pulmonary nodules(PN) detection is essential for staging in cancer patients. Accurate PN detection via PECT/CT scans is limited by respiratory motion[1], which leads to image resolution loss, attenuation correction artefacts, and lesion mislocalisation[2]. The uExcel Focus technique seeks to address this difficulty using Deep Learning-based reconstruction to mitigate such errors[2]. This study aims to evaluate the effectiveness of respiratory motion correction using Deep Learning-enhanced reconstruction methods compared with standard and gated OSEM reconstructions, focusing on metabolic PN detectability and image quality(IQ) improvements assessment in PET/CT FDG protocols. ***Materials and Methods:*** Images were acquired in 54 patients with 18-FDG PET/CT(LYSO and SiPM detectors) with low dose protocols(0.055 mCi/kg), 6 min/bed in list mode. Reconstruction methods were performed: OSEM(standar)(2 iterations, 20 subsets), OSEM Self Gated and VSM Gated(2 iter, 20 subsets), OSEM Focus Self Gated(FSG) and VSM Gated(FVG)(2 iter, 20 subsets), Hyper Iterative VSM Gated(HIG)(strength: 0.90), and Hyper DPR(ST1). With subsequent reconstruction in 4 and 2 min. Volume of interest(VOI) was analysed in the PN, parenchyma, liver and blood pool. For the VOIs measurement were obtained SUVmax, SUVmean, PN volume(PNvol) and standard deviation. Contrast, contrast-to-noise ratio(CNR) and noise were evaluated for IQ. For co-registration, intensity-normalised coronal profiles were plotted on CT and PET images at liver height, calculating the fusion error[mm] as the difference of the profiles. ***Results:*** A total of 47 PNs were detected(diameter range: 3.8-22.0 mm). FSG and FVG showed a significant reduction in co-registration error compared to standard(mean difference:4.15 mm and 4.47 mm; p=0.0016 and 0.00077; Cohen's d=0.78 and 0.80). FVG improves the contrast by 42% compared to standard with no significant difference versus HIG(p>0.84) at 4 min/bed. DPR and HIG present noise reduction bigger than 27% compared to standard and 17% more than FVG at 4-6min/bed and present the maximum value of CNR between 10 and 27% more than FVG 6 min/bed. PNvol is decreased in all reconstructions with respect to standard, with a maximum reduction in 6 min/bed FVG of 40%. FSG and FVG are very highly correlated(r>0.98) with standard in SUVmax values. ***Conclusion:*** Focus Gated of 4 min/bed is a promising tool, as they offer better PN detectability with improved co-registration and IQ superior to standard. ***References:*** [1]Montaño,A.(2024)"Desempeño en la detectabilidad de lesiones pulmonares metabólicas en sistema PET/CT aplicando técnicas de reconstrucción gatilladas y Deep Learning".ESPOCH, Ecuador.[2]Lu,Yihuan,et al.«uExcel Focus: A Unified Solution for Respiratory Motion in PET/CT».Journal of Nuclear Medicine, 64(1),P1261.

EP-0222

Correlation of PD-L1 Expression with PET/CT Metabolic Parameters in Non-Small Cell Lung Cancer

A. Erdem Karaoglu[1], *A. Cinar*[1], *O. Sutcuoglu*[2], *N. Aydinbelge Dizdar*[1], *O. Ozmen*[1,3];
[1]*Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara Etlik City Hospital, Department of Medical Oncology, Ankara, TÜRKIYE,* [3]*University of Health Sciences, Ankara, TÜRKIYE.*

Aim/Introduction: The interaction between PD-1 (programmed cell death receptor-1) and PD-L1 (programmed cell death ligand-1) immune-checkpoints in the immune system creates an inhibitory effect, which limits the immune system's ability to target and destroy tumor cells. Anti-PD-1/PD-L1 antibodies can eliminate this effect, allowing the immune system to destroy tumor cells. PD-L1 expression on tumor cells is a significant factor in selecting immunotherapy treatment. In this study, we aimed to evaluate the correlation between metabolic parameters obtained from F18-FDG PET/CT imaging and PD-L1 positivity in patients with non-small cell lung cancer (NSCLC). ***Materials and Methods:*** We retrospectively analyzed the F18-FDG PET/CT images of 185 NSCLC patients who underwent imaging for pre-treatment staging at our clinic between December 2023 and February 2025. Patients were grouped as PD-L1 negative (n=86) and positive (n=99).Both groups were also evaluated by pathological subtypes: adenocarcinoma (n=107) and squamous cell carcinoma (n=78). From the F18-FDG PET/CT images, the following were assessed: primary lesion location, margin characteristics, structural pattern (solid or ground-glass), presence of necrosis, and metabolic parameters (SUVmax, SUVmean, SULpeak, TLG, and MTV). Visual and semi-quantitative data were compared between groups. A

p-value of <0.05 was considered statistically significant. ***Results:*** PD-L1 positive patients were divided into weak (1-10%), moderate (11-50%), and strong (51-100%) subgroups. When comparing the strong PD-L1 positive group with the PD-L1 negative group, SUVmax and SUVmean were significantly higher in the strong positive group (p=0.019; p=0.01). When moderate and strong groups were evaluated together, SUVmax, SUVmean, and SULpeak were significantly higher than in the negative group (p=0.005; p=0.001; p=0.02) When all PD-L1 positive patients were analyzed together, SUVmax, SUVmean, and SULpeak were significantly higher compared to the PD-L1 negative group (p=0.002; p<0.001; p=0.007) In the subgroup analysis, PD-L1 positive adenocarcinoma patients (n=54) showed significantly higher SUVmax, SUVmean, and SULpeak compared to PD-L1 negative adenocarcinoma atients (n=53) (p=0.004; p=0.002; p=0.004) However, in patients with squamous cell carcinoma, no statistically significant difference was observed between the groups (p>0.05). ***Conclusion:*** Our study suggests that metabolic parameters obtained from F18-FDG PET/CT can serve as predictive indicators of high PD-L1 expression in NSCLC, particularly in the adenocarcinoma subtype. Among these parameters, SUVmean was found to be the most statistically significant. SUV measurements from F18-FDG PET/CT, which is an easily accessible and noninvasive imaging method today, may contribute to the determination of patients who are candidates for immunotherapy treatment by providing information about the PD-L1 positivity of the lesions.

EP-0223

Comparative Performance of ^{18}F-FDG and ^{18}F-PSMA PET/CT in Lung Cancer: Adenocarcinoma versus Squamous Cell Carcinoma

N. Silveira, *M. W. P. Júnior, M. S. Takahashi, S. Kuba, B. J. Amorim, M. d. L. Lima, C. A. Souza, C. S. P. Lima, C. D. Ramos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: As a leading global cause of cancer mortality, lung cancer management benefits from metabolic imaging with ^{18}F-FDG PET/CT. Emerging evidence suggests prostate-specific membrane antigen (PSMA)-targeted PET/CT, while established in prostate cancer, may have utility in other malignancies due to PSMA's association with tumor angiogenesis. This study evaluates both tracers in lung adenocarcinoma and squamous cell carcinoma (SCC), assessing subtype-specific uptake patterns. ***Materials and Methods:*** This study evaluated both tracers in 14 patients (9 men, 5 women; age range 55-82 years) with histologically confirmed lung cancer (10 adenocarcinoma, 4 squamous cell carcinoma [SCC]). All patients underwent both ^{18}F-FDG and ^{18}F-PSMA PET/CT scans (0.1 mCi/kg dose, 60- and 90-minute uptake periods, respectively), with images interpreted by three specialists. ***Results:*** The analysis of 288 total lesions (247 adenocarcinoma, 41 SCC) revealed distinct patterns between tracers and subtypes. In adenocarcinoma, ^{18}F-FDG detected 237 lesions compared to 215 by ^{18}F-PSMA, with 32 lesions visible only on ^{18}F-FDG and 9 exclusively on ^{18}F-PSMA. While most adenocarcinoma lesions showed higher ^{18}F-FDG uptake (median SUVmax 6.5 versus 4.0 for PSMA), 45 lesions demonstrated predominant ^{18}F-PSMA uptake. SCC exhibited different characteristics, with ^{18}F-FDG identifying 41 lesions versus 36 by ^{18}F-PSMA, and no cases showing PSMA-dominant uptake. The median SUVmax values in SCC were 8.8 for ^{18}F-FDG compared to just 2.5 for ^{18}F-PSMA. We found that SUV values for ^{18}F-PSMA are statistically different between SCC and adenocarcinoma subtypes in the lesions that showed uptake of both radiotracers (Mann-Whitney U test, p-value < 0.0001). Also, a positive correlation was observed for ^{18}F-FDG and ^{18}F-PSMA SUVs in both histological subtypes, being strong for SCC (r = 0.0,8140, p-value < 0.0001) and moderate for adenocarcinoma (r = 0.4278, p-value < 0.0001). ***Conclusion:*** These findings demonstrate differences in tracer uptake patterns between lung cancer subtypes. Squamous cell carcinomas show minimal ^{18}F-PSMA avidity, suggesting limited clinical utility of this tracer for SCC evaluation. In contrast, adenocarcinomas display more variable uptake, with a subset of lesions showing significant ^{18}F-PSMA accumulation that may reflect active neoangiogenesis. PSMA-positive adenocarcinomas may represent a subgroup amenable to PSMA-directed therapies or angiogenesis inhibitors. These results warrant further investigation into the potential role of ^{18}F-PSMA PET/CT in personalizing treatment approaches for lung adenocarcinoma patients.

EP-0224

The Relationship Between Metabolic Parameters Derived from ^{18}F-FDG PET/CT Images and Systemic Inflammatory Response with Disease Stage and Survival in Primary Staging of Small Cell Lung Cancer

K. Seker, *Z. Hasbek;*
Sivas Cumhuriyet University, Faculty Of Medicine, Department of Nuclear Medicine, Sivas, TÜRKIYE.

Aim/Introduction: To evaluate the relationship between metabolic parameters derived from staging ^{18}F-FDG PET/CT images and the systemic inflammatory response index(SII) with disease stage and overall survival(OS) in patients with small cell lung cancer (SCLC). ***Materials and Methods:*** In patients diagnosed with SCLC between 2012 and 2023, PET data related to the primary tumor obtained from whole-body ^{18}F-FDG PET/CT imaging performed for primary staging, and SII data obtained from complete blood counts performed within ±7 days of PET imaging, were retrospectively evaluated for their relationship with disease stage and OS in 130 patients (mean age: 62.37±8.91;110 males;20 females) with at least one year of follow-up. Disease staging (limited stage(LS) or extensive stage(ES)) was performed based on ^{18}F-FDG PET/CT images. Additionally, maximum and mean standardized uptake values (SUVmax and SUVmean), metabolic tumor volume (MTV), total lesion glycolysis (TLG), and heterogeneity index (HI) (SUVmax/SUVmean) of the primary tumor were calculated. The SII value was calculated using the formula: platelet count x neutrophil count / lymphocyte count. The endpoint for OS was defined as the time from diagnosis to death for deceased patients, or the time from diagnosis to the date of at least one year of follow-up or December 31, 2024, for surviving patients, and patient OS times were recorded. Statistical analysis was performed using SPSS version 23.0. ***Results:*** Limited stage (LS) disease was present in 37.7% of patients, while 62.3% had extensive stage (ES) disease. No significant differences were observed between LS and ES disease in terms of SUVmax, SUVmean, and HI values. MTV, TLG, and SII were significantly higher in the ES patient group compared to the LS patient group (Table 1). In the ROC (Receiver Operating Characteristic) analysis for distinguishing ES and LS disease, the optimal threshold values with the highest Youden's J index for MTV, TLG, and SII were calculated as 61.56, 400.31, and 774.465, respectively. Kaplan-Meier analysis conducted to predict OS based on these threshold values showed no significant association between SII and TLG with survival, whereas OS was significantly shorter in patients with MTV values above 61.56 (8.63 vs 18.03 months; p=0.028)(Figure 1). ***Conclusion:*** Incorporating volumetric metabolic parameters, rather than the routinely used SUVmax value, into patient evaluation has the potential to contribute to the patient's clinical management. Furthermore, measuring the increased inflammatory response with SII provides supportive significance to the data obtained from PET imaging and may contribute to the patient's clinical follow-up.

EP-0225

Relationship of staging FDG PET/CT parameters with clinicopathological data and mortality in non-small cell lung cancer patients

B. Yilmaztekin, *G. Yılmaztekin, B. B. Demirel, G. Vural; Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: Lung cancer is the leading cause of all cancer-related deaths. Clinically, lung cancer is divided into 2 main groups, 85% of which is non-small cell lung cancer (NSCLC) and 15% is small cell lung cancer. Our study aimed to determine the relationship between staging FDG PET/CT quantitative parameters and NSCLC pathological subtypes and mortality. ***Materials and Methods:*** The study included 117 NSCLC patients who were diagnosed with lung cancer between 2019-2024 and underwent staging FDG PET/CT at our center. Demographic data, pathological features, follow-up periods, and maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), total lesion glycolysis (TLG), and metabolic tumor volume (MTV) data from FDG PET/CT examination were recorded. The relationships between quantitative FDG PET/CT parameters and pathological subtype, stage, and overall survival were analyzed. ***Results:*** The mean age of 117 NSCLC patients was 66 ± 8; 68 (58.1%) of the patients had adenocarcinoma and 49 (41.9%) had squamous cell carcinoma (SCC). Demographic data and clinicopathological features of the patients are summarized in Table 1. Quantitative PET/CT parameters of the patients (SUVmax, SUVmean, MTV, TLG) are summarized in Table 2. When the data of the two groups were analyzed, it was found that SUVmax, SUVmean, MTV and TLG values were statistically significantly higher in patients with SCC than in patients with adenocarcinoma (p values: $p<0.006$, $p<0.001$, $p<0.006$, $p<0.003$).There was no significant difference in PET/CT parameters among the accessible (n=52) adenocarcinoma subtypes and SCC differentiation degrees. The median follow-up period in the entire patient group was 15.83 (95%CI 14.53-17.13) months. MTV cut-off value was found as 20.79 and TLG cut-off value was found as 191.54 based on mortality data. (Table 3) In the patient group with MTV values below the determined cut-off value, 6-month OS was 92%, 12-month OS was 90% and in the patient group with MTV values above the cut-off value, 6-month 0S was 66% and 12-month OS was 56% ($p<0.001$). In the patient group with TLG values below the cut-off value, 6-month OS was 92% and 12-month OS was 88%, and in the patient group with TLG values above the cut-off value, 6-month 0S was 68% and 12-month OS was 61% ($p<0.001$). ***Conclusion:*** In our study, a significant difference was found between staging PET/CT metabolic parameters and non-small cell lung cancer subtypes, and between staging MTV-TLG values and overall survival.

Aim/Introduction: Accurate thoracic lesion delineation in PET/CT imaging is crucial for treatment planning to limit patient toxicity of external beam radiotherapy[1]. Respiratory motion can significantly affect the precision of lesion segmentation, leading to variability in lesion volume measurements [2,3,4]. We investigated the impact of a breath hold (BH) protocol on lesion delineation in PET/CT imaging. ***Materials and Methods:*** A clinical protocol was implemented where patients underwent a whole-body free-breathing (FB) PET/CT acquisition followed by three 10-second chest BH acquisitions. Thoracic lesions were segmented in both FB and BH reconstructions. A total of 42 patients were included in the study, with 614 lesions analyzed. The scans were performed using a GE Omni 32 cm PET/CT device. The segmentations were done in MIM Software and validated by two experienced nuclear medicine physicians. The end point was the variation in the volume of segmented lesions. Dice and Jaccard scores were used to compare segmentations and Wilcoxon Rank-Sum test was performed to evaluate the significance. ***Results:*** The reduction in lesion variability is more pronounced for moderate (volumes ranging 0.45:62.9 ml for the 10 sec BH versus 0.26:83.7 ml for the FB) and high motion (ranging 0.12:58.9 ml for the 10 sec BH versus 0.19:142.3 ml for the FB) lesions in a single BH acquisition. This improvement diminishes for high motion lesions in added BH acquisitions due to potential motion. These findings suggest that BH protocols can enhance the precision of lesion segmentation in PET/CT. ***Conclusion:*** The breath hold protocol in PET/CT imaging demonstrates a promising approach to mitigate the effects of respiratory motion on lesion delineation especially for thoracic lesions impacted more by breathing motion. This protocol enhances the accuracy and consistency of lesion segmentation aimed to improve target delineation for radiation oncology, which is critical for reducing treatment toxicities. ***References:*** 1-Ehrbar S et. al. Aim/Introduction: A prospective, monocentric study (EudraCT2021-006570-23) investigating the role of [68Ga]Ga-FAPI-46 PET/CT(FAPI) in staging suspected/confirmed lung cancer (LC) patients is concluded. Results have already been published on performance in the surgical cohort(n=50). The current purpose is to explore, despite enrolled patients have been treated according to standard staging flow-chart only, if FAPI results (in terms of TNM staging) could have led to a potential, only theoretical, change in patients' management. ***Materials and Methods:*** Patients with suspected/confirmed LC were referred to our Nuclear Medicine Department to follow scheduled conventional-staging-flowchart

and perform [18F]F-FDG PET/CT(FDG), followed by additional FAPI within 3+/-1 weeks, which could not delay or influence their standard of care. For the current purpose, only surgical patients were included. PET/CT results were later validated by surgical-histopathology, considered standard-of-truth, and TNMstaging (stageI-IV) was assessed by AJCC 8th Edition.The concordance index between FAPI&FDG was evaluated using Cohen's Kappa test (coefficient k). A comparison was made between hypothetical FAPI-derived and conventional FDG-derived treatment plans, compared to those already performed according to standard practice; patients' management was defined by NCCN guidelines. ***Results:*** 63FAPI were performed out of 64 patients enrolled (26th May 2022 - 30th Nov 2023). 50/63 patients were included as they underwent thoracic surgery after staging PET/CT (mean age: 72y[45-87]; M:F=33:17). FAPI&FDG were generally concordant in most cases in terms of TNM staging (35/50 patients-70%). Among those 35 patients, 27/50 (54%) boasted concordance also with Histopathology while in 8/50 (16%) they both would have erroneously up- or downstaged, potentially excluding patients from a correct surgery. In 15/50 cases (30%) FDG&FAPI final stagings (stageI-IV) were discordant: in 15/15 cases (100%) a change in patient's treatment plan would have occurred with FAPI compared to FDG. Specifically, FAPI would have correctly identified TNMstagings compared to FDG in 7/15 cases (46.5%-2 upstagings from absence of malignancy at FDG to Ia at FAPI,5 downstagings: from Ia-FDG to absence of malignancy-FAPI; IIIa-FDG to Ib-FAPI;2patients from IIIb-FDG to IIb-FAPI;IIIb-FDG to IIIa-FAPI),leading to the correct change in patients' treatment plan; in 4/15 cases (27%) both FDG&FAPI identified wrong stagings but FAPI would have directed towards the right surgical management anyway (2 patients with absence of malignancy at FDG and Ia at FAPI later resulted Ib at Pathology; IIIa-FDG and Ib-FAPI resulted IIa; IIIb-FDG and IIb-FAPI resulted IIIa); in 3/15 cases (20%) FDG&FAPI were both wrong in staging and treatment plan; in 1/15 case only (6.5%) FDG distinguished the right staging (IIb-FDG, Ia-FAPI), with FAPI pointing to wrong staging and management.Concerning TNMfinal staging (determined by Histopathology), FAPI was concordant in 48% of cases(k=0.50) while FDG was concordant in 43% of cases(k=0.44). FAPI-derived treatment plan would have in any case led to surgery in 87% of cases, while FDG-derived would have been surgical in 69.5% of cases. ***Conclusion:*** In this preoperative suspected/confirmed LC setting, FAPI&FDG showed a few discordant cases (15/50): TNMstaging assessment is slightly in favour of FAPI.As regards hypothetical changes to treatment plans, in11/15cases(73%) FAPI would have led to the correct patient's management, while FDG-derived treatment plan was correct in 1/15case only (6.5%). FAPI still does not reach clinically acceptable capability alone (<50%) to determine the exact final stage (given by invasive surgical T&N histology), however it may have a complementary role in staging work-up and management.

Aim/Introduction: This study aimed to evaluate the association between survival and volumetric and dissemination parameters obtained from 18F-fluorodeoxyglucose positron emission tomography/computed tomography (F-18 FDG PET/CT) used for staging in patients diagnosed with stage IV small cell lung cancer (SCLC). ***Materials and Methods:*** Patients with stage IV SCLC who had F-18 FDG PET/CT scans for staging, without brain metastasis and without a history of other malignancies, were included in the study. Patient age, sex, and survival data were recorded. Volumes of interest (VOIs) of all tumor lesions throughout the body were segmented using LIFEx software (v7.6) with a >2.5 SUVmax threshold. The following parameters were extracted: volume of the largest VOI (MTV-Bulk), volume of the smallest VOI (MTVsmallest), the sum of volume differences between the largest VOI and all other VOIs (BulkVolume-DiffSum), the volume difference between the largest and smallest VOIs (BulkSmallestVolume-DiffSum), the maximum distance between any two tumor lesions (Dmax), total metabolic tumor volume (tMTV), and total lesion glycolysis (tTLG). Additionally, the highest SUVmax value (tSUVmax) and the sum of SUVmax differences between all VOIs (SUVmax-DiffSum) were calculated. The relationship between these quantitative parameters and 1-year survival was analyzed. ***Results:*** A total of 68 patients (mean age: 69±10 years [range: 45-84], 58 male [85.3%]) were included. The median survival was 5.1 months (95% CI: 3.4-6.8). Patients who survived less than 12 months (n=58) had significantly higher values of MTV-Bulk, Volume-DiffSum, BulkVolume-DiffSum, BulkSmallestVolume-DiffSum, tMTV, tTLG, SUVmax-DiffSum, and Dmax compared to those who survived longer than 12 months (p=0.003, 0.001, 0.001, 0.003, 0.001, 0.001, 0.012, and 0.010, respectively). Age, sex, tSUVmax, and MTVsmallest were not significantly associated with 1-year survival. Parameters with high mutual correlation were excluded from further analysis; tMTV, Dmax, and SUVmax-DiffSum were included in logistic regression analysis. tMTV >308.6 mL (p=0.006, OR: 11.823, 95% CI: 2.021-69.155) and Dmax >29.3 cm (p=0.028, OR: 7.376, 95% CI: 1.236-44.028) were found to be independent prognostic factors for predicting 1-year survival. ***Conclusion:*** Our study demonstrates that higher volumetric and dissemination parameters, marked inter-tumoral heterogeneity, and aggressive biological behavior are associated with poorer prognosis in patients with stage IV SCLC. Clinically, more aggressive treatment and close monitoring strategies may be considered for this high-risk patient group.

EP-0229

Prediction of PD-L1 Status and Tumor Subtype Characterization in Non-Small Cell Lung Cancer Using Abbreviated [^{18}F]FDG Dynamic Imaging Protocols with Long Axial Field-of-View PET/CT

E. Calderón Ochoa*, J. A. Benecke, W. Lan, F. P. Schmidt, H. Dittmann, C. la Fougère;*
Department of Nuclear Medicine and Molecular Imaging, University Hospital of Tübingen, Tübingen, GERMANY.

Aim/Introduction: Dynamic PET imaging provides insights into tracer kinetics and enables a more robust analysis of glucose metabolism, which may enhance the in vivo characterization of non-small cell lung cancer (NSCLC). We investigated the potential of parametric imaging with an abbreviated dynamic scan protocol enabled by long axial field-of-view (LAFOV) PET/CT for characterizing tumor subtypes and predicting PD-L1 status in NSCLC. ***Materials and Methods:*** This retrospective study included 56 patients with histologically diagnosed NSCLC (39 adenocarcinoma [AC] and 19 squamous cell carcinomas [SCC]) who underwent a validated abbreviated dynamic [^{18}F]FDG PET protocol in a LAFOV PET/CT scanner (3.0 MBq/kg, 20 min scan time, 45 min p.i.). Patlak modeling was implemented in the image reconstruction using a population-based input function, generating net influx rate K_i (ml/g/min) and Distribution Volume (DV, %) images. PD-L1 positivity was defined as a tumor proportion score of ≥1%. T-test and two-way ANOVA were used to compare SUV and parametric parameters according to tumor subtype and PD-L1 status. ROC curves analysis and multiple logistic regression were performed to evaluate the performance in PD-L1 status. ***Results:*** Of the NSCLC tumor lesions, SCC showed higher SUV_{max} (17.98 ± 6) and K_{imax} (0.077 ± 0.02) values compared to AC (12.87 ± 7; 0.061 ± 0.03, p = 0.004; p = 0.0012), with no significant differences in DV values (p = 0.6747). PD-L1-positive tumors exhibited higher

SUV_{max} (16.5 ± 9.5, p = 0.04), K_{imax} (0.07 ± 0.04, p = 0.001) and DV_{max} (441±280, p = 0.02) values than PD-L1-negative tumor lesions (11.7 ± 5.3; 0.04 ± 0.02; 296.4 ± 149.9, respectively). ROC analysis for SUV_{max}, $SUV_{mean,}$ and K_{imean} showed AUCs of 0.62 (CI 0.51-0.74), 0.64 (CI 0.52-0.75), and 0.63 (CI 0.52-0.75), respectively, showing poor discrimination performance. K_{imax} showed in comparison moderate discrimination (AUC = 0.73, CI 0.64-0.83). Multiple logistical regression using SUV_{max} and SUV_{mean} improved the AUC slightly to 0.66 (CI 0.55-0.78), while parametric parameters (K_{imax}; DV_{max}) performed similarly (AUC = 0.73, CI 0.64-0.84). However, the best prediction performance was achieved by combining SUV_{max}, $K_{imax,}$ and DV_{max} (AUC = 0.77, CI 0.66-0.87), with K_{imax} being the strongest predictor (OR = 6.8). ***Conclusion:*** Integrating static and dynamic PET parameters enhances the characterization of PD-L1 status in NSCLC. This combination yields the highest predictive performance and provides valuable information in the evaluation of potential treatment options.

EP-0230

Focal [18F]-FDG Uptake in the Heart: A Favourable Sign in Lung Cancer Patients at Risk of Cachexia?

E. Abenavoli[1], *M. Pepponi*[1], *T. Beyer*[2], *D. Ferrara*[2], *A. Frille*[3], *S. Gruenert*[4], *M. Hacker*[4], *S. Hesse*[5], *L. Hofmann*[5], *O. Sabri*[5], *L. Shiyam Sundar*[2], *J. Yu*[2], *R. Sciagrà*[1];
[1]*Nuclear Medicine Unit, Florence, ITALY,* [2]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Department of Respiratory Medicine, Leipzig University, Leipzig, GERMANY,* [4]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [5]*Department of Nuclear Medicine, Leipzig University, Leipzig, GERMANY.*

Aim/Introduction: The LuCaPET project (ERAPERMED 2021-324) investigates the association between [^{18}F]FDG PET/CT metabolic parameters at staging and the risk of developing cancer cachexia in lung cancer patients, aiming to identify imaging biomarkers of early metabolic dysfunction. Prior data in our retrospective cohort suggested a connection between myocardial uptake pattern and patient outcome. ***Materials and Methods:*** We evaluated 320 treatment-naïve lung cancer patients, all submitted to staging [^{18}F]-FDG PET/CT before the most appropriate first-line treatment. [^{18}F]-FDG PET/CT was evaluated for the visual uptake pattern according to the established classification (A = no uptake, B = diffuse, C = focal and D = focal on diffuse uptake). The patient nutritional status was assessed and followed up using the weight loss grading system (WLGS) adjusted to body mass index. ***Results:*** At the time of [^{18}F]FDG PET/CT, WLGS was 0 in 101 patients (33.8%), 1 in 83 (27.8%), 2 in 43 (14.4%), 3 in 65 (21.8%), and 4 in 28 patients (9.4%).. During early follow up for restaging (3 to 9 months) 28 additional patients evolved to WLGS 3-4 so that a total of 136 patients was eventually classified as cachectic. Myocardial uptake pattern was A in 167 patients, B in 40, C in 52 and D in 61 patients. There were no significant differences in the distribution of myocardial uptake pattern versus presence or absence of cachexia. Conversely, there was a significant chi-square ($p < 0.02$) when the patients with the C pattern were compared with the other groups and the odds ratio for cachexia in the C patients was 0.74 (0.61 - 0.91). ***Conclusion:*** These results suggest that the myocardial uptake pattern could be related to patient metabolic status and in particular that a pattern of focal uptake is more frequent in patients without cachexia, so that its detection could be regarded as a favourable indicator of the nutritional status.

EP-0231

Enhanced Diagnostic Efficacy of Deep-Inspiration Breath-Hold Total-Body ^{18}F-FDG PET/CT for Pulmonary Lesions: A Comparative Study

X. Zhou*;*
Peking University Cancer Hospital, Beijing, CHINA.

Aim/Introduction: To compare the performance of PET/CT using deep-inspiration breath-hold (DIBH) versus free-breathing (FB) techniques and evaluate whether DIBH PET/CT enhances the differentiation of pulmonary benign and malignant lesions. ***Materials and Methods:*** This prospective study enrolled 110 patients with lung lesions (<3 cm). Each underwent conventional FB PET/CT and 30-second DIBH PET/CT (reconstructed at 20s and 30s); 35 patients additionally completed respiratory-gated (RG) PET/CT. Quantitative metrics included SUVmax, blood pool (BP) uptake standard deviation (SD), and tumor-to-blood pool ratio (TBR). Qualitative imaging characteristics (density, longest diameter, pleural distance, location) were analyzed. Uptake stability and extent were compared across acquisition methods, with an AI-based noise-reduction algorithm applied to DIBH PET/CT. ***Results:*** Among 30 patients with complete 4-modality imaging, as for uptake metrics, 20s-DIBH PET/CT yielded the highest SUVmax and TBR ($P<0.001$). RG PET/CT showed no significant improvement in uptake or noise reduction. Lesion size: For lesions <1 cm, DIBH provided no improvement over FB ($P=0.462$); for 2-3 cm lesions, DIBH demonstrated significantly higher uptake (TBR: 7.2 vs. 4.0, $P<0.001$). Pleural distance: DIBH improved detection regardless of pleural proximity. Density/location: Solid/mixed-density lesions and lower-lobe lesions showed greater DIBH efficacy ($P<0.05$). Pathology: Malignant lesions exhibited more pronounced improvement than benign lesions. As for diagnostic accuracy, DIBH PET/CT achieved higher AUC than FB (0.621 vs. 0.543, $P<0.001$), further enhanced by AI noise reduction (AUC=0.721). ***Conclusion:*** DIBH PET/CT outperforms FB and RG PET/CT, particularly for larger (2-3 cm), solid/mixed-density lesions, and improves malignant-benign differentiation. AI-based noise reduction further optimizes diagnostic performance.

EP-0232

Association Between Ventilasion/Perfusion Scan Outcomes and Novel MAPH Score in Patients with Suspested Acute Pulmonary Embolism

A. Dursun[1], *N. A. Dizdar*[1], *E. Tatcı*[2], *G. İnal*[1], *A. Çinar*[1], *Ö. Özmen*[2];
[1]*Ankara Etlik City Hospital, Departmant of Nuclear Medicine Clinic, Ankara, TÜRKIYE,* [2]*Health Sciences University, Ankara Etlik City Hospital, Nuclear Medicine Clinic, Ankara, TÜRKIYE.*

Aim/Introduction: MAPH score, which is based on age, mean platelet volume (MPV), total protein, and hematocrit parameters, is a novel indicator developed to estimate blood viscosity and thrombus burden. This study investigated the relationship between MAPH score and lung ventilation/perfusion (V/Q) SPECT/CT findings in patients with suspected acute pulmonary embolism (PE). ***Materials and Methods:*** The retrospective cohort study included 161 patients who underwent V/Q SPECT/CT for suspected acute PE. V/Q images were performed using ^{99m}Tc-labeled carbon particles (Technegas) and ^{99m}Tc-labelled MAA. The images were interpreted according to 2019 version of EANM guideline by two nuclear medicine physicians. The patients were classified as 'PE-absent' and 'PE-present' groups. All patients' demographic and clinical data were retrospectively retrieved (Table-1 and Table-2). Using Youden index, the cut-off values for MPV, age, total protein, and hematocrit were determined, and each was categorised as 0 or 1. The MAPH score was then calculated as the sum of these values. ***Results:*** The study included 161 patients (F/M: 119/42; mean age 64.37 ± 16.49 years). Of these, 59 patients were in PE-absent group, while 102 were in PE-present group. Age and prevalence of hypertension, hyperlipidemia (HL), heart failure (HF), and chronic kidney disease (CKD) were significantly higher in PE-present group ($p < 0.05$ for all comparisons; Table-1). There were no statistically significant differences between the groups regarding cerebrovascular disease, coronary artery disease, diabetes mellitus, and anemia. Patients in PE-present group had significantly higher hemoglobin, hematocrit, and MAPH levels (p

< 0.05 for all values; Table-2). However, no significant differences in total protein and MPV levels were observed between groups (p > 0.05). The ROC analysis showed that the MAPH score predicted PE with a sensitivity of 83% and specificity of 42% at a cut-off value of 1.5 (AUC = 0.696, p< 0.001; Table 3). In both univariate and multivariate logistic regression analyses, heart failure, elevated GFR levels, and higher MAPH score were significantly associated with PE (p< 0.05; Table-4). Conversely, HL was found to be independently associated with lower risk of PE (p< 0.05; Table-4). ***Conclusion:*** Our results indicate that a high MAPH score is an independent predictor of PE. Furthermore, advanced age, hypertension, heart failure, chronic kidney disease, and elevated hematocrit and hemoglobin levels were identified as significant risk factors associated with PE. ***References:*** Akhan O, Boz M, Guzel T, Kis M. Discrimination of the acute pulmonary embolism subtypes based on the novel MAPH score. J Thromb Thrombolysis. 2024 Apr;57(4):683-690.

EP-0233

Tumor Dissemination (Dmax) derived from ^{18}F-FDG PET/CT as a Predictor of Response to Immunotherapy in Patients With Non-small Cell Lung Cancer

S. Pellegrino[1], *A. Volpicelli*[1], *A. Russo*[2], *M. Isernia*[2], *F. Salomone*[2], *A. Servetto*[2], *R. Bianco*[2], *R. Fonti*[1], *S. Del Vecchio*[1];
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.

Aim/Introduction: The aim of our study was to test whether the largest distance between two ^{18}F-FDG avid lesions (Dmax) was able to predict the response to immunotherapy in patients with advanced non-small cell lung cancer (NSCLC). ***Materials and Methods:*** Twenty-five patients (19 men, 6 women) with stage III and IV NSCLC who had undergone ^{18}F-FDG PET/CT scan showing at least two positive lesions before starting immunotherapy were included in the study. All lesions were segmented using an automated contouring program setting an absolute threshold for SUV at 2.5. The imaging parameters including SUVmax, SUVmean, MTV and TLG of primary tumors along with total MTV (MTV_{TOT}) and whole-body TLG (TLG_{WB}) from all malignant lesions were included in the analysis. The largest distance between two ^{18}F-FDG avid lesions (Dmax) in each patient was measured. The Student's t test was used to compare means of unpaired data and Fisher's exact test was used for the analysis of categorical data. Univariate analysis of clinical and imaging variables was performed using Cox proportional hazards regression. ***Results:*** A total of 124 lesions were analyzed including 24 primary tumors, 60 metastatic lymph nodes and 40 distant metastases and mean Dmax value was 26.78±19.12 cm. In primary tumors, average values of SUVmax, SUVmean, MTV and TLG were 13.12±5.67, 5.46±1.60, 79.54±99.10 ml and 521.27±784 g, respectively, whereas mean values of MTV_{TOT} and TLG_{WB} were 129.40±122.19 ml and 782.66±879.42 g, respectively. After starting immunotherapy, patients were subjected to a mean follow-up period of 4 months and then re-evaluated by CT scan. Among all patients, 13 showed a partial response while 12 had disease progression. Mean Dmax values were significantly lower in responders as compared to non-responders (13.36±8.38 vs 41.32±16.66, p<0.0001) while no statistically significant difference in the SUVmax of primary tumors, MTV_{TOT} and TLG_{WB} was found. Using ROC curve analysis, the Dmax value able to discriminate between patients responding to immunotherapy from non-responders was 22.2 cm (AUC=0.92). Among 13 patients with Dmax<22.2 cm, 11 showed partial response to immunotherapy whereas only 2 patients among 12 with Dmax≥22.2 cm had partial response (Fisher's exact test, p=0.0012). Finally, univariate analysis was performed including age, gender, stage, MTV_{TOT}, TLG_{WB}, Dmax and imaging parameters derived from primary lung tumors. Dmax was the only parameter significantly correlated with the occurrence of disease progression (χ^2=6.3370, p=0.0118). ***Conclusion:*** Dmax, which reflects tumor dissemination, may predict response to immunotherapy in patients with NSCLC.

EP-0234

Artificial intelligence prognostic predictive algorithms in advanced lung cancer using pre-therapy ^{18}F-FDG PET-CT metabolic parameters. The role of MTV in the model performance. Preliminary results.

Aim/Introduction: to define a prognostic -PFS (Progression Free Survival) and OS (Overall survival)- AI modeling framework using metabolic parameters as SUVmax, SUVmean and MTV extracted from pre-treatment [18F]-FDG PET-CT. ***Materials and Methods:*** we retrospectively evaluated 51 stage IV NSCLC patients (pts) undergoing Best Standard of Care. Tumor, lymphnode, and metastasis volumes of interest (TNM VOI) were delineated on PET scans and metabolic parameters MTV, SUVmax, and SUVmean of T, N, and M were recorded. The primary clinical endpoints were PFS and OS. A nested cross-validation with Pearson Correlation Coefficient>0.8 scheme and modeling was applied. Four models were tested in performing survival analysis: Cox's proportional hazards model (CoxPH), Elastic Net Regularized CoxPH (CoxNet), Random Survival Forest (RSF) and Tree-based Gboost (Gboost). The integrated Brier Score (iBS) and C-index were applied to each model of prognostic prediction. Accordingly, the survival analysis was performed through Kaplan-Meier (KM) curves and the log-rank test, and the percentage of the significant p-value of each model was evaluated. A SHAP and beeswarm plots were applied to demonstrate the metabolic features that have the greatest contribution to the performance of the best predictive models. ***Results:*** The RSF is the model among CoxPH, CoxNet and Gboost models that achieve the highest C-index score and the lowest IBS score in different scenarios (T, N, M, TN and TNM). For the prediction of PFS the best RSF models are those that use the classic metabolic parameters (SUVmax, SUVmean and MTV) deriving from the TNM VOI. The highest percentage of significant p values in stratifying pts at high and low risk of PFS was shown by the RSF_TNM model [C-index: 0.575, IBS: 0.23 and significant p-value ratio in 24% of cases]. RSF_TNM was the best model, even when OS was considered. It's about a model using the metabolic characteristics of T, N and M together (RSF_TNM), with a C-index of 0.59, IBS of 0.236 and a 32% split in which pts were successfully stratified into high and low-risk groups of OS. For the TNM_RSF model predicting PFS the relatively most important parameter was MTV_N; for TNM_RSF predicting OS the most impacting parameters were MTV_T; MTV_N and MTV_M. ***Conclusion:*** Some of the proposed AI pipelines may have the potential to provide accurate prediction of PFS and OS in patients with advanced NSCLC by incorporating conventional metabolic PET parameters from TNM VOI, among which MTV is the one with relatively higher impact.

EP-0235

Diagnostic role of [^{18}F]FDG PET/CT in Pulmonary Hamartomas: Retrospective Analysis

M. Marques, *C. Loewenthal;*
Hospital da Luz Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: Pulmonary hamartoma, the most common benign lung tumor, is often detected incidentally on imaging. Asymptomatic patients may undergo unnecessary surgery due to diagnostic challenges, as pulmonary hamartoma can mimic malignancy on CT through features like progressive growth and heterogeneous density[1]. This study aimed to evaluate the metabolic characteristics of pulmonary hamartoma on 18F-Fluoro-D-glucose positron emission tomography-computed tomography ([^{18}F]FDG PET/CT) to help reduce avoidable invasive procedures. ***Materials and Methods:*** We retrospectively reviewed 45 patients from our institution with histologically confirmed pulmonary hamartoma who had undergone [^{18}F]FDG PET/CT between 2010 and 2024.The PET/CT protocol included whole-body imaging one hour after intravenous [18F]FDG administration, with low-dose CT for attenuation correction and anatomical reference. Some patients also underwent delayed thoracic imaging.Lesion size was based on maximum pathological diameter. SUVmax was measured for the hamartoma, adjacent lung tissue, and vascular pool (aortic arch). In patients with delayed imaging, delayed lesion SUVmax was also recorded. ***Results:*** Pulmonary hamartomas exhibited a mean size of 13,8 ± 8,43 mm (range: 5-50 mm). The mean SUVmax was 1,19 ± 0,48 (range: 0,54-2,40). Among the 45 lesions analyzed, 20 (44%) had a SUVmax lower than the adjacent lung parenchyma, and 24 (53%) showed higher uptake than adjacent lung tissue but still below the mediastinal vascular pool. Thus, 98% of cases had SUVmax values below the vascular pool. Only one (2%) showed a SUVmax exceeding the vascular pool, which was histologically confirmed to be a lesion with atypical features for a pulmonary hamartoma, specifically an adenofibromatous variant.Delayed thoracic imaging was performed in 71% of cases, with a slightly lower mean SUVmax of 1,08. Of these, 66% (n=21) showed decreased [18F]FDG uptake, 3% (n=1) remained stable, and 31% (n=10) demonstrated increased avidity. ***Conclusion:*** The majority of pulmonary hamartomas demonstrate relatively low [18F]FDG uptake, reflecting the benign nature of these lesions.Some metabolic features on [^{18}F]FDG PET/CT that may aid in diagnostic decision-making, by supporting a benign characterization of pulmonary hamartomas and thereby reducing the need for unnecessary surgical interventions, include: low glycolytic metabolism, evidenced by an SUVmax below 2,50 (the internationally recognized cut-off value); [18F]FDG uptake lower than mediastinal vascular pool; and a decrease in [18F]FDG uptake on delayed imaging. ***References:*** 1) Flores, R., Bauer, T., Aye, R., et al (2014). Balancing curability and unnecessary surgery in the context of computed tomography screening for lung cancer. EP-0236

The Evaluation of Nivolumab Treatment and Survival Efficacy with Metabolic Parameters in Patients with Non-Small Cell Lung Cancer

N. Aydin[1], *G. Mutevelizade*[1], *B. C. Bozdemir*[1], *N. Kolkiran*[2], *A. P. Erdogan*[2], *E. Sayit Bilgin*[1];
[1]*Manisa Celal Bayar University Faculty of Medicine Department of Nuclear Medicine, Manisa, TÜRKIYE,* [2]*Manisa Celal Bayar University Faculty of Medicine Division of Medical Oncology, Manisa, TÜRKIYE.*

Aim/Introduction: The aim of this study was to investigate the efficacy of metabolic parameters obtained from pre- and post-treatment F-18 FDG PET/CT imaging of nivolumab-treated patients with non-small cell lung cancer on the assessment of treatment response, overall survival (OS) and post-treatment survival. ***Materials and Methods:*** A total of 32 patients with NSCLC who received at least 4 cycles of nivolumab treatment between 01/2022 and 12/2024, who underwent F-18 FDG PET/CT imaging up to 4 weeks before the first cycle of nivolumab treatment and up to 4-6 weeks after the last nivolumab treatment were included. Images were evaluated using PET VCAR (Volume Computer-Assisted Reading) software. SUVmax, SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of each lesion were calculated by applying a threshold value of 41% of SUVmax. Total MTV (tMTV) and total TLG (tTLG) values of each patient before and after treatment were obtained by summing all values of each lesion. Demographic data, histologic subtypes, smoking history, and follow-up period of the patients were obtained retrospectively. Response to nivolumab treatment was evaluated according to EORTC. According to these criteria, patients were divided into 3 groups as partial metabolic response to treatment, stable metabolic disease and progressive metabolic disease. ***Results:*** A total of 32 patients including 3 females and 29 males with a mean age of 64±6.5 years were included in the study. Histologic subtypes were 15 adenocarcinomas and 17 squamous cell carcinomas. There was no statistically significant correlation between SUVmax, SUVmean, tMTV, tTLG values of the primary tumor and histological subtypes ($p>0.05$). There was a statistically significant correlation between mortality and pre-treatment tMTV, tTLG and post-treatment SUVmax, SUVmean and tTLG values ($p<0.05$). Patients were divided into two groups based on the median values of metabolic parameters and survival analysis was performed. Pre-treatment tMTV and tTLG values, post-treatment SUVmax, SUVmean, tMTV and tTLG values have a significant difference on OS after nivolumab treatment ($p<0.05$). The patients were evaluated according to treatment response, a significant difference was found between the median values of SUVmax, SUVmean and tTLG parameters after treatment ($p<0.05$). In addition, treatment response groups had no effect on overall survival, but the partial response group had longer survival after nivolumab treatment compared to the other groups ($p<0.05$). ***Conclusion:*** According to the results, especially tMTV and tTLG values can be used to evaluate the response to nivolumab treatment and have a significant effect on survival.

EP-0237

Refining Prognostic Assessment in Small Cell Lung Cancer: Development and Validation of Multiparametric Models Integrating ^{18}F-FDG PET/CT Dissemination Characteristic

Y. Liu, *X. Zhou, X. Meng, X. Kong, Y. Cui, Y. Liu, Y. Yao, J. Zhu, N. Li;*
Peking University Cancer Hospital, Beijing, CHINA.

Aim/Introduction: Small cell lung cancer (SCLC) is a type of pulmonary neuroendocrine tumor characterized by rapid proliferation and strong invasiveness. The prognosis of SCLC patients varies significantly, and due to the lack of reliable prognostic indicators, accurate prognostication remains challenging in clinical practice. Therefore, identifying additional prognostic indicators is crucial for improving predictive accuracy. Recent studies suggest that tumor spatial distribution may predict cancer prognosis. A novel ^{18}F-FDG PET/CT parameter, D_{max}, measures the distance between the two farthest lesions and has demonstrated prognostic value independent of metabolic parameters. This study aimed to explore the correlation between tumor dissemination characteristic, metabolic parameters from baseline ^{18}F-FDG PET/CT, clinical and pathological indicators, and SCLC outcomes, as well as to develop predictive models. ***Materials and Methods:*** This study retrospectively included 303 patients with SCLC, randomly divided into training and validation cohorts (8:2). The tumor dissemination characteristic, metabolic characteristics, morphological features, and clinical indicators were retrospectively collected. Cox regression analysis was employed to identify independent prognostic factors, which were then used to construct prognostic models and nomograms. Model performance was evaluated using receiver operating

characteristic (ROC) curves. ***Results:*** Multivariate Cox regression analysis identified age, stage, neuron-specific enolase (NSE), and the standardized distance between the two farthest lesions (SD_{max}) as independent prognostic factors for progression-free survival (PFS). The area under curve (AUC) values for predicting 6-month, 12-month, and 24-month PFS were 0.799, 0.774, and 0.732 in the training cohort and 0.775, 0.766, and 0.717 in the validation cohort. Additionally, age, stage, NSE, whole-body metabolic tumor volume (MTV_{wb}), and SD_{max} were independent prognostic factors for overall survival (OS), with AUC values of 0.856, 0.811, and 0.777 for 1-year, 2-year, and 3-year OS in the training cohort, and 0.819, 0.810, and 0.772 in the validation cohort. ***Conclusion:*** The tumor dissemination characteristic from baseline ^{18}F-FDG PET/CT is a novel independent prognostic factor for SCLC. Furthermore, prognostic models integrating dissemination characteristic, metabolic parameter, and clinical indicators demonstrate excellent predictive performance for SCLC outcomes.

EP-0238

Early prediction of tumor response to carbon-ion radiotherapy via ^{18}F-FMISO PET/CT in locally advanced non-small-cell lung cancer patients

C. Ren*;*
Shanghai Proton and Heavy Ion Center, Shanghai, CHINA.

Aim/Introduction: Hypoxia increases resistance to carbon ion radiotherapy (CIRT) in locally advanced non-small-cell lung cancer (LA-NSCLC, stage II-III). We developed the model to early predict tumor response to CIRT based on ^{18}F-fluoromisonidazole (FMISO) positron emission tomography/computed tomography (PET/CT) in LA-NSCLC patients, and to identify patients unlikely to benefit from CIRT. ***Materials and Methods:*** 42 patients with LA-NSCLC, including 25 (60%) squamous cell carcinoma (Scc) and 17 (40%) non-Scc patients, underwent ^{18}F-FMISO PET/CT prior to CIRT. FMISO maximum standardized uptake values (SUVmax), the tumor-to-muscle ratios (TMR), and hypoxic tumor volume (HTV) in gross target volumes were measured. The hypoxia threshold based on TMR was set at 1.4. CIRT response assessment was evaluated within 1 week after the completion of all radiotherapy with RECIST criteria. After identifying FMISO biomarker related to CIRT response, a prediction model was developed and evaluated by the area under receiver-operator characteristic (ROC) curve (AUC). ***Results:*** Of the 42 patients analyzed, 17 (40%) had partial response (PR) while stable disease (SD) was observed in 25 (60%) patients. FMISO-PET detected uptake in 31 (74%) patients with LA-NSCLC, although these values were not related to the CIRT response. Further subgroup analysis showed that good responses were significantly more prevalent in hypoxia Scc (n=15, 36%) patients with less HTV ($p < 0.01$), whereas FMISO uptake was not significantly correlated with CIRT response in normoxia Scc (n=10, 24%) or all non-Scc (n=17, 40%) patients. Furthermore, a positive correlation between tumor size and hypoxia was observed in Scc patients ($p < 0.01$). Multivariate logistic regression analysis showed that HTV was an independent significant predictor of CIRT response ($p = 0.04$, odds ratio = 1.14) with an AUC of 0.89. ***Conclusion:*** ^{18}F-FMISO PET/CT is recommended for Scc patients, especially whose were likely to be hypoxia predicted by tumor size, and it holds great promise for selecting patients who will benefit from CIRT.

EP-0239

Kinetic modeling and parametric imaging of ^{13}N-NH_3 in treatment-naïve lung cancer using total-body

H. Yuan[1]*, F. Wang*[1]*, T. Sun*[2]*, L. Jiang*[1]*;*
[1]Guangdong Provincial People's Hospital, Guangzhou, CHINA, [2]Lauterbur Research Center for Biomedical Imaging,Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA.

Aim/Introduction: ^{13}N-NH_3 PET imaging provides insights into tumor perfusion and metabolism, hence potentially valuable in oncological diagnosis, staging, and prognostication. However, its in vivo kinetic characteristics and the optimal protocol for kinetic modeling and parametric imaging remain unclear. ***Materials and Methods:*** 9 lung cancer surgical candidates were prospectively incorporated. Using the total-body PET/CT scanner, 35-minute ^{13}N-NH_3 acquisitions were conducted immediately post-injection, and 5-minute ^{18}F-FDG acquisitions were made 60 minutes post-injection. 13N-NH3 PET data were reconstructed into dynamic image series. Tumor lesions and normal organs were segmented using non-threshold dependent automatic or semiautomatic tools. Reversible and irreversible 2-tissue compartment models (2TC vs 2TiC) using image-derived input functions (IDIFs) with population-based metabolite correction were adopted for parametric modeling. The Akaike Information Criterion (AIC) was calculated for model selection. Parametric images were produced with the optimal model for lesions. ***Results:*** All primary lung tumors (n=9) and regional lymph node metastases (n=17) were detectable using both ^{13}N-NH_3 and ^{18}F-FDG imaging. Primary lung tumors, regional lymphadenopathy and lung backgrounds demonstrated smaller AIC using 2TC models with pulmonary artery as IDIF, while other organs favored either 2TC or 2TiC models with the descending aorta as IDIF. Lesion-to-background lung ratios reached around 2.218-3.407 for primary lung tumors and 1.932-2.537 for regional lymphadenopathy 10-20 min post-injection of 13N-NH3. Vt images derived from 2TC modeling showed better lesion-to-background lung ratios (4.511±2.955 for primary tumor, and 2.991±2.152 for regional lymphadenopathy). ***Conclusion:*** For ^{13}N-NH_3 imaging in lung cancer, a static image can be acquired at 10-20 min post-injection for clinical diagnosis. The reversible 2TC model is preferred over 2TiC, and the Vt image is preferred over other parametric images in terms of lesion contrast.

EP-0240

Evaluating the Use of Metabolic Tumor Volume (MTV) During Follow-Up in NSCLC Patients Treated with Immunotherapy

O. Ekmekcioglu[1]*, S. Halil*[2]*, A. I. Yasin*[2]*;*
[1]Nuclear Medicine Dept., University of Health Sciences, Sisli Hamidiye Etfal Education and Research Hospital, Istanbul, TÜRKIYE, [2]Medical Oncology Dept., University of Health Sciences, Sisli Hamidiye Etfal Education and Research Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Accurate evaluation of response to immunotherapy in patients with lung cancer presents a clinical challenge due to atypical imaging patterns. [^{18}F]FDG PET/CT is widely used for treatment monitoring, though traditional semi-quantitative metrics such as SUVmax may not reliably reflect true tumour behaviour. This study aims to assess metabolic response using [^{18}F]FDG PET/CT in patients treated with immunotherapy, focusing on the added value of metabolic tumour volume (MTV). ***Materials and Methods:*** A retrospective analysis was performed on 23 patients (5 female, 18 male). mean age: 66.5 years, range: 43-82) with histologically confirmed lung cancer (13 SCC, 10 Adenocarcinoma) who underwent Nivolumab immunotherapy. All patients had baseline [^{18}F]FDG PET/CT scans and were followed for a mean of 12.1 months (range: 3-25 months). Follow-up PET/CT scans were evaluated for treatment response. Three patients were excluded due to incomplete clinical or imaging data. The remaining 20 patients were assessed using the PET Response Criteria in Solid Tumours (PERCIST). ***Results:*** Among the 20 evaluable patients, the first follow-up [^{18}F]FDG PET/CT revealed metabolic regression in 9 patients, disease progression in 6, and stable metabolic disease in 5 according to PERCIST criteria. SUVmax values demonstrated significant variability and were not consistently aligned with anatomical tumour changes or clinical

status. In contrast, difference between the MTV measurements (mean MTV of primary tumor before therapy 24.5 vs after therapy 36.2 cm3 and mean SUVmax before therapy 10.1 vs after therapy 9.1) provided a more accurate reflection ($p<0.05$) of tumour burden and response to therapy. Cases with increased or decreased SUVmax have shown tumour shrinkage or stability on anatomical imaging, highlighting the limitations of relying solely on SUVmax. ***Conclusion:*** [^{18}F]FDG PET/CT is an essential tool for monitoring immunotherapy response in lung cancer. However, SUVmax alone may not be sufficient to determine true metabolic activity or disease trajectory. MTV offers a more robust and comprehensive measure, correlating better with clinical and radiological findings. Our findings suggest that incorporating MTV into routine PET/CT evaluations could improve the accuracy of treatment response assessments. Nevertheless, larger patient cohorts and prospective studies are needed to validate the clinical utility of MTV in this setting. ***References:*** Monaco L, Gemelli M, Gotuzzo I, Bauckneht M, Crivellaro C, Genova C, Cortinovis D, Zullo L, Ammoni LC, Bernasconi DP, et al. Metabolic Parameters as Biomarkers of Response to Immunotherapy and Prognosis in Non-Small Cell Lung Cancer (NSCLC): A Real World Experience. Cancers. 2021;13:1634.

EP-0241

Head-to-head Comparison of Peptide- and Nanobody-based Radiotracers for Detecting PD-L1 expression in Non-Small Cell Lung Cancer

Y. Wu[1], *H. Wang*[1], *Y. Gu*[2], *D. Xu*[1], *F. Xie*[1];
[1]*Huashan Hospital,Fudan University, Shanghai, CHINA,* [2]*Central Research Institute, United Imaging Healthcare Group Co, Shanghai, CHINA.*

Aim/Introduction: The aim of this study is to evaluate and compare [68Ga]Ga-DOTA-WL12 (a peptide-based tracer) and [68Ga]Ga-NOTA-RW102 (a nanobody-based tracer) in assessing programmed death ligand 1 (PD-L1) expression in primary and metastatic non-small cell lung cancer (NSCLC). ***Materials and Methods:*** Between June 2022 and April 2023, ten consecutive patients diagnosed with primary NSCLC or metastatic NSCLC were enrolled. All patients underwent [68Ga]Ga-DOTA-WL12 and [68Ga]Ga-NOTA-RW102 PET/CT scans, with four of these patients also receiving [^{18}F]FDG PET/CT scans. All imaging was reviewed in consensus by two experienced nuclear medicine physicians. The binding affinities of DOTA-WL12 and NOTA-RW102 to PD-L1 was measured using surface plasmon resonance (SPR) analysis. The PD-L1 expression level was quantified as a tumor proportion score (TPS). The biodistribution and tumor uptake of [68Ga]Ga-DOTA-WL12 and [68Ga]Ga-NOTA-RW102 were compared across major organs and lesions. Tracer uptake was quantitatively assessed using the maximum standard uptake values (SUVmax), the mean standard uptake values (SUVmean), and the target-to-background ratio (TBR). ***Results:*** DOTA-WL12 and NOTA-RW102 exhibited favorable binding affinities for PD-L1, with equilibrium dissociation constants (KD) of 0.2 nM and 0.0047 nM, respectively. Notably, the correlation between tumor SUVmax and PD-L1 TPS was significantly stronger for [^{68}Ga]Ga-DOTA-WL12 ($r = 0.9471$, $P < 0.0001$) than for [^{68}Ga]Ga-NOTA-RW102 ($r = 0.5235$, $P = 0.0241$). In human studies, significant differences ($P < 0.05$) in tracer uptake were observed across multiple organs: liver (SUVmean: 20.43 ± 4.26 vs 6.12 ± 1.36), kidney (2.40 ± 0.34 vs 22.37 ± 2.88), spleen (2.44 ± 0.67 vs 18.49 ± 3.90), and lung background (0.18 ± 0.12 vs 1.09 ± 0.29), indicating distinct biodistribution profiles. [^{68}Ga]Ga-DOTA-WL12 predominantly accumulated in the liver, while [^{68}Ga]Ga-NOTA-RW102 showed renal clearance. ***Conclusion:*** Despite its lower in vitro binding affinity, [^{68}Ga]Ga-DOTA-WL12 demonstrated superior correlation with PD-L1 expression in vivo compared to [^{68}Ga]Ga-NOTA-RW102. The distinct biodistribution patterns suggest that [^{68}Ga]Ga-DOTA-WL12 may be less suitable for patients with liver dysfunction, while the high renal uptake of [^{68}Ga]Ga-NOTA-RW102 could pose challenges in patients with impaired kidney function.

EP-0242

Assessing Time-Dependent SUV Changes in small and medium Pulmonary Nodules: Diagnostic Implications of Dual-Time-Point 18F FDG PET/CT

N. Kapsoritakis[1], *F. Tsitoura*[2], *O. Bourogianni*[1], *G. Barmparis*[2], *G. Tsironis*[2], *A. Bertsias*[3], *N. Tzanakis*[4], *S. Koukouraki*[1];
[1]*Nuclear Medicine Department, Medical School Univercity of Crete, Heraklion, Crete, GREECE,* [2]*Department of Physics, Univercity of Crete, Heraklion, Crete, GREECE,* [3]*Rheumatology Department, Medical School Univercity of Crete, Heraklion, Crete, GREECE,* [4]*Department of respiratory Medicine, University Hospital, Heraklion, Crete, Greece and School of Medicine, Heraklion, Crete, GREECE.*

Aim/Introduction: Characterization of pulmonary nodules remains a diagnostic challenge, particularly in oncological patients where early and accurate differentiation between benign and malignant lesions is crucial. Standard ^{18}F-FDG PET/CT imaging relies on SUV (Standardized Uptake Value) metrics obtained at a single time point, which may be limited in sensitivity and specificity for pulmonary lesions. Dual-time-point imaging, involving both early and delayed PET acquisitions, has been proposed to improve diagnostic accuracy. The purpose of this study is to evaluate whether dual-time-point ^{18}F-FDG PET/CT imaging enhances SUV-based diagnostic accuracy mostly for small and medium pulmonary nodules (≤30 mm) across a range of primary cancer types. ***Materials and Methods:*** This prospective study included 622 PET/CT scans from 311 patients with small and medium sized PNs. Dual time point 18F FDG PETCT imaging, early phase image acquisition 1hr (PET1) and delayed phase images after 2hrs p.i (PET2), was performed on a digital PETCT (GE discovery MI 4R Gen 2). Regions of interest (ROIs) were drawn around the lesion in both PET scans. A semiquantitative analysis was followed using the Standardized Uptake Value, (SUV1) for early and SUV2, for delayed images. Patients were classified into 3 groups: group 1 (malignant either primary or metastatic), group 2 (benign) and group 3 (indeterminate lesions). Changes in SUVmax (ΔSUV) were calculated. PET findings were compared to histopathology, radiological and clinical follow-up to determine diagnostic performance. The reference standard in characterizing PNs was SUV ≥2,5. ***Results:*** Biopsy or treatment results were obtained for 111/311: 84 malignant nodules, 15 benign, and 12 non diagnostic findings. Statistical analysis and plots were based on 99 pts. Cut-off point identification for SUV1 was 3.35, SUV2 5,17 and ΔSUV 0,69. Results for SUVmax 1 were: true positive: 67/84 (79%), true negative 10/15 (66%), false positive 5/15 (33%) and false negative 17/84 (20%) vs ΔSUVmax: true positive 74/84 (88%), true negative 9/15 (60%), false positive 6/15 (40%) and false negative 10/84 (11%). The sensitivity, specificity, and overall diagnostic accuracy of dual-time-point PET/CT were higher compared to single-time-point imaging, particularly in nodules with low initial uptake. ***Conclusion:*** Dual-time-point ^{18}F-FDG PET/CT imaging may improve the SUV-based diagnostic accuracy of small pulmonary nodules in oncologic patients with potential to influence clinical management and treatment planning.

EP-0243

Comparison of SUV, MTV and TLG volumetric changes in early and delayed FDG PET/CT: A prospective analysis for optimized pulmonary nodule evaluation.

N. Kapsoritakis[1], *F. Tsitoura*[2], *G. Barmparis*[2], *O. Bourogianni*[1], *G. Tsironis*[2], *A. Bertsias*[3], *N. Tzanakis*[4], *S. Koukouraki*[1];
[1]*Nuclear Medicine Department, Medical School Univercity of Crete, Heraklion, Crete, GREECE,* [2]*Department of Physics, Medical School, University of Crete, Heraklion, Crete, GREECE,* [3]*Department of Rheumatology, Medical School, University of Crete, Heraklion, Crete, GREECE,* [4]*Department of Respiratory, Medical School, University of Crete, Heraklion, Crete, GREECE.*

Aim/Introduction: Pulmonary nodules (PNs) pose a diagnostic challenge, especially in oncology, due to the overlap between benign-inflammatory and malignant lesions. While FDG PET/CT using SUVmax is widely used, its limitations in sensitivity and specificity have prompted interest in alternative volumetric

parameters such as Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG). This study evaluates the diagnostic utility of SUV, MTV, and TLG changes between early and delayed PET/CT scans. ***Materials and Methods:*** this prospective study included 622 PET/CT scans from 311 patients with PNs (5mm-3cm) in a period of a year. Early (1hr p.i PET1) and delayed images (2hrsp.i PET2) were performed on a digital PETCT system. Standardized Uptake Value (SUVmax), Metabolic TumorVolume (MTV) and Total lesion glycolysis (TLG) for PET1 (SUV1, MTV1, TLG1) and PET2 (SUV2, MTV2 and TLG2) and percentage changes between PET studies (ΔSUVmax, ΔMTV and ΔTLG) were analyzed. Patients were classified into 3groups: group 1, group 2 (benign) and group 3 equivalent lesions (no significant differences). The final diagnosis was based on biopsy results and on clinical decision. ***Results:*** Histopathological findings were obtained in 104/311 pts. Among these 84/104 were diagnosed as malignancy, 14/104 as benign, and 6/104 pts were non diagnostic. For ΔSUV: true positive 64/84, false negative 20/84, true negative 7/14, false positive 7/14. For ΔMTV: true positive 29/84, false negative 55/84, true negative 12/14, false positive 2/14 and for ΔTLG true positive 55/84, false negative 29/84, true negative 11/14 and false positive 3/14. The sensitivity, specificity, accuracy, PPV and NPV were for ΔSUV (76%, 50%, 72%, 90%, 35%), for ΔMTV (35%, 85%, 42%, 93%, 15%) and for ΔTLG (65%, 88%, 68%, 93%, 28%) respectively. ***Conclusion:*** Among the three parameters, TLG demonstrated the highest specificity and PPV, indicating its potential as a reliable adjunct to SUVmax in characterizing pulmonary nodules.

Aim/Introduction: The aim of this study was to assess the detection rate of 18F PSMA in pts with biochemical recurrence (BCR) of prostate cancer (PC) with low and very low PSA levels classified as early and very early biochemical recurrence (eBCR). ***Materials and Methods:*** A total of 104 patients with BCR after radical prostatectomy were prospectively evaluated over an 8-month period using ^{18}F-PSMA PET/CT. Among them, 77 patients presented with PSA levels <1.5 ng/mL and were stratified into two groups: Group A: 36 patients with very low PSA levels (<0.5 ng/mL) and PSA doubling time (dtPSA) <6 months and Group B: 41 patients with low PSA levels (0.5-1.5 ng/mL) and dtPSA >6 months. All patients underwent conventional imaging (CT and mpMRI) alongside PET/CT. Recurrence sites were classified as local (prostate fossa/pelvic lymph nodes), extrapelvic lymph nodes, and distant metastases (bone/visceral). A positive ^{18}F-PSMA PET scan was defined by the presence of at least one PSMA-avid lesion. Lesions were considered true-positive if a >50% PSA decline was observed post-treatment or confirmed by histopathology, primarily in bone lesions. ***Results:*** Out of 77 patients, 44 (57.1%) had at least one PSMA-avid lesion. Group A (n=36): 16 patients (44.4%) had positive findings: Local recurrence: 8/16 (50%) | SUVmax range: 7.2-15.2, Bone metastases: 6/16 (37,5%), Lung metastases: 2/16 (12,5%). No PSMA-avid lesions in 20/36 (55.5%). Group B (n=41): 28 patients (68.3%) had positive findings: Local recurrence: 15/28 (53.6%), Bone metastases: 10/28 (35.7%), Visceral metastases (all lung): 3/28 (10.7%). Therapeutic management changed in 44% of Group A and 68% of Group B based on PSMA PET/CT results. ***Conclusion:*** ^{18}F-PSMA PET/CT demonstrates high diagnostic accuracy in detecting recurrent disease even at very low PSA levels, significantly influencing clinical decision-making and enabling personalized treatment approaches. However, the clinical implications of negative PSMA scans in patients with very low PSA remain an area of uncertainty and warrant further investigation.

EP-0245

Is M1c1 a Distinct Prognostic Entity? Survival Impact of Single-Organ Extrathoracic Metastasis in the Proposed TNM-9 Lung-Cancer Classification

D. Nak[1], *O. Bülbül*[1], *B. Demir*[2], *M. H. Baltacioğlu*[3];
[1]Recep Tayyip Erdoğan University Training and Research Hospital, Rize, TÜRKIYE, [2]Mehmet Akif İnan Training and Research Hospital, Şanlıurfa, TÜRKIYE, [3]Trabzon University Faculty of Medicine Trabzon Kanuni Research and Training Hospital, Trabzon, TÜRKIYE.

Aim/Introduction: The 9th edition AJCC/IASLC TNM classification subdivides extrathoracic spread into M1b (single metastasis in a single organ), M1c1 (multiple metastases limited to a single organ) and M1c2 (multiple organs). It remains unclear whether M1c1 adds prognostic detail over M1b. We compared overall (OS) and progression-free survival (PFS) between these subcategories and explored organ-specific outcomes within M1c1. ***Materials and Methods:*** We retrospectively restaged 823 consecutive stage IV lung cancer patients (mean age 68 ± 10 years) with baseline ^{18}F-FDG PET/CT between 2016 and 2023. Extrathoracic disease was classified as M1b, M1c1 or M1c2 according to TNM-9. Log-rank tests and Kaplan-Meier curves assessed OS and PFS; subgroup analyses assessed bone, brain, adrenal, liver and distant lymph node involvement. The median follow-up was 11 ± 12 months (range 0.1-97). ***Results:*** In the cohort of 823 stage-IV lung cancer patients restaged according to the proposed 9th edition TNM classification system, median overall survival (OS) was 21.7 months for M1a, 17.0 months for M1b, 13.5 months for M1c1, and 9.8 months for M1c2; global comparison between the M1a, M1b, and M1c1 groups was not statistically significant ($p = 0.167$), with the worst prognosis observed in M1c2. Median progression-free survival (PFS) showed a similar pattern-11.40, 13.07 and 8.80 months for M1a, M1b and M1c1, respectively-and there was no significant difference between these three groups ($p = 0.278$). Organ-specific analyses reinforced the relative advantage of M1b: in patients with bone metastases, median OS was 15.4 months in M1b vs 12.8 months in M1c1 and 9.5 months in M1c2 ($p = 0.010$ for M1b-M1c2 comparison; $p = 0.404$ for M1b-M1c1); PFS was similarly longer in M1b than in M1c2 (12.3 vs 6.7 months; $p = 0.012$). A similar picture was observed in patients with brain metastases: Mean OS was 15.6 months in M1b, 17.6 months in M1c1, and only 10.0 months in M1c2 ($p = 0.025$ for M1b-M1c2 comparison; $p = 0.702$ for M1b-M1c1). In the M1c1 subgroup, the specific organ involved (brain, adrenal, liver, distant lymph node or bone) did not affect survival. ***Conclusion:*** These results suggest that M1c1 represents a distinct prognostic category, with outcomes closer to M1b than M1c2, reinforcing the clinical relevance of the new TNM subclassification. Further validation is needed to optimize treatment strategies for this subgroup. ***References:*** Detterbeck, F. C., Woodard, G. A., Bader, A. S., et al. (2024). The proposed ninth edition TNM classification of lung cancer. Chest, 166(4), 882-895.

EP-0246

Can F-18 FDG PET/CT Metabolic Parameters Predict STAS in Non-Small Cell Lung Cancer Patients?

B. Kocabeyoglu, *R. H. Tokac, A. Akgun;*
Ege University Nuclear Medicine Department, Izmir, TÜRKIYE.

Aim/Introduction: In patients with Non-Small Cell Lung Cancer (NSCLC), STAS (spread through air spaces) is a histological term describing the spread of cancer cells through airways outside the main tumor borders. In this study, we aimed to preoperatively

predict STAS, which is a prognostic factor for local recurrence and considered as an invasive pattern for NSCLC, using metabolic parameters obtained by F-18 FDG PET/CT imaging. ***Materials and Methods:*** The pathological data and F-18 FDG PET/CT findings of 75 patients who underwent F-18 FDG PET/CT imaging for metabolic characterization of solitary pulmonary nodules and NSCLC staging in our clinic between 2019 and 2024 were retrospectively included in the study. Metabolic tumor volume (MTV) and total lesion glycolysis (TLG), which are classical fixed threshold (42%) volumetric parameters with SUVmax values showing the highest uptake in the primary lesion area on PET/CT images, were calculated. In addition, different threshold values (lower limit SUVmax 2.5) were determined according to the primary lesion SUVmax value of each patient and maximum MTV and TLG values were calculated. Then, peripheral zonal MTV and TLG values, which are the difference of these values around the borders of the primary tumor, were obtained in accordance with the STAS term. ***Results:*** The patient age group was between 47-88 years (mean: 67) at the time of diagnosis, 14 were female and 61 were male. Lobectomy was performed in 43 patients, wedge resection in 29 patients and pneumonectomy in 3 patients. 38 patients were diagnosed with NSCLC including adenocarcinoma (20 acinar dominant, 7 solid dominant, 7 micropapillary dominant, 4 lepidic dominant subtypes), 24 squamous cell carcinoma, 3 large cell carcinoma and 10 other subtypes. According to histopathologic results, 55 patients were STAS positive and 20 patients were STAS negative. Primary tumor diameter (p=0.016), SUVmax (p=0.019) and peripheral zonal TLG (p=0.042) were statistically significantly correlated with STAS. On the other hand, no significant correlation was found between MTV, TLG, maximum MTV, TLG and peripheral zonal MTV values and STAS. ***Conclusion:*** It was concluded that STAS, which has an important role in lung cancer treatment management and prognosis prediction, can be predicted by SUVmax and peripheral zonal TLG values obtained in preoperative F-18 FDG PET/CT imaging and may be helpful in operation preferences.

EP-0247

Predicting PD-L1 expression status in NSCLC using radiomic analysis of FDG-PET/CT images

F. Kiss, *I. Járó, K. Szigeti, T. Györke;*
Semmelweis University, Budapest, HUNGARY.

Aim/Introduction: Lung cancer is the most common form of malignancy worldwide; its prognosis and treatment depend significantly on the results of histological and molecular analysis. Some molecular pathological features, such as PD-L1 positivity, provide an opportunity for immunotherapy. Taking histological samples is often problematic. Radiomic analysis of the imaging data is promising in the non-invasive determination of tumor phenotype by characterizing tumor heterogeneity and capturing complex patterns complementary to other clinical information. This study aims to investigate the potential of radiomics for predicting PD-L1 expression status in NSCLC patients based on FDG-PET/CT images. ***Materials and Methods:*** In this retrospective study, the staging FDG-PET/CT scans of 105 patients with NSCLC of different phenotypes (72 ACC, 33 SCC, 64 PD-L1 positive, 41 PD-L1 negative) were analysed. Different types of segmentation schemes were assessed. Radiomic features were obtained from the original and transformed images using the PyRadiomics package. After splitting the records into training and test sets in a 7:3 ratio, Mann-Whitney U test, LASSO regression, and Spearman correlation analysis were applied to reduce the number of examined features. A logistic regression model was trained using the selected features under different settings. The performance of the model was evaluated on the test set using ROC curve, AUC score, and various other performance metrics. ***Results:*** The extensive comparison of the tested models revealed that the best-performing one, which utilized translated masks and original and transformed images, achieved an AUC of 0.783 (95% confidence interval: 0.625, 0.942) and demonstrated high accuracy (81.25%), sensitivity (90.00%) and notably high NPV of 80.00%. These results indicate the reliability of the model in predicting the minority class, PD-L1 negative status in the imbalanced dataset. ***Conclusion:*** The results indicate that models built from radiomic features extracted from FDG-PET/CT images can distinguish between PD-L1 positive and PD-L1 negative NSCLC. Thus, radiomics with multimodal imaging holds significant potential for predicting the phenotype of NSCLC, providing a non-invasive alternative for selecting patients benefiting from targeted immunotherapy. ***References:*** Li B, Su J, Liu K, et al. Deep learning radiomics model based on PET/CT predicts PD-L1 expression in non-small cell lung cancer.

Baseline PET/MR Imaging for Lung Cancer Patients with Immunotherapy: A Correlation and Prognostic Study of IVIM, CTRW Diffusion and PET Metabolic Parameters

Y. Jiang[1], *S. Xie*[1], *C. Zhou*[1], *C. Sun*[2], *Y. Guo*[3], *Y. Wu*[1], *W. Fan*[1];
[1]*Sun Yat-sen University Cancer Center, Guangzhou, CHINA,*
[2]*United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA,*
[3]*Shenzhen United Imaging Healthcare Co., Ltd., Shenzhen, CHINA.*

Aim/Introduction: This study aimed to investigate the baseline chest PET/MR imaging with multi-b value sequences in lung cancer patients undergoing immunotherapy, focusing on the correlation between intravoxel incoherent motion (IVIM) [1] and continuous time random walk (CTRW) models[2]with PET metabolic parameters, and their prognostic significance. ***Materials and Methods:*** Forty-five lung cancer patients were included, with baseline PET/MR imaging acquired, including multi-b value MR sequences. Following the scan, biopsy was performed for pathological confirmation. Patients subsequently underwent chemotherapy combined with immunotherapy. The biopsy lesions were semi-automatically contoured on PET images, and the corresponding mask was registered to diffusion-weighted imaging (DWI). The IVIM and CTRW diffusion models were fitted to obtain the parameters: α_CTRW, β_CTRW, D_CTRW, ADC, D_ivim, D_star_ivim, and f_ivim. PET metabolic parameters, including SUVmax, SUVmean, total lesion glycolysis (TLG), and metabolic tumor volume (MTV), were also calculated. Median values for these parameters were used for binary categorization, and univariate and multivariate analyses were performed to evaluate their prognostic value. The median survival time for the cohort was 5.03 [2.767-9.200] months. ***Results:*** Univariate and multivariate analyses revealed that the high and low of SUVmean and β_CTRW depending on median values were identified as independent prognostic risk factors for survival in lung cancer patients undergoing immunotherapy. Kaplan-Meier survival analysis showed that both high SUVmean ($p = 0.0084$) and low β_CTRW ($p = 0.044$) were associated with better survival outcomes. These results suggest that SUVmean and β_CTRW are significant independent prognostic factors for survival. ***Conclusion:*** Baseline chest PET/MR imaging, incorporating IVIM and CTRW diffusion models, can provide valuable information regarding tumor microenvironmental characteristics and is predictive of immunotherapy prognosis. SUVmean and β_CTRW were identified as independent prognostic factors, potentially aiding in personalized treatment strategies. ***References:*** 1. ^{18}F-FAPI PET/CT Imaging in Pneumoconiosis:a new tool for early diagnosis and guiding treatment of pulmonary fibrosis

C. Liu, *S. Li;*
First hospital of shanxi medical university, Taiyuan, CHINA.

Aim/Introduction: Pneumoconiosis is characterized by pulmonary fibrosis. The activation of fibroblasts play an important role in the pathological development of pulmonary fibrosis. Chest CT, as a conventional examination to diagnose pulmonary fibrosis of pneumoconiosis, cannot evaluate the fibrosis activity. The application value of ^{18}F-FAPI in pneumoconiosis is unclear. This study aimed to clarify the feasibility of ^{18}F-FAPI PET/CT in non-invasively monitoring the activity evolution of pulmonary fibrosis in pneumoconiosis and the anti-fibrotic treatment. ***Materials and Methods:*** A preliminary clinical study was conducted on 6 pneumoconiosis patients and 4 healthy control individuals, correlation analysis was performed between the ^{18}F-FAPI uptake in pulmonary fibrosis areas and the pulmonary diffusing function. Sprague-Dawley rat experiments were performed on three groups concluding pneumoconiosis model, pirfenidone-treated, and normal control groups. ^{18}F-FAPI and ^{18}F-FDG PET/CT, histopathologic, and hematological analysis were assessed monthly from modeling until 6 months. ***Results:*** ^{18}F-FAPI uptake in fibrotic areas was found in the pneumoconiosis patients, and negatively correlated with the diffusing function ($r = -0.929$, $P = 0.022$). In the pneumoconiosis model, ^{18}F-FAPI activity preceded one month earlier than relative collagen content (%) in Masson trichrome staining and the level of connective tissue growth factor in plasma, an indicator reflecting the fibroblast activation. The uptake of ^{18}F-FAPI, rather than ^{18}F-FDG, significantly decreased in the pirfenidone-treated group compared to the pneumoconiosis group ($P < 0.05$). ***Conclusion:*** ^{18}F-FAPI PET/CT imaging holds promise for the early identification of pulmonary fibrosis activity and monitoring its evolution in pneumoconiosis, offering a precise clinical opportunity for targeted anti-fibrotic treatment.

EP-0250

Comparative Evaluation of 68-Gallium-Fibroblast Activation Protein Inhibitor (FAPI) PET/CT and 18-F-Fluorodeoxyglucose (FDG) PET/CT in Non-Small Cell Lung Cancer: Insights from an Expanded Cohort

S. Sathoo, *D. Halanaik, R. Manju, S. Pradeep;*
Jawaharlal Institute of Postgraduate Medical Education & Research, Puducherry, INDIA.

Aim/Introduction: Lung cancer remains a major global health challenge, where precise staging is essential for guiding treatment. Although ^{18}F-FDG PET/CT is well established in clinical imaging, the newer 68Ga-FAPI PET/CT, which targets cancer-associated fibroblasts, has shown potential advantages. This study compares the effectiveness of ^{18}F-FDG and 68Ga-FAPI PET/CT in assessing non-small cell lung cancer (NSCLC). ***Materials and Methods:*** This single-centre study included 31 patients with newly diagnosed, treatment-naive NSCLC. Each patient underwent both 68Ga-FAPI and ^{18}F-FDG PET/CT scans within one week for baseline staging. Primary lesions, lymph nodes, and distant metastases were evaluated and compared across both imaging methods. Semi-quantitative metrics, including SUVmax (adjusted for body surface area) and Tumour-to-Background Ratio (TBRmax), were calculated and analysed using Paired T-tests. The tumours were staged according to the 9th edition of the TNM classification for lung cancer. ***Results:*** Among the participants (mean age 58.5 ± 9.4 years; 23 males, 8 females), 68Ga-FAPI PET/CT identified more metastases: lymph nodes (157 vs 124), bone (154 vs 135), liver (7 vs 5), pleura (39 vs 33), lung (42 vs 37), adrenal (8 vs 7) and brain (1 vs 0). SUVmax was higher for 68Ga-FAPI in primary lesions (5.1±1.8 vs 3.9±1.7, p<0.001), lymph nodes (3.3±1.4 vs 2.3±1.2, p<0.001), bone (3.8±1.7 vs 2.1±0.9, p<0.001), liver (5.3±2.5 vs 2.5±0.6, p=0.04) and pleural (2.7±1.1 vs 1.6±0.6, p<0.001) metastases. The TBRmax was significantly higher in 68Ga-FAPI scans across all these lesions (p<0.05). 68Ga-FAPI improved metastasis visualisation in bone, brain, and liver compared to ^{18}F-FDG due to reduced background uptake. No significant differences were found in SUVmax or TBRmax for lung (SUVmax: 2.0 ± 1.0 vs 1.8 ± 0.9, p>0.05; TBRmax: 3.8 ±2.1 vs 3.3 ±1.7, p>0.05) or adrenal metastases (SUVmax: 3.0 ± 1.1 vs 2.5 ± 1.5, p>0.05; TBRmax: 4.5 ±1.9 vs 3.3 ± 3.4, p>0.05). The 68Ga-FAPI PET/CT scan led to N-stage upstaging in 16% of patients (5 out of 31) and resulted in an overall TNM stage upstaging in approximately 10% (3 out of 31). ***Conclusion:*** 68Ga-FAPI PET/CT demonstrates superior performance compared to ^{18}F-FDG PET/CT in detecting metastatic lesions in lymph nodes, bone, liver, pleura, lung, adrenal and brain among patients with non-small cell lung cancer (NSCLC). Its higher SUVmax values and improved tumour-to-background ratios contribute to more accurate staging and may enhance therapeutic planning for metastatic disease.

EP-0251

Prognostic Value of Cerebral Metabolic Activity in Metastatic Non-Small Cell Lung Cancer (NSCLC) Patients

J. Auriac[1], *G. Lemoudda*[1], *N. Hovhannisyan-Baghdasarian*[1], *M. Pires*[2], *L. K. Shiyam Sundar*[3], *P. Salamoun-Feghali*[4], *R.-D. Seban*[1,5], *N. Jehanno*[1,5], *C. Nioche*[1], *M. Luporsi*[1], *T. Beyer*[2], *N. Girard*[4], *I. Buvat*[1], *F. Orlhac*[1];
[1]*Institut Curie, Université Paris-Saclay, Inserm LITO U1288, Orsay, FRANCE,* [2]*Quantitative Imaging and Medical Physics (QIMP) Team, Medical University of Vienna, Vienna, AUSTRIA,* [3]*DIGIT-X Lab, Department of Radiology, LMU University Hospital, Munich, GERMANY,* [4]*Institut Curie, Institut du Thorax Curie-Montsouris, Paris, FRANCE,* [5]*Institut Curie, Department of Nuclear Medicine, Paris-St-Cloud, FRANCE.*

Aim/Introduction: Whole-body PET/CT images associated with automated segmentation tools offer new opportunities to investigate inter-organ metabolic connections. Doing so, we identified an unexpected relationship between brain FDG uptake and overall survival (OS) in metastatic Non-Small Cell Lung Cancer (NSCLC) patients that we thoroughly investigated in this study. ***Materials and Methods:*** Whole-body FDG-PET/CT images were retrospectively collected for 380 metastatic NSCLC patients before treatment, chronologically divided into discovery/test sets according to the scan date. All lesions were automatically segmented on PET using LION[1] followed by SUV>4. The whole brain was segmented using TotalSegmentator[2] based on CT. Maximum distance between two lesions (Dmax), maximum uptake (maxSUVmax) and average uptake (TSUVmean) across all lesions, Total Metabolic Tumor Volume (TMTV) and whole-brain average FDG uptake ($SUVmean_{brain}$) were extracted using LIFEx[3]. Univariable analysis was performed using the Cox proportional hazard model. Features with p<0.05 were included in a Cox multivariable model without (Model1) and with $SUVmean_{brain}$ (Model2). A risk score was derived and binarized by the median in the discovery set to stratify patients into two groups. Survival analyses were performed using the Kaplan Meier method. The relationship between $SUVmean_{brain}$ and clinical/imaging features was investigated using Spearman coefficients (rS) and Wilcoxon tests. ***Results:*** The discovery and test sets included 234 and 146 patients respectively. In univariable analysis, ECOG Performance Status ≥2 (Hazard Ratio=2.20, Wald test: p<0.001), smoking history (HR=1.63, p=0.01), Dmax (HR=1.07, p=0.009), TMTV (HR=1.12, p<0.001) and $SUVmean_{brain}$ (HR=0.83, p<0.001) were associated with OS. In multivariable analysis, $SUVmean_{brain}$ remained an independent prognostic factor (HR=0.88; 95%CI: [0.80-0.98]; p=0.02). Model2 outperformed Model1 (χ^2 test: p=0.02). The median survival gap between low- and high-risk patients with Model2 (Log-rank test: p<0.001) was larger than with Model1 in the discovery (14.9 vs. 14.4 months) and test sets

(13.5 vs. 7.3 months). $SUVmean_{brain}$ was lower in patients who died within one year (Wilcoxon test: p<0.001). $SUVmean_{brain}$ was significantly correlated with CRP (rS=-0.44), neutrophils (rS=-0.44) and albumin (rS=0.39) and was neither correlated with radiomic features (rS<0.24) nor associated with brain metastases (p=0.68). ***Conclusion:*** $SUVmean_{brain}$ was an independent prognostic factor in metastatic NSCLC patients. Low-cerebral metabolism might be associated with immune response and systemic inflammation, which warrants further evaluation. ***References:*** 1.Pires et al. EJNMMI 2024. 2.Wasserthal et al. Radiology: AI 2023. 3.Nioche et al. Cancer Res 2018.

EP-0252

Spatial radiomics features derived from SUVmax location in resectable NSCLC are associated with tumor aggressiveness

Z. Jiang, *D. Haberl, C. P Spielvogel, J. Yu, K. Lukas, H. Marcus;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Accurate non-invasive prediction of histopathologic invasiveness and recurrence risk remains a clinical challenge in resectable non-small cell lung cancer (NSCLC). Radiomics has shown promise in extracting biologically meaningful information from imaging. In this study, we developed and validated the Edge Proximity Score, a novel spatial PET radiomic feature that quantifies the displacement of metabolic activity from the tumor center, to predict invasive histopathologic features and progression-free survival (PFS). ***Materials and Methods:*** We retrospectively analyzed 244 NSCLC patients with baseline ^{18}F-FDG PET/CT and complete clinical-pathological data. The Edge Proximity Score was calculated based on the normalized distance between the SUVmax and both the tumor centroid and perimeter. PET-derived radiomics features (n = 105) were extracted. The dataset was randomly split 80:20 into training and validation cohorts, and models were trained using 10-fold cross-validation. Eight machine learning classifiers were developed to predict lymphovascular invasion (LVI), visceral pleural invasion (VPI), and spread through air spaces (STAS). Feature selection was conducted using minimum redundancy maximum relevance (mRMR), and SHAP was used to visulize feature contributions. Cox regression and Kaplan-Meier analyses were performed to assess the prognostic value of the Edge Proximity Score. RNA sequencing data from 76 TCIA patients were used for biology analysis. ***Results:*** The Edge Proximity Score was significantly elevated in STAS-positive ($P = 6.7\times10^{-12}$), VPI-positive ($P = 8.3\times10^{-5}$), and LVI-positive ($P = 9.9\times10^{-5}$) tumors. Logistic regression achieved the best predictive performance (AUC = 0.74 for STAS, 0.69 for LVI, and 0.66 for VPI), with the Edge Proximity Score ranking among the top five features in SHAP analysis. In multivariable Cox regression, the Edge Proximity Score was an independent predictor of PFS (HR = 2.629, 95% CI: 1.178-5.870; P = 0.018), along with TNM stage (P = 0.014), VPI (P = 0.037), and age (P = 0.009). Patients with high Edge Proximity Scores showed significantly worse PFS in both the internal cohort (P = 1e−4) and external TCIA cohort (P = 0.0045). Transcriptomic analysis revealed upregulation of cell cycle and metabolic pathways in high-risk tumors, while immune-related pathways (e.g., interferon responses, IL6-JAK-STAT3) were enriched in the low-risk group. Immune cell deconvolution confirmed higher infiltration of neutrophils, monocytic lineages, and myeloid dendritic cells in low-risk tumors ($P < 0.005$). ***Conclusion:*** The Edge Proximity Score is a non-invasive, interpretable biomarker associated with tumor invasiveness, recurrence, and immune activity in NSCLC, with potential to enhance preoperative risk stratification.

EP-0253

Performance of [18F] FDG PET/CT versus FAPI PET/CT for lung cancer assessment

M. Komarova, *N. Meshcheryakova, I. Nazarenko, O. Ryzhova, A. Pronin, V. Solomyany;*
N.N. Blokhin National Medical Research Center of Oncology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: to compare the diagnostic performance of 18-fluorodeoxyglucose (FDG) PET/CT and fibroblast activating protein inhibitor (FAPI) PET/CT in the assessment of primary tumors, lymph nodes and distant metastases in lung cancer patients. ***Materials and Methods:*** In this retrospective study, patients (pts) with lung cancer who underwent FAPI PET/CT and FDG PET/CT between 2022-2024 were analyzed. Lesion uptake was converted to SUVmax. Mann-Whitney test was used to compare the SUVmax and the number of positive lesions detected by the two methods was recorded. We calculated the diagnostic efficiency (sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and accuracy (Ac)) for each modality on a per-region basis and for lymph nodes metastasis detection. Positive tumor lesions on PET/CT images were verified by biopsy or follow-up. ***Results:*** In total 20 participants (median age: 66,5 years; 3 females/ 17 males; histopathologic findings: adenocarcinoma 12 pts, squamous cell carcinoma 5 pts, neuroendocrine tumor 2pts and non-small-cell lung cancer 1 pts) were assessed. There were no significant differences between uptake of FAPI and of FDG in both primary lesions, metastatic lymph nodes and other metastases. The mean SUVmax in primary lesions were 11,01 [8,98-14,69] for FDG PET/CT and 12,11[5,69-15,51] for FAPI PET/CT, p=0,98; in lymph nodes were 4,93 [3,77-7,53] vs. 7,25 [0,78-15,06] respectively, p= 0,69. The detection of lymph nodes lesions using FAPI PET/CT was superior to that with FDG PET/CT (total number of lesions were 73 vs. 53, respectively). However, the detection sensitivity for primary tumors using both modalities was comparable. The diagnostic capabilities were higher with FAPI PET/CT than FDG PET/CT on a per-region basis (Se 98,67% vs. 73,33%, Sp 87,80% vs. 63,41% and Ac 94,83% vs. 76,83%, respectively) and in the diagnosis of lymph nodes metastasis (Se 97,78% vs. 66,67%, Sp 96,97% vs. 60,61% and Ac 97,44 % vs. 64,10%, respectively). ***Conclusion:*** Compared to FDG PET/CT, FAPI PET/CT demonstrated better lesion detection capabilities for patients with lung cancer, particularly of metastasis to lymph nodes.

Towards Personalised Lung Cancer Screening: A Prospective Multicentre Study Integrating LDCT, [^{18}F] FDG-PET/CT and AI-Driven Risk Stratification

F. Gelardi[1], *P. Muriana*[1], *L. Antunovic*[1], *M. Sollini*[2,1], *D. Palumbo*[1], *R. Ferrara*[2,1], *R. Petrelli*[1], *R. Di Donato*[1], *R. Cuocolo*[3], *P. Veltri*[4], *P. Soda*[5], *G. Veronesi*[2,1], *A. Chiti*[2,1];
[1]*IRCCS Ospedale San Raffaele, Milan, ITALY,* [2]*Università Vita-Salute San Raffaele, Milan, ITALY,* [3]*Università di Salerno, Baronissi (SA), ITALY,* [4]*DIMES, Università della Calabria, Rende (CS), ITALY,* [5]*Università Campus Bio-Medico di Roma, Rome, ITALY.*

Aim/Introduction: Low-dose CT (LDCT) screening significantly increases the early detection of lung cancer and improves survival. However, its clinical utility is limited by high false-positive rates, overdiagnosis and a lack of consensus on optimal screening intervals. There is an urgent need to move from one-size-fits-all screening protocols to personalised strategies that improve diagnostic accuracy while minimising unnecessary interventions. This study investigates a comprehensive screening model that integrates individual risk factors, clinical data and advanced imaging - LDCT and [^{18}F]FDG PET/CT - augmented by artificial intelligence (AI) to improve the accuracy and efficiency of lung cancer detection. ***Materials and Methods:*** In this prospective, multicentre study, 334 high-risk patients (age>50yrs; PLCOm2012>4%) will be enrolled and assigned to one of two cohorts: Cohort 1 will receive combined LDCT and [^{18}F]FDG PET/CT; Cohort 2 will receive LDCT alone. LDCT findings will be classified according to Lung-RADS 2022 criteria, while PET/CT will be considered positive if significant FDG uptake is detected in lung nodules or extra thoracic sites. AI algorithms will synthesise patient-specific clinical and imaging data to refine nodule classification,

identify high-risk individuals and personalise screening intervals and modalities. ***Results:*** Recruitment began in January 2025 and is ongoing. To date, 17 participants have been enrolled in Cohort 1 (median age 66 years; 8 females, 9 males), all with a history of heavy smoking and no known occupational or environmental exposures. One patient presented with a Lung-RADS 4a nodule on LDCT, with no corresponding FDG uptake; 6-months follow-up CT was recommended. No significant nodules were identified in the remaining participants. PET/CT revealed incidental findings in three participants: FDG-avid colonic polyps, FDG-avid Warthin tumours, and an adrenal adenoma. ***Conclusion:*** This study aims to demonstrate that the integration of [^{18}F]FDG-PET/CT with LDCT improves screening specificity, reduces false positive rates and allows more accurate staging of regional and distant disease. In addition, PET/CT can detect clinically relevant smoking-related extrapulmonary malignancies not detected by chest LDCT alone. The AI-driven approach is expected to refine screening protocols by individualising the timing and imaging modalities based on patient risk profiles, thereby reducing unnecessary follow-up and procedures. Overall, this integrative approach has the potential to transform lung cancer screening into a more targeted, efficient and patient-centred practice. Early tumor response following transarterial radioembolization (TARE): preliminary data from 30 patients with primary and secondary liver tumors

A. Moretti*, A. Vizzuso, M. Renzulli, E. Giampalma, E. Del Giudice, D. Tirotta, R. Galassi, G. Pontone, F. Di Mauro, F. Matteucci;*
Ospedale Morgagni Forli, Forli, ITALY.

Aim/Introduction: Transarterial radioembolization (TARE) with Yttrium-90 microspheres is an established locoregional treatment for hepatocellular carcinoma (HCC) and selected liver metastases. However, its short-term efficacy and potential to downstage tumors for surgery remain areas of active investigation. This study aims to describe the early radiological response and clinical outcomes of patients treated with TARE at our institution. ***Materials and Methods:*** A retrospective analysis was conducted on 30 consecutive patients treated with TARE between April 2024 and April 2025. Diagnoses included hepatocellular carcinoma (HCC), intrahepatic cholangiocarcinoma, neuroendocrine tumors (NETs), and secondary liver metastases from colon cancer. For each patient, data were collected on tumor histology, treatment date, administered activity (GBq), radiological response at 1, 3, and 6 months (according to RECIST criteria: PR, partial response; CR, complete response; PD, progressive disease, SD, stabile disease), surgery after TARE, and vital status. ***Results:*** Histological distribution: HCC (73.3%), cholangiocarcinoma (13.3%), NETs (6.7%), and metastases (6.7%). Radiological response at 1 month (n = 18):- PR: 11 patients (61.1%)- CR: 3 patients (16.7%)- PD: 2 patients (11.1%)- Not assessable: 2 patients (11.1%). At 3 months (n = 8):- PR: 5 (62.5%)- CR: 2 (25.0%)- PD: 1 (12.5%). At 6 months (n = 3):- PR: 2 (66.7%)- CR: 1 (33.3%). Surgery post-TARE was performed in one patient (3.3%). At the time of data collection, 96.7% of patients were alive. ***Conclusion:*** Preliminary findings suggest that TARE achieves a high rate of tumor control in the early months following treatment, with over 60% of patients showing partial response and up to 25% complete response by 3 months. Although conversion to surgery was limited, possibly due to disease extent or comorbidities, the therapy appears to offer promising short-term outcomes. Further studies with longer follow-up and larger cohorts are warranted to confirm these results and better define TARE's role in integrated treatment strategies.

EP-0256

Fibroblast activation protein-targeted PET/CT with ^{18}F-Fibroblast activation protein inhibitor-74 for evaluating the staging and guiding clinical management of gastrointestinal cancers: comparison with contrast-enhanced CT

L. Ma*[1], Z. Quan[1], H. Chen[2], F. Kang[1], J. Wang[1];*
[1]Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi, CHINA, [2]The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, CHINA.

Aim/Introduction: The aim of this study is to compare the efficacy of ^{18}F-FAPI-74 PET/CT targeting fibroblast activation protein (FAP) labeled with ^{18}F and enhanced CT (Ce-CT) in the staging and clinical management of gastrointestinal cancer. ***Materials and Methods:*** A prospective dual-center study included 38 patients with pathologically confirmed gastrointestinal cancers (including gastric, colorectal and pancreatic). All patients underwent both ^{18}F-FAPI-74 PET/CT and Ce-CT within two weeks, with surgical or biopsy pathology as the reference standard.Compare the diagnostic performance of Ce CT and^{18}F-FAPI-74 PET/CT using the McNemar test, and compare them with the gold standard. ***Results:*** Finally, 38 patients were included in the analysis. In terms of lymph node metastasis detection, the sensitivity (60% vs. 32%), specificity (98% vs. 96.1%), and accuracy (92% vs. 85%) of ^{18}F-FAPI-74 PET/CT were significantly better than CE-CT (all P<0.05). The sensitivity (94% vs. 19%) and accuracy (97% vs. 58%) of 18F-FAPI-74 PET/CT in detecting distant metastases were significantly higher than those of CE-CT (all P<0.001), especially in the detection of peritoneal metastases. In terms of clinical management, 37% of patients changed their treatment decisions due to ^{18}F-FAPI-74 PET/CT (18% made significant adjustments, such as transitioning from direct surgery to neoadjuvant therapy or palliative care). ***Conclusion:*** ^{18}F-FAPI-74 PET/CT is significantly better than CE-CT in staging gastrointestinal cancer, especially in detecting small distant metastases (such as peritoneal metastases), which can more accurately guide personalized clinical management.

EP-0258

Multicentre Study Comparing [^{68}Ga] FAPI-04 PET/CT and [^{18}F]FDG PET/CT for Staging Gastrointestinal Tumours

P. Hj*[1], H. Nagaraj[2,3], K. G. Kallur[4,3], S. S P[1], M. Saini[2], P. Saini[2], R. Krishnappa[3], P. G. Ramachandra[3], D. Kumar[5], P. Wadhwa[5];*
[1]Aster Hospital, Banglore, INDIA, [2]The Nairobi West Hospital, Nairobi, KENYA, [3]HCG CCK Cancer Centre, Nairobi, KENYA, [4]HCG Cancer Center, Banglore, INDIA, [5]United Imaging Healthcare, Delhi, INDIA.

Aim/Introduction: [^{18}F] FDG PET/CT remains a widely adopted modality for assessing tumour metabolism, its diagnostic utility can be limited in certain GI malignancies due to variable glucose uptake and reduced sensitivity in tumours with low metabolic activity or mucinous components. In contrast, [^{68}Ga] FAPI-04 PET/CT has emerged as a promising alternative. This study aims to compare the diagnostic performance of FAPI-04 PET/CT and FDG PET/CT for staging GI tumours in a cohort of 75 patients, excluding those with gastrointestinal lymphomas. ***Materials and Methods:*** This retrospective, multi-center study was conducted across Aster Whitefield Hospital in Bangalore, India, The Nairobi

West Hospital, and HCG CCK Cancer Center in Nairobi, Kenya. It included 75 patients with either suspected or histologically confirmed gastrointestinal (GI) malignancies who were referred to these centers for diagnostic evaluation and staging. Each patient underwent both [^{18}F]FDG PET/CT and [^{68}Ga]FAPI-04 PET/CT within a 7-day interval. In India, both the scans were done at Aster Whitefield Hospital, Banglore, India, whereas, in Kenya FDG scans for the patients were conducted at The Nairobi West Hospital, whereas FAPI was conducted at HCG CCK Cancer Center. Across the cohort, 145 lesions were detected, encompassing colorectal, gastric, pancreatic, and esophageal cancers. Comparative analysis was performed between the two imaging modalities based on lesion localization, size, and tracer uptake characteristics. Diagnostic performance metrics—sensitivity, specificity, and overall accuracy—were determined using histopathological findings as the reference standard. ***Results:*** FAPI O4 PET/CT showed a higher sensitivity (92%) in detecting gastrointestinal tumors compared to FDG PET/CT (84%), particularly excelling in cases of pancreatic and colorectal cancers, where fibrotic stroma and low metabolic activity can limit FDG uptake. The specificity of FAPI O4 PET/CT was also greater (95%) than that of FDG PET/CT (88%), likely due to its reduced uptake in non-cancerous tissues. Lesion detection was more effective with FAPI O4 PET/CT, identifying 142 out of 145 lesions, whereas FDG PET/CT identified 124 ($p = 0.02$). Overall diagnostic accuracy favoured FAPI O4 PET/CT at 94%, compared to 86% for FDG PET/CT. FAPI O4 PET/CT also had superior performance in identifying metastatic spread to the liver, peritoneum, and lymph nodes. ***Conclusion:*** FAPI O4 PET/CT demonstrates superior performance over FDG PET/CT in staging gastrointestinal cancers, showing higher sensitivity, specificity, and overall diagnostic accuracy—especially in tumours with significant stromal components. ***References:*** 1. Giesel, F. L., et. al. (2021). JNM

EP-0259

Evaluating Protein-Losing Enteropathy Using 99mTc-MDP Scintigraphy: A Non-Invasive Diagnostic Approach

K. Vidhya[1], *S. K. Jha*[2], *P. Palanivel*[3], *S. L S*[4], *R. Mishra*[5], *V. K. Dhingra*[1]; *[1]AIIMS, Rishikesh, Rishikesh, INDIA, [2]Ranchi Cancer Hospital and Research Centre, Ranchi, INDIA, [3]American Oncology Institute, Coimbatore, INDIA, [4]AIIMS, Delhi, Delhi, INDIA, [5]Hope and Heal Cancer Hospital, Siliguri, INDIA.*

Aim/Introduction: Protein-losing enteropathy (PLE) is a rare disorder characterized by excessive loss of plasma proteins through the gastrointestinal tract, often presenting with diarrhoea, hypoalbuminemia, and peripheral edema. Etiologies include lymphatic obstruction, mucosal inflammation, or erosion. While 99mTc-labeled human serum albumin (HSA) scintigraphy is traditionally used, limited availability necessitates alternative tracers. 99mTc-methylene diphosphonate (MDP), commonly used for bone imaging, has emerged as a potential alternative for detecting intestinal protein loss and is a rarely-utilized yet readily available tracer for this pathology. ***Materials and Methods:*** Patients with clinical features of PLE—hypoalbuminemia, peripheral edema, and chronic diarrhea—underwent 99mTc-MDP scintigraphy. Each received 740 MBq (20 mCi) of 99mTc-MDP intravenously. Dynamic, blood pool, delayed planar whole-body, and SPECT/CT images were acquired using a dual-head gamma camera. Radiochemical purity was confirmed at 98% via chromatography, and physiological tracer biodistribution was evaluated to rule out free pertechnetate or contamination. ***Results:*** Here we present two female patients with symptoms of PLE and how MDP scintigraphy helped in their diagnosis. In Case 1, a 66-year-old woman demonstrated focal tracer accumulation in the ascending and transverse colon. Stool counts were elevated, and biopsy confirmed colitis as the site of protein loss. In Case 2, a 53-year-old woman showed diffuse uptake throughout the colon, with SPECT/CT localizing pooling in the caecum and proximal ascending colon. Elevated stool counts supported active protein loss. Previous biopsies from unrelated bowel segments were normal; based on imaging, targeted biopsy from the caecum was recommended. In both cases, physiological skeletal and renal excretion was observed without abnormal uptake in the thyroid, stomach, or liver, ruling out tracer impurities. ***Conclusion:*** 99mTc-MDP scintigraphy successfully localized intestinal protein loss in both patients, guiding further diagnostic biopsies and clinical management. As a widely available, cost-effective, and non-invasive alternative to 99mTc-HSA, 99mTc-MDP shows promising utility in evaluating PLE. These cases underscore its potential role in diagnosis and biopsy guidance, especially in resource-limited settings.

EP-0260

Timing is Everything: Unmasking Pancreatic Cancer with Multiple-Time-Point [^{68}Ga]Ga-FAPI-46 PET Imaging

P. Rasinski[1,2], *T. Nilsson*[1,2], *A. Gebremariam*[2], *M. Holstensson*[1,2], *E. Sparrelid*[1,3], *M. Löhr*[1,3], *T. Tran*[2,4], *R. Axelsson*[2,5]; *[1]Department of Clinical Science, Intervention, and Technology, Karolinska Institutet, Stockholm, SWEDEN, [2]Department of Nuclear Medicine and Medical Physics, Karolinska University Hospital, Stockholm, SWEDEN, [3]Department of Upper Gastrointestinal Diseases, Karolinska University Hospital, Stockholm, SWEDEN, [4]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, SWEDEN, [5]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN.*

Aim/Introduction: FAPI-PET imaging is a promising imaging technique, particularly in the assessment of pancreatic cancer (PC). However, differentiating between malignant and non-malignant lesions that are FAPI-positive remains a challenge. It has been suggested that multiple-time-point imaging could enhance the distinction between malignant and benign pancreatic tracer uptake when compared to single time-point imaging. The aim of this study was to establish whether multiple-time-point PET acquisition can improve the differentiation of PC in patients with concomitant pancreatitis. ***Materials and Methods:*** In an ongoing prospective clinical trial (EU2024-514967-25-00; NCT05172310), the diagnostic value of [68Ga]Ga-FAPI-46 PET/CT imaging in patients with suspected PC is investigated. Prior to surgery patients undergo FAPI PET imaging. A preliminary analysis was conducted of ten patients with histopathologically confirmed concomitant PC and pancreatitis. The patients were administered with [68Ga]Ga-FAPI-46 (mean activity 195±47 MBq), followed by a 45-minute dynamic PET acquisition with list mode, centred over the lesion in the pancreas. At 60 minutes post-injection, a whole-body static PET acquisition was performed (4 minutes per bed position). At 180 minutes post-injection, an additional static acquisition (14 minutes per bed position), centred over the pancreatic lesion was carried out. The dynamic PET raw data were statistically truncated and reconstructed to produce images of 4-minute acquisition duration, at 10, 20, 30, and 40 minutes post-injection. The images were co-registered, and lesion segmentation was conducted using Affinity (version 4.0.2) on the 40-minute images. Volumes of interest technique, with a 40% threshold, were drawn, and the volumes were copied to the other time-point images. ***Results:*** The mean SUVmax, SUVmean, and SUVpeak in PC remained relatively stable up to the 60-minute imaging and decreased slightly at 180-minute imaging. In pancreatitis lesions, the mean of all SUV parameters decreased relatively steadily between the subsequent time points. Notably, there were significant differences in SUVmax and SUVmean between PC and pancreatitis at both 60-minute and 180-minute imaging, as well as in SUVpeak at 180-minute imaging. ***Conclusion:*** Preliminary findings indicate that imaging at 60 and 180 minutes post-injection enhances the differentiation of PC in patients with concomitant pancreatitis compared to

earlier time-point imaging. Although the clinical value of repeated imaging at various time points was not clearly established in these results, further analyses are ongoing to determine its potential.

EP-0261

Prognostic Value of Preoperative Staging ^{18}F-FDG PET/MRI Findings in Surgically Resected Gastric Cancer Patients

R. Kalkan, *S. Gülbahar Ateş, U. Aydos, Ü. Ö. Akdemir, L. Ö. Atay;*
Gazi University Faculty of Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Our aim was to investigate the prognostic value of staging ^{18}F-FDG PET/MRI findings related to the primary tumor and lymph nodes (LN) in predicting overall survival in gastric cancer patients undergoing surgical resection. ***Materials and Methods:*** We included 78 patients with gastric cancer who underwent ^{18}F-FDG PET/MRI for primary staging before surgical resection and total/subtotal gastrectomy at follow-up between 2018 and 2024. Demographic characteristics, type of surgery, history of chemotherapy/radiotherapy, histopathological features of the tumor, tumor location, wall thickness, SUVmax, minimum apparent diffusion coefficient (ADCmin) values, SUVmax/liver SUVmean ratio, number and SUVmax of ^{18}F-FDG positive LNs, LN SUVmax/liver SUVmean ratio, the size of largest LN, presence of mortality during follow-up and last follow-up dates were recorded. Continuous variables were categorized by determining the optimum threshold values according to Youden index in ROC analysis. Cox regression analysis was performed with SPSSv27 to determine the factors predicting mortality and Kaplan-Meier analysis to determine survival. ***Results:*** The clinicopathologic characteristics of the patients are summarized in a table. The median follow-up period was 23.7 months and mortality was observed in 39 (50%) of the patients. In the univariate analysis performed to determine the factors predicting overall survival, type of surgery (p=0.002), histopathologic subtype (p=0.021), pT (p=0.025) and pN (p=0.004) stages, ADCmin (p=0.023), presence of lymphovascular (p=0.013) and perineural (p=0. 017) invasion, gastric tumor wall thickness (p=0.031), number of ^{18}F-FDG positive LNs (p=0.027), LN size (p=0.007) and tumor SUVmax/liver SUVmean ratio (p=0.008) were statistically significant. In multivariant analysis, tumor SUVmax/liver SUVmean ratio (p=0.002), and histopathological subtype (p<0.001) were found to be independent risk factors for mortality. A tumor SUVmax/liver SUVmean ratio above 2.6 was associated with an approximately 4.4-fold increased mortality risk at follow-up, while the presence of signet-ring cell carcinoma pathology was associated with an approximately 5.9-fold increased mortality risk. The mean survival of operated gastric cancer patients was calculated as 42.7 ±3.5 months. Overall survival was lower in patients with the histopathologic type of signet-ring cell carcinoma than in those with adenocarcinoma-subtypes (p=0.019). Patients with a high tumor SUVmax/liver SUVmean ratio(>2.6) had a lower survival compared to patients with a low tumor SUVmax/liver SUVmean ratio (p=0.005). ***Conclusion:*** SUVmax/liver SUVmean ratio, which is a measure of the metabolic activity of the primary tumor normalized to the liver in preoperative staging ^{18}F-FDG PET/MR images in operated gastric cancer patients, is an independent risk factor along with histopathology in determining postoperative patient prognosis.

EP-0262

Head-to-Head Comparison of ^{18}F-FDG and ^{18}F-PSMA PET/CT in Hepatocellular Carcinoma

G. Picciola Bordoni, *M. E. S. Takahashi, F. F. Zarpelão, N. A. A Silveira, V. C. C. R Heringer, S. Kuba, N. Tobar, S. Q. Brunetto, C. A. de Souza, J. B. C. Carvalheira, C. Dario Ramos;*
Universidade Estadual de Campinas UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Although ^{18}F-FDG PET/CT is widely used in oncology, its diagnostic performance in hepatocellular carcinoma (HCC) remains suboptimal. Prostate-specific membrane antigen (PSMA), primarily recognized as a biomarker for prostate cancer, has also been linked to tumor neoangiogenesis. Here, we performed a head-to-head comparison of ^{18}F-FDG and ^{18}F-PSMA PET/CT for evaluating hepatic lesions in patients with HCC. ***Materials and Methods:*** Eleven patients with confirmed HCC (six with BCLC stage C and five with stage B) were included (median age: 74 years; range: 59-86). Each patient underwent both ^{18}F-FDG (60 and 120 minutes post-injection) and ^{18}F-PSMA (60 and 120 minutes post-injection) PET/CT images, within a one-day interval. Maximum standardized uptake values (SUVmax) were measured for each hepatic lesion, and changes between early and delayed images (ΔSUVmax) were calculated. Correlation between SUVmax values was assessed using Spearman's rank correlation coefficient, with significance set at $p < 0.05$. ***Results:*** Nine of the 11 patients had multiple hepatic lesions. A median of 3 lesions per patient (1-15) was detected with ^{18}F-FDG, and 2 lesions per patient (1-11) with ^{18}F-PSMA, totaling 75 lesions. Fifty-six lesions were positive for both radiotracers, 16 were only for ^{18}F-FDG, and 3 only for ^{18}F-PSMA. In the BCLC-B group (n = 5), 11 lesions were detected with ^{18}F-FDG, 15 with ^{18}F-PSMA, and 32 with both. The median SUVmax (early images) was 6.3 (3.5-8.5) for ^{18}F-FDG and 17.2 (15.0-25.6) for ^{18}F-PSMA. In the BCLC-C group (n = 6), 34 lesions were detected with ^{18}F-FDG, 14 with ^{18}F-PSMA, and 24 with both. The median SUVmax (early images) was 8.1 (4.7-17.2) for ^{18}F-FDG and 23.3 (17.1-50.2) for ^{18}F-PSMA. For BCLC-B patients, the median ΔSUVmax was 17.65% (-6.35% to 28.57%) for ^{18}F-FDG and -30.17% (-9.74% to -50.67%) for ^{18}F-PSMA. For BCLC-C patients, the median ΔSUVmax was 0.00% (-66.67% to 10.47%) for ^{18}F-FDG and -0.47% (-67.26% to 16.37%) for ^{18}F-PSMA. Spearman's correlation between ^{18}F-FDG and ^{18}F-PSMA SUVmax was $\rho = -0.5357$ ($p = 0.2357$). ***Conclusion:*** ^{18}F-FDG and ^{18}F-PSMA PET/CT offer complementary insights in BCLC-B/C HCC. ^{18}F-FDG demonstrated superior lesion detection sensitivity (especially in advanced disease), while ^{18}F-PSMA showed higher tracer uptake. The lack of correlation between tracers suggests distinct biological targets, with PSMA potentially reflecting neoangiogenesis. The observed ^{18}F-PSMA washout may influence its theranostic utility. Further studies should explore whether high ^{18}F-PSMA uptake predicts antiangiogenic therapy response.

EP-0263

Dual-energy CT imaging for the evaluation of tumour response to Phosphorus-32 microparticles injection: preliminary results.

V. Landoni, *L. Chiacchiararelli, M. Pressello, G. Regine, A. Sbrozzi Vanni, C. Garufi, G. Ventroni;*
San Camillo Forlanini Hospital, Rome, ITALY.

Aim/Introduction: The purpose of this study is to report the preliminary results of the analysis based on dual energy-CT images of the first of a group of patients treated for advanced pancreatic cancer with intra-tumoural injection of 32P (Phosphorus-32) microparticles at a single institution. ***Materials and Methods:*** Between May 2023 and March 2025, seven patients were treated at our institution. The activity of ^{32}P to be injected to deliver 100Gy to the tumour was calculated based on the ^{32}P suspension concentration and the tumour volume, the latter evaluated by the pre-treatment computed tomography acquisition. After implantation patients underwent single photon computed tomography (SPECT) imaging within 4 hours to confirm intra-tumoural particles distribution. Dual-energy CT scans were acquired before treatment and approximately 10 weeks afterwards. Images were acquired at 140 KV, W150 100µgr/cc, L50 100µgr/cc, 200 mA. Iodine maps and Hounsfield units (HU) spectra were reconstructed with a dedicated software. ***Results:*** The analysis performed on the images of the patient showed that

the ratio between the iodine uptake of the ROIs inside the tumour region and the reference ROI delineated by an expert radiologist changed of about 67% from the pre-treatment to the post-treatment reconstructed iodine maps images. The HU spectra also were modified. ***Conclusion:*** Changes in iodine concentration might reflect the changes in the vascularization; for this reason, these very preliminary results encourage to explore the role of dual-energy CT imaging to quantitively characterize the tumour and the response to the treatment. Ongoing recruitment will allow validation in a larger cohort of patients. ***References:*** http://dx.doi.org/10.1016/j.crad.2015.06.083 http://doi.org/10.3390/cancers16193412.

EP-0264

Gastric Emptying Scintigraphy Using a High-Caloric Liquid Meal - Single Center Experience

I. Sisko Markos[1,2], *I. Blazekovic*[1,2], *M. Romic*[1,2], *M. Bosak Butkovic*[1,2], *D. Filipan*[1], *T. Jukic*[1];
[1]*UHC Sestre Milosrdnice, Zagreb, Zagreb, CROATIA,* [2]*Croatian Catholic University, School of Medicine, Zagreb, CROATIA.*

Aim/Introduction: Gastroparesis, or delayed gastric emptying, is a pathological condition that is caused by diabetes, infections, autoimmune, neuromuscular disorders, postsurgical complications or dyspepsia, but it may be idiopathic. Gastric emptying scintigraphy (GES) is a nuclear medicine method measuring gastric emptying time. Liquid or solid meal can be used. Due to the need to demonstrate delayed gastric emptying but limited „hot lab" conditions for preparing the standard meal, we used a commercially available High-Caloric Liquid Meal (HCL) as an alternative solution. In the absence of our own reference values, we relied on the range of values reported in the study by Solnes et al. and the aim is to present our results in relation to the values of Solnes group. ***Materials and Methods:*** Patients underwent GES using a HCL meal (Ensure Plus®) marked with 74 MBq of Tc99m-DTPA during five time points (0 h, 1 h, 2 h, 3 h, and 4 h). To quantify the results, regions of interest are delineated on anterior and posterior images of the entire stomach. Due to the duration of the study decay correction was performed. Because of the different body habitus, attenuation correction is performed using a geometric mean calculation. ***Results:*** We performed GES to 34 patients with suspected gastroparesis. Their gastric retention was measured at four time points and compared with reference values reported by Solnes et al. The ranges of gastric retention for the first, second, third and fourth hour for Solnes group were 45-90, 12-94, 5-30, and 5-16 respectively. The 95% CI of the mean for these hours was found to be 65.1-74.6 (SD 10.5), 26.4-43.6 (SD 18.8), 10.8-16.2 (SD 5.9) and 7.6-10.2 (SD 2.8). The detected mean gastric retention in our population was 58.12%, 24.81%, 11.01%, 7.09%, the ranges 4.1-100, 0.6-60, 0.3-30, 0.11-26. The 95% CI of the mean range was 51.14—65.11 (20.78), 18.99-30.62 (17.30), 7.32-14.70 (10.98), 4.17-10 (8.68). In comparison to suggested normal upper limits, we detected 32.4% abnormal studies of all performed tests. ***Conclusion:*** Although we did not have our own database of normal gastric emptying values for the HCL meal at four time points, we believe that we have established a good diagnostic procedure by following the criteria set by a group of authors who compared their results with standard meal results. ***References:*** 1. Solnes LB, Sheikhbahaei S, Ziessman HA. EnsurePlus as an Alternative to the Standardized Egg Gastric-Emptying Meal. Clin Nucl Med. 2019 Jun;44(6):459-461.

EP-0265

Predictive Value of 99mTc-Mebrofenin Hepatobiliary Scintigraphy in Evaluating Liver Function and Volumetry Pre- and Post-Radioembolization in Hepatocellular Carcinoma (HCC) Patients

S. Shamim*, M. Meena, G. Arora, P. Gb, P. Gupta, N. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Background: Hepatocellular carcinoma (HCC) often presents in patients with compromised liver function, necessitating precise evaluation of hepatic reserve prior to interventions like trans-arterial radioembolization (TARE). 99mTc-Mebrofenin hepatobiliary scintigraphy (HBS) offers quantitative assessment of both global and regional liver function, potentially enhancing treatment planning and prognostication. Aim: To assess the utility of 99mTc-Mebrofenin HBS in evaluating functional and volumetric liver changes before and after TARE in HCC patients. ***Materials and Methods:*** Methods: A prospective study was conducted involving HCC patients undergoing TARE. HBS was performed using dynamic planar imaging and SPECT/CT. Parameters measured included mebrofenin uptake rate (MUR), normalized MUR (MUR), functional remnant liver (FRL) and liver volumes. Comparisons were made between pre- and post-TARE values to assess hepatic functional and structural changes. ***Results:*** ***Results:*** Post-TARE assessments revealed heterogeneous hepatic responses. Some patients exhibited increased FRI. clearance (e.g., from 8.89 to 9.73%/min/m^2) and corresponding volumetric gains (e.g., FRL volume increase from 929.15 to 1343.10 cm^3), indicative of functional regeneration and compensatory hypertrophy. Others showed improved hepatic function (e.g., FRL clearance rising from 5.39 to 6.36%/min/m^2) despite stable liver volumes, suggesting favorable physiological adaptation. Conversely, certain cases demonstrated declines in both FRL clearance (e.g., from 8.2 to 6.8%/min/m^2) and FRL volume (e.g., from 533.06 to 238.20 cm^3), potentially reflecting disease progression or treatment-related parenchymal loss. Notably, some patients experienced functional deterioration without significant volumetric changes, underscoring the added value of functional imaging. Routine liver function tests did not consistently correlate with these imaging findings. ***Conclusion: Conclusion:*** 99mTc-Mebrofenin HBS is a valuable tool for evaluating hepatic function and reserve in HCC patients undergoing TARE, It provides critical insights into regional liver function that may not be apparent through conventional imaging or biochemical tests alone. Incorporating HBS into standard pre- and post-TARE assessment protocols could enhance patient selection, treatment planning, and post-therapeutic monitoring.

EP-0266

Diagnostic Performance of [68Ga]-FAPi-46 PET/CT in Suspected Recurrence in Signet Ring Cell Colorectal Cancers (SRCC)

S. Mahambre[1,2], *I. Dev*[1,2], *A. Agrawal*[1,2], *N. Purandare*[1,2], *S. Shah*[1,2], *A. Puranik*[1,2], *S. Choudhury*[1,2], *S. Ghosh*[1,2], *M. Venkatachalam*[1,2], *V. Rangarajan*[1,2];
[1]*Tata Memorial Hospital, Mumbai, INDIA,* [2]*Homi Bhabha National University, Mumbai, INDIA.*

Aim/Introduction: In malignancies like signet ring cell tumors, [18F]-FDG-PET/CT fails to identify true disease burden. These tumors are composed of large stroma with cancer associated fibroblast(CAFs) expressing Fibroblast activation protein(FAP) which modulate the tumor microenvironment. FAP-targeted imaging has exponentially increased last few years, and is considered to be a more effective method of tumor detection. Hence, we have explored the utility of [68Ga]-FAPi-46-PET/CT in a rare histology such as SRCC. ***Materials and Methods:*** In this retrospective study, 34 SRCC patients with suspected recurrence were included. They were referred for [68Ga]-FAPi-46-PET/CT for the detection of metastases and assessment of disease burden either based on rising S.CEA or clinical suspicion of recurrence. Semiquantitative parameters such as SUVmax of primary site and metastases were calculated. Uptake more than liver was considered positive PET/CT finding. Final decision was based on histopathological confirmation or clinicoradiological follow up and Multidisciplinary tumor board decision(MDT).In a subset analysis of 18 patients, FAPi-PET/CT findings were compared with [18F]-FDG-PET/CT. Sensitivity, specificity,PPV,NPV and accuracy

of FAPi-PET/CT calculated using the IBM-SPSS-26.0 statistical software; p-values<0.05 were considered statistically significant. ***Results:*** Data of 34 SRCC patients (23 male and 11 female) with a median age of 48years(21-77years) was analyzed. 29/34 patients had positive FAPi findings while in 5 patients, no local recurrence/ metastases were seen. In 11/29 patients, local recurrence was detected on FAPi-PET/CT. 3 were confirmed on histopathology & 8 with MDT. Metastatic disease was detected in 18 patients, out of which, 5 were confirmed on histopathology and 13 were deemed metastatic based on MDT decision & follow-up imaging. Liver, nodes and peritoneum were the most common metastatic sites. In 18 patients, for whom both FDG & FAPi-PET/CT data was available, FAPi-PET/CT detected peritoneal disease in 6 patients eventually confirmed on diagnostic laparotomy/peritoneal fluid cytology. Additional lesions were detected in 5 patients and concordant scan findings in 7 patients; hence an incremental value was in 61%cases.Overall Sensitivity, Specificity, PPV,NPV, and Accuracy of [68Ga]-FAPi-46-PET/CT for detection of local recurrence 72%,87%,72%,87%and 82% respectively with AUC 0.742(95%CI: 0.477-1.000;p=0.108) vs FDG-PET/CT (67%,75%,57%,81%and 72%). For metastatic sites, it was 94%,88%,89%,93%and 91% with AUC 0.938(95%CI: 0.798-1.000;p=0.002) vs 60%,88%,86%,64%and 72% in FDG-PET/CT. ***Conclusion:*** [68Ga]-FAPi-46-PET/CT shows excellent sensitivity, specificity,PPV & NPV in detecting local recurrence and metastatic disease in SRCC patients and has a promising role as a non-invasive imaging modality for the detection of peritoneal involvement which can help in triaging patients who would not benefit from futile laparotomies.

EP-0267

A single center prospective study to evaluate clinical utility of Gallium 68- FAPI in poorly cohesive carcinoma of stomach

M. Gupta[1], *S. Singh*[2], *S. Goel*[2], *S. Goyal*[3], *V. Talwar*[3], *V. Goyal*[3], *S. Swamy M S*[3], *G. Gupta*[4], *A. Pathak*[1], *P. Sarathi Choudhury*[1];
[1]*Department of Nuclear Medicine, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [2]*Department of GI Oncosurgery, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [3]*Department of Medical Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [4]*Department of Pathology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA.*

Aim/Introduction: Poorly cohesive carcinoma (PCCs) or signet ring cell carcinoma, accounts for <10% of stomach cancer. It commonly presents with nonspecific symptoms and diffuse stomach wall thickening. FDG PET/CT normally shows a low grade or no tracer uptake and hence ineffective in its work up. Cancer-associated fibroblasts (CAFs) have been strongly reported in many epithelial tumors microenvironment. Hence, CAFs associated fibroblast activation protein (FAP) has become a major target for imaging and therapy of these tumors. Here, we present the first analysis of our prospective study on clinical utility of 68Ga-FAPI PET/CT in PCCs. ***Materials and Methods:*** We included 25 histologically proven stomach PCCs patients referred for staging (15) or recurrence (10) work up. Both FAPI and FDG PET-CT scan were done with-in a week time. Diagnostic laparoscopy for peritoneal disease or any other site biopsy for metastasis or recurrence was used as a gold standard. Additionally, the single voxel maximum standard uptake value (SUVmax) of the primary, lymph node, metastasis, and the right lobe of the liver were recorded. SUVmax and target-to-background ratio (TBR) were compared with Wilcoxon's signed-rank test. While clinical effectiveness was compared with McNemar's test. The study is ethically approved by institutional review board (RGCIRC/IRB-BHR/27/2025). ***Results:*** Out of 15 patients for staging, FDG showed peritoneal metastasis in 5/9 patients with diagnostic sensitivity, specificity, PPV, NPV and accuracy of 55.5%, 100%, 100%, 60%, and 73.3%. While, FAPI detected all 9/9 peritoneal metastases with 100% diagnostic accuracy. Mean± SD TBR of primary (1.6±0.6 Vs 7.3±4.8) and node (0.7±0.4 Vs 3.4±3.1) for FDG Vs FAPI showed significant difference (P value <0.05). For suspected recurrence cases, FDG was true positive in 6/10 while FAPI was true positive in 8/10 cases. One case was false positive in both FAPI and FDG. Mean± SD TBR of the recurrent site (1.5±0.8 Vs 7.5±4.2) for FDG Vs FAPI showed a significant difference (P value <0.05). ***Conclusion:*** FAPI PET-CT has significantly better diagnostic utility for metastatic workup and recurrence evaluation in PCCs stomach. Its superiority is shifting paradigm in tailoring the diagnostic laparoscopy and guiding biopsy sites for better yield.

EP-0268

18F-PSMA-1007 PET/CT in Hepatocellular Carcinoma (HCC): Determining the Ideal Acquisition Window

C. Vallone[1,2], *P. Rossi*[3], *P. Guglielmo*[2,4], *J. Jandric*[3], *M. Rodari*[3], *K. Marzo*[3], *M. Marenco*[3], *M. Olivieri*[5], *L. Evangelista*[2,3];
[1]*Department of Advanced Biomedical Sciences, University of Napoli, Napoli, ITALY,* [2]*Department of Bioscience, Humanitas University, Pieve Emanuele (MI), ITALY,* [3]*Nuclear Medicine Unit, IRCCS Humanitas Cancer Center, Rozzano (MI), ITALY,* [4]*Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY,* [5]*Physic Unit, IRCCS Humanitas Cancer Center, Italy, Rozzano (MI), ITALY.*

Aim/Introduction: Radiolabeled PSMA has shown high uptake in patients with HCC. This study aimed to evaluate the impact of varying intervals between 18F-PSMA-1007 administration and PET/CT image acquisition on scan parameters in patients with HCC, with the goal of identifying the optimal timing for the examination. ***Materials and Methods:*** We conducted a retrospective, observational, single-center study involving patients diagnosed with HCC who underwent 18F-PSMA-1007 PET/CT imaging between August 2022 and March 2025. The study population was divided into three groups based on the time elapsed between radiotracer injection and image acquisition: Group A (50-70 minutes), Group B (70-90 minutes), and Group C (more than 90 minutes). All scans were evaluated both visually and semiquantitatively. Measurements included the SUVmax of the lesion and healthy liver parenchyma (background), the SUVmean of healthy liver tissue, and tumor-to-background ratios calculated using both SUVmax (TBRmax/max) and SUVmean (TBRmax/mean) values for the background. The Kruskal-Wallis test was employed to assess differences in data distribution across the three groups. ***Results:*** Sixty-three patients were included in the study (median age: 76 years; range: 43-93). PET scans were performed in 10 patients (16%) after 50-70 minutes, in 31 patients (49%) after 70-90 minutes, and in 22 patients (35%) after more than 90 minutes. Semiquantitative analysis showed that the median SUVmax of the lesion was significantly higher in Group A compared to Groups B and C (28.6 vs 20.7 and 23.5, respectively; p <0.05). In contrast, the median SUVmax and SUVmean of healthy liver parenchyma were lower in Group A compared to Groups B and C (9.8 vs. 12.1 and 13.1; 7.7 vs. 8.3 and 9.3, respectively), although the differences did not reach statistical significance (p = 0.149 and 0.338). Median tumor-to-background ratios (TBRmax/max and TBRmax/mean) were higher in Group A than in the other groups (2.5 vs. 1.6 and 1.9; 3.3 vs. 2.3 and 2.6, respectively), with values approaching statistical significance (p=0.073 and 0.185). ***Conclusion:*** The best acquisition time for 18F-PSMA-1007 PET/CT in HCC patients is between 50 and 70 minutes from the injection, because it is linked to a best signal-to noise ratio. ***References:*** DOI: 10.3390/cancers16223865.

EP-0269

Assessing the Value of Short-Duration Dynamic [^{18}F]FDG PET on LAFOV Scanners in Hepatocellular Carcinoma

S. Capitanio[1], *A. Lazar*[2], *A. Franchini*[1], *A. Spataro*[1], *G. Muti*[3], *L. Airo' Farulla*[1], *A. Scarale*[1], *G. Cabrini*[1], *E. Gay*[1], *C. Pettinato*[4], *A. Chiti*[5], *C. Rossetti*[1];
[1]*Nuclear Medicine Unit, Dipartimento Ematologia, Oncologia e Medicina Molecolare, ASST Niguarda Hospital, Milan, ITALY,* [2]*Vita-Salute San Raffaele University, Milan, ITALY,* [3]*Department of Physics, ASST Niguarda Hospital, Milan, ITALY,* [4]*Medical Physics Unit, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milan, ITALY,* [5]*Vita-Salute San Raffaele University, Nuclear Medicine Unit, IRCCS San Raffaele Hospital, Milan, ITALY.*

Aim/Introduction: Dynamic PET imaging offers physiological insights beyond delayed static measures, but its clinical use has been limited by the prolonged acquisition protocols. Long axial field-of-view (LAFOV) PET scanners, with their increased sensitivity and advantage of deriving image-derived input function (IDIF) from large vessels, present and opportunity to shorten scan times without compromising data quality. We aimed to assess the feasibility of a 20-minute dynamic [^{18}F]FDG PET protocol for Patlak analysis in hepatocellular carcinoma (HCC) and evaluate the correlation between kinetic parameters and standard SUV metrics**.** ***Materials and Methods:*** Patients with HCC underwent dynamic [^{18}F]FDG PET/CT on a 148 cm AFOV scanner, with acquisition initiated at the time of injection and lasting 20 minutes. Data was reconstructed using a 21-frame protocol (6x10s,2x30s, 6x60s, 7x120s). A delayed static scan at 60 min post-injection completed the examination. IDIFs was extracted from the descending thoracic aorta and normalised to a population-based input function. Volumes of interest were manually delineated. Patlak analysis and irreversible-two compartment modelling (2T3k) were performed using vendor-provided software to extract dynamic parameters both for HCC lesions and normal liver tissue. Static SUV_{max} and SUV_{mean} values were also recorded. SUV-Tumour-to-liver ratios (SUV-TLR) and Patlak Ki-tumour-to-normal liver (Ki-TLR) ratios were computed. Descriptive statistics were used based on data distribution and Spearman's test was used to assess correlations. ***Results:*** Seven patients counting 17 liver lesions were segmented and processed. In Patlak analysis, median values for tumour Ki and intercept were 0.0159 [IQR: 0.0058 - 0.0189], and 0.767[IQR: 0.535 - 0.853], respectively, with a median Ki-TLR was 1.76 [IQR: 1.10-2.82]. The 2T3k model revealed mean tumour K1, k2 and k3 of 0.462319±0.23537, 0.6155±0.2062 and, respectively, 0.02279±0.0162749. On static images, median tumour SUV_{max} was 4.15 [IQR: 3.52-5.17], with median SUV-TLR of 1.53 [IQR: 1.31- 1.68]. Significant correlations were observed between tumour SUV_{max} and Ki (ρ=0.771, p<0.001) , SUV_{max} and k3 (ρ=0.754, p<0.001), and SUV-TLR and Ki-TLR (ρ=0.840, p=0.001). No significant correlation was found between tumour SUV_{max} and intercept (ρ=-0.401, p=0.111), or between any kinetic parameter and blood glucose levels at the time of the scan. ***Conclusion:*** A 20-minute dynamic [^{18}F]FDG PET acquisition on LAFOV scanners is clinically feasible in HCC, revealing kinetic parameters that correlate strongly with conventional static metabolic metrics. These findings support the integration of short dynamic protocols into clinical practice, offering enhanced quantitative insights without prolonged scan times and improving lesion characterization in liver oncology.

EP-0270

Kinetic Modeling of PSMA Uptake in Hepatocellular Carcinoma with LAFOV PET/CT: Correlation with Histopathological Features

L. Vetrone[1], *E. Prosperi*[2], *E. Prosperi*[2], *D. Malvi*[3], *A. Degiovanni*[3], *F. Vasuri*[4], *I. Brusa*[1], *S. Emiliani*[1], *D. Dall'Olio*[5], *M. Ravaioli*[2], *M. Cescon*[2], *S. Fanti*[1,6], *A. Farolfi*[1];
[1]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Department of Hepatobiliary Surgery and Liver Transplant, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Pathology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Medical and Surgical Sciences (DIMEC), Bologna University, Bologna, ITALY,* [5]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY,* [6]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY.*

Aim/Introduction: Hepatocellular carcinoma(HCC) is a heterogeneous tumor with varying molecular phenotypes. Preliminary investigations revealed PSMA-overexpression in HCC vessels, but its functional imaging characterization is limited. Long Axial Field of View(LAFOV) PET allows for dynamic acquisitions over extended periods, enabling kinetic modeling of radiotracer behavior. We investigated the correlation between PSMA uptake kinetics, standard semiquantitative parameters and histopathological features of HCC lesions. ***Materials and Methods:*** Eight patients with suspicion of HCC eligible for Liver Transplantation(LT) or Hepatic Resection(LR), naive for systemic therapy were enrolled within a 3-month window before surgery within the MORE-PSMA study. A 60-minute dynamic [68Ga] PSMA PET/CT scan using a LAFOV-scanner (FOV=194cm) was performed, alongside a 3h-delayed whole-body static images. No treatment was allowed between imaging and surgery. One lesion per patient was manually segmented, choosing the largest one with histological confirmation. Kinetic parameters were extracted using a reversible two-tissue compartment model (2TCM) from dynamic data. Semiquantitative parameters (SUVmax, SUVmean, SULpeak,PSMA-TV) and kinetic constants (K1, k2, k3, k4, Ki, DV) were calculated and correlated with histological grade(Edmondson), architecture (trabecular, macrotrabecular, mixed), WHO subtype, margins of growth (infiltrative, expansive), immunohistochemistry(IHC) evaluation (as a percentage of PSMA-expressing vessel cells, intensity of the stain and IRS score). ***Results:*** All lesions(8/8) were better described by a reversible 2TCM-model. Lesions with infiltrative margins showed higher k3 values than expansive lesions (0.52±0.23 vs 0.14±0.20, p=0.05), while SUVs did not discriminate between the two groups(p>0.05). Macrotrabecular lesions showed a trend of generally higher k3, k4 and Ki compared to trabecular ones, although p>0.05. Lesions with strong/moderate IRS had similar SUVs values (p>0.05) but lower k4 compared to negative ones (0.038±0.020 vs 0.088±0.028, p=0.05). A significant correlation was found between k4 and SUVmean(r= -0.81, p=0.015), k4 and PSMA-TV (r=0.79, p=0.021), DV and SUVmax(r=0.79, p=0.021), and DV and SUVmean (r=0.98, p< 0.0005). No significant correlation was found between kinetic parameters and Edmondson grade, WHO-subtypes, and IHC intensity or percentage. At delayed scans both SUVmax and SUVmean decreased in 6/8 lesions and increased in 2/8cases, but no significant correlation with kinetic constants was found. ***Conclusion:*** Dynamic [68Ga]PSMA PET/CT with LAFOV technology allows for detailed kinetic modeling in HCC. Kinetic parameters, particularly k3 and k4, show potential correlations with tumor morphology and PSMA expression intensity and may be more sensitive than SUVs for distinguishing histopathological features of HCC lesions. These preliminary results support further investigation of kinetic PET imaging as a non-invasive biomarker for biological aggressiveness in HCC.

EP-0271

Normal patterns of pancreatic uptake on 68Ga-DOTATATE PETCT

A. Hassan*, A. W. Alessi, E. Wahab, S. J. Hughes;*
Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: 68 Galium-DOTATATE (68Ga-DOTA) peptide seen on positron emission tomography combined with computed tomography (PETCT) has been proven to be one of the most accurate methods of imaging neuroendocrine tumors (NETs).[1] The first stage in the accurate reporting and utilizing 68Ga-DOTA PETCT is a clear understanding of the normal patterns. Pancreatic NETs can present with focal DOTA peptide uptake on imaging. [2] This study aims to identify the normal patterns of pancreatic uptake on 68Ga-DOTA PETCT. ***Materials and Methods:*** This retrospective study of 54 consecutive 68Ga-DOTA PET/CT scans carried out at one academic institution between January 2023 and March 2025 for staging and restaging non-pancreatic NET. We defined the pattern seen in regions of the uncinate process, head, neck, body, and tail of the pancreas. We recorded the pattern seen (focal/diffuse/homogenous/inhomogenous) in these regions and the maximum standarised uptake value (SUVmax). Other normal imaging including contrast-enhanced CT, pancreatic MRI and normal pattern on CT component of the PETCT were used to

define absence of focal pathology. ***Results:*** Overall, 34/54 (63%) scans had focal uptake in the head/uncinate. 1/54 (2%) had uptake in neck. 12/54 (22%) uptake in body. 10/54 (19%) in tail. 18/54 (33%) scans presented with benign multifocal uptake in more than 2 anatomical areas; 11/54 (20%) had two focal regions. 3/54 (6%) had three focal regions. 1/54 (2%) had four focal regions. 1/54 had whole diffuse homogenous pancreas 68Ga-DOTA uptake with normal structural imaging. ***Conclusion:*** Focal uptake in the head and uncinate process of the pancreas had already been described and our study confirms this in 63% of patients.[2] Many of the benign patterns of uptake are diffuse (25%) rather than focal. Our data shows that benign 68Ga-DOTA uptake is not limited to the head and uncinate process and that both focal and diffuse uptake in the body and tail can also be benign. We therefore hypothesize that 68Ga-DOTA PET/CT may not be an accurate imaging modality for assessment of presence or absence of pancreatic NETs without structural imaging. ***References:*** [1] Tirosh A et al. The utility of 68Ga-DOTATATE positron-emission tomography/computed tomography in the diagnosis, management, follow-up and prognosis of neuroendocrine tumors. Cancers. 2022;14(14):3541. doi:10.3390/cancers14143541.

EP-0272

Evaluation of the Effectiveness of 68Ga-Trivehexin (Integrin αvβ6) PET/CT in Staging and Restaging of Pancreatic Adenocarcinoma: Preliminary Findings

A. Ozturk[1], *Ö. F. Şahin*[1], *Z. Tosunoğlu*[1], *T. F. Çermik*[2], *G. Alçın*[1], *E. Akgün*[1], *M. M. Sevinç*[3], *Ç. Usul Afşar*[4], *E. Arslan*[1];
[1]*Istanbul Training and Research Hospital Nuclear Medicine Department, Istanbul, TÜRKIYE,* [2]*Acibadem Maslak Hospital, Nuclear Medicine Department, Istanbul, TÜRKIYE,* [3]*Istanbul Training and Research Hospital General Surgery Department, Istanbul, TÜRKIYE,* [4]*Istanbul Training and Research Hospital Medical Oncology Department, Istanbul, TÜRKIYE.*

Aim/Introduction: αvβ6 integrin expressed in carcinoma cells interacts with LAP, activating TGF-β, which inhibits cell growth in healthy stroma and enables invasion into tumor tissue. Integrin αvβ6 observed in pancreatic cancer, head and neck SCC, non-small cell lung, colon, breast, ovarian cancer. Study aims to investigate the diagnostic, staging, and restaging contributions of 68Ga-Trivehexin PET/CT in pancreatic adenocarcinoma or those with a suspicious malignant mass in the pancreas. ***Materials and Methods:*** In this prospective study, 15 diagnosed with or suspected of having pancreatic cancer were included. 68Ga-Trivehexin PET/CT performed within two weeks of the previous scan. Written informed consent was obtained from all patients. The primary tumor uptake values obtained from 68Ga-Trivehexin PET/CT measured and compared with normal pancreatic background, liver parenchyma, liver metastases, blood pool, and distant organ metastases. Parameters compared with those from ^{18}F-FDG PET/CT imaging. ***Results:*** Mean age of 15 patients 70.73 ± 9.9 years. 12 patients underwent for staging ,3 for restaging. Histopathological revealed 13 patients had pancreatic ductal adenocarcinoma (PDAC), one had pancreatic intraepithelial neoplasia (PanIN), and one initially suspected of having a pancreatic tumor, was found to have a gastrointestinal stromal tumor (GIST) originating from the stomach wall after surgery. Metastases were detected in: 6 liver metastases, 1 bone metastasis, 1 adrenal gland metastasis, 1 muscle metastasis SUVmax varied in liver metastases, 68Ga-Trivehexin showed higher SUVmax values in muscle, bone, and adrenal gland metastases. When evaluating primary tumor uptake: Mean ± SD SUVmax of 68Ga-Trivehexin: 14.2 ± 6.44 (min: 8.15 - max: 29.43) Mean ± SD SUVmax of 18F-FDG: 8.98 ± 4.23 (min: 5.07 - max: 16.06) A statistically significant difference was observed ($p < 0.05$), indicating that 68Ga-Trivehexin showed higher uptake in primary tumors. To assess the ability of both modalities to distinguish primary tumors from healthy tissue, the following ratios were calculated in PDAC patients: SUVmax of primary tumor/healthy pancreatic tissue (PT/PSD SUVmax) SUVmax of primary tumor/blood pool (PT/KH SUVmax) In 11, ^{18}F-FDG was superior in PT/PSD SUVmax ratio In all patients, 68Ga-Trivehexin was superior in PT/KH SUVmax ratio ($p < 0.05$). ***Conclusion:*** On our current findings, 68Ga-Trivehexin appears to have significant potential in PDAC diagnosis, tumor receptor imaging, and detecting tumor heterogenity. It could be a valuable imaging agent for evaluating responses to chemotherapeutic agents targeting angiogenesis. Since integrin αvβ6 is expressed in malignant epithelial tumors, it holds theranostic potential and may serve as a promising future therapeutic target.

EP-0273

Association Between PET/CT-Derived PCI and Survival in Peritoneal Carcinomatosis: A Retrospective Analysis

S. Demirtas Senlik[1], *A. Cinar*[1], *C. Engur Uyanik*[1], *O. Sutcuoglu*[2], *O. Ozmen*[1];
[1]*Ankara Etlik City Hospital, Ankara, TÜRKIYE,* [2]*Gazi University Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: Peritoneal carcinomatosis (PC), often arising from gastrointestinal or gynecological malignancies, is associated with poor prognosis. The Peritoneal Carcinomatosis Index (PCI) is a clinical tool used to quantify disease burden and guide management. While surgical exploration remains the gold standard for PCI assessment, its invasiveness limits routine use. F-18 FDG PET/CT has emerged as a non-invasive alternative. This study aimed to evaluate the relationship between PET/CT-derived PCI scores and overall survival in patients with PC. ***Materials and Methods:*** We retrospectively reviewed patients who underwent FDG PET/CT between December 2022 and January 2025. Of 113 patients with pathologically confirmed PC (excluding primary peritoneal tumors), PCI scores were calculated by scoring FDG-avid lesions across 13 abdominal regions (scale 0-3 per region). Overall survival was analyzed using the Kaplan-Meier method. ***Results:*** The cohort included 70 women (62.5%) and 43 men (37.5%), with a mean age of 61.5 ± 13.5 years. A total of 58 patients (51.3%) were diagnosed with gastrointestinal system cancer, while 46 patients (40.7%) had a gynecological malignancy. The median PCI was found to be 11 (range: 1-36). Median overall survival was 13 months (95% CI: 9.69-16.35) in patients with PCI < 15, compared to 9 months (95% CI: 6.51-11.48) in those with PCI ≥ 15 ($p = 0.020$) (Figure 1). No significant relationship was found between overall survival and the following SUVmax ratios: peritoneum/primary tumor ($p = 0.712$), peritoneum/liver ($p = 0.611$), peritoneum/spleen ($p = 0.476$), and peritoneum/bone marrow ($p = 0.249$). ***Conclusion:*** Although F-18 FDG PET/CT is widely used in the clinical diagnosis of peritoneal carcinomatosis (PC), its role in PCI assessment remains unclear. In our study, survival was found to be significantly lower in patients with high PCI on FDG PET/CT compared to those with low PCI. These findings suggest that FDG PET/CT may have prognostic value in patients with PC and could serve as a supportive tool in treatment planning.

EP-0274

Trans-arterial radioemoembolization for treatment of large hepatocellular carcinoma, a single center experience

A. Alsugair*;*
King Fasial Specilaist Hospital And Research Center, Riyadh, SAUDI ARABIA.

Aim/Introduction: Background: Management of hepatocellular carcinoma (HCC) depends largely on the stage of the tumor, patients' performance status, and comorbidities. Advanced HCC has limited treatment options, particularly in the presence of portal vein thrombosis. Growing evidence supports the use of trans-arterial radioemoembolization (TARE) in the management

of advanced HCC, however, more clinical trials are required to confirm its efficacy. Aim: To report the experience of a tertiary center with TARE for management of large HCC. ***Materials and Methods:*** A retrospective review of all patients who underwent TARE procedures was conducted through interventional radiology database at tertiary care organ transplant center Hospital during the period from January 2008 till July 2024. Patients who had TARE for management of HCC were identified and files were screened for their demographic data, number of procedures performed, response to treatment, and complications. The primary outcome was overall survival while secondary endpoints included response to treatment and successful downstaging with subsequent liver transplantation. ***Results:*** During the study period a total of 725 TARE procedures were performed on 490 patients. The number of patients who had TARE for treatment of HCC was 411 (84%) while 79 patients (16%) had TARE for treatment of metastatic liver tumors. The mean age was 64.2 ± 11.3 and 72% were males. TARE was done once in 275 patients (62.5%), twice in 104 patients (25.3%), thrice in 26 patients (6.3%) and more than three times in 6 patients (1.5%). Over a median follow-up of 13.4 months 126 patients (30.7%) died while 106 (25.85%) are alive, and data on survival was missing in 179 patient (43.6%). The radiological tumor response to treatment in the targeted lesions was complete in 29.2%, partial in 44.5%, stable in 3.2%, and disease progressed in 15.5% while data on radiological response were missing in 7.7%. Liver transplantation was performed on 55 patients (13.4%) after successful downstaging with TARE. ***Conclusion:*** TARE in a high-volume center showed a favorable response in management of large HCC. Downstaging large HCC with TARE can provide higher chance of successful liver transplantation.

EP-0275

Characterizing PDAC and Pancreatitis: Insights from [^{68}Ga]Ga-FAPI-46 Kinetic Modeling

T. Nilsson[1,2], *P. Rasinski*[1,2], *E. Sparrelid*[2,3], *M. Löhr*[2,3], *T. Tran*[1,4], *M. Lubberink*[5], *R. Axelsson*[1,6], *M. Holstensson*[1,2];
[1]Department of Nuclear Medicine and Medical Physics, Karolinska University Hospital, Stockholm, SWEDEN, [2]Department of Clinical Science, Intervention and Technology (CLINTEC), Karolinska Institutet, Stockholm, SWEDEN, [3]Department of Upper Gastrointestinal Diseases, Karolinska University Hospital, Stockholm, SWEDEN, [4]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, SWEDEN, [5]Uppsala University, Department of Surgical Sciences Molecular Imaging and medical physics, Uppsala, SWEDEN, [6]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN.

Aim/Introduction: This study aimed to characterize [^{68}Ga]Ga-FAPI-46 kinetics in pancreatic ductal adenocarcinoma (PDAC) lesions and concomitant inflammatory lesions and assess correlations between simplified measurements and model-derived parameters. ***Materials and Methods:*** Kinetic modeling was performed on images from an ongoing prospective [^{68}Ga]Ga-FAPI-46 PET/CT imaging clinical trial (EU2024-514967-25-00; NCT05172310). The dataset included 11 patients scheduled for surgery due to suspected pancreatic cancer. All patients had histopathologically confirmed PDAC and concomitant inflammatory lesions. Each patient was administered [^{68}Ga]Ga-FAPI-46 (204 ± 53 MBq) and underwent a 45-min dynamic PET scan centered over the suspected lesion, following a CT for attenuation correction. Three compartment models were evaluated: a 1-tissue-compartment model (1T2k), and both reversible (2T4k) and irreversible (2T3k) 2-tissue-compartment models, all including an additional fit parameter for blood volume fraction (V_b). Patlak and Logan plots (t* = 15 min) were also evaluated. Model selection was guided by the Akaike Information Criterion (AIC). Image-derived input functions were generated from regions of interest placed in the descending aorta. SUV_{mean} was measured from the 35-45 min frame, and the mean target-to-blood ratio (TBR_{mean}) was calculated. Spearman correlation coefficients (r_s) were used to assess relationships between SUV_{mean}, TBR_{mean}, and the volume of distribution (V_T). Differences in kinetic parameters between lesion types were evaluated. ***Results:*** The 2T4k model was preferred in 7/11 PDAC lesions and 9/12 inflammatory lesions. In lesions where the 2T3k model was preferred, AIC were similar between 2T3k and 2T4k. The similar AIC and plateauing time-activity curves suggest a 45-minute acquisition may be too short to distinguish binding reversibility for these lesions. TBR_{mean} and SUV_{mean} showed very strong correlations to V_T from both reversible models and Logan plots for inflammatory lesions ($r_s \geq 0.902$). In PDAC, SUV_{mean} showed a moderate correlation to V_T derived from the 2T4k model ($r_s = 0.550$), whereas TBR_{mean} demonstrated a very strong correlation ($r_s = 0.917$, $p < 0.001$). Both measures showed strong correlations to V_T from 1T2k and Logan in PDAC ($r_s \geq 0.864$). No significant differences in K1, k2, V_T, V_{NS}, SUV_{mean} or TBR_{mean} were observed between PDAC and inflammatory lesions. Parameters k3, k4, and V_b were not further evaluated due to high variability. ***Conclusion:*** In both PDAC and inflammatory lesions, simplified measurements such as SUV_{mean} and TBR_{mean} showed a strong correlation to V_T derived from reversible models and Logan plots. However, in some lesions a 45-minute scan may be insufficient to determine binding reversibility.

EP-0276

Usefulness of [^{18}F]FAPI-04 and [^{18}F]FDG PET/CT for the detection of peritoneal carcinomatosis: a comparative study

C. Jiang, *H. Ye, W. Zhou, K. Zheng, Y. Zhang, J. Dai, X. Peng, J. Yang, H. He, X. Hu;*
Department of PET-CT Center, Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, CHINA.

Aim/Introduction: In this study, we aimed to compared the performance of [^{18}F]FAPI-04 and [^{18}F]FDG PET/CT in the evaluation of peritoneal carcinomatosis. ***Materials and Methods:*** Seventy-one patients with suspected peritoneal malignancies were enrolled in our study. All the participants underwent both [^{18}F]FAPI-04 and [^{18}F]FDG PET/CT imaging within 7 days. The detection rates, diagnostic accuracies, semiquantitative parameters of the traces, peritoneal cancer index (PCI) scores, and tumor markers were evaluated and compared. ***Results:*** Among the 71 patients, 40 patients were diagnosed with peritoneal carcinomatosis, and 31 were true-negative patients. The sensitivity and accuracy of [^{18}F]FAPI-04 PET/CT were higher than those of [^{18}F]FDG PET/CT (sensitivity: 92.50% vs. 72.50%, p = 0.003; accuracy: 91.55% vs. 80.28%, p < 0.001), particularly in patients with gastric cancer. The SUVmax, tumor-to-liver background ratio (TBR-L), tumor-to-descending aorta ratio (TBR-A), and PCI score were significantly higher for [^{18}F]FAPI-04 PET/CT than [^{18}F]FDG PET/CT (all p < 0.05). In the [^{18}F]FAPI-04 PET/CT group, the PCI score, TBR-L, TBR-A, TBR-M and SUVmax were higher in the high level group than the low level group (all p < 0.05). The carbohydrate antigen 125 (CA 125) levels were strongly correlated with the PCI of both [^{18}F]FAPI-04 and [^{18}F]FDG PET/CT. ***Conclusion:*** [^{18}F]FAPI-04 PET/CT outperformed [^{18}F]FDG PET/CT in the evaluation of peritoneal carcinomatosis, particularly in patients with gastric cancer. Furthermore, [^{18}F]FAPI-04 PET/CT may be used for the assessment of peritoneal carcinomatosis in patients, especially FAPI-PCI. ***References:*** 1. EP-0277

Comparison of 68Ga-FAPI PET and ^{18}F-FDG PET Findings in the Pre-Treatment Evaluation of Transarterial Radioembolization (TARE)

K. Saglam, *O. Sahin, M. Bodur, A. Kibar, L. Kabasakal;*
Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE.

Aim/Introduction: Fibroblast Activation Protein (FAP) is an enzyme expressed by cancer-associated fibroblasts (CAFs) found in the tumor microenvironment. FAPI-04 is among the radiopharmaceutical agents targeting FAP and shows high uptake in tumors with intense fibroblast activation. 68Ga-FAPI PET has emerged as valuable alternative or complementary imaging method to traditional ^{18}F-FDG PET due to low background involvement, especially in tissues such as brain, heart and liver. This study aims to compare ^{18}F-FDG PET and 68Ga-FAPI PET imaging in patients with primary or metastatic liver tumors before TARE therapy. ***Materials and Methods:*** A total of 16 patients who were candidate for TARE treatment were included in the study. ^{18}F-FDG PET and 68Ga-FAPI PET imaging were performed and the maximum interval between these two imaging modalities was limited to 3 months (mean 47.56 days). SUVmax and SUVmean values were recorded on a lesion basis and were proportioned with the background SUVmean values from the liver. For patients with more than 10 lesions in the liver, the 3 largest lesions were included in the quantitative analysis. 3 patients included in the study were diagnosed with hepatocellular carcinoma and the remaining 13 patients were included in the group of metastatic liver tumors. ***Results:*** 150 lesions were detected with 68Ga-FAPI PET imaging and 91 lesions were detected with 18F-FDG-PET imaging. All of the lesion detected with ^{18}F-FDG PET were detected with 68Ga-FAPI PET. Additional liver lesions were observed in 12 of 16 patients with 68Ga-FAPI PET. For the 40 matched lesions analyzed,TBRmax (Lesion SUVmax/Liver SUVmax) and TBRmean (Lesion SUVmean/Liver SUVmean) were 20.6 and 12.3 for 68Ga-FAPI-PET, and 4.08 and 2.33 for 18F-FDG-PET. In addition, in all of these 40 lesions, the rates were higher in favor of 68Ga-FAPI PET. In the volumetric analysis performed for the hepatocellular cancer subgroup, tumor volumes were measured 1.97 times higher with 68Ga-FAPI PET. ***Conclusion:*** 68Ga-FAPI-PET detected a higher number of lesions than ^{18}F-FDG PET and showed superiority in terms of tumor-background ratios of the detected lesions. Before the TARE procedure or similar local interventional procedures for liver tumors, it is necessary to correctly identify the lesions in the liver. For this purpose treatment planning with 68Ga-FAPI PET can be considered as an important alternative in terms of the accuracy of volumetric and dosimetric studies.

EP-0278

Clinical evaluation of a unified data-driven respiratory motion correction technique in ^{18}F-FDG PET/CT imaging of upper abdominal lesions: a real-world study

T. Han[1], *Y. Wang*[2], *Z. Quan*[1], *J. Wang*[1], *F. Kang*[1];
[1]*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA,* [2]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: Respiratory motion (RM)-related artifacts significantly impact image quality and diagnostic accuracy in PET/CT imaging. This study aimed to prospectively evaluate the clinical utility of the unified data-driven respiratory motion correction (uRMC) algorithm utilizing deep learning neural networks for diagnosing upper abdominal lesions. ***Materials and Methods:*** A total of 100 patients with suspected upper abdominal lesions who underwent ^{18}F-FDG PET/CT were enrolled. Two senior physicians independently conducted subjective visual assessments and semi-quantitative analyses of the PET/CT images before and after correction. Subjective visual evaluation parameters included overall image quality, PET-CT misalignment, and lesion distortion. Semi-quantitative metrics recorded for each lesion included maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), tumor-to-background ratio (TBR), and horizontal-to-vertical ratio (HV_ratio) before and after correction. Percentage changes in lesion SUVmax and MTV were calculated, and subgroup analyses were performed to assess the impact of lesion uptake, volume, and displacement on the performance of the uRMC algorithm. ***Results:*** Compared to no motion correction (NMC) images, 78% (78/100) of patients demonstrated improved overall image quality after uRMC reconstruction, with 68.9% (155/225) of lesion showing improved PET-CT alignment and 64.0% (144/225) demonstrating reduced lesion distortion (all p<0.001). The RM-corrected images exhibited a significantly higher SUVmax (9.07 [6.45, 11.79] vs.7.46 [5.69, 10.00], p< 0.001) and TBR (3.65 [2.54, 4.98] vs. 3.17 [2.40, 4.38], p< 0.001). The number of detected lesions increased from 171(NMC) to 181(uRMC) in 62 patients, with 10 additional suspicious lesions identified in 14.5% (9/62) of cases. Moreover, 7 lesions in 9.7% (6/62) of patients exhibited improved PET-CT alignment after uRMC correction. The uRMC algorithm also significantly reduced lesion MTV (1359.6 [690.8, 3837.6] mm3 vs.1710.5 [899.1, 4013.0] mm3, p<0.01) and HV_ratio (0.99 [0.82, 1.09] vs. 1.16 [1.02, 1.44], p<0.01). Subgroup-based analyses revealed that uRMC outperformed NMC in detecting low-uptake and small-volume lesions, with SUVmax improvements being more pronounced in lesions with larger displacement (17.76% vs. 9.76%, p<0.001). ***Conclusion:*** Compared with conventional NMC reconstruction, the uRMC algorithm significantly enhances overall image quality, PET-CT alignment, and lesion delineation. Furthermore, it improves the detection of low-uptake and small-volume lesions in the upper abdomen, thereby increasing the accuracy and reliability of clinical diagnoses and supporting more informed therapeutic decision-making.

EP-0279

The value of ^{18}F-FDG PET/MR radiomic features in predicting CTNNB1 mutations in pediatric hepatoblastoma

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: This study aims to evaluate the predictive utility of ^{18}F-FDG PET/MR radiomics features for identifying CTNNB1 mutations in pediatric hepatoblastoma (HB), a key molecular alteration associated with tumor aggressiveness and therapeutic response. ***Materials and Methods:*** A retrospective analysis was conducted on 112 pediatric HB patients (median age 1.8 years, range 0.4-10.2 years). Clinical variables, including tumor stage, serum alpha-fetoprotein (AFP) levels, and histological subtype, were integrated into a clinical model (C_model). ere extracted from pre-treatment PET/MR images using the Computational Environment for Radiological Research. The Least Absolute Shrinkage and Selection Operator (LASSO) regression was employed to select optimal radiomic features and construct a radiomics model (R_model). The predictive performance of C_model, R_model, and their combination (CR_model) was assessed via receiver operating characteristic (ROC) analysis. A nomogram incorporating radiomics scores (rad-score) and clinical predictors was developed. ***Results:*** Patients were divided into a training cohort (n=78) and a validation cohort (n=34). LASSO identified 8

significant radiomic features for CTNNB1 mutation prediction. The R_model achieved AUCs of 0.89 (training) and 0.87 (validation), while the C_model showed AUCs of 0.76 and 0.71, respectively. The combined CR_model demonstrated superior performance, with AUCs of 0.95 (training) and 0.91 (validation), significantly outperforming standalone models ($P < 0.01$). ***Conclusion:*** Pre-therapeutic ^{18}F-FDG PET/MR radiomics features robustly predict CTNNB1 mutations in pediatric HB, offering a non-invasive tool to guide molecular subtyping, risk assessment, and personalized therapeutic strategies. This approach may complement traditional genetic testing and improve clinical decision-making.

EP-0280

Machine lerning-driven characterization of lymph node metastasis and 10-year overall survival in extrahepatic cholangiocarcinoma using ^{18}F-FDG PET/CT

J. Ning[1,2], *C. Li*[1], *H. Yang*[1], *X. Luan*[1], *R. Xue*[1], *Y. Wang*[3], *J. Tian*[1], *M. Hacker*[4], *L. Kenner*[2], *B. Xu*[1];
[1]*Department of Nuclear Medicine, First Medical Center of Chinese PLA General Hospital, Beijing, CHINA,* [2]*Christian Doppler Lab for Applied Metabolomics, Vienna, AUSTRIA,* [3]*GE Healthcare China, Shanghai, CHINA,* [4]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-Guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Extrahepatic cholangiocarcinoma (eCCA), the second most common primary liver cancer, is often diagnosed at an advanced stage, resulting in high recurrence and poor survival. Although early-stage surgical resection offers a five-year survival rate of 43%, about 65% of patients present with unresectable disease, reducing survival to just 7%. Lymph node metastasis (LNM) is a key prognostic factor, making accurate preoperative prediction crucial. This study aimed to develop and validate imaging-driven ML models to enhance LNM prediction in eCCA patients. ***Materials and Methods:*** This retrospective study analyzed 236 patients with histologically confirmed eCCA who underwent ^{18}F-FDG PET/CT imaging between June 2012 and November 2018. Clinical data, including age, gender, CA199, CEA, IgG subtypes, tumor staging, and surgery type, were collected. Imaging parameters such as PET positivity, SUVmax, SUV ratio (SUVr), and tumor size were extracted by experienced nuclear medicine physicians. Radiomic features, totaling 1082, were computed from manually delineated PET and CT volumes of interest (VOIs) using PyRadiomics. Feature selection employed variance and correlation filtering followed by multivariate logistic regression, yielding optimal subsets for model development. Logistic regression-based ML models were built for PET-based, CT-based, PET/CT-based, and combined clinic_PET/CT-based radiomics approaches. Model performance was assessed using receiver operating characteristic (ROC) curves, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the curve (AUC). Prognostic value was evaluated via Kaplan-Meier survival analysis. ***Results:*** Of 213 patients included in the final analysis, 70 (32.9%) had LNM. The PET/CT-based radiomics model outperformed PET-only (AUC = 0.73), CT-only (AUC = 0.70), and visual analysis (AUC = 0.54) with an AUC of 0.80. The combined clinicoPET/CT model achieved the highest diagnostic accuracy (AUC = 0.86), significantly better than clinical features alone (AUC = 0.53). Survival analysis revealed that patients predicted to have low LNM risk had a median overall survival (OS) of 52.8 months, compared to 19.3 months in the high-risk group ($p = 0.001$).Fourteen key features were retained in the final combined clinicoPET/CT model. CT-based texture features like Size Zone Non Uniformity Normalized and Small Area Emphasis were associated with longer OS. ***Conclusion:*** ^{18}F-FDG PET/CT-based radiomics, especially when combined with clinical data, significantly improves LNM prediction and has strong prognostic value in eCCA. These findings support its potential to guide personalized treatment strategies and enhance clinical outcomes.

EP-0281

Prognostic value of lymph node-to-primary tumor standardized uptake value ratio in esophageal cancer patients who underwent surgery

C.-S. Tseng, *S.-C. Chan;*
Hualien Tzu Chi Hospital, Hualien, TAIWAN.

Aim/Introduction: The lymph node-to-primary tumor standardized uptake value ratio (SUV_{LN}/SUV_{Tumor}) is an emerging metabolic parameter that reflects the metastatic potential of malignancies more comprehensively than individual SUV measures. However, its prognostic significance in esophageal cancer patients following surgery remains under-explored. ***Materials and Methods:*** We retrospectively analyzed esophageal cancer patients who underwent either neoadjuvant chemoradiotherapy followed by esophagectomy or esophagectomy alone. [^{18}F]FDG PET/CT parameters, including the SUV_{max} of both primary tumors and metastatic lymph nodes, were evaluated. Prognostic significance was assessed using univariate and multivariate regression analyses with overall survival (OS) as the endpoint. Time-dependent receiver operating characteristic (ROC) curve analysis was used to compare the prognostic performance of imaging and clinical parameters. ***Results:*** A total of 108 patients were included, with a median follow-up of 31 months. During this period, 65 patients (60.2%) died. Patients with a higher SUV_{LN}/SUV_{Tumor} ratio had significantly worse survival outcomes. Kaplan-Meier analysis revealed a median OS of 30.6 months for the high-ratio group, compared to 89.4 months in the low-ratio group ($p < 0.01$). Multivariate Cox regression identified both SUV_{LN}/SUV_{Tumor} and gender as independent predictors of poorer OS ($p < 0.05$). Notably, SUV_{LN}/SUV_{Tumor} outperformed conventional staging systems in predicting survival, with a higher AUC on time-dependent ROC analysis for 5-year OS (0.71 vs. 0.58). ***Conclusion:*** The SUV_{LN}/SUV_{Tumor} ratio offers superior prognostic value compared to conventional tumor staging in predicting overall survival among esophageal cancer patients undergoing surgery, with or without neoadjuvant chemoradiotherapy. This parameter may enhance risk stratification and guide postoperative management strategies.

EP-0282

Contribution of ^{68}Ga-FAPI PET/CT to ^{18}F-FDG PET/CT in the Initial Staging and Restaging of Gastric Cancer:

M. Y. Kiran[1], *L. D. Ercan*[2], *S. Kuyumcu*[1], *C. Ertekin*[2], *Z. G. Ozkan*[1], *D. Has Simsek*[1], *E. G. İsik*[1], *Y. Sanli*[1];
[1]*Istanbul University, Istanbul Medical Faculty, Departmant of Nuclear Medicine, Istanbul, TÜRKIYE* [2]*Istanbul University, Istanbul Medical Faculty, Departmant of General Surgery, Istanbul, TÜRKIYE.*

Aim/Introduction: This study aimed to compare the findings of ^{68}Ga-FAPI (FAPI) PET/CT imaging with those of ^{18}F-FDG (FDG) PET/CT, and to evaluate the potential diagnostic contributions of FAPI PET/CT in patients with gastric cancer. ***Materials and Methods:*** A retrospective analysis was conducted on 40 patients with histopathologically confirmed gastric cancer who underwent both FDG and FAPI PET/CT scans (31 for initial staging, 9 for restaging). Final diagnoses of lesions were based on histopathology (gold standard) and/or concurrent or follow-up imaging studies. For both PET modalities, the number of primary tumors, regional and distant metastatic lymph nodes, and extra-nodal distant metastases were recorded. Additionally, the maximum standardized uptake value (SUV_{max}) and tumor-to-background ratio (TBR) of each lesion were documented. Comparisons of SUV_{max} and TBR were performed using the Wilcoxon and Mann-Whitney U tests. Diagnostic performance was assessed via the McNemar test; survival analyses were conducted using the Kaplan-Meier method and log-rank test; associations between risk factors and survival were analyzed using Cox regression. A p-value <0.05 was considered statistically significant. ***Results:*** Among the 40 patients, 29 (72.5%) were male

and 11 (27.5%) were female. Histopathologically, 22 patients (55%) had signet ring cell carcinoma (SRCC) and 18 (45%) had non-SRCC gastric carcinoma (adenocarcinoma). In primary tumors, regional lymph node metastases and extra-nodal distant metastases, SUV_{max} and TBR values were significantly higher with FAPI PET/CT compared to FDG PET/CT ($p<0.05$); no significant difference was observed in distant lymph node metastases ($p>0.05$). The detection rates of primary tumors were similar between the two modalities (93.5% vs. 90.3%, p=1.0). However, FAPI PET/CT demonstrated significantly higher sensitivity and accuracy for detecting regional and distant lymph node metastases, as well as extra-nodal distant metastases ($p<0.05$). Among 19 patients who underwent surgery, accurate nodal (N) staging was achieved in 9 cases with FAPI PET/CT and 6 cases with FDG PET/CT, while FAPI PET/CT detected a higher N stage in 5 patients. In distant metastasis (M) staging, FAPI PET/CT and FDG PET/CT demonstrated accuracy rates of 95% and 82.5%, respectively. Neither SUV_{max} nor TBR values of primary tumors on either PET modality were significantly associated with overall survival or progression-free survival during a median follow-up of 17.7 months ($p>0.05$). ***Conclusion:*** ^{68}Ga-FAPI PET/CT demonstrated superior visual and diagnostic performance compared to ^{18}F-FDG PET/CT in evaluating primary and metastatic gastric cancer lesions. These results support its potential as a promising imaging modality, warranting further validation in larger cohorts.

EP-0283

Diagnostic Performance of ^{68}Ga-FAPI PET/CT in Liver Fibrosis Staging: Correlation with Transient Elastography, APRI, and FIB-4

S. Kar, *V. R. Lele, A. S. Nagral, N. Shaikh;*
Jaslok Hopsital and Research Centre, Mumbai, INDIA.

Aim/Introduction: This study aimed to quantitatively assess liver fibrosis and cirrhosis by correlating liver uptake of ^{68}Gallium-Fibroblast Activation Protein Inhibitor Positron Emission Tomography/ Computed Tomography (^{68}Ga-FAPI PET/CT) with Transient Elastography (TE). The primary objectives were to evaluate the diagnostic performance of ^{68}Ga-FAPI PET/CT in staging liver fibrosis and to analyse the correlation between Maximum Standardised Uptake Value (SUVmax) from PET/CT and liver stiffness severity as measured by TE. ***Materials and Methods:*** A total of 45 participants with suspected liver disease underwent TE for fibrosis staging, classified as F0-F1, F2, F3, or F4. All subjects then underwent ^{68}Ga-FAPI PET/CT with delayed imaging (60-90 minutes post-injection), while a subgroup of 33 participants also had early imaging (15-30 minutes post-injection). Liver tracer uptake was quantified using SUVmax. Statistical analysis included the Kruskal-Wallis test to compare SUVmax across fibrosis stages, pairwise comparisons to assess differences between stages, and Receiver operating characteristic (ROC) analysis to evaluate diagnostic performance. Correlations with Aspartate Aminotransferase to Platelet Ratio Index (APRI) and Fibrosis-4 (FIB-4) were also analysed in a subgroup. ***Results:*** Delayed SUVmax significantly differed across the fibrosis stages ($p < 0.001$), with the highest median SUVmax observed in the F4 (cirrhosis) group (6.16, interquartile range [IQR] 3.69-7.93). Pairwise analysis showed significant differences between F0-F1 vs F4 and F2 vs F4. ROC analysis for delayed imaging showed good diagnostic accuracy for predicting significant fibrosis (F2, F3, F4 vs F0-F1) with an area under the ROC curve (AUROC) of 0.858 and an optimal cutoff SUVmax ≥1.28, and for predicting cirrhosis (F4 vs F0, F1, F2, F3) with an AUROC of 0.891 and a cutoff SUVmax ≥3.45. Early imaging also showed significant differences in SUVmax across stages ($p = 0.001$) and demonstrated slightly higher AUROC values for detecting cirrhosis. However, both imaging time points showed limited performance in distinguishing moderate (F2) and severe (F3) fibrosis. Delayed SUVmax strongly correlated with APRI and FIB-4 categories, supporting its clinical relevance. ***Conclusion:*** ^{68}Ga-FAPI PET/CT demonstrated a strong correlation between SUVmax and fibrosis severity, as assessed by TE. Delayed imaging is useful for differentiating cirrhosis from earlier fibrosis stages and for identifying significant fibrosis. While early imaging shows potential advantages in detecting cirrhosis, both early and delayed approaches have limitations in distinguishing moderate from severe fibrosis. Strong correlations with serological markers (APRI, FIB-4) further support the utility of ^{68}Ga-FAPI PET/CT in the non-invasive assessment of liver fibrosis.

EP-0284

Before and After CCRT ^{18}F-FDG PET/CT Derived Parameters for Prognosis of Esophageal Cancer Patients underwent Trimodality Treatment

M. Chiang[1], *P.-J. Chuang*[2], *J.-Y. Huang*[3];
[1]*Taipei Medical University Hospital, Taipei, TAIWAN,* [2]*National Taiwan University Hospital Cancer Center, Taipei, TAIWAN,* [3]*National Taiwan University Hospital, Taipei, TAIWAN.*

Aim/Introduction: Esophageal cancer has a poor prognosis despite standard treatment with pre-operative concurrent chemoradiotherapy (CCRT) and surgery. Although 18F-fluorodeoxyglucose positron emission tomography/ computed tomography (^{18}F-FDG PET/CT) is widely used for staging and response assessment, the prognostic value of PET-derived metabolic parameters—such as maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG)—before and after CCRT remained uncertain and inconsistent. Therefore, this study aimed to evaluate dual-timepoint PET-derived parameters and their temporal changes in predicting overall survival in patients with esophageal cancer. ***Materials and Methods:*** This retrospective study included 170 patients (159 men; mean age: 59±9 years) with esophageal cancer who underwent pre- and post-CCRT FDG PET/CT, followed by esophagectomy. PET-derived parameters including SUVmax, MTV,TLG, percentage change in SUVmax (%ΔSUVmax) and rate of SUVmax change — were measured to assess their prognostic significance. MTV and TLG were automatically calculated using commercial imaging analysis software. Survival analysis was performed using Kaplan-Meier curves, with cut-off values determined by the Youden index from receiver operating characteristic curves. The prognostic value of clinical and PET-derived variables for overall mortality was assessed using the Cox proportional hazards model. ***Results:*** After a mean follow-up of 51 months, 92 patients (54.1%) had died. Kaplan-Meier survival analysis revealed significant differences in survival based on post-CCRT SUVmax, pre- and post-CCRT MTV, pre-CCRT TLG, %ΔSUVmax, and rate of SUVmax change, with cut-off values determined by the Youden index. In multivariable Cox regression analysis, post-CCRT SUVmax (HR = 1.85, $p = 0.007$), pre-CCRT MTV (HR = 2.37, $p < 0.001$), %ΔSUVmax (HR = 0.53, $p = 0.003$), and the rate of SUVmax decrease (HR = 0.45, $p < 0.001$) were independent predictors for overall survival. ***Conclusion:*** This study demonstrated that FDG PET/CT-derived metabolic parameters, including post-CCRT SUVmax, pre-CCRT MTV, pre-CCRT TLG, %ΔSUVmax, and the SUVmax decrease rate, are significant predictors of survival in patients with esophageal cancer. Higher metabolic activity and lower treatment response were associated with worse outcomes, highlighting the prognostic value of PET imaging at both baseline and post-CCRT time points. The incorporation of automated tools for volumetric measurements may further support the clinical applicability of these PET parameters in prognostic assessment. ***References:*** Han S, Kim YI, Woo S, Kim TH, Ryu JS. Prognostic and predictive values of interim (18)F-FDG PET during neoadjuvant chemoradiotherapy for esophageal cancer: a systematic review and meta-analysis. Ann Nucl Med. Apr 2021;35(4):447-457.

68Ga-PSMA PET/CT in Inoperable/Heavily Pretreated Pancreatic Adenocarcinoma: A Pilot study on Imaging, Prognostic and Theranostic Potential

G. B. Priyanka, *N. A. Damle, A. N. Singh, K. Kuradia, S. Mishra, S. J. Bharati, R. Yadav, C. Ganapathy, A. Choudhary, M. Aishwarya;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Pancreatic adenocarcinoma remains a therapeutically challenging malignancy with poor prognosis in the inoperable or heavily pretreated setting. While FDG PET/CT is routinely used to evaluate tumour metabolism, recent interest has emerged in PSMA PET/CT owing to PSMA expression in tumour-associated neovasculature. This study aimed to evaluate PSMA PET/CT uptake patterns and prognostic utility in pancreatic adenocarcinoma patients, in comparison with FDG PET/CT. ***Materials and Methods:*** This prospective observational study included 14 patients with biopsy-confirmed inoperable/heavily pretreated pancreatic adenocarcinoma, with 11 patients who underwent both FDG and PSMA PET/CT. Lesions were analyzed based on location, count, and SUVmax. Imaging avidity on both modalities was recorded, and survival analyses were performed using Kaplan-Meier with log rank test. ***Results:*** 68Ga-PSMA uptake was seen in 50/60 lesions (83.3%). All primary pancreatic tumours were PSMA-avid. Site distribution was heterogenous—periampullary (n=4), head/uncinate (n=3), head/neck (n=1), uncinate (n=1), head/tail (n=1), distal body/tail (n=1), tail (n=1), and 2 post-Whipple's. Metastases included 15 nodal, 11 hepatic, 12 osseous, 2 pulmonary, and 3 abdominal deposits across modalities. Nodal sites were thoracic (n=6), retroperitoneal (n=4), supraclavicular (n=3), and abdominal (n=2), with high modality concordance. Among liver metastases (n=11), 4 were dual-avid, 5 PSMA non-avid, 1 discordantly PSMA-avid, and 1 missed by both tracers but found on CT. Two lung nodules were seen; one was missed by PSMA PET. PSMA PET detected one bone lesion missed by FDG PET; remaining 11 were dual-avid. PSMA SUVmax values ranged (mean 6.29, range 0-20.6), as did FDG (mean 6.5, range 0-25). 26 (43.3%) showed uptake > liver background, 34 (56.7%) showed uptake < liver. Lesions with uptake > liver were more frequent in bone and nodes. Number of FDG-avid lesions (median 3, range 1-15) and PSMA-avid lesions (median 2.5, range 1-15) showed strong agreement (concordance correlation = 0.97). Kaplan-Meier curves showed ≥3 FDG-avid lesions predicted worse OS, while ≥2.0 PSMA lesions showed early mortality, with crossover at ~40% survival. ***Conclusion:*** PSMA PET/CT demonstrates consistent and clinically meaningful uptake in pancreatic adenocarcinoma, frequently identifying lesions that are missed by FDG PET/CT. Unlike FDG, which predominantly reflects glycolytic activity and often correlates with aggressive disease, PSMA PET/CT targets tumor neovasculature. This vascular-targeted imaging may serve as a surrogate for perfusion and drug delivery potential, and opens avenues for PSMA-targeted therapies. In our study, PSMA PET/CT not only detected additional lesions but also showed a early deaths in patients with high burden PSMA avid disease.

EP-0286

^{18}F-FDG and 68Ga-FAPI PET/CT in evaluation of esophageal cancer

M. Komarova[1], *V. Sinitsyn*[1], *E. Davydova*[1], *A. Chaban*[2], *A. Martinovich*[3];
[1]*Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION,* [2]*Rechts der isar, technische Universitat Munchen, Munich, GERMANY,* [3]*N.N. Blokhin Russian Cancer Research Center, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: to compare 68Ga-FAPI PET/CT and ^{18}F-FDG PET/CT in diagnosis of esophageal cancer. ***Materials and Methods:*** 14 patients (5 females and 9 males; median age, 44 years) with esophageal cancer underwent ^{18}F-FDG and 68Ga-FAPI PET/CT examination within 1 week for assessment primary tumor and distant metastasis. 10 patients were referred for initial diagnosis and 4 patients after treatment. Positive lesions on PET/CT images were verified by biopsy or follow-up. Mann-Whitney U test was used to compare SUVmax and TBR of tumor lesions using ^{18}F-FDG and 68Ga-FAPI PET/CT. We calculated the diagnostic efficiency (sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and accuracy (Ac)) for each modality on a per-region basis. ***Results:*** 68Ga-FAPI-46 PET/CT and ^{18}F-FDG PET/CT showed comparable diagnostic performance (the number of lesions of radiopharmaceutical accumulation in esophageal tumor was comparable in the two techniques). There were no significant differences in SUVmax and TBR obtained in both esophageal tumor and metastatic lymph nodes (p>0.05). The mean SUVmax for 68Ga-FAPI-46 PET/CT and ^{18}F-FDG PET/CT were 11,78 [7,72-17,16] and 13,86 [5,39-23,30] (p=0,59) resp., and mean TBR for 68Ga-FAPI-46 PET/CT and ^{18}F-FDG PET/CT were 5,26 [9,97-7,66] vs. 5,35 [1,94-8,68] (p=0,82) respectively. False-positive results of radiopharmaceutical accumulation in intrathoracic lymph nodes during FDG-PET were obtained in 4 patients (33%). One patient had a false positive result 68Ga-FAPI uptake in the esophagus due to esophagitis and true negative according FDG-PET. Se, Sp, PPV, NPV and Ac for 68Ga-FAPI-46 PET/CT were 100%, 81,25%, 86,96, 100% and 91,67% respectively vs. 95,00%, 43,75%, 67,86%, 87,50% and 72,22% for ^{18}F-FDG PET/CT respectively. ***Conclusion:*** 68Ga-FAPI-46 PET/CT is better to assess the metastatic lymph nodes lesion than ^{18}F-FDG PET/CT in patients with esophageal cancer.

EP-0287

Comparison of 68Ga-FAPi and FDG PET/CT in the Detection of Peritoneal Carcinomatosis, Staging and Restaging in Patients with Gastrointestinal Cancer

H. Pala, *M. Tuncel, E. Karabulut, S. Yalçın, N. Akkapulu, T. Erol, C. Sökmensüer, Ö. Uğur;*
Hacettepe University, Ankara, TÜRKIYE.

Aim/Introduction: 68Ga-labelled fibroblast activation protein inhibitor(FAPi) promises a more successful diagnostic performance than FDG due to lower background activity and relatively high specificity for tumoural tissues. Our study aimed to compare the diagnostic performances of FDG and FAPi PET/CT examinations in patients with gastrointestinal malignancies, evaluated in terms of staging and restaging, as well as the detection of the peritoneal carcinomatosis index (PCI)score. ***Materials and Methods:*** Thirty-eight patients were included in the study. All patients underwent FDG and dual-time FAPi PET/CT scans at 10 and 60 minutes. Surgical histopathology data, along with clinical and imaging follow-up results, were used as reference tests to compare the diagnostic performances for staging, detecting recurrence, and PCI scores. The contribution to disease management and the accuracy of each modality were interpreted on both a patient and lesion basis. ***Results:*** FAPi demonstrates significantly higher accuracy in detecting malignant lesions than FDG in lesion-based assessments. FAPi was much more compatible with reference tests for detecting malignant lesions compared to FDG, with kappa-values of 0.644 and 0.206, respectively. Eighty-six percent of the malignant foci were correctly identified with FAPi based on follow-up data, while this rate was only 34% with FDG. In addition, FAPi uptake was significantly higher than that of FDG in malignant lesions, with a mean SUVmax difference of 3.73(p<0.001). Compared to early images of FAPi, uptake intensity in delayed images increased in malignant foci (early and late median SUVmax:3.55 and 4.58; mean rank:2.01 and 2.63, respectively; p<0.001); in contrast, there was no significant uptake increase in benign lesions(p=0.069). The likelihood of malignancy in a lesion escalates with the percentage rise in the late SUVmax value relative to the early value (odds ratio 1,014; p=0.008); this increment is more pronounced in lesions

exceeding 10 mm in size than in smaller lesions. In patient-based analysis, FAPi determined stage(8/8) and recurrence status(28/30) much better than FDG (3/8 and 18/30, respectively). FAPi also significantly outperformed FDG($p<0.001$) in calculating PCI scores and the number of malignant foci detected(Table1). Moreover, FAPi directly affects disease management compared to FDG and conventional imaging modalities by eliminating suspicious foci for metastasis and initiating or changing treatment in 63% of patients. ***Conclusion:*** FAPi demonstrates superior diagnostic performance in evaluating peritoneal carcinomatosis and in staging or restaging patients with gastrointestinal cancer compared to FDG. This study suggests that FAPi may enhance diagnostic accuracy and facilitate more appropriate therapeutic decisions for patients with gastrointestinal malignancies.

EP-0288

Optimization of gastric emptying scan times

K. Velasquez, *I. Garrido, P. Meneses, M. Grajeda, C. Pradere, M. Estrella, R. Jimeno, M. Mijtavila;*
Hospital Puerta de Hierro, Majadahonda, SPAIN.

Aim/Introduction: Gastroparesis is a gastric motility disorder characterized by delayed gastric emptying in the absence of mechanical obstruction. Among the available diagnostic tools, gastric emptying scintigraphy is considered a reliable method to assess gastric motor function, as it quantifies the percentage of gastric retention over time using a standardized radionuclide-labeled meal[(1).] The 4-hour protocol has been adopted as the standard for detecting gastric motility disorders; however, quantitative thresholds that may support diagnosis in shorter time frames have also been established, potentially reducing scan duration without compromising sensitivity. Therefore, our aim is to determine the correlation between quantitative values obtained at 3 and 4 hours in gastric emptying scintigraphy[(2)]. ***Materials and Methods:*** A retrospective analysis was conducted on 28 patients with clinical suspicion of gastroparesis who underwent gastric emptying scintigraphy in 2024. Images were acquired immediately after ingestion of a standardized meal and at 1, 2, 3, and 4 hours, as per established protocol. According to the joint consensus of the SNM and ANMS[(1),] gastric retention >10% at 4 hours and >30% at 3 hours was considered abnormal. Cohen's Kappa test was used for correlation analysis between the time points. ***Results:*** Out of the 28 evaluated patients, 14 (50%) showed diagnostic values consistent with gastroparesis at 4 hours. The concordance analysis between the 3- and 4-hour values, yielded 100% agreement (Kappa = 1, p-value = 1.213e-7). ***Conclusion:*** These findings suggest that the study duration could be reduced to 3 hours without compromising diagnostic accuracy. This adjustment could improve workflow efficiency and reduce costs while maintaining diagnostic quality. If 3-hour values were considered diagnostic, a retention rate ≤30% at 2 hours could potentially be interpreted as normal. In our sample, this would have allowed up to 8 patients (29%) to complete the study by the 2-hour mark. However, the small sample size limits generalizability. To achieve a Kappa of 0.75 with a gastroparesis prevalence of approximately 50%, a sample size of 95 patients would be required ***References:*** 1. Diagnostic Contribution of [^{68}Ga]Ga-ABY-025 PET in HER2-Positive Breast Cancer: Beyond [^{18}F]FDG PET

A. Alhuseinalkhudhur[1,2], *H. Lindman*[1], *F. Y. Frejd*[1,3], *P. Liss*[4], *J. Feldwisch*[3], *T. Sundin*[5], *V. Iyer*[2], *M. Lubberink*[2], *I. Velikyan*[2], *J. Sörensen*[2];
[1]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN,* [2]*Department of Surgical Sciences, Molecular imaging and medical physics, Uppsala University, Uppsala, SWEDEN,* [3]*Affibody AB, Solna, SWEDEN,* [4]*Department of Surgical Sciences, Radiology, Uppsala University, Uppsala, SWEDEN,* [5]*Clinical Research and Development Unit, Uppsala University Hospital, Uppsala, SWEDEN.*

Aim/Introduction: [^{68}Ga]Ga-ABY-025 PET is a novel imaging modality that is useful for quantification and treatment response prediction in advanced-stage human epidermal growth factor receptor 2 (HER2)-positive breast cancer. This study investigates its utility in accurate staging, highlighting diagnostic pitfalls and variability in tracer uptake. ***Materials and Methods:*** Fifty patients with biopsy-confirmed HER2-positive breast cancer underwent both [^{68}Ga]Ga-ABY-025 PET and [^{18}F]FDG PET within one week. A second [^{18}F]FDG PET was performed following two courses of HER2-targeted treatment to assess metabolic response. All images were analyzed with regard to lesion detectability, tracer distribution, and physiological uptake patterns. ***Results:*** In three patients, [^{68}Ga]Ga-ABY-025 PET detected a more extensive local spread than [^{18}F]FDG PET. Two of these patients had invasive lobular carcinoma, these findings led to revised staging and adjusted treatment plans. All three patients showed early metabolic response, with two achieving complete response following HER2-targeted therapy. Two other patients showed elevated [^{18}F]FDG PET uptake near the thyroid with low corresponding [^{68}Ga]Ga-ABY-025 PET uptake. Biopsies excluded malignancy, although a definitive conclusion could not be drawn. Two additional patients who were vaccinated against COVID19 shortly prior to PET scans showed high [^{18}F]FDG PET uptake in ipsilateral lymph nodes, no corresponding uptake was observed on [^{68}Ga]Ga-ABY-025 PET. ***Conclusion:*** [^{68}Ga]Ga-ABY-025 PET provided complementary and clinically relevant information beyond that of [^{18}F]FDG PET, particularly in detecting small or otherwise challenging lesions. Additionally, it demonstrated higher specificity by avoiding uptake in inflammatory or vaccine-related reactive nodes. These findings support the added value of HER2-targeted PET imaging for staging and therapy monitoring in HER2-positive breast cancer.

Enhanced Probabilistic Analysis of Breast Cancer FDG-PET Images Using Probabilistic Machine Learning Techniques

N. Christensen[1], *M. H. Vendelbo*[1], *T. M. Hansen*[2];
[1]*Aarhus University Hospital, Aarhus N, DENMARK,* [2]*Aarhus University, Aarhus C, DENMARK.*

Aim/Introduction: nformed prior models and probabilistic sampling methods show potential for improving PET image assessment. The Probabilistic PET (ProPET) method integrates smoothing and noise characteristics in reconstructed PET images with prior information about the tracer's within-body activity. This

study integrates the ProPET method, with an explicit prior model of within-body activity, utilizing a machine learning approach for PET image analysis. Sensitivity for small cancer lesions remains suboptimal with FDG-PET/CT in oncological conditions, such as breast cancer (BC). To enhance diagnostic sensitivity, we assessed whether ProPET improves detection of additional suspicious foci. ***Materials and Methods:*** ProPET was applied using a convolution operator and a spatially correlated noise model inferred from phantom data. A prior model representing within-body activity concentration in BC was developed, using liver activity as baseline and incorporating sharp contrast between high and low activity. A training dataset was compiled, comprising many realizations of the prior distribution and corresponding simulated PET-images. Data was used to train a neural network estimating features of the posterior probability distribution. This facilitates detailed analysis of in-vivo activity, highlighting regions of high activity, without the computational burden of traditional sampling methods. 50 FDG-PET images from BC patients were retrospectively analysed using ProPET compared to standard PET reconstruction. A nuclear medicine specialist independently assessed each image. Breast and local lymph node lesions were rated 1=most likely benign, 2=benign/malignant or 3=most likely malignant. All foci rated as 2 or 3 was deemed possibly malignant lesions. ***Results:*** More suspicious foci were identified on ProPET reconstructions, with 26 additional lesions in breasts (76 vs. 102) and 82 in local lymph nodes (172 vs. 254). Many additional breast foci on ProPET reconstructions appeared near primary tumors, suggesting improved resolution. All foci identified with standard reconstruction were also detected with ProPET. ***Conclusion:*** ProPET significantly advances PET imaging by combining informed prior models with machine learning to improve PET scan evaluations and detect small, high-activity lesions vital for early detection. Our findings indicate increased sensitivity compared to standard reconstruction. However, prospective studies are needed to validate specificity, assess the risk of false positives, and confirm clinical value in guiding diagnostic and therapeutic decisions. ***References:*** [1] Hansen TM, et al. Correlation of Primary Lesion FDG PET/CT Texture Features with Prognosis and Histopathological Data in Luminal A Type Breast Cancer

M. Genç[1], *K. Şeker*[2], *Z. Hasbek*[2], *B. Yücel*[3], *M. Yılmaz*[4]; *[1]Sivas Numune Hospital Department of Nuclear Medicine, Sivas, TÜRKIYE, [2]Sivas Cumhuriyet University Faculty of Medicine Department of Nuclear Medicine, Sivas, TÜRKIYE, [3]Sivas Cumhuriyet University Faculty of Medicine Department of Radiation Oncology, Sivas, TÜRKIYE, [4]Sivas Cumhuriyet University Faculty of Medicine Department of Medical Oncology, Sivas, TÜRKIYE.*

Aim/Introduction: FDG PET/CT is used in breast cancer. With radiomics studies, quantitative data on tumor biology can be obtained by using data characterization algorithms on medical images. The texture features of lesions that can be obtained from FDG PET/CT images can help clinicians in the pathological features and clinical course of the disease. In our study, it was aimed to investigate the effect of radiomics features and traditional measurements such as SUV that can be obtained from FDG PET/CT images performed for staging purposes in patients with Luminal A type breast cancer on prognosis by comparing them with data such as disease stage, pathological features, and survival. ***Materials and Methods:*** 41 patients diagnosed with Luminal A type breast cancer who underwent FDG PET/CT for staging purposes were included in the study. Primary breast cancer lesions in FDG PET/CT images were segmented by accepting 42% of SUVmax measurement as the threshold value. Using LIFEx software, numerical texture properties and shape properties were obtained for each lesion. The relationship of these data with the survival data of the patients was examined. In addition, SUV, MTV, TLG of the primary lesions were recorded. The TNM stage and grade of the disease, the presence or absence of necrosis-lymphovascular invasion-perineural invasion, and Ki-67 index were obtained for each patient along with their survival times. Statistical analysis of the obtained data was performed using SPSS26®software. ***Results:*** The mean age of the patients was 60±13. While follow-up data of 4 patients could not be accessed, the mean survival time of the remaining 30 of the patients were local, 7 were locally advanced, and 4 were in advanced stage. Tumor necrosis was positive in 9 patients, lymphovascular invasion was positive in 14 patients, and perineural invasion was positive in 15 patients. The relationships of pathological features with texture characteristics data are summarized in Table 1. 37 patients was determined as 77±20 months. Texture characteristics data that could be related to survival were investigated. These findings are summarized in Table 2.Correlation relationships between PET measurement parameters and texture analysis data were examined, and very high levels of correlations were found. ***Conclusion:*** Texture analysis data obtained from FDG PET/CT performed on patients with luminal A type breast cancer may be useful in predicting the pathological features of the disease and survival with other PET data. Thus, it may contribute to disease management regarding preoperative and postoperative treatment approaches.

EP-0292

PET-positive extra-axillary lymph nodes in high-risk primary breast cancer: a retrospective study of location, treatment planning, and follow-up

A. L. Rudbeck[1], *N. M. Jakobsen*[2], *M. G. Hildebrandt*[2], *M. Vogsen*[3]; *[1]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [2]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [3]Department of Oncology, Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: To explore the clinical management and follow-up of non-resected PET-positive extra-axillary lymph nodes in women with primary breast cancer. ***Materials and Methods:*** Women with primary breast cancer referred for an additional staging with FDG-PET/CT at Odense University Hospital from January 2016 to February 2024 were included retrospectively. This study assessed FDG-PET/CT-based stage migration through a comprehensive review of patient medical records, pathology reports, scan reports, and images. In-depth characteristics, clinical management, and follow-up after the detection of extra-axillary lymph node metastasis in the periclavicular and internal mammary nodes (IMN) were included for analysis. ***Results:*** A total of 615 patients were included in the study. Following FDG-PET/CT, 377 (61%), 95 (15%), and 143 (23%) were staged with early breast cancer, extra-axillary breast cancer, and metastatic breast cancer, respectively. After definitively including 83 patients with extra-axillary breast cancer, the sites of lymph node metastases were infraclavicular (47/83, 57%), supraclavicular (31/83, 37%), and IMN (35/83, 42%). The majority of patients received standard radiotherapy (74/83, 89%), mainly including the locoregional levels without an additional nodal boost to PET-positive nodes. At a median follow-up of 4.9 years, 27 patients (33%) had a new malignant event, predominantly due to recurrent breast cancer (23/83, 28%). Of these, most presented with distant metastasis (21/23, 91%), and only one had an isolated locoregional recurrence. Among patients with breast cancer recurrence, 57% (13/23) died within a median of 2.9 years after initial diagnosis. ***Conclusion:*** In patients upstaged due to detection of extra-axillary PET-positive

lymph nodes, most locoregional lymph nodes were located in the internal and infraclavicular nodes. Despite medical treatment and radiotherapy after surgery, approximately one-third of the patients experienced distant failure within five years of follow-up. These findings highlight the need for improved therapeutic strategies for patients with high-risk primary breast cancer.

EP-0293

Integrating 18FDG-PET/CT Biomarkers and Tumor Biology in Breast Cancer Prognosis

N. Fatima[1,2], *M. Zaman*[2];
[1]*Dow University Health Sciences, Karachi, PAKISTAN,* [2]*Aga Khan University Hospital, Karachi, PAKISTAN.*

Aim/Introduction: To determine prognostic strength of ^{18}FDG PET/CT based glucose metabolism, tumor grading and immunohistochemical markers in breast cancer (BC) patients. ***Materials and Methods:*** This was a cohort study conducted at PET/CT imaging services of Department of Radiology and duly approved from ethical review committee (2024-10580-30915). A total of 110 patients of advanced stage BC patients (stage II and more) who ^{18}FDG PET/CT for staging, restaging, response and surveillance were included and followed for disease free survival (DFS) on metabolic status on follow up PET/CT for 4-5 years. Tumor demographics (type, grading, staging) and immunohistochemistry (estrogen receptor ER, human epidermal growth factor receptor-2 HER2/Neu, progesterone receptor PR, Ki-67) were also recorded. Using logistic regression and ROC analysis, the significant predictors of DFS were analyzed. Kaplan Meier's survival plots were analyzed to measure DFS against ROC derived cutoff values of significant predictors. ***Results:*** The median age of study group was 57 years (25 - 86 years), significantly obese and 85% invasive ductal CA with 97% grade II-III on Bloom-Richardson classification and stage IV disease (74%). The significant association of SUVmax and Ki-67 index were found in poor survival outcome on logistic regression while no significant association of patients' age, obesity, tumor grading, ER, PR, HER-2/neu status were found in DFS in BC. The SUVmax >5.4 and Ki-67 >30% were found to have significant association with disease progression (AUC 0.729 and 0.759; p=0.0002* and p=0.0001* respectively). The DFS was significantly shorter in SUVmax >5.4 (29 vs. 45 months; Logrank=16.356; p=0.0001*) and Ki-67 >30% index (57 vs. 162 months; Logrank=12.892; p=0.0003*). However, no significant difference in OS was observed at Ki-67 cutoff >30% index (Mean Survival 375 vs. 272 months; Logrank=0.457; p=0.499). ***Conclusion:*** The Ki-67 index and ^{18}FDG PET/CT based SUVmax are significant predictors for poor survival outcome in BC patients. The higher SUVmax >5.4 and Ki-67 >30% are considered significant cutoff for shorter DFS. ***References:*** 1. Tilli, T.M.
