EANM Focus Meeting 7 S1012

ICNC: International Conference On Nuclear Cardiology S1013

Dear Colleagues,

It is with great pleasure that I invite you to the EANM'25—the 38th Annual Congress of the European Association of Nuclear Medicine (EANM). The EANM'25 will be held in the vibrant city of Barcelona from October 4-8, 2025.

This year marks a significant milestone for our association as we celebrate four decades of pioneering advancements and collaborative efforts in the field of nuclear medicine. Our congress will be a unique opportunity to reflect on our journey,celebrate our achievements since 1985, and look ahead to securing the brightest future for our specialty.

The EANM Annual Congress is a truly global event, attracting about 10,000 participants from all over the world. This diverse gathering of professionals provides a rich platform for the exchange of ideas, fostering international collaboration and innovation. We are committed to exploring novel formats and interactions with experts, ensuring that our congress remains at the forefront of scientific discourse and professional development.

One of the highlights of this year's congress will be the continued focus on novel advances in theranostics. This rapidly evolving field continues to revolutionise our approach to diagnosis and treatment, offering unprecedented precision and personalised care for our patients. We have an exciting programme lined up, featuring leading experts who will share their insights and latest research findings.

But our congress is also designed to cater to all fields of research and clinical activity within nuclear medicine. We have specific tracks dedicated to all the various specialities, ensuring that every participant can find sessions relevant to their interests and expertise. Whether you are involved in clinical practice, research, or education, there will be something for you at the EANM'25.

In addition to the scientific sessions, the EANM'25 will provide ample opportunities for networking, collaboration, and professional development. We are particularly proud of our EANM Next-Gen programme, which was launched last year to support our younger collaborators. This initiative offers free registration and accommodation to selected participants to facilitate their attendance and integration into the scientific community, ensuring that the next generation of nuclear medicine professionals is well-represented and engaged. This year again, we will also offer a Young Professionals Lounge for congress participants under 38.

I am also very happy to travel once again to Barcelona, with its rich cultural heritage and dynamic atmosphere, which will serve as the perfect backdrop for our gathering. We look forward to welcoming you to what promises to be an inspiring and memorable event. Your participation and contributions are invaluable to the continued success and growth of our community.

Warm regards,

Valentina Garibotto
EANM Congress Chair 2023–2025

In vivo detection of tumor senescence by [^{18}F]FPyGal PET

J. Schwenck, *N. Trautwein, S. Mattern, J. Cotton, F. Reche-Perez, A. Wäschle, B. Gückel, M. Pritzkow, B. Zhou, M. Krüger, W. Ehrlichmann, G. Kienzle, A. Maurer, S. Singer, G. Reischl, L. Zender, B. J. Pichler, C. la Fougere;*
University of Tübingen, Tübingen, GERMANY.

Aim/Introduction: Tumor senescence and the senescence-associated secretory phenotype are crucial factors in the progression and therapeutic resistance of solid tumors. To improve the outcome of cancer patients, the non-invasive in vivo detection of senescence could support therapeutic stratification towards senolytic treatments. Here, we investigated [^{18}F]FPyGal, a first-in-class PET tracer to non-invasively detect the activity of β-galactosidase, a commonly used senescence marker. ***Materials and Methods:*** The radiolabeled β-galactosidase substrate [^{18}F]FPyGal was developed and thoroughly validated in vitro in various tumor cell lines (colon cancer HCT116, lung adenocarcinoma A549, hepatocellular carcinoma Myc^{OE}Akt1) as well as in vivo in experimental tumor models. After a single-dose acute toxicity study in rats, a Phase I clinical study in healthy male volunteers (n=8) using 370±50 MBq [^{18}F]FPyGal and a subsequent Phase II study in patients with lung, esophageal and rectal cancer after neoadjuvant therapy was performed (EudraCT 2019-002846-19). In an interim analysis of the Phase II study (n=14 of 27), the [^{18}F]FPyGal uptake in the tumors was correlated to the ex vivo β-galactosidase activity assessed by X-gal staining in the resected tumor tissue as well as to the immunohistological markers p16, p21, p53 and HMGA2 as at least 3 positive markers are needed to confirm senescence according to current standards. ***Results:*** We observed a reliable detection of tumor senescence in tumor cell lines and in preclinical tumor models. The clinical Phase I study confirmed the safe use of [^{18}F]FPyGal in healthy volunteers with no relevant adverse effects. Dosimetry revealed a low effective whole-body radiation dose (8.1±0.2 µSv/MBq) comparable to other routinely applied PET tracers. The Phase II study in cancer patients after neoadjuvant therapy revealed inhomogeneous [^{18}F]FPyGal uptake patterns in the tumors. After resection, areas with high and low [^{18}F]FPyGal uptake were correlated to the X-gal stained tissue. Tumors with X-gal positive areas greater than the median of all analyzed samples (>0.4%) had a significantly higher [^{18}F]FPyGal tumor uptake (lesion/liver ratio, 46-60 min p.i) than tumors with X-gal positive areas below the median. Furthermore, tumor lesions with senescence confirmed by ≥3 positive markers tended towards a higher [^{18}F]FPyGal uptake compared to lesions evaluated as negative. ***Conclusion:*** We present the first clinical evidence of the successful noninvasive in vivo detection of tumor senescence by [^{18}F]FPyGal PET in cancer patients. Nevertheless, further clinical studies are needed to prove the ability of [^{18}F]FPyGal PET to successfully guide senolytic treatments.

OP-018

Nectin4-Targeted Radiotheranostics Probe: Molecular Imaging-Guided Precision in Cancer Diagnosis and Therapy

M. Hu, *N. Wei, D. Zheng, Y. Song, Y. Feng, B. Yang, W. Hu, X. Wang, Y. Gai, Y. Zhang, X. Lan;*
Wuhan Union Hospital, Wuhan, CHINA.

Aim/Introduction: Nectin cell adhesion molecule 4 (Nectin4) is overexpressed in multiple malignancies, making it a promising molecular target for cancer diagnosis and therapy. This study aimed to develop and evaluate PET imaging and radionuclide therapy probes targeting Nectin4 for noninvasive tumor monitoring and precision radiotheranostics. ***Materials and Methods:*** Two Nectin4-targeting antibody fragments, HA22 and N41 Fab, were radiolabeled with ^{68}Ga and assessed for tumor uptake and imaging contrast in xenograft mice bearing human bladder cancer (SW780) and triple-negative breast cancer (TNBC, MDA-MB-468). The optimal Fab fragment was selected. Along with Minibody and monoclonal antibody (mAb) derivatives, they were then radiolabeled with ^{177}Lu for imaging and therapy. The antitumor effect was evaluated by administering 11.1 MBq of [^{177}Lu]Lu-DOTA-Fab, 11.1 MBq of [^{177}Lu]Lu-DOTA-Minibody, 4.44 or 11.1 MBq of [^{177}Lu]Lu-DOTA-mAb, or phosphate buffered saline (PBS, control) to SW780 (n = 5) and MDA-MB-468 (n = 6) xenograft mice. Blood, major organs, and tumor tissues were collected for biosafety evaluation and efficacy analysis. ***Results:*** Both [^{68}Ga]Ga-NOTA-N41 and [^{68}Ga]Ga-NOTA-HA22 were successfully synthesized with high radiolabeling yields and radiochemical purity. PET imaging revealed significant tumor uptake of [^{68}Ga]Ga-NOTA-HA22 in SW780(4.89±0.44 %ID/g) and MDA-MB-468(4.44±0.69 %ID/g) xenografts at 2 h post-injection. [^{68}Ga]Ga-NOTA-HA22 exhibited a superior tumor-to-muscle ratio compared to [^{68}Ga]Ga-NOTA-N41 (P = 0.014), leading to its selection for therapy. [^{177}Lu]Lu-DOTA-Fab$_{HA22}$, [^{177}Lu]Lu-DOTA-Minibody$_{HA22}$ and [^{177}Lu]Lu-DOTA-mAb$_{HA22}$ were successfully synthesized, exhibiting distinct pharmacokinetics. [^{177}Lu]Lu-DOTA-Fab$_{HA22}$ exhibited peak tumor uptake of 5~6 %ID/g and cleared rapidly with renal excretion. [^{177}Lu]Lu-DOTA-Minibody$_{HA22}$ and [^{177}Lu]Lu-DOTA-mAb$_{HA22}$ demonstrated peak tumor uptake of 10~20 %ID/g and 15~28 %ID/g, and both showed prolonged circulation and hepatobiliary elimination. Substantial tumor growth inhibition without severe toxicity was observed in SW780 and MDA-MB-468 xenograft mice after [^{177}Lu]Lu-DOTA-Fab$_{HA22}$ (11.1 MBq), [^{177}Lu]Lu-DOTA-Minibody$_{HA22}$ (11.1 MBq) or [^{177}Lu]Lu-DOTA-mAb$_{HA22}$ (4.44 MBq) administration. Treatment-related mortality occurred between 14th~16th days in SW780 xenograft mice receiving [^{177}Lu]Lu-DOTA-mAb$_{HA22}$ (11.1 MBq), indicating dose-limiting toxicity. Post-treatment histological analysis revealed significant downregulation of Nectin4 and ki67 in treated tumors, confirming effective tumor suppression. ***Conclusion:*** This study establishes [^{68}Ga]Ga-NOTA-HA22 as a promising PET tracer for Nectin4-expressing tumors and highlights the therapeutic potential of [^{177}Lu]Lu-DOTA-Minibody$_{HA22}$, which presents a novel theranostic approach targeting Nectin4, providing an innovative strategy for the diagnosis and treatment of Nectin4-expressing tumors.

OP-019

Development and preclinical evaluation of PD-L1-targeted small molecule theranostic radionuclide probe

H. Xie[1,2];
[1]West China Hospital of Sichuan University, Chengdu, Sichuan Province, CHINA, [2]Beijing Anzhen Hospital,Capital Medical University, Beijing, CHINA.

Aim/Introduction: Programmed cell death protein ligand 1 (PD-L1) serves as a critical biomarker for predicting immunotherapy outcomes. This study aimed to develop small-molecule theranostic probes for noninvasive PD-L1 quantification and evaluate their potential in targeted radionuclide therapy combined with immune checkpoint blockade. ***Materials and Methods:*** The radiotracers ^{68}Ga-HX-01, ^{68}Ga-HX-02, and ^{68}Ga-HX-03 were synthesized based on the scaffolds of (2-methyl-3-biphenylyl) methanol and [3-(2,3-dihydro-1,4-benzodioxin-6-yl)-2-benzyl] methanol, with modifications to their pharmacokinetic properties achieved through the incorporation of dimeric structures, piperidine acid,

and water-soluble functional groups. The labeling efficiency, stability, and lipophilicity (logP) of the probes were systematically evaluated. Cellular uptake assays and competitive blocking experiments were conducted to assess their target specificity. PET imaging was performed in B16F10 (PD-L1-high) and MCF-7 (PD-L1-low) tumor models to assess targeting efficacy. ^{177}Lu-HX-01-targeted radionuclide therapy (TRT) and its combination therapies with anti-PD-L1 immune checkpoint blockade (ICB) were evaluated using B16F10-bearing mice. The synergistic therapeutic effects of ^{177}Lu-HX-01 TRT and ICB were further validated through histopathological analysis and longitudinal tumor volume monitoring in treated mice. ***Results:*** The compounds HX-01, HX-02, and HX-03 were synthesized via multi-step chemical reactions, and their structures were confirmed by ^{1}H NMR and ^{13}C NMR. In vitro competitive binding assays revealed high PD-L1 affinities, with IC50 values of 28.73 nM (HX-01), 23.42 nM (HX-02), and 15.65 nM (HX-03). Radiolabeling with ^{68}Ga-HX-01, ^{68}Ga-HX-02, and ^{68}Ga-HX-03 through simplified procedures, achieving radiochemical yields >95% with favorable stability (>90% purity at 4 h). PET imaging demonstrated 2-3-fold higher uptake of all tracers in PD-L1-high B16F10 tumors compared to PD-L1-low MCF-7 tumors. At 180 min post-injection (p.i.), ^{68}Ga-HX-02 and ^{68}Ga-HX-03 exhibited tumor-to-muscle ratios of 9-13. The dimeric ^{68}Ga-HX-01 showed prolonged tumor retention with peak uptake of 11.03 ± 1.15 %ID/g (6 h p.i.). In therapeutic studies, ^{177}Lu-HX-01 displayed high PD-L1-specific binding and prolonged intratumoral retention, correlating with significant antitumor efficacy. The combination of ^{177}Lu-HX-01-targeted radionuclide therapy (TRT; 18.5 MBq) and anti-PD-L1 monoclonal antibody (mAb) synergistically suppressed tumor growth (tumor growth inhibition is 87.38%). Mechanistically, ^{177}Lu-HX-01 TRT enhanced immunotherapy by upregulating tumoral PD-L1 expression and promoting $CD8^+$/$CD4^+$ T-cell infiltration, thereby activating T-cell-mediated antitumor immunity. ***Conclusion:*** The developed ^{68}Ga-labeled probes (^{68}Ga-HX-01, ^{68}Ga-HX-02, and ^{68}Ga-HX-03,) enable reliable PD-L1 quantification through molecular imaging. ^{177}Lu-HX-01 demonstrates dual functionality as a targeted radiotherapeutic and immunotherapy enhancer, with its therapeutic synergy arising from localized radiation damage and subsequent T-cell-mediated immune activation. This radiotheranostic strategy provides a promising approach to optimize combination therapies against PD-L1-expressing tumors.

OP-020

Development and Translational Study of Mesothelin-Targeted Molecular Imaging Probes for Early Diagnosis of Ovarian Cancer

Y. Deng, *X. Zhang, X. Lv, Z. Lin, D. Zheng, R. An, Y. Zhang, D. Jiang, X. Lan;*
Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Early detection of ovarian cancer remains a significant clinical challenge. Mesothelin (MSLN), a tumor-associated antigen, is overexpressed in 80-85% of ovarian cancers, making it an ideal target for molecular imaging. This study aimed to develop and evaluate MSLN-targeted single-chain variable fragment (scFv) and fragment antigen-binding (Fab) probes for PET/CT imaging. ***Materials and Methods:*** Bioinformatics analysis was performed using the GEO and TCGA databases to assess MSLN expression in ovarian cancer and its correlation with prognosis. Differential gene expression, GO, and KEGG pathway analyses were conducted between MSLN-high and MSLN-low groups. For in vitro validation, cellular uptake experiments were performed using MSLN-high/low (OVCAR-3/SKOV3) cell lines and MSLN-blocked controls. Ovarian (OVCAR-3, SKOV3) cancer xenograft models were established for in vivo evaluation of ^{68}Ga-labeled probes via PET/CT imaging, biodistribution, and immunohistochemistry (IHC). For clinical translation, six patients were enrolled following ethical approval. Surgical patients underwent tumor IHC, while non-surgical patients had ascites immunostaining for MSLN validation. ***Results:*** Bioinformatics analysis confirmed MSLN's epithelial-specific expression and identified associated pathways in ovarian cancer, correlating with poor prognosis. In vitro studies demonstrated significantly higher uptake of both probes in MSLN-high cells ($p < 0.01$), which was effectively blocked by MSLN antibodies. In vivo, the ^{68}Ga-scFv probe showed excellent tumor-to-muscle ratios (10.6 ± 1.4 at 2 h) with rapid clearance, while the ^{68}Ga-Fab probe exhibited prolonged tumor retention (6.4 %ID/g ± 0.8 at 4 h) in OVCAR-3 xenograft models. Clinical imaging successfully differentiated MSLN-positive tumors (n=4) from negative cases (n=2), correlating perfectly with pathological findings (tumor/ascites IHC staining). No adverse events were observed during 72-hour safety monitoring. ***Conclusion:*** The ^{68}Ga-labeled scFv and Fab probes demonstrate exceptional specificity and safety for MSLN-targeted imaging. Combined bioinformatics and experimental validation confirms their potential for early ovarian cancer detection, particularly in epithelial subtypes. Ongoing clinical trials are further evaluating their diagnostic performance in larger cohorts.

OP-021

Theranostic potential of kinin B1 receptor targeting in glioblastoma therapy

S. Ghanaatgar[1], *M. Savard*[1], *M. Gagnon*[1], *D. Fortin*[2], *M. Lepage*[3], *B. Guérin*[3], *Y. Dory*[4], *F. Gobeil*[1];
[1]*Department of Pharmacology and Physiology, Faculty of Medicine and Health Sciences, Université de Sherbrooke, sherbrooke, QC, CANADA,* [2]*Department of Surgery, Universite´ de Sherbrooke, Sherbrooke, Quebec, Canada., sherbrooke, QC, CANADA,* [3]*Department of Medical Imaging and Radiation Sciences, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, Québec, CANADA., sherbrooke, QC, CANADA,* [4]*6Department of Chemistry, Faculté des Sciences, Université de Sherbrooke, Sherbrooke, Québec, Canada, Sherbrooke, QC, CANADA.*

Aim/Introduction: Glioblastoma (GBM), the most common and aggressive primary brain tumor in adults, remains uniformly fatal with no effective therapies available. The inducible kinin B1 receptors (B1R) may be considered attractive targets as biomarkers and for molecular imaging and therapeutic interventions in cancer. This is because they are frequently overexpressed on the surface of cancer cells and play a role in regulating cancer growth. In this study, we examined the theranostic potential of B1R in glioblastoma. ***Materials and Methods:*** Transcriptomic data from the CGGA and TCGA databases, along with IHC and immunoblotting, were used to examine B1R expression in human glioma specimens. The impact of B1R depletion (via shRNA knockdown) on the growth of F98 GBM cells was evaluated both in vitro, using MTT assays, and in vivo, by MRI monitoring of tumor progression in orthotopic rat GBM models using F98-wt and F98-B1R knockdown cells, respectively. Additionally, the theranostic potential of the B1R antagonist 64Cu/NOTA-R954 was tested via PET/CT imaging and targeted radiotherapy in F98wt GBM-bearing rats. ***Results:*** Transcriptomic data identified B1R upregulation in IDH-wildtype gliomas (the most clinically aggressive), correlating negatively with patient survival ($p=0.03$, $\beta=0.538$). Immunohistochemical studies confirmed elevated B1R protein expression in high-grade glioma specimens. MRI demonstrated an approximately 70% reduction in tumor growth in B1R-knockdown F98 models compared to wild-type controls. These in vivo findings were supported by MTT assay results, which showed reduced cell proliferation following B1R knockdown in vitro. PET/CT imaging with 64Cu/NOTA-R954 showed specific localization to GBM tumors, with no detectable uptake in contralateral brain regions. Therapeutic administration of 64Cu/NOTA-R954 —whether as a

single 7.5 mCi dose or fractionated 3.75 mCi doses—significantly prolonged survival compared to untreated controls. ***Conclusion:*** Our results support a role of B1R in GBM development, identifying it as a potential target for brain cancer theranostics. The use of 64Cu/NOTA-R954 yielded promising results in both imaging and therapeutic applications, highlighting the need for further investigation in the context of GBM.

OP-022

In vitro and in vivo preclinical side by side comparison of ^{177} Lu-DOTA-A1K2 and^{161}Tb-DOTA-A1K2 directed against mesothelin.

[1]*Univ. Grenoble Alpes, INSERM U1039, LRB, Grenoble, FRANCE,* [2]*CHU Grenoble Alpes, Department of Nuclear Medicine, LRB, Grenoble, FRANCE,* [3]*Departement Biomédical, Centre Scientifique de Monaco, Monaco, MONACO,* [4]*Univ. Grenoble Alpes, CNRS U5525, TIMC-Tree, Grenoble, FRANCE,* [5]*Institut Laue-Langevin, Grenoble, FRANCE.*

Aim/Introduction: Mesothelin (MSLN) is a 40 kDa glycoprotein overexpressed in several malignancies, such as triple-negative breast cancer (TNBC), while its expression in normal tissues is restricted to mesothelium. It has therefore emerged as a promising target for novel therapies, such as immunotoxins, antibody-drug conjugates or CAR-T cells. We hypothesized that, as an alternative strategy, the anti-MSLN single-domain antibody DOTA-A1K2 could be employed as a radio-theranostic agent and that ^{161}Tb might provide additional efficacy over ^{177}Lu, due to abundant Auger electron emission. The aim of this study was therefore to compare in vitro and in vivo the efficacy of ^{177}LuDOTA-A1K2 and ^{161}Tb-DOTA-A1K2. ***Materials and Methods:*** Radiolabeling was performed using n.c.a. ^{177}Lu (ITM radiopharma) and n.c.a. ^{161}Tb (provided by PRISMAP). Then, the efficacy of ^{177}Lu-DOTA-A1K2 and ^{161}Tb-DOTA-A1K2 was investigated using MDA-MB-231 human TNBC cell line, transfected either with MSLN or with LAC-z as negative control. In vitro, clonogenic assay was performed following 24h incubation of either ^{177}Lu-DOTA-A1K2 or 161Tb-DOTA-A1K2. In vivo, their therapeutic efficacy was evaluated up to 9 weeks following a single intravenous injection of 2, 5, 10, or 20 MBq of each radiotracer (n=6-12 per group). ***Results:*** Radiolabeling of DOTA-A1K2 was successfully performed with radiochemical purity >95% for both ^{177}Lu and ^{161}Tb. In vitro, both ^{177}Lu-DOTA-A1K2 and ^{161}Tb-DOTA-A1K2 were found to inhibit colony formation. However, this effect was significantly higher for 161Tb-DOTA-A1K2, with 88% and 78% reduction in colony number at 1 and 0.3 MBq/mL, in comparison to 35% and 24% for ^{177}Lu-DOTA-A1K2 ($P < 0.001$). In vivo, both ^{177}Lu-DOTA-A1K2 and ^{161}Tb-DOTA-A1K2 were found to inhibit tumor growth at 5, 10 or 20 MBq ($p < 0.001$ vs vehicle). However, unlike what was observed in vitro, ^{161}Tb-DOTA-A1K2 was not found to be more potent than ^{177}Lu-DOTA-A1K2 (p=NS). ***Conclusion:*** In vitro, DOTA-A1K2 successfully reduced the viability of MSNL+ cells and, as hypothesized, ^{161}Tb-DOTA-A1K2 was significantly more potent than ^{177}Lu-DOTA-A1K2. In vivo efficacy of DOTA-A1K2 was also demonstrated. However, similar effects were observed using ^{177}Lu and ^{161}Tb. Additional experiments will be conducted to investigate this discrepancy. It might be attributable to mesothelin shedding in vivo, resulting in its release and preventing Auger electrons to reach radiation-sensitive parts of tumor cells, while beta- particles with longer range, might retain this ability. Acknowledgements: This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No101008571 (PRISMAP), INCA_16111 (PLBIO21-243), Fondation ARC and ANR-11-INBS-0006 (France Life Imaging).

OP-023

Radiosynthesis and Preclinical Evaluation of ^{77}Br-hGTS13 for Non-Small Cell Lung Cancer Treatment

R. Malek, *P. Cheung, A. Moses, S. Abdi, M. Landry, C. Beinat;*
Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: System xc- is an amino acid antiporter mediating the exchange of cystine for glutamate. It is overexpressed in multiple cancers such as glioma, pancreatic cancer and Non-Small Cell Lung Cancer (NSCLC) and is associated with cancer cell proliferation, invasion, metastasis, development of chemo-resistance and poor survival. We previously reported [18F]hGTS13 a second-generation radiotracer targeting system xc- showing an improved tumour uptake in NSCLC rat models, and lower pancreas and kidney retention compared to the reference [18F]FSPG. We report here the development and preclinical evaluation of the therapeutic counterpart [77Br]hGTS13 labelled with the Auger electron emitter bromine 77 [77Br]. ***Materials and Methods:*** We synthesized [77Br]hGTS13 by the nucleophilic displacement of the tosyl group by [77Br], followed by a deprotection with HCl. We evaluated the product's stability in human serum by incubation at 37 °C for 30 and 60 min. We then measured its cellular uptake over 0.5, 1, 2 and 4h in the NSCLC cell lines, A549 and H460. We assessed its specificity for system xc- in A549 and H460, by competition with the natural transporter substrate L-glutamic acid, and the system xc--specific inhibitor erastin2 with final well concentrations of 1 mM and 10 µM, respectively. Cells were preincubated for 10 min with the competitor in HBSS, before adding [77Br]hGTS13 (~48 kBq/well) and incubating for 1h. Cells were then lysed and the cell-associated activity counted on a γ-counter and protein content determined using the bicinchoninic acid assay. ***Results:*** [77Br]hGTS13 was obtained with a non-decay corrected radiochemical yield (RCY) at the end of synthesis of 24.2 ± 7.4% (n=7), and in 99% radiochemical purity. Analytical HPLC showed the product remained 96 and 93% intact in human serum after 30 and 60 min incubation, respectively. The cellular uptake of [77Br] hGTS13 peaked at 1 hour in H460 cells with 549 ± 72% uptake per mg protein and then decreased over time. In A549 cells, [77Br]hGTS13 uptake reaches a plateau after 1h then slowly starts decreasing after 2h. The competition assay in A549 cells showed that L-glutamic acid and erastin2 reduced [77Br]hGTS13 uptake by 91 and 98% respectively. In H460 cells, all competitors blocked over 94% of [77Br]hGTS13 uptake. ***Conclusion:*** We successfully radiolabelled 77Br-hGTS13 and showed its stability in human serum. Competition assay proves that our therapeutic counterpart remains a substrate for system xc-. We are now studying its biodistribution in rat models of NSCLC and will then assess its therapeutic efficacy.

Aim/Introduction: Neurotensin receptor 1 (NTSR1) has been demonstrated to play a crucial role in the tumorigenesis, proliferation, invasion, and metastasis of various malignancies. It was significantly overexpressed in multiple tumors and emerged as a promising molecular target for clinical diagnosis and therapy. In this study, we designed and synthesized five novel NTSR1-targeted radiopharmaceuticals and evaluated their diagnosis and radiotherapy potential in H1299 xenograft tumor models. ***Materials and Methods:*** Five structurally distinct radiopharmaceuticals were designed, synthesized, and radiolabeled with ^{68}Ga or ^{177}Lu. The radiolabeling efficiency and radiochemical purity (RCP) were determined using Radio-HPLC. The stability, log P values, and in vivo blood clearance half-life were

systematically evaluated. Micro-PET/CT imaging was performed to screen for optimal diagnostic probes. Additionally, micro-SPECT/CT imaging, biodistribution studies, and therapeutic efficacy assessments were conducted to identify suitable radiotherapeutic ^{177}Lu labeled-agents and determine the optimal dosages. ***Results:*** All five radiopharmaceuticals were successfully synthesized with high RCP (>95%). In vitro stability assays confirmed that all probes maintained >95% RCP after 3 h incubation in saline and FBS. Log P measurements indicated favorable hydrophilicity for all probes. Pharmacokinetic analysis revealed significant differences in blood clearance half-lives (Probe 1-5): 3.83 ± 0.76 h, 4.14 ± 0.75 h, 36.0 ± 7.2 min, 29.0 ± 7.0 min, but the data for Probe 5 were not detected yet. Micro-PET/CT imaging demonstrated that the tumor uptake of five probes (Probe 1-5) was 9.50 ± 0.36 %ID/g, 9.17 ± 1.26 %ID/g, 7.77 ± 1.07 %ID/g, 3.97 ± 1.42 %ID/g, and 2.87 ± 0.81 %ID/g. The T/M (Probe 1-5) were 3.17 ± 0.52, 1.63 ± 0.29, 8.66 ± 2.10, 7.46 ± 2.72, and 5.42 ± 2.66. Probe 3 showed significantly high tumor uptake and T/M. Following ^{177}Lu labeling, SPECT imaging of Probes 1 and 2 revealed prolonged tumor retention. Biodistribution studies at 48 h post-injection indicated that the tumor uptake of two probes was 8.12 ± 0.54 %ID/g (Probe 1) and 10.78 ± 1.97 %ID/g (Probe 2), and Probe 1 had superior clearance liver: 0.75 ± 0.12 %ID/g (Probe 1) vs 3.74 ± 0.44 %ID/g (Probe 2). Further long-term biodistribution and therapeutic efficacy studies are ongoing. ***Conclusion:*** We successfully developed five NTSR1-targeted radiopharmaceuticals. ^{68}Ga-labeled Probe 3 emerged as the most promising PET imaging agent, demonstrating high tumor uptake and excellent T/M contrast at 2 h post-injection. Additionally, ^{177}Lu-labeled Probes 1 and 2 exhibited favorable in vivo pharmacokinetics, supporting their potential for targeted radionuclide therapy.

Selective Killing of Tumor Associated Macrophages with a [^{177}Lu]Lu-Nanomedicine Unlocks Checkpoint Inhibition

J. Cleland[1], *S. S. Minami*[2], *M. Paborji*[2], *W. Thomas*[2], *X. Li*[2], *H. Roth*[2], *M. Feng*[2], *A. Brus*[3], *R. Stagaard*[3], *S. Al-Haidar*[3], *N. Nielsen*[3], *M. A. Islam*[3];
[1]*Ironfist Therapeutics, Redwood City, CA, UNITED STATES OF AMERICA,* [2]*Programmable Medicine, Redwood City, CA, UNITED STATES OF AMERICA,* [3]*Minerva Imaging ApS, Ølstykke, DENMARK.*

Aim/Introduction: Tumor associated macrophages (TAMs) inhibit T cell engagement and reduce the efficacy of checkpoint inhibitors. Hydroxyl dendrimers (HDs), novel nanomedicines known to selectively target activated macrophages, conjugated with [^{64}Cu]Cu-NOTA without a targeting ligand, demonstrated significant tumor uptake by PET imaging in the 4T1 triple negative breast cancer model. This study next aimed to optimize the chelator for ^{177}Lu and demonstrate the ability of [^{177}Lu]Lu-HDs to unlock checkpoint inhibition and have therapeutic efficacy in the 4T1 tumor model. ***Materials and Methods:*** NOTA, NODAGA, and DOTA conjugates of HDs were synthesized and ^{177}Lu chelation was performed. Stability of the [^{177}Lu]Lu-HDs was evaluated in buffer and plasma. In vivo and ex vivo biodistribution in mice was assessed after a single intravenous administration by SPECT/CT imaging 24 and 96 h after injection in tumor mice and by gamma counting of excised tissues at 24 and 72 h after injection in normal healthy mice. For the efficacy study, mice were implanted subcutaneously with 4T1 cells, known to be unresponsive to anti-PD-1 therapy, and once tumors were ~130 mm^3, mice were treated with either vehicle, 10 mg/kg anti-PD-1 antibody, or [^{177}Lu]Lu-DOTA-HD alone (4.9, 10.1 or 14.9 MBq) or in combination with anti-PD-1 antibody. ***Results:*** ^{177}Lu incorporation was 46.6%, 93.0%, and 98.6% in NOTA, NODAGA, and DOTA-HDs, respectively. In buffer or mouse plasma after 72h at 37°C, [^{177}Lu]Lu-DOTA-HDs radiochemical purity was unchanged (98%), while the other HDs had decreased purity. Ex vivo biodistribution in normal healthy mice indicated the highest uptake of [^{177}Lu]Lu-NOTA-HD in kidney and bone (most likely free ^{177}Lu), whereas [^{177}Lu]Lu-NODAGA-HD and [^{177}Lu]Lu-DOTA-HD had higher uptake in liver and spleen. Treatment with doses of up to 14.9 MBq [^{177}Lu]Lu-DOTA-HD appeared to halt tumor progression and in combination with anti-PD-1 antibody resulted in tumor regression. SPECT/CT scans confirmed tumor uptake and accumulation over time as observed with [^{64}Cu]Cu-NOTA-HD. ***Conclusion:*** These results demonstrated the potential of selective TAM killing as a therapeutic approach in oncology, especially in checkpoint inhibitor resistant tumors. Additional preclinical efficacy studies with [^{177}Lu]Lu-DOTA-HD are planned to include PSMA-negative prostate cancer, which lacks a clear target and remains an unmet medical need.

OP-026

Application of Automatic Organ Segmentation for Audit and Optimisation in FDG PET/CT

L. Bonney[1,2], *K. M. Bradley*[3], *A. B. Hassan*[2], *D. R. McGowan*[1,4];
[1]*Department of Medical Physics and Clinical Engineering, Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM,* [2]*Sir William Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM,* [3]*Wales Research and Diagnostic Positron Emission Tomography Centre (PETIC), University Hospital of Wales, Cardiff, UNITED KINGDOM,* [4]*Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Automatic deep-learning based segmentation methods for organs are now well established and known to be highly accurate. This work enables region generation at a much larger scale for lower resource cost than previously possible. This work looked to explore using automatic organ segmentation for image quality control in a large retrospective PET/CT dataset (N=1,000, 3,045 scans). ***Materials and Methods:*** A consecutive single centre patient cohort of 1,000 adult patients who received an FDG PET/CT scan were selected. All PET/CT scans these patients had received in a ten-year period at the centre were included in the analysis (3,045 scans). All scans were acquired on a GE D690 or D710 PET/CT scanner with consistent protocols. Organ segmentation was generated using Total Segmentator [1]. Regions were eroded by 10mm to minimise edge effects and motion artefacts. Methods were designed to have low levels of user input or data cleaning, using a large dataset to mitigate errors. This work validated this approach against published quantitative results in the liver, before exploring more novel areas. ***Results:*** Results in liver reproduced standard results from literature that used more time intensive data annotation methods using spherical volumes of interest amongst other results mean population SUV_{MEAN}=2.09 [2,3]. Automated methods enabled measurement for volumes of interest beyond liver at low resource cost. Notably distributions for organs other than liver including kidneys and lung were relatively narrow and of comparable width to liver [Liver: mean=2.09, std=0.41; Kidney: mean=2.56, std=0.63; Lung: mean=0.51, std=0.18]. Patient groups were compared. An interesting significant difference was observed in standard deviation of SUV in the gluteus maximus between sexes [Male: 0.13, Female: 0.16] with the higher noise observed in women likely explained by sex-based differences in body fat distribution. Application of the measured distributions demonstrated the ability to detect height and weight data entry errors. ***Conclusion:*** Automated organ segmentation methods can enable automated image quality audit in large datasets,

with minimal data cleaning or selection required. This enabled measurement of SUV_{MEAN} distribution for a number of regions little studied before and has potential applications in optimisation, harmonisation and quality control. With the benefit of including data from a representative patient population. The next stage of this work is to extend to more complex image measurements and consider impact in longitudinal data. ***References:*** 1. Wasserthal et al., Radiol Artif Intell., 5:5 (2023)2. OP-027

A hybrid deep learning model for tumor and pulmonary nodule segmentation in non-small cell lung cancer using MedSAM.

H. Habchi[1], *B. Daoud*[2], *S. Mensi*[3,4], *K. Chatti*[5];
[1]*Department of Biophysics and Medical Imaging, Higher Institute of Medical Technologies of Tunis, University of Tunis El Manar, Tunis, TUNISIA,* [2]*University of Texas, MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA,* [3]*Nuclear Medicine department, CHU Sahloul, Sousse, TUNISIA,* [4]*Department of biophysics, School of medicine of Sousse, University of Sousse, Sousse, TUNISIA,* [5]*School of Medicine of Monastir, University of Monastir, Monastir, TUNISIA.*

Aim/Introduction: The segmentation of lung tumor lesions and pulmonary nodules in patients with non-small cell lung cancer (NSCLC) within ^{18}F-FDG PET-CT imaging plays a vital role in choosing the right treatment. However, it is difficult to accurately define the target areas because breathing movements lead to noticeable changes in the shape and size of the tumor between PET and CT scans. Additionally, undetectability of small pulmonary nodules can affect the accuracy of treatment decisions, so complicating the diagnosis of their benign or malignant character. To deal with these challenges, the aim of this study was to develop a specific deep learning model for automatic segmentation of lung tumors and pulmonary nodules structures from PET-CT images. ***Materials and Methods:*** The dataset includes 188 ^{18}F-FDG PET-CT scans of NSCLC patients, with manually segmented tumor lesions (lung tumor and pulmonary nodules) using the PET Tumor Segmentation extension in 3D Slicer and confirmed by our nuclear doctor. The collection includes data from 168 patients who took part in the autoPET MICCAI 2022 challenge and were published in the Cancer Imaging Archive, alongside an additional 20 patients from our institution. We developed a novel hybrid model that integrates PET-CT and CT images for improved medical image segmentation. All the individual input modalities are processed through the Segment Anything in Medical Images (medSAM) model separately to extract features, then merged using an adaptively weighted ensemble approach to produce a more complete segmentation output while using two separate loss functions for joint learning. We then use the same process with nnU-Net and train the individual PET-CT images with medSAM and nnU-Net to evaluate performance. The autoPET data were randomly divided into under 5-fold cross-validation with 100 training, 34 validation, and 34 test PET-CTs, while our institution's data were used as external testing data. The accuracy of the four models was evaluated using the Dice similarity coefficient (DSC) and surface DSC at 2 mm (sDSC2mm). ***Results:*** Hybrid models segmented the tumor lesions more accurately compared with the individual models, and hybrid-medSAM was higher than hybrid-nnUnet. The average DSC values for hybrid-medSAM, hybrid-nnUnet, individual-medSAM, and individual-nnUnet were 0.80±0.016, 0.77±0.047, 0.72±0.018, and 0.71±0.057, respectively. The average sDSC2mm values for hybrid-medSAM, hybrid-nnUnet, individual-medSAM, and individual-nnUnet were 0.83±0.021, 0.81±0.052, 0.76±0.027, and 0.77±0.013, respectively. ***Conclusion:*** Our hybrid-medSAM model is effective for segmenting the tumor lesions in PET-CT images. The proposed model holds promise for its potential application in various cancer types.

OP-028

How accurately can artificial intelligence identify metabolic tumour volume (MTV) in large B-cell lymphoma on ^{18}F-FDG PET/CT? Validation of a Deep Learning tool in a large B-cell lymphoma patient cohort

M. Santoro[1], *S. Proto*[2], *A. Farolfi*[3], *R. Ussia*[3], *S. Fanti*[3,2], *L. Strigari*[1];
[1]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Automated segmentation tools for identifying metabolic tumour volume (MTVs) and extracting related features hold significant potential for accelerating standardization and harmonization in multicentric studies. They also enable the broader application of radiomics to predict treatment response and clinical outcomes. A preliminary research version of a commercial deep learning(DL) tool for automatic MTV segmentation on ^{18}F-FDG PET/CT was implemented in our Institution. An independent external validation was conducted using a large monocentric cohort of patients with large B-cell lymphoma, examined across multiple PET/CT scanner vendors. ***Materials and Methods:*** Baseline PET/CT images from different scanners of 94 consecutive patients undergoing CAR-T therapy were analysed. Two experienced nuclear medicine physicians manually delineated MTVs using either freehand contours(MTV_m) or a fixed SUV threshold of 4.0(MTV_{th}). DL-based automatic segmentations(MTV_a) were performed and refined using the liver SUV_{max} as a reference. Inter-method agreement was assessed using relative volume differences, Dice Similarity Coefficient(DSC), and Mean Distance to Agreement(MDA), with results stratified by liver SUV_{max} ranges, i.e., 0≤liver SUV_{max}<4 and liver SUV_{max}≥4. The time required for DL-based segmentation was recorded, and the reproducibility of MTV_a produced by the DL tool was evaluated with the repositioning of the liver volume of interest by two independent operators for the liver SUV_{max} determination. ***Results:*** Based on a total of 188 MTVs, the mean liver SUV_{max} was 3.2±1.03. The median[range] of MTVa and MTV_m or MTV_{th} were 209.1[2.9-8895.3] and 142.4[2.9-7936.3] cm^3, respectively. The mean DSC of MTV_a compared to MTV_m or MTV_{th} was 0.72[0.35-0.93] and 0.68[0.30-0.91], respectively, for 0≤liver SUV_{max}<4. In patients with metastatic liver disease, the mean DSC was lower, i.e., 0.54[0.50-0.58] and 0.70[0.57-0.82] for MTV_a versus MTV_m and MTV_a versus MTV_{th} respectively. When MTV_a underestimated MTV_m or MTV_{th}, the median MDA was 11.5 mm and 5.4 mm, respectively. In other cases, median MDA values resulted in 4.8 mm and 8.58 mm for MTV_a versus MTV_m and MTV_a versus MTV_{th}, respectively. DL-based segmentation was efficient, with a mean[range] processing time of 33[27-40] seconds per patient. Reproducibility of MTV_a between operators was within 10%. ***Conclusion:*** A good agreement between DL-based and expert segmentations was found, with greater divergence at smaller MTVs. The DL-based software speed, reproducibility and level of agreement with expert contours support its potential for future clinical investigations.

OP-029

Evaluation of Single-Channel PET and Dual-Channel PET/CT nnU-Net Deep Learning 3D Segmentations from Diffuse Large B-Cell Lymphoma to Follicular Lymphoma

M. Luo[1,2], *F. Yousefirizi*[2], *C. Gowdy*[3], *J. O*[4], *A. Rahmim*[1,2];
[1]*Faculty of Medicine, The University of British Columbia, Vancouver, BC, CANADA,* [2]*BC Cancer Research Centre, Vancouver, BC, CANADA,* [3]*BC Children's Hospital, Vancouver, BC, CANADA,* [4]*College of Medicine, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Accurate segmentation of lymphoma lesions in PET/CT imaging is crucial for the quantification of imaging-based biomarkers, such as total metabolic tumor volume (TMTV). Many studies examining segmentation approaches have focused predominantly on the most common subtypes of lymphoma, including Diffuse Large B-Cell Lymphoma (DLBCL). Although TMTV quantification is well studied, limited research has specifically addressed its application in follicular lymphoma (FL), despite the heterogeneous ^{18}F-FDG uptake patterns commonly encountered in clinical practice and the known limitations of visual assessment in reliably differentiating FL from DLBCL. This study aims to evaluate the performance of single-channel PET and dual-channel PET/CT nnU-Net trained on DLBCL for segmenting lesions in FL. ***Materials and Methods:*** Single- and dual-channel nnU-Net models were trained using a 3D full-resolution architecture with 5-fold cross-validation. Training was performed on a multi-centre dataset of 258 DLBCL cases (n=41 from Center I and n=217 from Center II). For dual-channel input, CT images were resampled using linear interpolation to match the spatial dimensions of PET images. Nuclear medicine physicians provided ground truth reference segmentations. Models were evaluated on 1) 19 FL cases from FOLL12 and RELEVANCE trials benchmarked by Boellaard et al.; and 2) 33 Primary Mediastinal B-Cell Lymphoma (PMBCL) cases from Center I. ***Results:*** In 5-fold cross-validation on DLBCL, the single-channel model achieved a mean Dice score of 0.65±0.05 with a mean intra-fold Dice standard deviation of 0.32 (precision/recall 0.87/0.71). The dual-channel model yielded similar performances with a mean Dice score of 0.65±0.04 with a mean intra-fold Dice standard deviation of 0.33 (precision/recall 0.85/0.72). On FL, mean Dice scores of 0.53±0.25 (precision/recall 0.37/0.81; single-channel) and 0.52±0.29 (precision/recall 0.47/0.60; dual-channel) were achieved. On PMBCL, mean Dice scores of 0.60±0.41 (precision/recall 0.80/0.93; single-channel) and 0.62±0.41 (precision/recall 0.86/0.90; dual-channel) were achieved. Generally, mean relative error (RE) decreased as ground truth lesion volume increased (single-channel: RE 6.34 (0.216mL-21.607mL) to RE 0.27 (501.251mL-5920.354mL); dual-channel: RE 3.75 (0.216mL-21.607mL) to RE 0.22 (501.251mL-5920.354mL)). ***Conclusion:*** Both single- and dual-channel nnU-Net 3D segmentation models demonstrated similar performance with reasonable generalizability to FL. The decrease in performance on FL cases may be due to variability in FDG avidity of FL. These findings suggest that more resource-efficient single-channel models may achieve comparable performance and that segmentation models trained on DLBCL cases may be a good starting point for extension to other lymphoma subtypes.

OP-030

Deep Learning-Driven Automated Segmentation for Mantle Cell Lymphoma in ^{18}F-FDG PET: Towards Prognostic and Clinical Applications

Z. Zhang[1], *W. Xu*[2], *C. Jiang*[1], *H. Huang*[1], *X. Zheng*[2], *Y. Teng*[3], *Y. Liu*[1], *Z. Jiang*[4], *J. Xu*[3], *S. Liu*[2], *R. Tian*[1];
[1]West China Hospital of Sichuan University, Cheng Du, CHINA, [2]School of Computer Science, Nanjing University of Posts and Telecommunications, Nanjing, CHINA, [3]Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nan jing, CHINA, [4]West China Biomedical Big Data Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China, Cheng Du, CHINA.

Aim/Introduction: This study aims to develop and validate an automated deep learning model for segmenting mantle cell lymphoma (MCL) lesions in 18F-FDG-PET images and to assess its prognostic value. ***Materials and Methods:*** A total of 169 MCL patients from two independent centers (118 patients from West China Hospital and 51 patients from Nanjing Drum Tower Hospital) were included in the study. All patients had histologically confirmed MCL, underwent pretherapy ^{18}F-FDG PET/CT scans, and received R-CHOP-like regimens. A deep learning model based on the nnU-Net architecture was employed to segment MCL lesions, and the derived total metabolic tumor volume (TMTV) was evaluated for prognostic significance. Model performance was evaluated using standard metrics, with the prognostic value of TMTV validated in an external cohort. ***Results:*** Predicted total metabolic tumor volume (pTMTV) demonstrated strong agreement with ground truth TMTV (gtTMTV) in both training and validation cohorts, as shown by Bland-Altman analysis, with biases of −22.9 (−394.1 to 348.3) cm3 in the training cohort and −2.0 (−698.9 to 694.8) cm3 in the validation cohort. Predicted TMTV was identified as an independent predictor of Disease-Free Survival (DFS) in multivariate analysis (HR = 1.001, p = 0.038). The cut-off value for pTMTV to predict DFS was 1068.5 cm^3. Predicted TMTV was significantly associated with DFS, with high pTMTV correlating with poorer DFS (p< 0.05). ***Conclusion:*** The nnU-Net-based automated segmentation model for MCL lesions in FDG-PET images is a reliable and precise tool for TMTV assessment, offering potential to enhance clinical decision-making and prognosis prediction in MCL patients. Funding: This study was supported by the 1·3·5 project for disciplines of excellence, West China Hospital, Sichuan University (grant ZYAI24014).

OP-031

Deep-Learning blind-spots in PET/CT tumour segmentation: validating different deep-learning tumour segmentation models against Nuclear Medicine Physicians/Radiologists and describing their limitations.

D. Lim[1], *N. Leow*[2], *C. Tang*[1], *W. Chua*[1], *W. Tham*[1], *Y. Khor*[1], *D. Ng*[1], *W. Lam*[1];
[1]Singapore General Hospital, Department of Nuclear Medicine and Molecular Imaging, Singapore, SINGAPORE, [2]National University Hospital, Department of Diagnostic Imaging, Singapore, SINGAPORE.

Aim/Introduction: Several imaging biomarkers are shown to correlate well with treatment outcomes and disease prognostication[1]. These biomarkers require tumour segmentation which is tedious to achieve prospectively during reporting. Deep learning models have been developed to improve efficiency of segmentation and generate biomarkers. We validated two deep learning based models on 477 F-18 FDG PET/CTs performed in our institutions on lymphoma patients (n = 216). DICE scores comparing the model performance against Nuclear Medicine Physicians/Radiologists were calculated for 15% of the scans which were randomly selected. The deep learning models validated included a publicly available TMTV segmentation model ("TMTV-net"), and a modified CT-based segmentation model ("Total Segmentator" with SUV thresholding applied. We also present examples of lesions missed by the models and the false positives. ***Materials and Methods:*** DICOM images of 477 F-18 FDG PET/CT studies for 216 patients with lymphoma were extracted. All studies were performed on scanners of the same model and used the same reconstruction methods. A model was developed to segment lesions above the threshold of SUV 4.0 and the output was put through the deep learning model "TotalSegmentator" to exclude sites of physiological FDG-uptake. This model and a publicly available "TMTV-net" were applied on the dataset. For validation, 65 studies (15%) were randomly selected. Manual segmentation of all FDG-avid lesions were performed by Nuclear Medicine Physicians/Radiologists. The DICE score for each model was calculated. Lesions missed or wrongly segmented were tabulated. ***Results:*** The DICE score for TMTV-net was 0.782 on our institution scans. The DICE score for the SUV4.0 thresholding based model was 0.20, likely due to inability to exclude sites of physiological uptake. Examples of false positive lesions segmented by TMTV-net included: IV cannula site and post surgical changes. The model showed incomplete segmentations for large lesions. There was under-segmentation of marrow disease and small volume FDG-avid nodes in patients with extensive nodal disease. The thresholding-based model had more false positives

including: edges of the brain, sites of skin contamination, brown fat and muscle uptake. ***Conclusion:*** Deep learning models can improve efficiency in reporting, however externally developed models run the risk of exhibiting variable performance when applied in a different environment. Thus validation is crucial before incorporation into daily practice. Understanding a model's performance is critical to build upon existing models and to allow for safe use of models in clinical care.

OP-032

Deep-Learning-Based Automated Delineation of Non-Hodgkin Lymphoma in [^{18}F]FDG PET/CT

P. Nikulin[1], *S. Hoberück*[2], *F. Hofheinz*[1], *J. Maus*[1], *C. Hanoun*[3], *A. Hüttmann*[3], *U. Dührsen*[3], *K. Kopka*[1], *J. Kotzerke*[2], *R. A. Bundschuh*[2], *A. Braune*[1];
[1]*Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY,* [2]*University Hospital Carl Gustav Carus, Department of Nuclear Medicine, Dresden, GERMANY,* [3]*University Hospital Essen, Department of Hematology, Essen, GERMANY.*

Aim/Introduction: Total metabolic tumor volume (TMTV) is a significant prognostic factor in patients with aggressive non-Hodgkin lymphoma. Extraction of image-based biomarkers however requires delineation of all tumor lesions which is non-trivial, time-consuming, and error-prone with the currently available semi-automated methods. The goal of this study was the development and evaluation of a deep-learning-based method for automated delineation of lymphoma in [^{18}F]FDG PET/CT. ***Materials and Methods:*** Automated delineation was performed with a 3D U-Net convolutional neural network (CNN) developed from scratch using nnU-Net framework [1]. 1133 [^{18}F] FDG PET/CT scans of non-Hodgkin lymphoma patients acquired within the PETAL prospective multicenter study [2] were used for network training and testing using a 5-fold cross-validation scheme. The ground truth delineations were developed iteratively by an experienced observer with assistance of intermediate CNN models trained on smaller subsets of the data. All tumor lesions were included regardless of their volume or maximum uptake. ***Results:*** The derived CNN models are capable of accurate delineation, achieving a Dice similarity coefficient of 0.889. The dataset included 6602 tumor lesions which were detected with sensitivity of 0.671 and positive predictive value of 0.809. The average (median) volume of missed lesions was 3.3 (0.5) ml. After exclusion of the outliers (worst 1%), manually and automatically derived TMTVs were highly correlated with R2=0.983 while the mean absolute error of TMTV determination was 13.1 ml with the average TMTV of 133.4 ml. ***Conclusion:*** In this work, we present a CNN able to perform delineation of tumor lesions in lymphoma with only minimal manual corrections possibly required. It thus is able to accelerate study data evaluation in quantitative PET and does also have potential for supervised clinical application. ***References:*** [1] Isensee, F. et al. Aim/Introduction: Assisted tumour segmentation in PET/CT is critical for automated biomarker extraction. Despite progress with deep-learning models, dataset construction still relies on blindly accruing large numbers of scans followed by manual segmentation — an inefficient process that burdens clinicians. Deep-learning models only generalize to variations seen during training, making variability critical. By selectively targeting cases that introduce new variations, we can efficiently fill gaps in the training data. Here, we propose Tumour Occurrence Maps (TOMs) — a data-driven framework to characterise tumour spatial distributions and guide efficient training dataset construction. ***Materials and Methods:*** We retrospectively collected 3,857 [18F] FDG-PET images: 170 melanoma cases, 713 lung cancer cases, 2,866 lymphoma cases, and 108 breast cancer cases. Nuclear medicine physicians were instructed to manually segment the entire tumour load on each scan. We trained 4 separate segmentation models — one per cancer type — using nnU-Net with the DA5 trainer. The models' generalizability was evaluated by testing each model on the other tumour types. Performance was quantified using lesion-level sensitivity. TOMs were generated by first obtaining body masks using MOOSE [1]. Tumour segmentations and body masks were registered to a common anatomical template with affine registration, producing three-dimensional voxel-wise probability maps. For each of the 4 TOMs, the proportion of non-zero voxels (%) was computed as a tumour spatial coverage metric. ***Results:*** The lung cancer model achieved the highest cross-cancer sensitivity (72%) with a TOM coverage of 46%, followed by the melanoma model (68% sensitivity, 28% coverage) and the lymphoma model (66% sensitivity, 90% coverage). The breast cancer model showed the lowest performance (45% sensitivity, 17% coverage). However, the non-breast cancer models yielded strong sensitivity on breast cancer cases: melanoma (86%), lung (85%), and lymphoma (83%). This asymmetry suggests that generalisability is driven more by spatial coverage than cancer type. Models trained on anatomically diverse tumours effectively captured breast cancer lesions despite not encountering them during training. In contrast, the breast model's restricted coverage limited its ability to detect lesions beyond its learned distribution. ***Conclusion:*** This study demonstrated the utility of TOMs to quantify anatomical variability of tumours in training datasets. Broader spatial coverage, rather than cancer type, emerged as essential in cross-cancer model generalisability, supporting TOMs as a tool to efficiently curate more variable training datasets for tumour segmentation. ***References:*** [1] Sundar et al. "Fully automated, semantic segmentation of whole-body ^{18}F-FDG PET/CT images based on data-centric artificial intelligence." JNM 63.12 (2022): 1941-1948.

Gaze-Guided Clinician-in-the-Loop AI Platform for total tumor volume segmentation in PET/CT and SPECT/CT

R. Hamidpour[1], *A. Toosi*[1,2], *F. Yousefirizi*[1], *Y. Salimi*[3], *H. Zaidi*[3], *C. Uribe*[1,2], *A. Rahmim*[1,2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA,* [3]*Geneva University Hospital, Geneva, SWITZERLAND.*

Aim/Introduction: Total-Tumor-Volume(TTV) has emerged as a valuable prognostic biomarker across various cancer types, including PSMA PET/CT, and is needed for dosimetry in SPECT/CT imaging. Routine tumor delineation is an excessive burden on

clinicians and is not routinely performed. Such delineations can also be used to generate additional quantitative features (e.g., radiomics analyses). Meanwhile, interactive foundation models such as MedSAM and nnInteractive can provide strong performance on segmenting tumors. Still, mouse-based interaction models can induce user fatigue in large-scale dataset annotations. In this study, we propose and publicly-share a Gaze-Guided Clinician-in-the-Loop AI platform for TTV segmentations to facilitate feasible, routine quantification guided by clinicians looking at regions-of-interests (ROIs). We compare the results of two foundation models over SPECT/CT and PET/CT imaging, with Gaze-Tracking(GaTr) and Bounding-box(Bbox) prompt-types. ***Materials and Methods:*** We implemented our pipeline for MedSAM and nnInteractive, enabling interactive 2D and 3D segmentations, as an extension to the popular 3D-Slicer platform to simplify the process for public use. The 3D-Slicer extensions were integrated with the GaTr tool by connecting a standard Webcam(60 Frame-Rate-per-Seconds) to the GaTr server and then communicating with the Software Development Kit(SDK). When the physician is looking at a ROI, the GaTr server catches the point over the screen, and our extension retrieves it through the SDK. We utilize this point as a center-of-a-Bbox or a point-prompt to our models. We assessed our study via zero-shot learning to evaluate pipeline performance for 177Lu-DOTATATE-SPECT/CT and 18F-PSMA-PET/CT. ***Results:*** As initial assessment, we compared two prompt-types with nnInteractive over 10 patients from each modality, focusing on the difficult task of segmenting TTV of PSMA-PET and DOTATATE-SPECT. In terms of segmentation-accuracy and interaction-time, nnInteractive for DOTATATE-SPECT/CT with Bbox achieved a Dice-Score(DS) of 0.63+-0.15, while with GaTr, DS over the same dataset was 0.62+-0.17. Meanwhile, the interaction-time median on each prompt-type was 5.65+-2.8s and 0.28+-0.14s, respectively. On the PSMA cohort, nnInteractive achieved DS of 4.56+-1.25s (Bbox) and 0.67+-0.15s(GaTr) while the interaction-time was 4.3+-2.5s(Bbox) and 0.25+-0.02s(GaTr). By contrast, MedSAM with Bbox performed better for SPECT/CT with DS 0.38+-0.38 while DS over PET/CT images was only 0.21+-0.16. MedSAM median-interaction-time was 5.59+-2.04s(SPECT/CT) and 6.72+-1.73s(PET/CT). ***Conclusion:*** Our publicly-shared platform enables significantly-faster segmentations via gaze-tracking coupled with state-of-the-art AI solutions. Researchers and clinicians can take advantage of this system for clinical trials and, ultimately, in routine-care to annotate various types of lesions, cancers, and modalities for quantification, prognosis and dosimetry.

Sentinel Lymph Node Biopsy in Breast Cancer: Guideline Updates and Real-World Insights

F. Silva-Ribeiro, *B. Martins, C. V. Pinto, V. C. Sousa;*
Unidade Local de Saúde de Loures / Odivelas, Lisboa, PORTUGAL.

Aim/Introduction: Sentinel lymph node biopsy (SLNB) is the conventional approach for assessing nodal involvement in early-stage breast cancer patients with clinically negative nodes. SOUND and INSEMA trials indicate that omitting SLNB does not compromise invasive disease-free survival. This prompted reevaluation reflected in the April 2025 American Society of Clinical Oncology (ASCO) guideline, supporting omission of SLNB in postmenopausal women ≥50 years, clinically T1, Nottingham grade 1-2, hormone receptor-positive, HER2-negative breast cancer. This study reflects real-world evidence from our institution. ***Materials and Methods:*** Demographic data, tumor profiles, treatment data, incidence of pathological positive lymph nodes and follow-up information (registry of events like breast recurrence, axillary recurrence, distant recurrence and death) of breast cancer patients who underwent lymphoscintigraphy between January 2012 and December 2019, were retrospectively collected and analyzed. This ensured a median (IQR) follow-up of 8 years (6.0-9.8). A subgroup analysis was conducted based on ASCO recommendations for SLNB omission. ***Results:*** Over the eight-year period, 532 breast lymphoscintigraphies were performed, corresponding to 507 patients, with a median age of 62.0 (range: 28-94) of which four were male. Invasive breast cancer was observed in 90.2% (480/532) of cases, of which 265 were cT1, 191 cT2 and 24 >cT2. 86.0% (413/480) were hormone receptor-positive, 86.5% were HER2-negative and, 83.1% (399/480) were low or medium grade tumours (G1: 27.3%, G2: 55.8%, G3 13.3%). Subgroup analysis included 131/507 patients (25.8%) who met SLNB eviction criteria, with median (IQR) age of 65.0 (59.5-73.0). In this subgroup, sentinel lymph node positivity represented 19.8% of cases. The registry of follow-up revealed an event rate of 5.3% (1/131 breast and 1/131 axillary recurrences, 4/131 distant metastases and 1/131 death), occurring at a median (IQR) period of 6 (5-7) years. Of these events, only one was observed in a patient with nodal involvement. ***Conclusion:*** According to current recommendations for SLNB eviction, the incidence of nodal positivity in our subgroup was higher than the INSEMA study (19.8% vs 15.1%). In the subgroup analysis, events were observed in 5.3% (similar to INSEMA rate), with no events reported before 5 years of follow-up. Although longer follow-up periods are needed to clearly evaluate the impact of this recommendation, our data suggests that omitting SLNB in this subgroup may not negatively impact the overall and disease-free survival. ***References:*** Park KU, Somerfield MR, Anne N, et al. OP-036

Sentinel Node Scintigraphy for Breast Cancer on CZT-Based Whole-Body SPECT/CT: Description of an 18-Month Monocentric Experience and Workflow Efficiency

F. Serani[1], *C. Gagliani*[1], *P. Zucchetta*[2], *R. Simeone*[2], *V. Bodanza*[2], *G. Grassetto*[2], *D. Cecchin*[1];
[1]*Nuclear Medicine Unit, Department of Medicine DIMED, University-Hospital of Padova, Padova, ITALY,* [2]*Nuclear Medicine Unit, University-Hospital of Padova, Padova, ITALY.*

Aim/Introduction: Over the past 18 months, our department has introduced a novel technique for sentinel node scintigraphy in breast cancer patients, utilising a cadmium zinc telluride (CZT)-based whole-body SPECT/CT system. Unlike the traditional method employing liquid crystal collimators and preoperative skin marking, this approach omits skin marking and relies on CT imaging for intraoperative guidance. The aim of this retrospective analysis was to evaluate the feasibility, workflow efficiency, and surgical impact of the new method. ***Materials and Methods:*** We retrospectively reviewed all breast cancer sentinel node scintigraphy procedures performed with the CZT-based system over an 18-month period. A short survey was administered to three breast surgeons to assess their intraoperative experience and

any perceived differences compared to the traditional technique. ***Results:*** A total of 325 breast cancer patients underwent sentinel node scintigraphy. Among these, anomalous lymphatic drainage pathways were identified in 57 cases, clearly visualised through the CT images. The new technique allowed simultaneous acquisition of functional and anatomical information, resulting in reduced procedure times due to the elimination of manual skin marking. Surgeon feedback indicated that none of the respondents noticed the absence of the skin marker during surgery, suggesting no negative impact on surgical localisation or planning. From the nuclear medicine perspective, the improved workflow and enhanced visualisation of "in-transit" lymph nodes and lymphatic vessel tortuosity were identified as major advantages. ***Conclusion:*** The adoption of CZT-based whole-body SPECT/CT for sentinel node scintigraphy in breast cancer patients appears feasible and efficient. It streamlines workflow, enhances anatomical visualisation, and maintains surgical effectiveness. Further studies involving larger cohorts and objective surgical outcome measures are recommended to validate these findings.

OP-037

Systematic evaluation of the performance of hybrid tracers in image-guided sentinel node biopsy

T. Buckle[1], *M. Vreeburg*[2], *F. van Leeuwen*[1], *D. Rietbergen*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2] *Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.*

Aim/Introduction: In solid tumors patient prognosis is primarily influenced by the presence of nodal metastases, which are found in 10-25% of clinically node-negative patients. Sentinel node biopsy (SNB) has been introduced to address the need to identify micro-metastases. This technology is globally integrated into routine clinical care for e.g. melanoma, oral cavity, penile, breast and gynecological cancer. Since 2011 hybrid SN tracers that contain both a radio- and fluorescent label have been clinically applied. Besides having been applied in 11 tumor types and > 2000 patients, a systematic performance assessment of their use in SNB has not yet been performed. ***Materials and Methods:*** Comprehensive bibliographic screening was performed according to Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines for clinical reports (PROSPERO registration number: CRD42023431662, 2011-2024). 61 of the 563 selected articles described clinical use of radioactive and fluorescent hybrid tracers in SNB. Risk of bias assessment was performed using the Newcastle-Ottawa Scale (low risk of bias: ≥7). Tracer preparation, preoperative findings (lymphoscintigraphy, SPECT/CT), intraoperative findings (radioactive and/or fluorescent nodes, sensitivity, specificity, negative predictive value (NPV) and false negative rate), pathological and oncological outcomes (including overall survival/mortality, biochemical and clinical recurrence, disease free survival), and complications were evaluated. ***Results:*** Risk of bias was low in 43% (N= 26) prospective studies performed in head-and-neck-, prostate-, penile-, vulvar-, gastric- and cervical cancer, and melanoma. The remaining studies included insufficient follow-up and/or solely proof-of-principle assessment. Inter-study comparison showed agreement in preoperative SN detection with solely radiolabelled parental SN tracers (e.g., ^{99m}Tc-nanocolloid), and between hybrid tracer variants. An ICG-HSA ratio of 0.5 was deemed most reliable and resulted in all radioactive nodes being fluorescent and vice versa. Intraoperatively, hybrid tracers were shown to outperform optical dyes. Hybrid guidance was proven to be most beneficial in more complex anatomies such as the pelvic- and head-and-neck region (NPV: 93.4-99.7%). Oncological outcome was only reported for penile and prostate cancer showing lower rates of biochemical recurrence (0.79, 95% CI 0.63-0.98) and clinical recurrence (HR 0.76, p=0.035). No tracer-related complications were reported. ***Conclusion:*** Hybrid SN tracers are safe and reliable tracers for SNB, with similar effectiveness as the current golden standard (radioactivity alone). Use of hybrid tracers is most beneficial more complex anatomies (e.g., pelvic and head-and-neck area) and shows favorable effects on oncological outcome. Recommendations for future clinical studies emphasize the need for additional oncological outcome reporting.

OP-038

Diagnostic accuracy and interrater agreement of FDG-PET/CT lymph node staging in high-risk endometrial cancer: The SENTIREC-endo study

J. Holm[1,2], *A. H. Dias*[3], *O. Gerke*[1,2], *A. Loft*[4], *K. Bouchelouche*[3,5], *M. H. Vilstrup*[6], *S. M. Bjørnholt*[7,5], *S. E. Sponholtz*[8], *K. M. Jochumsen*[8], *M. G. Hildebrandt*[1,2], *P. T. Jensen*[7,9];
[1]*Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK,* [2]*Department of Clinical research, University of Southern Denmark,, 5230 Odense, DENMARK,* [3]*Department of Nuclear Medicine and PET-centre, Aarhus University Hospital, 8000 Aarhus, DENMARK,* [4]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Copenhagen, DENMARK,* [5]*Department of Clinical Medicine, Aarhus University, 8000 Aarhus, DENMARK,* [6]*Department of Radiology and Nuclear Medicine, Esbjerg and Grindsted Hospitals, University of Southern Denmark, 6705 Esbjerg, DENMARK,* [7]*Department of Gynecology and Obstetrics, Aarhus University Hospital, Aarhus, DENMARK,* [8]*Department of Gynecology and Obstetrics, Odense University Hospital, 5000 Odense, DENMARK,* [9]*Department of Clinical Medicine, Aarhus University, 8200 Aarhus, DENMARK.*

Aim/Introduction: The SENTIREC-endo study established a safe algorithm combining sentinel lymph node mapping with PET-positive node dissection, achieving results comparable to lymphadenectomy in patients with high-risk endometrial cancer (EC) [1]. This study further evaluates the diagnostic accuracy of [18F]FDG-PET/CT alone for lymph node staging and examines interrater agreement across three Danish centers. ***Materials and Methods:*** This prospective multicenter study included women with high-risk endometrial cancer from the Danish SENTIREC study database (2019-2023). All patients underwent preoperative FDG-PET/CT, with pathology-confirmed results and postoperative clinical information serving as the reference standard. The primary outcome was the diagnostic accuracy FDG-PET/CT, assessed by location, size, and standardized uptake value (SUV). The secondary outcome was interrater agreement between readers at three Danish hospitals. Lymph nodes detected on FDG-PET/CT were classified as 'test-negative' or 'test-positive' for metastasis, with an 'equivocal' category included for interrater agreement evaluations. Readers were blinded to each other and to the reference standard. ***Results:*** Among 227 patients with high-risk endometrial cancer, 52 women (23 %) had lymph node metastasis. FDG-PET/CT diagnosed lymph node metastases with a sensitivity of 56% (CI 95%: 42-68) , specificity of 91% (CI 95%: 86-94) and positive and negative predictive values of 64% (CI 95%: 50-77) and 87% (CI 95%: 82-91), respectively. Sensitivity of paraaortic nodes remained low (56%), while specificity was very high (97%). Lymph node size and SUVmax showed moderate diagnostic value (AUC-ROC ~0.7), limiting their clinical applicability for cutoff determination. Interrater agreement for lymph node classification as 'benign', 'malignant', or 'equivocal' was 95% wich is almost perfect ($\kappa = 0.84$, CI 95%: 0.73-0.94). ***Conclusion:*** FDG-PET/CT demonstrated high specificity but limited sensitivity in staging lymph node metastasis in high-risk endometrial cancer, consistent with previous studies. Due to its excellent specificity and high interrater reliability, FDG-PET/CT is valuable when combined with the highly sensitive sentinel lymph node biopsy for targeted dissection of PET-positive lymph nodes, particularly identifying malignant lymph nodes in the paraaortic region. ***References:*** 1. Bjørnholt, S.M., et al., Identifying safe diagnostic algorithms for sentinel lymph node mapping in high-risk endometrial cancer: The SENTIREC-endo study. Gynecol Oncol, 2024. 182: p. 179-187.

OP-039

Is Visceral Adipose Tissue Metabolism Linked to Aggressiveness in Endometrial Cancer?

J. Sæterstøl[1,2], *J. Lavik*[1], *L. P. Lunde*[1], *C. Krakstad*[3,4], *I. S. Haldorsen*[1,2], *K. E. Fasmer*[1];
[1]*Mohn Medical Imaging and Visualization Centre, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY,* [2]*Department of Clinical Medicine, University of Bergen, Bergen, NORWAY,* [3]*Department of Obstetrics and Gynaecology, Haukeland University Hospital, Bergen, NORWAY,* [4]*Centre for Cancer Biomarkers, Department of Clinical Science, University of Bergen, Bergen, NORWAY.*

Aim/Introduction: Obesity is a well-established risk factor for endometrial cancer. A few studies have also linked visceral obesity to poor disease-specific survival for patients with endometrial cancer. One proposed mechanism is that visceral adipose tissue (VAT) produces cytokines, creating an inflammatory environment that promotes tumorigenesis and poor outcomes. The metabolic activity of VAT can be measured by [^{18}F]fluoro-deoxy-glucose (FDG) positron emission tomography/computed tomography (PET/CT). This study aimed to assess VAT metabolic activity in a large cohort of endometrial cancer patients, and explore whether VAT metabolic activity is related to lymph node metastases (LNM), International Federation of Gynecology and Obstetrics (FIGO) stage, and postoperative histological risk (low risk: endometrioid endometrial cancer (EEC) grade 1-2; high risk: EEC grade 3 and non-EEC). ***Materials and Methods:*** Preoperative [^{18}F]FDG PET/CT scans of 274 patients with endometrial cancer were retrospectively collected and analyzed. The patients were part of a larger prospective population-based study cohort. Metabolic activity of VAT was measured in regions of interest (ROIs) at the level of vertebra L4 on standardized uptake value (SUV) images. The ROIs were individually adjusted to avoid signal interference from adjacent organs/tissues, and confined to VAT by restricting placement to tissue with CT Hounsfield units ranging from -195 to -45. Mean and maximum SUVs in the ROI (VAT_{mean} and VAT_{max}) were recorded for all patients. To account for differences between two PET/CT systems, SUV values were harmonized with ComBat before they were assessed in relation to high-risk features using Kruskal-Wallis equality-of-populations rank test. ***Results:*** Median VAT_{mean} [95% confidence interval (CI)] was 0.26 [0.26,0.28] and the median VAT_{max} [95% CI] was 0.46 [0.44,0.49]. Mean (standard deviation) ROI size was 5.4 (3.8) cm^2. Patients with histologically verified LNM (n=24) had a higher median VAT_{mean} of 0.30 [0.24,0.37] compared to patients verified with no LNM (0.26 [0.25,0.27], p=0.03) (n=123). Similarly, patients with advanced FIGO stage (3-4) (n=47) had a higher median VAT_{mean} of 0.29 [0.25,0.36] compared to patients with low FIGO stage (1-2) (n=227) (VAT_{mean}: 0.26 [0.25,0.27], p=0.03). The VAT_{mean} was not significantly different for high-risk versus low-risk postoperative histology, and VAT_{max} showed no significant associations to LNM, advanced FIGO stage or high-risk histology. ***Conclusion:*** Median VAT_{mean} was higher in patients with LNM and advanced FIGO stage than in patients with no LNM and lower FIGO stage. However, future studies are needed to explore the underlying biological mechanisms linking VAT metabolic activity to aggressive endometrial cancer disease.

OP-040

Prediction of Treatment Response Using PET-CT Radiomics Features in Patients Undergoing Radical Chemoradiotherapy with a Diagnosis of Cervical Cancer

O. Senmevsim[1], *B. Kocabas*[1], *I. F. Ozsarikaya*[2], *S. Butuner*[3], *B. Erol*[4], *Z. Guzeloz*[1];
[1]*Izmir City Hospital, Izmir, TÜRKIYE,* [2]*Ministry of Health Tepecik Training and Research Hospital, Izmir, TÜRKIYE,* [3]*Beykent University, Department of Software Engineering, Istanbul, TÜRKIYE,* [4]*Beykent University, Istanbul, TÜRKIYE.*

Aim/Introduction: There has been an increasing interest in "Radiomics" assessment, which is based on the extraction and analysis of quantitative features from medical images (1-3). Texture features are extracted from statistical matrices based on density spatial distribution relationships and reflect the FDG distribution, and therefore the heterogenity of the tumor (4).In this study, we aimed to develop a classification model that can predict treatment response with FDG/PET-CT radiomics assessment in patients undergoing treatment with a diagnosis of cervical cancer. ***Materials and Methods:*** The study included 62 patients, whose staging and response evaluation FDG/PET-CTs were performed on the same device. These patients underwent brachytherapy after chemoradiotherapy. Complete response was defined as the SUV max value of the tumor or metastatic lymph nodes/node regressing to background activity. Using the staging and response evaluation FDG/PET-CT, the primary tumor and the metastatic lymph node with the highest SUV uptake were manually segmented using LIFEx (Local Image Features Extraction version 7.6.0) software, and ROIs were obtained. Six different machine learning algorithms were developed and their performances were evaluated for the classification problem: decision tree (DT), random forest (RF), k-nearest neighbor (KNN), bagged KNN, support vector machines (SVM), and artificial neural networks (ANN). Performance evaluation was carried out using metrics such as accuracy, precision, recall, F1-score, and area under the curve (AUC). ***Results:*** The median age was 52 (34-78). 41.9% of the patients (n=26) were Stage 1.The most common histology was SCC, at 90.3% (n=58). 56.5% of the patients (n=35) were evaluated as having a complete response, and 43.5% (n=27) as having no complete response. According to the results obtained, the random forest (RF) algorithm showed the highest performance in all metrics (Accuracy: 0.89, Precision: 0.87, Recall: 0.94, F1-Score: 0.89, AUC: 0.96). The RF algorithm was followed by DT and SVM methods. ***Conclusion:*** Our study has revealed the usability of radiomics features in the classification for predicting treatment response in inoperable cervical cancer. ***References:*** 1- Lambin P, Leijenaar RTH, Deist TM, et al. OP-041

FDG-PET/CT response assessment is predictive of survival and recurrence in locally advanced cervical cancer

M. Markus[1], *H. Sartor*[2], *M. Bjurberg*[3], *D. Minarik*[4], *E. Trägårdh*[1];
[1]*Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, SWEDEN,* [2]*Diagnostic Radiology, Department of Translational Medicine, Lund University, Skåne University Hospital, Lund, SWEDEN,* [3]*Department of Hematology, Oncology and radiation Physics, Skåne University Hospital, Lund, SWEDEN,* [4]*Radiation Physics, Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, SWEDEN.*

Aim/Introduction: [18F]-fluorodeoxyglucose (FDG) positron emission tomography with computed tomography (PET-CT) is routinely performed in patients with advanced cervical cancer for staging and evaluation of treatment response. The maximum standardised uptake value (SUVmax) is the most used PET parameter in clinical routine but more advanced metabolic parameters (e.g metabolic tumour volume (MTV) and total lesion glycolysis (TLG)) may better predict survival. This study investigates the prognostic significance of SUVmax, MTV, and TLG in assessing treatment response, using overall survival (OS) and

local recurrence as outcome measures. ***Materials and Methods:*** This study included women with locally advanced cervical cancer who were referred for radiochemotherapy between 2011 and 2019 and underwent PET-CT scans at baseline and at a 6-month follow-up post-treatment. Treatment response on PET-CT was evaluated according to the European Organization for Research and Treatment of Cancer (EORTC) criteria, comparing SUVmax, MTV, and TLG. Response outcomes were categorized as complete metabolic response (CMR), progressive metabolic disease (PMD), partial metabolic regression (PMR), or stable disease (SD). These outcomes were correlated with OS and recurrence using regression analysis, and the predictive potential of the different measures was visualized using the C-index. ***Results:*** A total of 133 patients were included in the study. Age- and clinical stage-adjusted analyses revealed a statistically significant association ($p<0.001$) between treatment response and OS for SUVmax (hazard ratio [HR] 16 for PMD, 4.0 for PMR/SD), MTV (HR 16 for PMD, 2.9 for PMR/SD), and TLG (HR 16 for PMD, 2.9 for PMR/SD), with CMR as the reference. Additionally, C-index values from adjusted Cox models were comparable between the PET parameters (SUVmax 0.84, MTV and TLG 0.86). Logistic regression for recurrent disease based on treatment response showed a statistically significant association ($p<0.001$) for all PET parameters, with similar results across the parameters. ***Conclusion:*** Treatment response evaluation using FDG-PET/CT, according to the EORTC criteria, is predictive of OS and local recurrence in patients with advanced cervical cancer. The prognostic value was similar for SUVmax, MTV, and TLG.

OP-042

Avidination for Radionuclide THerapy (ARTHE) in nonpalpable breast cancer. Phase I IRST "Dino Amadori-IRCSS' trial"

M. Sansovini[1], *P. Sanna*[2], *P. Possanzini*[2], *I. Grassi*[1], *P. Caroli*[1], *M. Amadori*[2], *I. Marini*[1], *S. Nicolini*[1], *M. Belli*[1], *L. Fabbri*[1], *E. Scarpi*[1], *A. Matteucci*[1];
[1]*IRST, Meldola (Fc), ITALY,* [2]*AUSL della Romagna, Forlì, ITALY,* [3]*IOR Istituto Oncologico Romagnolo, Forlì, ITALY.*

Aim/Introduction: Non-palpable breast lesions account for ~30% of breast tumours requiring surgery. Vacuum assisted breast biopsy (VABB) can only completely remove 10-30% of small lesions. Our phase I trial proposes targeted radionuclide therapy after VABB using a biotin-DOTA-90Y compound delivered into the biopsy cavity. The idea is to irradiate and destroy residual microscopic tumour cells in situ. ***Materials and Methods:*** Up to 52 pts were enrolled in Part 1 (18 in dose-escalation phase) and Part 2 (44 in dose expansion). Pts were divided into 6 cohorts in Part 1 to establish biotin-DOTA-^90Y's DLT and MAD. The ARTHE procedure consists of an ultrasound-guided injection of avidin into the breast tissue at the VABB site, followed immediately by an injection of biotin-DOTA-90Y. Avidin dose: 6-10 mg in a volume of 0.3-0.5 mL. Biotin-DOTA-90Y dose: 28-126 MBq (0.2-0.3 mL), with a specific activity of 3.7 GBq/mg. According to worldwide and national norms, pts underwent surgery 4 to7 weeks after ARTHE therapy. ***Results:*** From July 2024 to January 2025, 18 pts underwent VABB for the presence of breast carcinoma with a median size of 10 mm. Histological diagnosis showed ductal carcinoma in situ in 6 pts (33.3%), invasive ductal carcinoma in 1 pts (5.6%), invasive carcinoma of no special type in 5 pts (27.8%) and other hystotypes in 6 pts (33.3%). In Part 1, pts were divided into 3 cohorts of 6 pts each and treated with dose of 90Y-biotin of 28 MBq (dose A), 57MBq (dose B) and 126 MBq (dose C), respectively. Within 1 month after ARTHE, all pts underwent quadrantectomy. Postoperative histological examination showed pCR in 5 pts (27.8%) and persistence of disease in the remaining 13 pts. There were no haematological toxicities or major acute skin toxicities (>G3) at the inoculation site. Grade 1 adverse reactions were reported, consisting of pain (22.2%), erythema (11.1%) and skin toxicity/redness in 1 patient in dose group B (5.5%). ***Conclusion:*** ARTHE may be an interesting nuclear medicine approach as it has proven to be a rapid, minimally invasive procedure with no major side effects. The evaluation of its antitumour activity is in progress and further studies on larger cohorts will be necessary to assess its impact on the management of breast cancer, especially in elderly women with comorbidities that do not recommend a surgical approach ***References:*** Paganelli G, et al. Eur J Nucl.Med mol Imaging.2010; 37: 203-11

OP-043

Combined External Beam Radiation Therapy and Peptide Receptor Radionuclide Therapy in Progressive Meningiomas: A Retrospective Analysis of Feasibility, Safety, and Prognostic Factors

N. Hasenauer[1], *M. Müller*[1], *R. Sweeney*[2], *B. Polat*[3], *H. Hänscheid*[1], *R. A. Werner*[4], *M. Heinrich*[1], *A. K. Buck*[1], *P. E. Hartrampf*[1];
[1]*Department of Nuclear Medicine, University Hospital Wuerzburg, Wuerzburg, GERMANY,* [2]*Department of Radiotherapy and Radiation Oncology, Leopoldina Hospital Schweinfurt, Schweinfurt, GERMANY,* [3]*Department of Radiation Oncology, University Hospital Wuerzburg, Wuerzburg, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Ludwig-Maximilians-Universitaet Muenchen, Muenchen, GERMANY.*

Aim/Introduction: In patients with irresectable meningiomas, external beam radiation therapy (EBRT) may be limited by the safely deliverable dose, particularly in cases involving multiple lesions or tumors adjacent to critical structures. Combining EBRT with somatostatin receptor (SSTR)-targeted peptide receptor radionuclide therapy (PRRT) may offer a strategy to intensify treatment. The aim of this study was to evaluate the feasibility, safety, and prognostic factors of this combined approach. ***Materials and Methods:*** This monocentric retrospective study analysed 75 patients who received combined standard EBRT and PRRT within a 30-day interval. Baseline clinical, laboratory, and PET-derived parameters (SUVmean, SUVmax, SUVpeak, and SSTR-positive tumor volume) were evaluated for their prognostic value regarding progression-free survival (PFS) using Cox regression models. PFS and OS were estimated using Kaplan-Meier analysis. Toxicity was assessed according to CTCAE v5.0, and clinical follow-up data were reviewed for treatment-related adverse events and subjective outcomes. ***Results:*** After a median follow-up of 57 months, 25/75 patients experienced disease progression, and 17 died. Both, median PFS and median OS had not been reached. Patients with WHO grade I meningioma showed longer PFS (NR) compared with grade II (38 months, HR 5.4, $p<0.01$) and grade III tumors (15.5 months, HR 15.1, $p<0.01$). On univariable analysis, higher WHO grade (HR 4.7, $p<0.01$) as well as elevated baseline levels of C-reactive protein (HR 2.2, $p<0.01$), lactate dehydrogenase (per 100, HR 1.5, $p<0.05$), creatinine (per 0.1, HR 1.3, $p<0.05$), and alkaline phosphatase (per 10, HR 1.5, $p<0.05$) were associated with shorter PFS. In multivariable analysis, WHO tumor grade remained an independent prognostic factor (HR 4.7, $p<0.01$). No associations were found between PET parameters and PFS. Lesion dosimetry after PRRT was available in 37 cases; estimated doses did not differ between patients who received PRRT before versus after EBRT ($P=0.5$). PFS did not significantly differ between patients with solitary versus multifocal meningiomas (HR 0.84, $p=0.7$), nor between patients treated with reduced (<54 Gy) versus standard-dose EBRT (≥54 Gy). 13 patients developed mild (CTCAE I-II) hematologic or renal toxicities. Among 58 patients with available clinical follow-up data, 18 worsened, mainly involving concentration difficulties and fatigue. 44 reported stable or improved well-being. ***Conclusion:*** Combined EBRT and PRRT represents a feasible and well-tolerated treatment option for patients with progressive meningiomas, potentially enabling dose intensification in complex cases. WHO tumor grade is the strongest predictor of PFS, while baseline PET parameters showed no prognostic value.

OP-044

Clinical value of ^{18}F-PI-2620 Tau-PET in the diagnostic workup of patients with suspected Progressive Supranuclear Palsy

M. Brendel[1], *C. Palleis*[1], *N. Franzmeier*[1], *J. Gnörich*[1], *A. Jäck*[1], *A. Bernhardt*[1], *S. Katzdobler*[1], *U. Fietzek*[1], *E. Weidinger*[1], *L. Frontzkowski*[1], *S. Roemer-Cassiano*[1], *R. Werner*[1], *A. Zwergal*[1], *H. Barthel*[2], *O. Sabri*[2], *J. Levin*[1], *G. Höglinger*[1];
[1]*LMU Hospital, Munich, GERMANY,* [2]*University of Leipzig, Leipzig, GERMANY.*

Aim/Introduction: Progressive Supranuclear Palsy (PSP) is a rapidly progressing 4-repeat tauopathy, presenting with clinically heterogeneous phenotypes. Currently, diagnoses are based solely on clinical criteria but reliable diagnostic classification remains particularly challenging at early stages. ^{18}F-PI-2620 tau-PET is an evolving neuroimaging biomarker to capture 4-repeat tau (4RT) deposits with clear diagnostic potential in research settings. To determine the added clinical value of ^{18}F-PI-2620 tau-PET in the diagnostic workup of PSP, we evaluated whether ^{18}F-PI-2620-assessed 4RT positivity (i.e. using the basal ganglia as a target readout) predicts subsequent increases of diagnostic certainty for PSP, indicative of 4RT pathology driving clinical progression. ***Materials and Methods:*** We collected monocentric longitudinal data at the LMU Hospital in Munich, from a non-randomized prospective cohort study between October 2018 and December 2024. Data collection included pre-PET visits with routine clinical classification following the Movement Disorders Society PSP criteria. Levels of certainty are graded as suggestive of, possible, probable and definite PSP. In addition, we performed ^{18}F-PI-2620 tau-PET with dichotomous visual read assessments of 4RT pathology by an expert reader and collected clinical follow-up data or autopsy information. ***Results:*** 342 patients with a pre-PET differential diagnosis of PSP were referred to ^{18}F-PI-2620 tau-PET in clinical routine. Of those, 200 patients (61.5% male, mean±sd age 69.2±8.3 years) had a post-PET clinical follow-up between 12-24 months (mean±sd 17.1±4.2 months). 90 patients were rated as suggestive of PSP, 49 as possible PSP and 61 as probable PSP. The two most common differential diagnoses were Parkinson's Disease (39%) and Multiple Systems Atrophy (12%). 68.5% (137/200 patients) were rated 4RT-positive at baseline. The positive predictive value of a positive tau-PET read at baseline for a PSP diagnosis at follow-up visit was 98.5% (135/137 patients). Change to a non-PSP diagnosis at follow-up occurred in 23.5% (47/200 patients), identified by a negative baseline tau-PET in 95.5%. Regarding the diagnosis of suggestive of PSP, 79% of tau-PET-positive patients progressed to a higher diagnostic certainty, 3% had histopathological confirmation of PSP diagnosis, 13% remained suggestive of PSP, and 5% received a non-PSP diagnosis at follow-up. ***Conclusion:*** ^{18}F-PI-2620 tau-PET can successfully identify patients that progress along expected 4RT clinical spectra. This supports ^{18}F-PI-2620 tau-PET as a 4RT biomarker, with the potential to facilitate early biomarker-based diagnosis when clinical criteria may still lack sensitivity and specificity. This development can be transformative for clinical decision making, early identification of PSP and stratifying patients for disease modifying clinical trials.

OP-045

Patterns and their Correlations of PET Imagings with FDG, DAT and Tau in patients with Progressive Supranuclear Palsy

M. Liang[1], *C. Jia*[1], *z. Huang*[1], *T. Zhang*[2], *Q. Li*[1], *T. Yen*[3], *h. Wang*[4], *R. Cui*[1];
[1]*Department of Nuclear Medicine, Peking Union Medical College Hospital Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA,* [2]*Beijing Engineering Research Center of Radiographic Techniques and Equipment, Institute of High Energy Physics, Chinese Academy of Sciences, Beijing, CHINA,* [3]*APRINOIA Therapeutics Co, Ltd, Suzhou, CHINA,* [4]*Department of Neurology, Peking Union Medical College Hospital Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

Aim/Introduction: The latest diagnostic criteria for Progressive Supranuclear Palsy (PSP) highlight the supportive roles of various PET imaging methods in improving diagnostic accuracy, such as 18F-Fluorodeoxyglucose(18F-FDG), 18F-FP-CIT and Florzolotau(18F) PET. In this study, we simultaneously analyzed the patterns of 18F-FDG, 18F-FP-CIT and Florzolotau(18F) PET imaging and their correlations in a cohort of PSP patients, trying to investigate the interplay between these pathological processes. ***Materials and Methods:*** Twenty-eight patients clinically diagnosed with PSP underwent ^{18}F-FDG, ^{18}F-FP-CIT and Florzolotau(^{18}F) PET examinations, and imaging data were analyzed using voxel-based and region-of-interest (ROI) methods. Standardized uptake value ratios (SUVRs) were compared with age-matched healthy controls, and inter-tracer correlations were assessed. ***Results:*** PSP patients demonstrated elevated Florzolotau(^{18}F) uptake in the thalamus, midbrain, pons, and precentral gyrus. Glucose hypometabolism was prominent in the frontal and parietal lobes, cerebellum, midbrain, medulla, caudate, and thalamus. ^{18}F-FP-CIT PET revealed reduced striatal and midbrain DAT availability. A weak negative correlation was observed between Florzolotau(^{18}F) and ^{18}F-FDG SUVRs in the midbrain (r=-0.39, p=0.04), but no association was found in the frontal cortex (r=0.04, p=0.85). Notably, frontal hypometabolism correlated with hypometabolism in subcortical structures including the thalamus, caudate, pons, and midbrain. Only a moderate negative correlation between ^{18}F-FP-CIT and Florzolotau(^{18}F) SUVRs in the left putamen was observed(r =-0.42, p = 0.03). ***Conclusion:*** The study reveals distinct spatial patterns of tau pathology, metabolism, and dopaminergic degeneration in PSP. The inverse correlation between midbrain tau burden and metabolism suggests region-specific interactions in brainstem regions, while the lack of correlations between tau and metabolism in the frontal cortex, as well as between tau and dopamine transporter (DAT) levels in most regions, points to divergent pathogenic mechanisms across cortical and subcortical areas. These findings highlight the complex, multifactorial nature of PSP pathophysiology, with tau accumulation, metabolic dysfunction, and dopaminergic decline exhibiting region-specific relationships.

OP-046

Association between tau-burden and eye movement disorders in progressive supranuclear palsy

M. Zaganjori[1], *J. Gnörich*[1], *S. Katzdobler*[2], *L. Frontzkowski*[3], *U. Fietzek*[2], *G. Nübling*[2], *J. Levin*[2], *N. Franzmeier*[4], *G. Höglinger*[2], *R. Werner*[1], *M. Brendel*[1], *A. Zwergal*[2];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Neurology, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Institute for Stroke and Dementia Research (ISD), University Hospital, LMU Munich, Munich, Germany, Munich, GERMANY,* [4]*Institute for Stroke and Dementia Research (ISD), University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Progressive supranuclear palsy (PSP) is a severe neurodegenerative disorder pertaining to 4R-tau aggregation. PSP can present as different clinical phenotypes including the classical PSP-Richardson Syndrome (RS) type, which is characterized by predominant supranuclear saccadic impairment. Assessing the extent to which tau pathology influences the manifestation of saccadic and other eye movement abnormalities could be crucial to better understanding the pathomechanisms of PSP. In this study, we aimed to explore regional associations between tau burden and differential ocular motor phenotypes in PSP. ***Materials and Methods:*** We included 44 patients with a suspected or probable PSP diagnosis according to current MDS-criteria, of which 28 had PSP-RS. Patients underwent dynamic 60 minute 18-F-PI-2620 tau-PET and a comprehensive video-oculographic ocular motor examination within an interval of 12 months. Distribution volume ratios (DVR) of tau aggregation and perfusion surrogates (R1) were computed for all regions of the brainnetome atlas. Whole brain voxel-wise analysis and region-of-interest-based analysis corrected for age and sex were performed to test for associations between tau burden or perfusion deficits and different eye movement parameters (esp. saccade velocity and latency, smooth pursuit gain, respectively for the vertical and horizontal axis). ***Results: Results:*** Voxel-wise analysis showed that increased tau-PET DVR correlated significantly with decreased saccadic velocity, particularly in the horizontal axis, in the pontomesencephalic brainstem tegmentum (r: -0.4, p< 0.05) and frontal cortex (r: -0.33, p< 0.05), whereas basal ganglia tau-PET DVR did not correlate significantly with saccadic velocity (r: -0.27, p=0.08). Higher mean saccadic latency correlated significantly with increased tau-PET DVR in the temporal (r: 0.38, p<0.05) and occipital cortex (r: 0.31, p<0.05), whereas smooth pursuit did not show any associations. There was no significant association between brain perfusion and saccadic velocity. ***Conclusion:*** Our findings suggest that tau burden in in the pontomesencephalic brainstem tegmentum and frontal cortex has an impact on saccadic phenotypes in PSP.

Aim/Introduction: There is a need for simplified classification systems capable of effectively stratifying Parkinson's disease (PD) in routine clinical practice. Objectives: Identification of PD subtypes integrating neuroimaging and clinical features, widely used to support clinical diagnosis. ***Materials and Methods:*** We included, from Parkinson's Progression Markers Initiative (PPMI), n=249 de novo early diagnosed PD patients. Two step clustering analysis was run on 123I-FP-CIT-SPECT striatal uptake [D+/D] and motor impairment [M+/M]. The emerging subgroups were evaluated for demographic, clinical, cerebrospinal fluid biomarkers, brain morphometry and longitudinal clinical progression. Mediation analysis evaluated the effect of biomarkers on the relationship between subgroups and cognitive decline. We validated the proposed classification algorithm through an independent validation cohort (n=84). ***Results:*** Four distinct subtypes emerged: [D+/M+]: poorer memory performance, greater Aβ1-42 and α-synuclein pathology and atrophy in the inferior temporo-occipital cortex. At follow-up D+/M+ showed faster progression of motor disability, motor complications and cognitive decline. [D/M]: higher levels of anxiety and gray matter volume reductions in the precuneus, fusiform gyrus and the precentral gyrus. [D/M+]: marked by pronounced rigidity and apathy, atrophy in motor and sensorimotor areas, and a more rapid progression of rigidity. [D+/M]: severe impulsiveness, lower working memory performance and thalamic atrophy. Aβ1-42 showed significant mediational effect on the relationship between D+/M+ and cognitive decline. The validation cohort supported the clinical findings observed in the PPMI cohort. ***Conclusion:*** PD can be categorized into distinct subgroups using information widely available in clinical and research settings. These data offer valuable insights into the underlying co-pathology, disease progression and severity.

OP-048

Dopamine Loss in Putamen and Caudate Drives Distinct Motor and Cognitive Symptoms in Parkinson's Disease Progression

V. Dzialas[1,2], *K. Giehl*[1,3], *G. N. Bischof*[1,3,4], *A. Ophey*[5], *K. Möllenhoff*[6], *A. Drzezga*[1,3,7], *T. van Eimeren*[1,8];
[1]*Nuclear Medicine, Faculty of Medicine, University Hospital and University of Cologne, Cologne, GERMANY,* [2]*Faculty of Mathematics and Natural Sciences, University of Cologne, Cologne, GERMANY,* [3]*Molecular Organization of the Brain, Institute for Neuroscience and Medicine II, Research Centre Juelich, Juelich, GERMANY,* [4]*Life Molecular Imaging GmbH, Berlin, GERMANY,* [5]*Department of Medical Psychology | Neuropsychology and Gender Studies, Center for Neuropsychological Diagnostics and Intervention (CeNDI), Faculty of Medicine, University Hospital and University of Cologne, Cologne, GERMANY,* [6]*Institute of Medical Statistics and Computational Biology (IMSB), Faculty of Medicine, University of Cologne, Cologne, GERMANY,* [7]*German Centre for Neurodegenerative Diseases, Bonn, GERMANY,* [8]*Department of Neurology, Faculty of Medicine, University Hospital and University of Cologne, Cologne, GERMANY.*

Aim/Introduction: Imaging biomarkers for motor and cognitive progression in Parkinson's disease (PD) remain limited. While the putamen has been associated with motor dysfunction and the caudate nucleus with cognitive impairment, longitudinal studies validating the relationship between dopamine transporter (DaT) decline and symptom progression are scarce. We recently showed that putaminal DaT decline may track motor progression in early PD[1]. However, comparable imaging markers for cognitive decline are lacking. Considering the dual syndrome hypothesis[2], two distinct mechanisms contribute to cognitive impairment in PD: fronto-striatal dopaminergic loss leading to executive dysfunction, and posterior cholinergic degeneration underlying memory and visuospatial deficits. We examined and compared caudate and putamen DaT signal loss as potential longitudinal biomarkers of cognitive decline, particularly in executive functions. ***Materials and Methods:*** We analysed 5-year follow-up data from early-stage PD patients (diagnosis<2 years) enrolled in the Parkinson's Progression Markers Initiative, including scores from nine cognitive tests: Clock Drawing (CDT), Lexical Fluency (FAS), Hopkins Verbal Learning-Revised (HVLT-R), Judgment of Line Orientation (JLO), Letter-Number Sequencing (LNS), Modified Boston Naming (mBNT), Symbol Digit Modalities (SDMT), Semantic Fluency (SE), and Trail Making-A (TMT-A). Based on the dual syndrome hypothesis[2] and PD-MCI criteria[3], we classified LNS, SDMT, SE, TMT-A, and FAS as primarily executive and CDT, JLO, mBNT, and HVLT-R as memory/visuospatial tests. Using linear mixed-effects models, we tested whether cognitive decline was associated with progressive DaT loss in the caudate or putamen, captured by the time×DaT interaction. We hypothesized significant effects only for caudate DaT and executive tests. ***Results:*** 783 participants (~62% male; 62±9 years, MoCA: 27±3) contributed 2148 data points, with 49 patients classified as having mild cognitive impairment at baseline based on expert clinical assessment. Significant interactions (pone-sided<.05) were found between declining caudate DaT signal and worsening performance in LNS, SDMT, SE,

TMT-A, and HVLT-R (Table 1). No such associations were observed for putaminal DaT signals. ***Conclusion:*** audate DaT loss emerged as a promising marker for cognitive decline in PD, particularly in executive functions. Our results mainly aligned with assumptions derived from the dual syndrome hypothesis, while findings for FAS and HVLT-R did not align. This may reflect strong engagement of executive (for HVLT-R) and language/memory functions (for FAS), as also controversially discussed in the literature. Importantly, while cognitive progression was associated exclusively with DaT loss in the caudate, motor symptom progression was linked solely to putamen degeneration—supporting a functional dissociation between striatal subregions in PD. ***References:*** 1)doi:10.1002/ana.27223, 2)doi:10.1159/000341998, 3)doi:10.1002/mds.24893

OP-049

Validation of a 360° CZT-SPECT Normal Database for [123I]-FP-CIT SPECT/CT Imaging

P. Schaefer[1], *M. Doyen*[1], *A. El-Barkaoui*[2], *A. Flaus*[2], *L. Imbert*[1], *A. Verger*[1];
[1]*Nancy University Hospital of Lorraine, Nancy, FRANCE,* [2]*Hospices Civils de Lyon (Lyon University Hospital), Lyon, FRANCE.*

Aim/Introduction: Three-hundred-sixty-degree CZT SPECT cameras provide superior image quality for [123]-FP-CIT SPECT/CT imaging compared to conventional systems, enabling reduced radiotracer doses and acquisition times. However, currently available quantification software still relies on normal databases derived from conventional cameras. This study aimed to validate a locally developed normal database for [123I]-FP-CIT SPECT/CT imaging acquired using a 360° CZT-SPECT system. ***Materials and Methods:*** Patients who underwent [123I]-FP-CIT SPECT/CT imaging using a 360° CZT-SPECT camera (injected dose: 130 MBq; acquisition time: 15 minutes) for suspected Parkinson's disease (PD), and who were clinically classified as either normal or having PD based on follow-up of at least two years post-scan, were included. This CZT-derived normal database was compared with a previously validated database acquired using a conventional SPECT/CT camera (injected dose: 185 MBq; acquisition time: 30 minutes). Specific binding ratios (SBRs) for the striatum and putamen were extracted following CT-based spatial normalization. General linear models (GLMs) were used to assess the effects of age, sex, and age-sex interaction on striatal SBRs in both databases. Additionally, patients with clinically confirmed PD were analyzed for diagnostic performance using semi-quantification with both databases. Sensitivity, specificity, and accuracy were calculated for minimal putaminal SBRs, using cross-validation and optimal thresholds from ROC curve analysis. ***Results:*** The CZT database included 139 patients (mean age 70.1±11.6 years, 77 women), and the conventional database, 233 patients (mean age 62.6±15.8 years, 115 women). Additionally, 107 PD patients (mean age 69.6±9.6 years, 45 women) were included for diagnostic evaluation. GLMs identified a significant effect of age ($p \leq 0.01$) on striatal SBRs in both databases, with no significant effect of sex or age-sex interaction. Age-related decline in SBR was estimated at -7.1% per decade for the CZT database and -4.9% for the conventional one. After age correction, both databases showed low standard deviations and coefficients of variation (CZT: 0.0079 and 0.0021; conventional: 0.0139 and 0.0028). For semi-quantification, the CZT database yielded 76% sensitivity, 84% specificity, and 81% accuracy, compared to 92%, 52%, and 69%, respectively, for the conventional database. ***Conclusion:*** This study presents the first validated normal database for [123I]-FP-CIT SPECT/CT imaging using a 360° CZT-SPECT system. The age-related effects and dispersion were consistent with those observed in a validated conventional database. Importantly, semi-quantification using the CZT-derived database demonstrated superior diagnostic performance in identifying PD, supporting its integration into routine clinical practice for patients imaged with CZT systems.

Brain Metabolic Contribution in CANVAS

S. Naranjo Sancho*, C. Vigil Díaz, A. Álvarez Alonso, D. Santirso Rodríguez, G. Morís de la Tassa, J. Álvarez Carriles, M. Álvarez Martínez, A. Álvarez Amigo, J. Guzmán de la Cerda, F. González García;*
Central University Hospital of Asturias, Oviedo, SPAIN.

Aim/Introduction: Cerebellar ataxia, neuropathy and vestibular areflexia syndrome (CANVAS) is a late-onset progressive disorder primarily caused by a recessive expansion in the replication factor C subunit 1 (RFC1) gene. In addition to the classical pathological triad of cerebral atrophy, bilateral vestibular hypofunction and somatosensory impairment, CANVAS frecuently presents with other clinical features, such as autonomic dysfunction or cronic cough. As the condition becomes increasingly recognized, its clinical phenotype continues to expand. Recent studies suggest that cognitive impairment—particularly affecting executive function, language, visuospatial cognition, and emotional-affective regulation—may also be part of the spectrum. ***Materials and Methods:*** We studied 37 patients (24 females, 13 males), aged between 46 and 81 years, with genetically confirmed RFC1 mutation, aiming to evaluate brain metabolic compromise and the potential prevalence of cognitive impairment in this population. All participants underwent a 18F-fluorodeoxyglucose PET/CT (FDG-PET), with both visual and quantitative assessment of the presence, distribution and severity of hypometabolism in the cerebral and cerebellar cortex. Clinical examination findings were compared with the FDG-PET results. ***Results:*** In our series, cerebellar hypometabolism was observed in 67.6% of cases (25/37): severe in 21.6% (8/37), moderate in 16.2% (6/37), and mild in 29.7% (11/37). Vermis involvement was found in 43.2% of patients (16/37), with 37.5% of these (6/16) showing severe hypometabolism and 62.5% (10/16) presenting with mild to moderate changes. Pontine hypometabolism was detected in 43.2% of patients (16/37), most commonly at a moderate level (56.3%, 9/16). Gait disturbances were identified in 31/37 patients and were significantly associated with cerebellar hypometabolism ($p<0.05$). Additionally, cerebral hypometabolism—mainly affecting the medial and/or lateral prefrontal cortex—was observed in 59.5% (22/37), although cognitive decline was identified in only one patient. ***Conclusion:*** FDG PET has proven to be a valuable tool in the evaluation of the cerebellar involvement in CANVAS both visually and quantitatively. Our preliminary findings reveal a consistent pattern of cerebellar hypometabolism associated with the presence of gait disorders in patients with CANVAS. However, significant cognitive decline was not evident in this cohort, despite the prevalence of cerebral hypometabolism. Continued follow-up and the integration of molecular neuroimaging and neuropsychological evaluation are essential to further characterize the clinical phenotype and optimize patient management.

In vivo measurement of P-glycoprotein function in the brain and gut of patients with Parkinson's disease: a preliminary [^{18}F]MC225 PET study

G. Salvi de Souza[1,2], *W. Liu*[2], *J. F. Somsen*[2], *P. Mossel*[2,3], *N. A. Verwey*[4], *A. L. Bartels*[5], *S. K. Meles*[6], *C. R. Furini*[1,7], *R. A. Dierckx*[2], *A. A. Lammertsma*[2], *C. Tsoumpas*[2], *G. Luurtsema*[2];
[1]*PUCRS, Porto Alegre, BRAZIL,* [2]*Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,* [3]*Department of Radiology, Leiden University Medical Center,, Leiden, NETHERLANDS,* [4]*Memory clinic, Department of Neurology, Medisch Centrum Leeuwarden, Leeuwarden, NETHERLANDS,* [5]*Department of Neurology, Ommelander Ziekenhuis Groep, Scheemda, NETHERLANDS,* [6]*Department of Neurology, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS,* [7]*Laboratory of Cognition and Memory Neurobiology, Brain Institute, PUCRS, Porto Alegre, BRAZIL.*

Aim/Introduction: Parkinson's disease (PD) is a neurodegenerative disorder involving α-synuclein aggregation, neuroinflammation, and blood-brain barrier (BBB) dysfunction. P-glycoprotein (P-gp), an efflux transporter at the BBB, is involved in the clearance of neurotoxins, and reduced P-gp function may contribute to toxin accumulation in the brain[1]. P-gp is also present in the intestines, where it maintains barrier integrity and interacts with the gut microbiota. This study aims to assess P-gp function at the BBB and in the small intestines of PD patients compared to healthy volunteers (HV), using [^{18}F]MC225 positron emission tomography (PET) imaging. ***Materials and Methods:*** Seven HV and four PD subjects underwent 60-min dynamic PET scans using a long axial field of view PET/CT scanner. Five arterial manual blood samples were collected during the scan to estimate plasma-to-whole blood ratios and plasma parent fractions. Brain tissue time-activity curves were extracted using the Hammers maximum-probability atlas. A two-tissue compartment model was used to estimate the brain's volume of distribution (V_T). Parametric Logan V_T images were generated, and V_T values were extracted for the small intestines. ***Results:*** No significant differences were observed between the HV and PD groups in whole blood arterial concentrations or plasma parent fractions. Whole brain V_T values (white and grey matter) showed no significant differences between PD and HV groups. However, regional differences emerged: increases in V_T in the brainstem (14.6%) and pallidum (12.7%) in PD patients suggest potential P-gp alterations in these regions. In contrast, decreases in V_T in the caudate nucleus (-17.9%), ventricles (-29.5%), and corpus callosum (-17.6%) indicate potential reductions in P-gp function. These findings are particularly relevant as the brainstem, pallidum, and caudate nucleus are closely linked with motor control and cognitive functions affected in PD[2]. In the small intestine, mean V_T was 40.7% lower in PD, though not statistically significant. High intersubject variability was observed, and one PD subject with long disease duration showed markedly lower V_T. ***Conclusion:*** Our findings show no significant differences in P-gp function in the BBB and small intestines of PD patients and HV, assessed by [^{18}F]MC225 PET. However, the small sample size limits these results' statistical power and generalizability. Interestingly, changes were observed in brain regions associated with PD pathology, which warrants further investigation in larger PD groups concerning disease stage and symptom severity. ***References:*** 1. OP-052

Study on the Value of Whole-Brain Dopamine Transporter Loss in Parkinson's Disease and Its Subtypes Based on ^{11}C-CFT PET Imaging

X. Guo[1], *J. Li*[1], *J. Guo*[2,3,4], *S. Hu*[1,5,6];
[1]*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA,* [2]*Department of Neurology, Xiangya Hospital, Central South University, Changsha, CHINA,* [3]*Key Laboratory of Hunan Province in Neurodegenerative Disorders, Central South University, Changsha, CHINA,* [4]*Hunan International Scientific and Technological Cooperation Base of Neurodegenerative and Neurogenetic Diseases, Changsha, CHINA,* [5]*National Clinical Research Center for Geriatric Disorders, Xiangya Hospital, Central South University, Changsha, CHINA,* [6]*Key Laboratory of Biological Nanotechnology, Changsha, CHINA.*

Aim/Introduction: This study utilized whole-brain ^{11}C-CFT PET imaging to investigate alterations in dopaminergic pathways of Parkinson's disease (PD), explore pathogenic differences between tremor-dominant (TD) and postural instability/gait difficulty (PIGD) subtypes, and develop machine learning models for early PD diagnosis and subtype differentiation. ***Materials and Methods:*** In this retrospective study, we enrolled 197 PD patients (80 TD, 117 PIGD) and 21 age- and gender-matched healthy controls (HCs) underwent ^{11}C-CFT PET scans. Differential analysis was performed across whole-brain regions. Spearman correlation analysis was employed to assess the relationships between regional tracer uptake and clinical scores. Support Vector Machine (SVM), Logistic Regression (LR), and Random Forest (RF) algorithms were used to construct diagnostic and subtype classification models, and the best performing classifier was further applied to subtype classification based on distinct brain regions. ***Results:*** ^{11}C-CFT uptake was reduced not only in nigrostriatal regions but also more extensively in areas associated with other dopaminergic pathways, including the ventral tegmental area, amygdala, nucleus accumbens (NAcc) and insula. Correlation analysis indicated that DAT loss in these limbic regions was correlated with non-motor symptoms, with the NAcc specifically linked to depression and freezing of gait. Compared to the TD group, the PIGD group showed significantly lower ^{11}C-CFT uptake in the putamen, caudate nucleus, pallidum, and NAcc contralateral to the most clinically affected side, and these reductions strongly correlated with PD severity ($|r|>0.4$, $p<0.01$). For early PD diagnosis, SVM, LR, and RF models all achieved perfect discrimination (AUC = 1.00). For subtype differentiation, models based on nigrostriatal regions, extra-nigrostriatal regions, and whole-brain regions yielded AUC values of 0.78 (specificity = 76%, sensitivity = 64%), 0.64 (specificity = 61%, sensitivity = 100%), and 0.84 (specificity = 79%, sensitivity = 94%), respectively. ***Conclusion:*** Our findings demonstrate widespread degeneration across multiple mesolimbic dopamine pathways in PD and highlight the diagnostic value of extra-nigrostriatal regions in early PD detection and subtype differentiation. The progression from TD to PIGD subtype may reflect further deterioration of dopaminergic projections in the striatum, pallidum, and NAcc contralateral to the most clinically affected side. Additionally, we successfully developed effective models for early PD diagnosis and subtype classification.

Pittsburgh compound B positron emission tomography detects cardiomyopathy in hereditary transthyretin amyloidosis patients with negative bone scintigraphy

H. Tingen, G. N. Stormezand, J. H. van Snick, ***Y. Hu****, P. A. van der Zwaag, P. van der Meer, B. P. C. Hazenberg, G. Luurtsema, H. L. A. Nienhuis, R. H. J. A. Slart;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Transthyretin (ATTR) amyloidosis is a systemic disease characterized by deposition of misfolded transthyretin protein. Bone scintigraphy can generally diagnose ATTR related cardiomyopathy (ATTR-CM) with high accuracy. However, it has reduced sensitivity in certain transthyretin gene (TTR) variants, which complicates screening and may delay diagnosis of ATTR-CM in individuals carrying these variants. Previous studies suggest that [^{11}C]-Pittsburgh Compound-B ([^{11}C]PiB) positron emission tomography (PET) and can detect cardiac and brain ATTR deposits in patients with TTR variants associated with reduced bone scintigraphy sensitivity. This case series evaluates the effectiveness of PET with [^{11}C]PiB for detecting ATTR-CM and brain involvement in patients with TTR variants associated with reduced bone scintigraphy sensitivity. ***Materials and Methods:*** This prospective case series included four ATTRv amyloidosis patients with TTR variants associated with reduced bone scintigraphy sensitivity,

and two control patients (one ATTRv and one wild-type ATTR (ATTRwt) amyloidosis patient) with cardiac radiotracer uptake bone scintigraphy. All patients underwent diagnostic work-up between April 2024 and March 2025, including [^{11}C]PiB PET/CT. Cardiac and brain [^{11}C]PiB uptake were assessed visually. For cardiac evaluation, target-to-background ratios (TBR) were calculated by comparing myocardial radiotracer uptake to blood pool uptake. TBR ≥1.09 was considered positive for ATTR-CM. For brain analysis, cortical SUV ratios were calculated, comparing radiotracer uptake in the prefrontal cortex, orbitofrontal cortex, temporal cortex and anterior cingulate cortex to uptake in the pons. SUV ratios ≥0.7 were considered positive for brain involvement. ***Results:*** Cardiac [^{11}C]PiB uptake was observed in three of four ATTRv patients despite negative bone scintigraphy. In the one of four patients, there was visually equivocal radiotracer uptake, but elevated TBRs did indicate ATTR-CM. Conversely, both ATTRv and ATTRwt patients with a positive bone scintigraphy had negative or inconclusive [^{11}C]PiB PET results. Brain uptake was observed in two asymptomatic patients, while no uptake was seen in two patients with suspected brain involvement, including one patient with magnetic resonance imaging confirmed leptomeningeal amyloid deposits. ***Conclusion:*** [^{11}C]PiB PET is an effective tool for detecting ATTR-CM in patients with TTR variants associated with reduced bone scintigraphy sensitivity, and could serve as an alternative non-invasive method for cardiac screening in individuals with these variants. However, its utility for detecting brain involvement in symptomatic ATTRv patients remains uncertain and further research is warranted.

New Quantitative SPECT-CT Parameters in the Diagnosis of Cardiac Amyloidosis

Ü. Aksu[1], *E. M. Kaya*[1], *D. İnan*[2], *C. Yağmur*[1], *B. E. Akkaş*[1];
[1]*Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Basaksehir Cam and Sakura City Hospital, Department of Cardiology, Istanbul, TÜRKIYE.*

Aim/Introduction: Traditional methods, including visual assessment based on planar imaging and the heart/contralateral lung(H/CL) ratio, are subject to observer variability and may pose diagnostic challenges, particularly in the early stages of the disease or in the presence of blood pool uptake. The aim of this study is to propose a more objective and sensitive method for the diagnosis of ATTR-CA by calculating a quantitative ratio between myocardial wall and blood pool uptake using 99mTc-PYP SPECT/CT. ***Materials and Methods:*** 336 patients who underwent Tc-PYP scintigraphy with suspected cardiac amyloidosis were retrospectively evaluated. Planar and SPECT-CT imaging were performed 1 and 3 hours after injection of 99mTc-PYP. From planar images, the H/CL ratio and Perugini score were determined. On SPECT/CT, spherical volumes of interest (VOI) with a diameter of 1.25 cm were drawn over the septum, left and right ventricular walls, and blood pool, and the S/BP, LV/BP, and RV/BP ratios were calculated. ***Results:*** Nineteen patients with monoclonal gammopathy were excluded from the study. The final cohort consisted of 317 patients (mean age: 62; 56% male). According to planar Perugini scores (PG), patients were grouped as PG 0 (n=84), PG 1 (n=172), and PG 2-3 (n=61). Patients with a C/CL >1.5, Grade 2-3 uptake, no significant blood pool uptake on SPECT and normal hematological tests were considered positive for ATTR-CA. Accordingly, 19 patients were positive (Grade 2-3), 42 patients were suspicious (Grade 2-3), and 256 patients (Grade 0-1) were evaluated as negative. After reevaluation with SPECT/CT, no change was observed in Grade 0-1 patients. Of the 19 patients evaluated as positive in Grade 2-3, 6 were reclassified as negative. Among the 42 suspicious patients, 1 was confirmed as positive, and the remaining 41 were evaluated as negative. This led to reclassification in 14% of the total patient group, while the reclassification rate reached 81% among the suspicious and positive groups. S/BP, LV/BP, and RV/BP ratios were 0.36, 0.40, and 0.38, respectively, in negative patients; 0.47, 0.49, and 0.44 in suspicious patients; and 2.72, 2.37, and 1.32 in positive patients. Using cut-off values of S/BP ≥0.73 and LV/BP ≥0.79, sensitivity was found to be 100% and specificity 92.5%. ***Conclusion:*** Quantitative ratios obtained from SPECT/CT provide higher diagnostic accuracy in the diagnosis of ATTR-CA compared to planar imaging. This method increases diagnostic precision by allowing the reclassification of most suspicious cases as negative and minimizes reader-related errors.

OP-055

A Diagnostic Nomogram for ATTR Cardiac Amyloidosis: Toward Smarter Use of Scintigraphy

A. Agosti[1,2], *G. Garelli*[1,2], *C. Dell'acqua*[1,2], *E. Califaretti*[1], *S. Grimaldi*[1], *M. Finessi*[1], *S. D. Morbelli*[1,2], *A. Lesca*[1], *R. Casoni*[1], *G. Rovera*[1,2];
[1]*Nuclear Medicine Unit, AOU Città della Salute e della Scienza, Turin, ITALY,* [2]*Department of Medical Sciences, University of Turin, Turin, ITALY.*

Aim/Introduction: The advent of disease-modifying therapies for transthyretin (ATTR) cardiac amyloidosis has made early and accurate diagnosis essential, both for timely treatment and genetic screening in at-risk family members. Scintigraphy with bone tracers enables non-invasive diagnosis when Perugini score is ≥2 and no monoclonal component is present. With rising referral rates but many negative results, better pre-test patient selection is needed. This study aimed to develop a clinical nomogram to identify patients at higher likelihood of a positive scintigraphy scan, enhancing diagnostic accuracy while reducing unnecessary imaging. ***Materials and Methods:*** A retrospective analysis was conducted on patients referred at our center for cardiac scintigraphy on suspicion of ATTR cardiac amyloidosis. Collected variables included demographics, imaging, laboratory markers, clinical findings, and comorbidities. Univariate and multivariate logistic regression (R v4.2.1) identified predictors of positive scans (Perugini ≥2), and the multivariate model was used to build a predictive nomogram. Model performance was evaluated via Nagelkerke-R^2, confusion matrix, ROC curve, calibration curve, and internal validation with bootstrapping. ***Results:*** Out of 234 patients referred for cardiac scintigraphy, 127 showed a Perugini score of 0, 12 a score of 1, and 95 a score ≥2. At multivariate logistic regression, male gender (OR 2.70, 95%CI 1.07-7.29, p=0.041), older age (OR 1.11, 95%CI 1.06-1.18, p<0.001), increased interventricular septal thickness (OR 1.40, 95%CI 1.21-1.66, p<0.001), grade II-III diastolic dysfunction (OR 3.23, 95%CI 1.43-7.55, p=0.005) and carpal tunnel syndrome (OR 5.86, 95%CI 2.44-15.16, p<0.001) were independently associated with positive scintigraphy (Perugini ≥2). Other variables - such as ECG low voltages, arrhythmia, and apical sparing - were significant in univariate analysis but not retained in the multivariate model. This could partly be due to the limited availability of apical sparing data in echocardiographic reports, underscoring the need for standardized imaging in suspected cardiac amyloidosis. The model demonstrated good fit (Nagelkerke-R^2 0.55) and diagnostic performance: accuracy 79.1% (95%CI 72.6-84.7), sensitivity 77.6%, specificity 80.2%, PPV 72.8%, NPV 83.9%, and AUC 0.88. Calibration showed good agreement between predicted and observed outcomes. Applying the nomogram at a 5% threshold could have avoided 24.3% of negative scans without missing diagnoses; at 7%, 33.3% of negative scans could be avoided with only 1.3% of true cases missed. ***Conclusion:*** The newly developed nomogram could represent an effective tool for predicting positive cardiac scintigraphy in ATTR amyloidosis, enhancing diagnostic precision while minimizing unnecessary imaging, and is now ready for external validation in an independent cohort.

OP-056

Prevalence and Clinical Outcomes of Incidental Cardiac Uptake in Bone Scintigraphies Unrelated to Cardiac Amyloidosis: The Overlooked ATTR Cohort

R. Sá e Silva, *J. Escaleira, L. Costa, P. Monteiro, L. Lobato, P. Rodrigues;*
Centro Hospitalar Universitário do Porto, Porto, PORTUGAL.

Aim/Introduction: Cardiac amyloidosis (CA), particularly the wild-type transthyretin (ATTRwt-CA), is an underdiagnosed condition with increasing relevance. Bone scintigraphy (BS) using 99mTc-DPD can incidentally reveal cardiac uptake, offering an opportunity for early identification of ATTR-CA. This study aims to evaluate the prevalence of incidental cardiac uptake (ICU) in routine BS performed for non-CA indications, patient's outcomes, and to determine the proportion of patients meeting the 2021-ESC criteria for CA screening. ***Materials and Methods:*** Retrospective, observational study including all BS performed between January/2023-March/2025 for non-CA indications. Two independent readers assessed Perugini's visual score. For patients with ICU, medical records were reviewed to assess referrals to Cardiology consultation (CC); p-value<0.05 was considered statistically significant. ***Results:*** Out of 1561 BS performed for non-CA purposes, ICU was observed in 17 cases (1.1%). After excluding 3repeated exams, 14 cases were analyzed, all conducted in the context of prostate cancer staging or follow-up (71%). Patients, with median age of 85 years, presented with multiple cardiovascular (CV) risk factors. Notably, 50% had pre-existing CV symptoms, dyspnea being the most prevalent (Table I).The Perugini score was positive (score 2/3) in 64% of cases and indeterminate (score 1) in 36%. ICU was detailed in all BS reports, although included in the conclusion only in 43%. Referral to a CC occurred in 29% of patients and more frequent when ICU was mentioned in the BS report conclusion (p=0,015); the patients were diagnosed with ATTRwt-CA after exclusion of monoclonal gammopathies and verifying normal TTR gene sequencing. A diagnostic delay was present, with a median of 18 months between the BS and the ATTR-CA diagnosis.In patients with recent TTE, 71% met screening criteria for CA. "Red flags" included heart failure with preserved ejection fraction (50%), increased septal wall thickness (64%), bilateral carpal tunnel syndrome (14%), AV conduction disorders (29%), and reduced global longitudinal strain (29%). In patients with prior BS, 40% demonstrated positive variation in Perugini score. ***Conclusion:*** Incidental cardiac uptake in BS offers a valuable opportunity for earlier recognition of ATTRwt-CA, particularly in elderly male undergoing BS for prostate cancer staging. Our cohort reinforce the diagnostic complexity by the coexisting CV comorbidities. An attentive incorporation of BS, clinical evaluation and genetic tests lead us to advise a structured direct referral from Nuclear Medicine to Cardiology, adjusting for timely treatment and evading the complexity of a multisystem disease related to heart failure.

OP-057

Implementation of a predictive model for mortality using AI in patients with TTR cardiac amyloidosis confirmed by ^{99m}Tc-DPD scintigraphy.

F. Sebastián Palacid, *N. Álvarez Mena, R. C. Zambrano Infantino, M. García Aragón, B. M. Jaramillo López, Á. R. Suazo Montero, J. Gómez Hidalgo, C. Riola Parada, R. Ruano Pérez;*
Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To develop and validate a model to predict mortality risk in patients with TTR cardiac amyloidosis using key clinical parameters to support clinical decision making. ***Materials and Methods:*** A total of 121 patients with a diagnosis confirmed by 99mTc-DPD scintigraphy were included. A 3-year follow-up was performed to determine the number of deaths. The most relevant parameters for the model were identified: age, sex, presence of arrhythmias, arterial hypertension and LVEF calculated by gated SPECT-CT. The prediction model was developed by ChatGPT using Random Forest with class balancing to counteract the imbalance between deceased and non-deceased. Its performance was measured by cross-validation and ROC curve analysis. ***Results:*** The sample consisted of 79 men and 42 women (mean age 78.6 ± 11.7 years). During follow-up, 29 patients (24%) died.LVEF calculated by gSPECT contributed 12% to the overall model power, with the most influential parameters being age (27%) and the presence of arrhythmias (22.5%). The model achieved an overall accuracy of 70.3% and an area under the curve (AUC) of 0.71.In the non-deceased, it achieved an accuracy of 87.5% and a sensitivity of 72.4%; in the deceased, it achieved an accuracy of 38.5% and a sensitivity of 62.5%.In addition, an interface was designed to allow rapid data entry, resulting in efficient risk estimation. ***Conclusion:*** The proposed model represents a practical and effective tool for predicting mortality in patients with TTR cardiac amyloidosis. Its implementation could contribute to better risk stratification, optimise the allocation of clinical resources and promote more personalised care.

OP-058

Myocardium-to-cavity ratio as a novel quantitative index in cardiac amyloidosis: dual-isotope ^{99m}Tc-pyrophosphate/^{201}Tl imaging with D-SPECT

K. Nakajima[1], *S. Yamashita*[2], *T. Kitano*[2], *H. Kato*[2], *H. Yamamoto*[2], *K. Yokoyama*[2];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Public Central Hospital of Matto Ishikawa, Hakusan, JAPAN.*

Aim/Introduction: In cardiac amyloidosis imaging using ^{99m}Tc-pyrophosphate (PYP), the heart-to-contralateral lung (H/CL) ratio from planar images has been widely adopted. However, cardiac-dedicated cadmium-zinc-telluride cameras such as D-SPECT do not employ planar acquisition, and H/CL ratio using an Anger camera has limitations in distinguishing myocardial from blood-pool activity, particularly near the diagnostic threshold of 1.3-1.5. This study aimed to evaluate the feasibility of a myocardium-to-cavity (M/C) ratio, derived from dual-isotope ^{99m}Tc-PYP/^{201}Tl SPECT, as an alternative quantitative index. ***Materials and Methods:*** We studied 121 consecutive patients with suspected cardiac amyloidosis who underwent dual-isotope ^{99m}Tc-PYP/^{201}Tl imaging. The clinical diagnosis of cardiac diagnosis followed Japanese Circulation Society's guidelines. Anterior planar images were acquired with an Anger camera 1 hour post ^{99m}Tc-PYP injection. D-SPECT dual-isotope images were acquired 10 minutes after ^{201}Tl injection at 1 and/or 3 hours after ^{99m}Tc-PYP administration. For M/C ratio calculation, three short-axis slices were summed. The slice with the maximum ^{201}Tl count was used to define myocardial regions with appropriate zooming, and eight circular regions of interest (ROIs) were placed over the myocardium and left ventricular cavity on base, mid, and apical slices (3 added slices ? 3 levels ? 8 ROIs corresponding to 72 volumes of interest). These ROIs were then applied to the ^{99m}Tc-PYP image with a complete match between perfusion and PYP uptake. Diagnostic accuracy of H/CL and M/C ratios was compared. Functional parameters of volume and ejection fraction were obtained from the ^{201}Tl images, and segmental perfusion was compared with ^{99m}Tc-PYP uptake. ***Results:*** Optimal cut-offs were 1.5 for H/CL and 1.0 for M/C ratios. Among 121 patients, 19 (16%) were visually PYP-positive. Both H/CL and M/C ratios were significantly higher in PYP-positive cases. Five patients with H/CL > 1.5 but M/C < 1.0 were visually negative, and correctly classified by M/C ratio. M/C ratio showed 100% sensitivity, specificity, and predictive values. H/CL yielded 100% sensitivity, 95% specificity, 79% positive predictive value, and 100% negative predictive value, reflecting ambiguity near H/CL = 1.5. Among 19 PYP-positive patients, 13 (68%) showed a mismatch pattern—reduced ^{201}Tl uptake corresponding to high ^{99m}Tc-PYP uptake. ***Conclusion:*** In D-SPECT-based imaging, the M/C ratio offers superior diagnostic accuracy over the planar H/CL

ratio, especially in reducing false positives near the conventional threshold. The method is simple, reproducible, and uses a clinically convenient threshold (1.0), making it a promising candidate to replace H/CL when dual-isotope imaging is available.

OP-059

Early-phase 99mTc-HDP planar imaging in suspected cardiac amyloidosis: predictive value of heart-to-contralateral lung ratio for late-phase Perugini scoring

G. Fiorillo[1], *A. Della Morte*[1], *M. Coppola*[1], *M. Scarano*[1], *M. Bellino*[2], *S. Migliarino*[2], *L. Pace*[2];
[1]*Azienda Ospedaliera Universitaria San Giovanni di Dio e Ruggi d'Aragona, Salerno, ITALY,* [2]*Dipartimento di Medicina, Chirurgia e Odontoiatria, Università degli Studi di Salerno (UNISA), Salerno, ITALY.*

Aim/Introduction: Late-phase 99mTc-HDP scintigraphy with Perugini scoring is a widely accepted method to identify transthyretin-related cardiac amyloidosis. However, the diagnostic value of early-phase quantitative indices and tomographic parameters such as SUV from SPECT/CT imaging is still under investigation. This study aims to evaluate whether early heart-to-contralateral lung (H/CL) ratios and quantitative data from SPECT/CT correlate with 3-hour Perugini scores, providing predictive value in the diagnostic workflow. ***Materials and Methods:*** This ongoing retrospective study began in September 2018 and includes 80 patients with suspected cardiac amyloidosis. All patients underwent planar imaging with 99mTc-HDP at both 5-10 minutes (early phase) and 3 hours (late phase), as well as SPECT imaging. Following a technological upgrade in 2023, all patients with a positive Perugini score subsequently underwent SPECT/CT instead of conventional SPECT, allowing extraction of SUVmax and SUVmean values. The myocardial uptake at 3 hours was visually scored using the Perugini scale (0-3). H/CL ratios were calculated for both phases. Pearson and Spearman correlations were used to assess the relationship between early and late-phase indices, SUV values, and Perugini scores. ***Results:*** Out of 80 patients, 18 (22.5%) had positive cardiac uptake (Perugini score ≥1). - H/CL (early phase) showed a strong positive correlation with Perugini score ($r = 0.742$, $p = 0.00099$) - H/CL (late phase) also correlated significantly with Perugini score ($r = 0.744$, $p = 0.00095$) - In the subgroup of patients undergoing SPECT/CT: - The mean SUVmean was 11.06 ± 6.68 (range: 1.579-21.04) - The mean SUVmax was 13.93 ± 6.77 (range: 1.73-22.45) - SUVmean demonstrated a very strong and statistically significant correlation with the Perugini score ($r = 0.851$, $p = 0.00045$) - SUVmax demonstrated a very strong and statistically significant correlation with the Perugini score ($r = 0.851$, $p = 0.00045$) ***Conclusion:*** The H/CL ratio measured in the early phase of 99mTc-HDP planar imaging is strongly predictive of the final Perugini score at 3 hours. These findings support the diagnostic value of early-phase quantification as a non-invasive predictor of cardiac amyloid burden, potentially aiding early diagnosis and improving decision-making in borderline or atypical cases. The transition to SPECT/CT imaging from 2023 has allowed enhanced quantitative assessment, with both SUVmean and SUVmax emerging as reliable markers strongly associated with myocardial amyloid deposition.

OP-060

Aortic valve calcium score from computed tomography for signal localization by cardiac amyloid radionuclide imaging to predict aortic stenosis and assess prognosis in patients with transthyretin cardiomyopathy

G. Bonnans*, R. Engel, E. Cariou, H. Malerbi, S. Cazalbou, Y. Lavie-Badie, E. Cassol, P. Fournier, O. Lairez;*
CHU Rangueil, Toulouse, FRANCE.

Aim/Introduction: Transthyretin cardiomyopathy (ATTR-CM) and aortic stenosis (AS) are two frequently associated pathologies. The diagnosis of ATTR-CM can be made by performing bone scintigraphy with tomographic acquisitions and a computed tomography (CT) scan to localize the signal if positive. Calcifications of the aortic valve can be seen on this CT scan. The aim of this study was to determine whether aortic calcifications on the CT scan performed at the time of bone scintigraphy for the diagnosis of ATTR-CM were predictive of AS and had an impact on prognosis. ***Materials and Methods:*** Consecutive patients referred to nuclear medicine and diagnosed with ATTR-CM on bone scintigraphy after exclusion of monoclonal gammopathy were included. Patients with a history of aortic valve replacement were excluded. CT images performed for signal localization were reviewed for the presence of aortic calcifications. In the presence of calcifications, a calcium score was calculated from axial slices using a threshold of 130 Hounsfield units. Calcium score results were compared with aortic valve hemodynamic parameters assessed by transthoracic echocardiography to classify patients according to the presence and severity of AS. A three-stage visual score was developed to assess the extent of aortic valve calcifications (score 0: absence or spotty calcification; score 1: < 50% of annulus circumference; score 2: ≥ 50%). Receiver operating characteristic (ROC) analysis and Cox proportional hazards models were used for statistical analysis. ***Results:*** Two hundred and sixty-three patients were included. Aortic calcifications based on visual score > 0 were present in 153 (58%) patients. Among them, the median calcium score was 430 [200-1140]. A cut-off calcium score ≥ 380 predicted AS with an area under the ROC curve of 0.93 ($P < 0.0001$), sensitivity 91%, specificity 81%. For severe AS, a threshold ≥ 1690 yielded an AUC of 0.98 ($P < 0.0001$), allowing a sensitivity of 94% and a specificity of 96%. A visual score of 2 predicted severe AS with 94% sensitivity and 90% specificity. Both the aortic valve calcium score and visual score were independent predictors of all-cause mortality during follow-up. ***Conclusion:*** Aortic calcifications on CT scan of bone scintigraphy are found in almost two-thirds of patients with ATTR-CM. Assessed using both a semi-quantitative visual score and a calcium score, they are strong predictors of AS severity and mortality. A calcium score ≥ 1690 and visual score 2 reliably identify severe AS.

Coronary Artery Calcification as a Complementary Marker in ATTRV30M Amyloidosis: Insights Across the ^{99m}Tc-DPD Uptake Spectrum

J. Rei da Cruz Escaleira[1,2], *R. Sá e Silva*[3], *J. Bessa*[4], *A. Campos*[4,2,5], *A. Cunha*[4], *J. Silva*[3], *L. Costa*[3], *P. Rodrigues*[6,2], *J. Santos*[4,2,5], *L. Lobato*[4,2,5];
[1]*Department of Nuclear Medicine, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL,* [2]*Unit for Multidisciplinary Research in Biomedicine (UMIB), Oporto, PORTUGAL,* [3]*Department of Nuclear Medicine, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL,* [4]*Department of Nephrology, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL,* [5]*Laboratory for Integrative and Translational Research in Population Health (ITR), Oporto, PORTUGAL,* [6]*Department of Cardiology, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL.*

Aim/Introduction: Bone-seeking tracers, such as DPD, are essential for the non-invasive detection of transthyretin(ATTR) amyloid deposits in the heart. Although the mechanism underlying tracer uptake remains unclear, microcalcifications have been proposed as a contributing factor. In addition to interstitial and valvular deposition, ATTR may also involve coronary vessels. This study investigates the extent of coronary artery calcification (CAC) in patients with ATTRV30M amyloidosis. ***Materials and Methods:*** We retrospectively analyzed ATTRV30M patients followed by nephrologists at a single centre from until 2025. Diagnostic criteria for cardiac amyloidosis (CA): interventricular septal thickening≥ 12 mm (without other cause) or a Perugini score≥ 2, besides no plasma cell disease. The cardiorenal assessment was established on the National Amyloidosis Centre (NAC) staging system. CAC was assessed using chest CT scans, either obtained during DPD

SPECT/CT imaging or from unrelated CT studies. CAC severity was graded using a visual ordinal scale as follows: 0,no CAC visualized; 1 (mild), isolated speckles of CAC in any coronary artery; 2 (moderate), greater than mild but less than severe; 3 (severe), at least one coronary segment with contiguous, extensive, or diffuse CAC. ***Results:*** Sixty-nine patients were included, of whom 35 had CA. Among these, 28(85.7%) had a Perugini score of 0 or 1, and only 5(14.3%) had scores of 2 or 3; 12(34.3%) cases with CA experienced heart failure, all with preserved ejection fraction. Ischemic events were infrequent (one myocardial infarction and two strokes). CAC was observed in 17 patients (24.6%), who were predominantly male (70.6%;p=.006) and tended to develop symptoms at a median age of 39 years, five years later than those without CAC(p=.052). No significant relationship was observed between NAC and CAC grades (Table I). A Perugini score of 0 was primarily observed in patients with absent or mild CAC, whereas detectable DPD uptake(score≥1) was more frequently associated with moderate/severe CAC (p<.001;Table II). In multivariate logistic regression adjusted for cardiovascular risk factors, DPD uptake remained an independent predictor of moderate to severe CAC (OR=9.8;p=.022). Conversely, while CAC in this range also predicted DPD uptake (OR=8.1;p=.030), this association may be modulated by sex (OR=4.9; p=.053). The presence of CAC, regardless of severity, was independently associated with CA (OR=5.9; p=.026). ***Conclusion:*** This study is the first to investigate the relationship between CAC/DPD uptake in ATTRV30M amyloidosis. CAC was overall uncommon in non-CA patients; however, it emerged as a potential complementary imaging marker in those with cardiac involvement, highlighting a possible calcium-mediated interplay between amyloid fibrils, the myocardium, and coronary vessels.

3-dimensional Microfluidic "Stacks" Platform for Advanced in vitro Radiobiology Studies

M. Lindsey[1], *E. Recchia*[1,2], *A. Thickens*[1], *M. Bio Idrissou*[1], *O. Kwon*[1], *B. Bednarz*[1], *D. Kosoff*[1,2,3], *R. Hernandez*[1];
[1]*University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*University of Wisconsin Carbone Cancer Center, Madison, WI, UNITED STATES OF AMERICA,* [3]*William S. Middleton Memorial Veterans' Hospital, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Development of robust and predictable methods for drug evaluation is a key priority of the FDA. Microphysiological systems, including spheroid or organ-on-a-chip models, better represent in vivo tissue architectures and biological responses. We have developed a microscale cell culture platform ("Stacks") that permits isotropic dose deposition from radiopharmaceutical therapy (RPT) to 3-dimensional clusters of cells. Our platform captures the increased radioresistance of cells seen in vivo, allowing for robust radiobiological analyses. ***Materials and Methods:*** Absorbed dose from free ^{225}Ac and ^{177}Lu was estimated using the MIRD formalism, with S-values computed in Geant4 with the G4EmLivermorePhysics model for both the Stacks platform and 96-well plate formats. LNCaP metastatic prostate cancer cells were seeded onto either the collagen-fibronectin matrices of the Stacks platform or the 96-well plate at a concentration of 5,000 cells/mL. Radioisotopes were suspended in media and applied at increasing activity concentrations. For ^{225}Ac, treatments were titrated up to 10 µCi/mL (Stacks) or 1 µCi/mL (96-well). For ^{177}Lu, treatments were titrated up to 10 mCi/mL (Stacks) or 200 µCi/mL (96-well). In the Stacks platform, convectively circulating treatment droplets envelope the cell culture, permitting isotropic dose deposition from suspended radioisotopes. Cells were incubated for 96 hours. Cellular vitality in the Stacks platform was determined via bioluminescent imaging with CellTiter-Glo. Cellular vitality in the 96-well plate was determined with PrestoBlue in a live-cell assay. ***Results:*** Computed S-values for the Stacks platform were orders of magnitude larger than those for the 96-well plate, reflecting the significant difference that 3-dimensional geometry plays in dose deposition. The LNCaP cells were more radioresistant in the Stacks platform at the same absorbed dose. For cells treated with 3 Gy ^{225}Ac, vitality was reduced to 29.55±5.15% in the 96-well plate but only 88.52±12.49% in the Stacks platform (p<0.0001). Likewise, for cells treated with 30 Gy ^{177}Lu, vitality was reduced to 32.07±5.76% in the 96-well plate but only 60.01±7.33% in the Stacks platform (p<0001). ***Conclusion:*** We have developed a microfluidic platform that more accurately models in vivo radiation dose response. Despite handling larger absorbed doses, radiobiological studies in the Stacks platform require less activity due to its microscale, making them more economic and limiting exposure. The Stacks platform allows for more clinically relevant in vitro radiobiological modeling without sacrificing throughput.

EPS-002

[^{177}Lu]Lu-PSMA: impacting the full transcriptome of prostate cancer cells.

F. Amoroso[1,2], *B. T. Cornelissen*[1,2];
[1]*Dept. of Nuclear Medicine and Molecular Imaging, University Medical Centre Groningen, Groningen, NETHERLANDS,* [2]*Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Radiotherapy is an effective therapeutic option for locally advanced prostate cancer (PCa). However, when PCa progresses, metastatic disease is incurable. Despite the promising results of the clinical trials with ^{177}Lu-labelled PSMA (1), and the ever-mounting interest, treatment with [^{177}Lu]Lu-PSMA is not yet curative. Improving our understanding of the (radio)biology of the damage induced by [^{177}Lu]Lu-PSMA will aid in designing new targeted and more effective treatments for PCa patients. ***Materials and Methods:*** We performed a comprehensive analysis on the full transcriptome of prostate cancer cells (22Rv1, LNCaP and C4-2B), treated with [^{177}Lu]Lu-PSMA for 2 hours, over a period of 6 days, using RNA-Seq. ***Results:*** We recorded a progressive enrichment of genes that are differentially expressed over time as a consequence of [^{177}Lu]Lu-PSMA treatment. Performing pathway analysis, we confirmed the activation of pathways that relate to the induction of genomic reorganization (e.g., of DNA and RNA synthesis-related processes), DNA damage repair (such as Nucleotide Excision Repair) and autophagic processes that are known to correlate with cellular responses to ionizing radiation (2). We also identified new biologies that are impacted by the treatment with this radiolabelled peptide. ***Conclusion:*** With this study we aimed to improve our understanding of the radiobiological effects that beta and gamma emitter [^{177}Lu]Lu-PSMA has on prostate cancer cell lines. Moreover, we shed the light on new pathways that are not strictly related to the induction of the DNA damage and can represent new therapeutic avenues for prostate cancer patients. ***References:*** (1) Novartis. Phase III VISION study. 2021 (2) Chaurasia M, et al., Free Radic Res. 2016;50(3):273-90. doi: 10.3109/10715762.2015.1129534. Epub 2016 Jan 14. PMID: 26764568.

EPS-003

Using ^{18}F-FES PET imaging of ERα re-expression in triple-negative breast cancer in response to anti-platelet derived growth factor C therapy

I. Burvenich[1], *S. Quazi*[1], *N. Huynh*[1], *A. Rigopoulos*[1], *A. McDonald*[1], *U. Ackermann*[2], *A. Scott*[1];
[1]*Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA.*

Aim/Introduction: Monoclonal antibody (mAb) 6B3 can cause re-expression of estrogen receptor alpha (ERα) in triple-negative breast cancer (TNBC) mouse models, via neutralisation of platelet derived growth factor C (PDGF-CC) in the tumour microenvironment (1). Here, we investigated if ^{18}F-FES PET imaging can be used to measure and quantify the re-expression of ERα in TNBC models following mAb 6B3 therapy or genetic ablation of PDGF-C. ***Materials and Methods:*** Ovariectomised BALB/c nude mice were subcutaneously injected with MCF-7 (5x10^6; n=5), 231HMclB2 (3x10^6; n=10) or 231HMclB2$^{pdgfc-/-}$ cells (3x10^6; n=5) in the shoulder. 231HMclB2-tumour-bearing mice were treated with 100 µL of 6B3 (50 mg/kg, twice weekly) or PBS vehicle control (n = 5). To support growth of ERα-expressing tumour cells, all mice received subcutaneous injections of 20µg 17β-estradiol (20µg/20µL; corn oil:ethanol, 9:1) in the nape of their necks starting 2 days prior to cell injection, followed by five injections per week for 5 weeks. Once tumour volumes reached approximately 100mm^3, 17β-estradiol injections were halted 3 days prior to mice receiving ^{18}F-FES (5-11 MBq) to avoid competitive binding to ERα. After 1 hour, a 15-minutes PET acquisition was performed on each mouse. ERα target expression was assessed using immunohistochemistry. ***Results:*** As expected, highly ERα-expressing MCF-7 tumours displayed specific uptake of ^{18}F-FES. In contrast, no uptake of ^{18}F-FES was observed in 231HMclB2$^{pdgfc-/-}$ tumours or 231HMclB2 tumours treated with either 6B3 or PBS. Ex vivo biodistribution study confirmed low uptake of ^{18}F-FES by 231HMclB2$^{pdgfc-/-}$ tumours or 231HMclB2 tumours treated with 6B3. Immunohistochemistry analysis confirmed the deletion of PDGF-C in 231HMclB2$^{pdgfc-/-}$ tumours, however, some ERα expression was observed in 231HMclB2 tumours treated with 6B3. ***Conclusion:*** Although some ERα re-expression was induced in 231HMclB2 tumours treated for 4 weeks with mAb 6B3, the low expression level of ERα could not be detected using ^{18}F-FES PET imaging. ***References:*** 1. Roswall P, et al. Microenvironmental control of breast cancer subtype elicited through paracrine platelet-derived growth factor-CC signaling. Nat Med. 2018 May;24(4):463-473. doi: 10.1038/nm.4494.

EPS-004

3D spheroids for analysis of targeted binding and toxicity of radionuclide-labeled affibodies

I. Zelepukin, *A. Herlina, A. Vorobyeva, V. Tolmachev; Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: The development of targeted therapeutics requires screening of their binding efficiency and therapeutic effects in cancer cells and tumor models. Tumor spheroids, a 3D cancer in vitro model, serve as a crucial step in the evaluation of therapeutics efficiency. Spheroids partially preserved architecture and features of tumor microenvironment, and can be used for high throughput screening of drugs, which is complicated in animals by ethical reasons. ***Materials and Methods:*** We established a 3D cell culture platform for evaluating the response of spheroids to targeted therapies. The platform features soft agarose microdishes with 81 U-shaped wells. Due to the non-adhesive properties of agarose, cells naturally aggregate into compact spheroids - a phenomenon observed across seven different human and mouse cancer cell lines.We utilized this 3D culture model to investigate the binding specificity and therapeutic efficacy of the $Z_{HER2:48937}$ affibody conjugated with ^{161}Tb. For this aim we prepared spheroids from EMT-HER2 murine cell line with overexpression of human HER2 receptors and parental EMT6/P line without receptors. [^{161}Tb]Tb-$Z_{HER2:48937}$ affibodies had a specific activity of 5 MBq/nmol. For specificity binding testing, spheroids were treated for 24 h with 1 nM solution of [^{161}Tb]Tb-$Z_{HER2:48937}$, while blocking was performed by 1-h preincubation with 100 nM solution of $Z_{HER2:48937}$. For therapy, spheroids were incubated for 8 h or 24 h with 1 nM solution of [^{161}Tb]Tb-$Z_{HER2:48937}$. The toxicity was analyzed by measuring spheroids growth kinetics over 2 weeks and measurement of migration distance of cells after spheroids attachment to adhesive plastic. ***Results:*** The agarose-based microdishes enable consistent formation of multiple spheroids with 6 ± 2% diameter variation. EMT-HER2 spheroids demonstrate specific binding of [^{161}Tb]Tb-$Z_{HER2:48937}$ affibody, which could be prevented by receptor blockade. Specific binding of affibodies was not observed in EMT6/P spheroids. Treatment with [^{161}Tb]Tb-$Z_{HER2:48937}$ has a drastic effect on spheroids growth. Spheroids volume increased ~8 and ~2.2 times in non-treated and 24-h-treated groups, respectively. Incubation of spheroids with [^{161}Tb]Tb-$Z_{HER2:48937}$ for 8 h did not induce decrease of the cells proliferation. Compared to not-treated group, median migration distances were 1.52-fold lower for group treated with [^{161}Tb]Tb-$Z_{HER2:48937}$ for 24 h. ***Conclusion:*** The developed 3D cell culture platform allows to perform screening of various targeted drugs for the development of chemo- and radiopharmaceuticals**.**

EPS-005

Visualizing cerebral plasticity mechanisms using [^{18}F] UCB-H and [^{18}F]FDG in animal models of acute unilateral vestibulopathy

I. Fuxjäger[1], *M. Antons*[2], *R. Oos*[3], *G. Palumbo*[3], *S. Lindner*[3], *S. Ziegler*[3,4], *K. Matiasek*[5], *M. Brendel*[3,6,7], *R. Werner*[3], *A. Zwergal*[1,8];
[1]*German Center for Vertigo and Balance Disorders, LMU University Hospital, LMU Munich, München, GERMANY,* [2]*Department of Radiology, LMU University Hospital, LMU Munich, München, GERMANY,* [3]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, München, GERMANY,* [4]*Clinic for Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY,* [5]*Section of Clinical & Comparative Neuropathology, Centre for Clinical Veterinary Medicine, LMU Munich, München, GERMANY,* [6]*German Center for Neurodegenerative Diseases (DZNE), München, GERMANY,* [7]*Munich Cluster for Systems Neurology (SyNergy), München, GERMANY,* [8]*Department of Neurology, LMU University Hospital, LMU Munich, München, GERMANY.*

Aim/Introduction: Acute unilateral peripheral vestibular loss in patients can result from lesions in the inner ear or the vestibular nerve. Animal models reflect this by inducing preganglionic (before the Scarpa's ganglion) or postganglionic (after the ganglion) lesions of the VIIIth cranial nerve. Over time, both patients and animals recover through adaptive functional and structural central neural plasticity. However, it is unclear how central compensation mechanisms differ as a function of the peripheral vestibular lesion mechanism. ***Materials and Methods:*** Twenty-four male Sprague Dawley rats (mean age: 9.5 weeks) underwent either unilateral chemical labyrinthectomy (cUL, preganglionic) or unilateral vestibular neurectomy (UVN, postganglionic). All animals received preoperative baseline [^{18}F]FDG and [^{18}F]UCB-H PET scans. Postoperatively, [^{18}F]FDG PETs were conducted weekly for four weeks to depict changes of regional cerebral glucose metabolism (rCGM) as a surrogate for functional plasticity, and [^{18}F]UCB-H PETs at three time points over nine weeks to visualize alterations in synaptic density indicating structural plasticity. Behavioral recovery was assessed weekly using a scoring system and Open Field tests. Regional SUVr values in segmented brain regions (Schiffer rat brain atlas) were compared to baseline and between groups using mixed-effects models and voxelwise SPM analysis. ***Results:*** Both[^{18}F]FDG and [^{18}F]UCB-H PET revealed a similar spatial pattern of affected brain regions in both models. However, while rCGM

changes in the UVN and cUL model appeared to a comparable extent in vestibular network hubs, [^{18}F]UCB-H PET showed more extensive and pronounced alterations in synaptic density in the UVN vs. cUL group. Specifically, synaptic density in the vestibular nuclei was significantly lower after UVN, which was accompanied by compensatory increases in frontal sensorimotor cortical areas. Behavioral data reflected comparable compensation dynamics between groups. ***Conclusion:*** Pre- and postganglionic vestibular lesion models exhibit similar patterns of behavioral recovery and glucose metabolism. However, postganglionic lesions induce more severe and widespread synaptic remodeling. This data suggest that synaptic density imaging may be a more sensitive method to depict subtle differences in mechanisms of lesion-induced adaptive neuroplasticity than traditional techniques such as imaging of glucose metabolism.

EPS-006

ImmunoPET imaging of c-Met using a nanobody-based tracer ^{68}Ga-NOTA-PFCM01 in pancreatic ductal adenocarcinoma

L. Kang, *X. Sun, T. Wang, Q. Yang, L. Song, Y. Lei, W. Huang, Z. Chen, Y. Qiu;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the most prevalent form of pancreatic cancer, with high malignancy and poor prognosis. The cellular mesenchymal-epithelial transition factor (c-Met) is overexpressed in 84% of PDAC and plays a critical role in tumor progression, which are closely associated with poor patient outcomes. The focus of this study is to develop a new ^{68}Ga-labeled nanobody (^{68}Ga-NOTA-PFCM01) for the visualization of c-Met in PDAC models. ***Materials and Methods:*** By immunizing an alpaca with recombinant human c-Met, the variable domain of the heavy chain of heavy-chain-only antibody (VHH) were screened, and the binding affinity was tested by bio-layer interferometry (BLI). c-Met expression in human PDAC cell lines was evaluated using western blot and flow cytometry. NOTA (1,4,7triazacyclononane-1,4,7-triacetic acid) chelator was labeled the nanobodies with ^{68}Ga. PET imaging and biodistribution studies were performed in tumor xenografts. ***Results:*** PFCM01 was screened with an excellent binding property with the K_D value of 286.2 pM. c-Met expression was the highest in BXPC-3 cells but the lowest in MIA PaCa-2 cells, which were set as the positive and negative models separately. Small animal positron emission tomography/computed tomography (PET/CT) imaging showed that the uptake of ^{68}Ga-NOTA-PFCM01 in BXPC-3 tumors was significantly higher than that in MIA PaCa-2 models. Additionally, no significant tumor uptake was observed in the blocking group, nor in the BXPC-3 tumor model injected with ^{68}Ga-NOTA-NC (a negative control nanobody), demonstrating receptor-specific binding of PFCM01. The biodistribution results showed that the uptake of BXPC-3 tumors (1.14 ± 0.08 %ID/g) is higher than that of MIA PaCa-2 tumors (0.34 ± 0.01 %ID/g, $P < 0.0001$) and tumors in blocking group (0.79 ± 0.11 %ID/g, $P < 0.01$), which was further reinforced the PET imaging results. ***Conclusion:*** ^{68}Ga-NOTA-PFCM01 showed a specific and high tumor uptake in c-Met-positive PDAC models, providing a noninvasive method to assess c-Met expression, suggesting its promise as a prospective PET imaging agent for future clinical applications.

EPS-007

Cancer-associated fibroblasts as a determinant for the tumor cells' response to targeted radionuclide therapy

J. D. Campeiro, *M. J. Klomp, C. D. van der Heide, J. W. K. Zhang, S. U. Dalm;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Next to high expression of the targeted biomarker, the radiosensitivity of tumors is key in determining responses to targeted radionuclide therapy (TRT). Research showed that multiple factors can play a role in the tumor cells' radiosensitivity. In line herewith, epithelial-to-mesenchymal transition (EMT), a process which can be induced by cancer-associated fibroblasts (CAFs), results in more aggressive tumors and is associated with resistance to external beam radiotherapy. CAF-induced EMT might also play a role in the observed suboptimal clinical outcomes after TRT. Accordingly, we aimed to determine whether CAF-induced EMT occurs in triple-negative breast cancer (TNBC) cells and how this affects TRT response. ***Materials and Methods:*** CAF-derived conditioned medium (CM) was obtained by culturing 100% confluent human breast CAFs (19TT-F) in fetal calf serum (FCS)-free medium for 3 days. Human TNBC cells (HCC1806, MDA-MB-231 and Hs 578T) were cultured for 4 days in daily refreshed medium containing 4% (v/v) FCS, with (primed) or without (unprimed) 50% (v/v) CM. Subsequently, cells were incubated for 6 days with 0, 1.0, 3.0 or 8.0 MBq/400 µL [^{177}Lu]Lu-DTPA, mimicking the low dose rate of TRT, followed by a viability assay. Moreover, cell morphology and EMT marker mRNA levels, i.e. mesenchymal markers TWIST1, SNAI1, SNAI2, VIM and FN1, and epithelial markers EpCAM and CLDN1, were assessed. ***Results:*** Primed MDA-MB-231 cells demonstrated a slight decrease in cell viability after treatment versus unprimed cells, i.e. 26.8±1.7% versus 33.2±0.7% using 3.0 MBq/400 µL [^{177}Lu]Lu-DTPA. In contrast, treatment with the same activity concentration resulted in 25.9±1.8% viable HCC1806 cells and 26.1±5.9% viable Hs 578T cells in primed condition, versus 7.8±0.6% and 8.4±1.9%, respectively, in unprimed cells. Although a more mesenchymal spindle-like morphology was only observed for primed Hs 578T, all cell lines showed changes in EMT markers; (1) MDA-MB-231 was characterized by decreased EpCAM and CLDN1, and increased SNAI1 and FN1, (2) HCC1806 demonstrated decreased CLDN1, and increased SNAI1 and VIM, and (3) Hs 578T showed a decrease in TWIST1, SNAI1, EpCAM and CLDN1, and an increase in FN1. ***Conclusion:*** Our preliminary results demonstrate that CAF-derived CM induced changes in TNBC cells in terms of EMT profile, suggestive for a more mesenchymal-like state, and radiosensitivity, which seems to be cell line-dependent. Future studies include analysis of relevant protein expression levels and cellular invasion capacity. Moreover, the mechanism underlying cell line-dependent effects and possibilities to reverse EMT to increase radiosensitivity towards TRT will be explored.

EPS-008

Preclinical evaluation of a ^{68}Ga/^{177}Lu theranostic targeting PARP for PARP-expressing cancers

C. Y. Chan[1], *J. Shi*[2], *F. Tsoi*[2], *U. S. Khoo*[2], *E. Parkes*[3], *K. V. Tan*[4];
[1]*The Institute of Cancer Research, London, UNITED KINGDOM,* [2]*University of Hong Kong, Hong Kong, HONG KONG,* [3]*University of Oxford, Oxford, UNITED KINGDOM,* [4]*Perceptive Inc., London, UNITED KINGDOM.*

Aim/Introduction: Radioligand therapy (RLT) represents a promising approach in cancer treatment, leveraging radiopharmaceuticals to deliver highly localised radiation directly to tumour cells. A notable target in this approach is poly(adenosine diphosphate-ribose)-polymerase (PARP), a key enzyme involved in DNA damage repair enzyme. PARP-targeting compounds, when radiolabelled with an appropriate therapeutic radionuclide, can selectively bind to damaged DNA within tumour tissue, where the emission of high-energy ionising radiation induces complex DNA damage ultimately leading to cancer cell death. Coupled with the elevated expression of PARP in many aggressive cancer cells relative to normal tissues (1), enables for more precise delivery of radiopharmaceuticals, hence enhancing the therapeutic index and minimising damage to surrounding tissues. Here, we report the development of KK02, a novel PARP-targeting compound designed for chelation with various radiometals, including ^{68}Ga

and ^{177}Lu, for use in PET imaging and RLT applications. ***Materials and Methods:*** Radiolabelling efficiency, purity and stability of the matched-pair radiopharmaceuticals, [^{68}Ga]Ga-KK02 and [^{177}Lu]Lu-KK02, were assessed using radio-TLC and HPLC. In vitro uptake and specificity of [^{68}Ga]Ga/[^{177}Lu]Lu-KK02 were determined in human triple-negative breast cancer (TNBC) and prostate cancer (PCa) cells. Therapeutic efficacy of [^{177}Lu]Lu-KK02 were evaluated in TNBC cells. In vivo imaging, biodistribution studies and autoradiography were conducted using naïve and TNBC-bearing mouse models. Preliminary assessment of efficacy and safety for [^{177}Lu]Lu-KK02 was performed in a murine PCa models. ***Results:*** [^{68}Ga]Ga-KK02 and [^{177}Lu]Lu-KK02 were obtained in good yields and remained stable in serum. In vitro studies showed selective uptake of [^{68}Ga]Ga/[^{177}Lu]Lu-KK02 across all models, and was dependent on cellular PARP-1 expression levels. A significant reduction in clonogenicity was observed after treatment with only 100 Bq of [^{177}Lu]Lu-KK02 in TNBC cells. In vivo studies demonstrated that both [^{68}Ga]Ga-KK02 and [^{177}Lu]Lu-KK02 exhibited similar hepatobiliary and renal clearance profiles and showed bioequivalence. For [^{177}Lu]Lu-KK02, rapid blood clearance was observed at 1 h (0.14±0.05 %ID/g), with little kidney retention seen at 24 h (0.28±0.05 %ID/g) post-injection. A single, high-dose administration of [^{177}Lu]Lu-KK02 (60 MBq) resulted in a significant delay in MyC-CaP tumour growth compared to the vehicle control, without causing body weight loss and hematopoietic toxicity. ***Conclusion:*** Our study demonstrates the strong potential for KK02 as a theranostic tool for the diagnosis and treatment of PARP-expressing cancers, with improved radiotoxicity profiles. Ongoing investigations are exploring the therapeutic effects of alternative radiometals and the impact of multiple-dose administration. ***References:*** 1. CY Chan, KV Tan, B Cornelissen; Clinical Cancer Research 27 (6), 1585-1594, 2021.

EPS-009

Preclinical Evaluation of a ^{47}Sc-labeled Gastrin Releasing Peptide-based Radioantagonist for the Targeted Management of Breast Cancer

N. Kumar[1], *A. Bilinska*[1], *E. Menéndez*[1], *T. Läppchen*[1], *E. S. Moon*[2], *M. Zoltowska*[3], *D. Pawlak*[3], *I. Cieszykowska*[3], *R. Mikolajczak*[3], *F. Rösch*[2], *A. Rominger*[1], *E. Gourni*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Chemistry-TRIGA site, Johannes Gutenberg University of Mainz, Mainz, GERMANY,* [3]*Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.*

Aim/Introduction: Radiolabeled gastrin-releasing peptide receptor (GRPR) antagonists appear as promising tools for the management of breast cancer. By targeting GRPR, which is often overexpressed in breast tumors, these radioantagonists enable precise imaging and targeted therapy, offering potential improvements in diagnosis, staging, and treatment monitoring. The goal of the current study was to preclinically evaluate a ^{47}Sc-labeled GRPR-based radioantagonist with the potential to be used for in-vivo imaging and therapy of breast cancer. ***Materials and Methods:*** The statine-based GRPR antagonist (AAZTA^5-Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH_2: LF1) was radiolabeled with scandium-47. Detailed in-vitro evaluation, including lipophilicity, protein binding, saturation and internalization studies, was carried out in T47D breast cancer cells. In-vivo studies (biodistribution, metabolic stability, blood and organs clearance kinetics, SPECT/CT imaging) were performed in T47D xenografts. ***Results:*** [^{47}Sc]Sc-LF1 was prepared in high radiochemical purity (> 99 %) with molar activities up to 40 MBq/nmol. [^{47}Sc]Sc-LF1 was stable for 6 days post-labelling and exhibiting a hydrophilic profile with a Log_D value of -2.8. [$^{nat/47}$Sc]Sc-LF1 exhibited affinity for T47D cells, with K_d values of 10.6 ± 3.0 nM and a low internalization rate in the cells, with values below 10% to the total cell bound activity. The metabolite analysis revealed the formation of three hydrophilic metabolites. In-vivo protein binding showed that approximately 3 % of the radioactivity is bound to blood protein after 15 min post-injection of [^{47}Sc]Sc-LF1 in mice. In T47D xenografts, [^{47}Sc]Sc-LF1 exhibited significantly high, retained and specific tumor uptake, with values of 9.5 ± 2.5 and 0.7 ± 0.1 % I.A./g at 1 and 72 h p.i., respectively. Blood retention level of [^{47}Sc]Sc-LF1 was low, decreasing from around 0.6 ± 0.1% IA/g at 1 h p.i to 0.1 ± 0.0 % IA/g at 4 h p.i. The effective half-life in blood was 21.3 min, demonstrating its rapid clearance. The clearance of the radioactivity from non-target organs was significantly faster compared to the tumor uptake with organ-specific half-lives of 2.5, 0.9 and 3.2 h for the kidney, pancreas and tumor, respectively. The favorable pharmacokinetic performance of [^{47}Sc]Sc-LF1 in combination with the excellent imaging properties of scandium-47 led to SPECT/CT images of high contrast. ***Conclusion:*** The high and persistent tumor uptake in the breast tumor model underscores the significant potential of [^{47}Sc]Sc-LF1 as a dual-purpose tool for both SPECT imaging and targeted therapy. ***References:*** This work is a PRISMAP contribution.

Granzyme B-Targeted PET Imaging Enables CarNK Cell Tracking and Prognosis Prediction in Adoptive Immunotherapy

L. Zhang, *X. Lan, Y. Gai, W. Cao;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Adoptive cell therapy (ACT) has demonstrated significant potential in cancer immunotherapy, with chimeric antigen receptor-engineered natural killer (CarNK) cells inducing tumor cell DNA damage and apoptosis via perforin-granzyme B delivery. This study aimed to noninvasively quantify CarNK cell infiltration dynamics and predict therapeutic outcomes using [68Ga]Ga-NOTA-GZP positron emission tomography (PET). ***Materials and Methods:*** In vitro, EGFRvIII-Car-NK92(abbreviation: CarNK) cells were co-cultured with A549$^{EGFRvIII+}$ non-small cell lung cancer cells. Cytotoxicity was assessed via LDH release and CCK-8 assays, while CD107a surface expression was analyzed by flow cytometry to evaluate CarNK activation. In vivo, two models were established: 1) Balb/c nude mice subcutaneously injected with CarNK/A549$^{EGFRvIII+}$ mixtures (ratios 1:1, 1:2 to 1:5) underwent [68Ga]Ga-NOTA-GZP PET/CT imaging; 2) SCID NOD mice bearing A549$^{EGFRvIII+}$ subcutaneous tumors received CarNK cell infusion, followed by longitudinal PET imaging at days 1, 3, 7, and 12 post-treatments. Survival analysis correlated imaging metrics with therapeutic efficacy. ***Results:*** In vitro, CarNK cells exhibited peak LDH release at an effector-to-target (E: T) ratio of 5:1, significantly surpassing wild-type NK92 cells ($P < 0.05$), while CCK-8 assays demonstrated minimal residual cell viability in the corresponding groups ($P < 0.05$). Flow cytometry confirmed A549$^{EGFRvIII+}$-specific CarNK activation for 4h (CD107a+ proportion: 21.7% vs. 12.6% in NK92, $P<0.05$). In vivo, Balb/c nude mice with CarNK: A549$^{EGFRvIII+}$=1:5 showed higher tracer uptake ($P<0.05$). In SCID NOD mice, CarNK group achieved maximal the ratios of T/B (The ratios of tumor %ID/g to blood %ID/g was defned as T/B). at day 7, 1.56-fold higher than NK92 controls ($P<0.05$). Kaplan-Meier analysis revealed prolonged median survival in high-uptake cohorts ($P<0.05$). ***Conclusion:*** [68Ga]Ga-NOTA-GZP PET enables noninvasive monitoring of granzyme B activity, indirectly reflecting CarNK infiltration and cytotoxic efficacy. This approach provides a translational imaging biomarker for ACT outcome prediction, with critical implications for personalized immunotherapy.

EPS-011

Dual-Modality NIRF/PET Imaging of Pre-targeted Glycoengineered CAR-NK Cells for Theranostic Monitoring in Glioblastoma

W. Cao, *L. Zhang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, 430022, Wuhan, China, Wuhan, CHINA.

Aim/Introduction: Glioblastoma (GBM), the most aggressive primary brain tumor, remains a therapeutic challenge. Despite emerging advances in chimeric antigen receptor (CAR)-engineered immune cell therapy, noninvasive tracking of CAR-NK cells in GBM treatment remains unexplored. This study aimed to develop a bioorthogonal click chemistry-based dual-modality imaging platform for real-time monitoring of adoptively transferred CAR-NK cells. ***Materials and Methods:*** A pre-targeted imaging strategy integrating metabolic glycoengineering and bioorthogonal click chemistry was established. Key procedures included:Cell Models:Lentiviral transduction generated U87-EGFRvIII-overexpressing and control U87-CON cell lines.CAR-NK cells were engineered from NK-92 cells using a second-generation CAR lentiviral vector targeting EGFRvIII. Metabolic Labeling: CAR-NK cells were incubated with N-azidoacetyl-D-mannosamine tetraacetate (Ac4ManNAz) to incorporate azide (N_3) groups onto cell-surface glycans, yielding N_3-CAR-NK cells. Probe Synthesis: NIRF probe: Cy5.5-conjugated dibenzocyclooctyne (DBCO-Cy5.5). PET probe: ^{68}Ga-labeled NETA-DBCO (^{68}Ga-NETA-DBCO). In Vivo Validation: Subcutaneous and orthotopic U87-EGFRvIII glioma models were established. N_3-CAR-NK cells were intravenously administered, followed by NIRF and PET imaging. ***Results:*** In Vitro: Western blot confirmed EGFRvIII overexpression in U87-EGFRvIII cells. Fluorescence microscopy demonstrated stable GFP expression in CAR-NK cells. CCK-8 assays revealed no cytotoxicity of Ac4ManNAz at ≤30 μM ($P>0.05$), while 60 μM reduced viability to 72% ($P<0.05$). LDH assays showed preserved cytolytic activity of 30 μM Ac4ManNAz-treated CAR-NK cells against U87-EGFRvIII ($P>0.05$). In Vivo: In subcutaneous tumors, Cy5.5-CAR-NK cells accumulated specifically by day 3, with signal persistence until day 12. Orthotopic models exhibited higher intracranial NIRF signal vs. controls ($P<0.05$), indicating blood-brain barrier penetration. PET imaging confirmed efficient ^{68}Ga-DOTA-DBCO binding to N_3-CAR-NK cells in vivo. ***Conclusion:*** This study pioneers a pre-targeted dual-modality NIRF/PET strategy for real-time tracking of CAR-NK cells, offering a transformative imaging tool to evaluate adoptive immunotherapy efficacy in GBM, with significant clinical translation potential.

EPS-012

^{225}Ac-NM600 Efficacy in Murine Models of Metastatic and Localized Triple Negative Breast Cancer

Y. Medina Guevara, *H. Comas Rojas, O. Bio Idrissou, L. Lambert, L. Wehner, M. Lindsey, A. Pinchuk, A. Carston, N. Clemons, J. Grudzinski, B. Bednarz, J. Weichert, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Advanced breast cancer remains incurable. The absence of estrogen receptor, progesterone receptor, and HER2 expression in triple-negative breast cancer (TNBC) limits the use of targeted therapies. Chemotherapy offers brief responses with poor prognosis. We have developed several alkyphosphocholine analogs (NM600) as tumor-selective targeted radioligands for radiopharmaceutical therapy (RPT). Herein, we investigate [^{225}Ac]Ac-NM600 therapeutic efficacy and safety in two murine models of TNBC ***Materials and Methods:*** In vitro, cytotoxicity studies were performed in 4T1 (metastatic murine TNBC cells) and 4T07 (non-metastatic murine TNBC cells). Monte Carlo-based ^{225}Ac dosimetry estimates enabled viability and clonogenic survival measurements in cells treated with ^{225}Ac (0.03-1 Gy). In vivo, female Balb/c 10-12 weeks old were subcutaneously implanted with 4T1 or 4T07 cells, and caliper measurement determined tumor volume. NM600 was radiolabeled with ^{225}Ac following previous methods. Longitudinal ex vivo biodistribution studies were performed in mice bearing 4T1 or 4T07 tumor grafts injected with 9.25 kBq [^{225}Ac]Ac-NM600 at 24, 72, 120, and 144 h post-injection (p.i.). Three groups of mice ($n=5$) received IV injections of vehicle, or 9.25 or 18.5 kBq [^{225}Ac]Ac-NM600. Tumor volume and overall survival were monitored thrice weekly. Toxicity was evaluated in groups of Balb/c mice ($n=3$) at days 7, 30, and 120 p.i. through complete blood count (CBC), serum chemistry, and histopathological analysis ***Results:*** In vitro, free ^{225}Ac showed comparable cytotoxicity in 4T1 and 4T07 cells, with an enhanced effect at higher estimated doses. In vivo, ex vivo biodistribution revealed elevated radioactivity in the blood and lungs, followed by a gradual decline over time. Due to the hepatobiliary excretion of [^{225}Ac]Ac-NM600, distribution in normal tissues was most prominent in the liver, with absorbed doses of 57 Gy/μCi and 63 Gy/μCi for mice bearing 4T1 and 4T07 tumors, respectively. Similarly to the liver, uptake in tumor regions progressively increased, resulting in 46 Gy/μCi and 42 Gy/μCi. Mice bearing 4T1 or 4T07 tumors and treated with [^{225}Ac]Ac-NM600 exhibited significant tumor growth inhibition ($p \leq 0.015$). Median survival for mice bearing 4T1 or 4T07 tumors was 18, 30, and 42 days, or 30, 84, and 90 days, for the vehicle, 18.5 kBq, and 9.25 kBq groups, respectively. Mice administered 9.25 or 18.5 kBq of [^{225}Ac]Ac-NM600 exhibited only mild effects, and no treatment-related mortality was observed ***Conclusion:*** These findings underscore the potential of [^{225}Ac]Ac-NM600 as a promising therapeutic agent for TNBC, warranting further assessments of efficacy and potential toxicities in additional TNBC animal models.

EPS-013

Preclinical evaluation of DOTAGA.PEG$_2$.Glu.(FAPI)$_2$, a FAP dimeric inhibitor, for developing theranostic radiotracers in FAP-positive malignancies

N. Kumar[1], *A. Bilinska*[1], *E. Menéndez*[1], *T. Läppchen*[1], *M. Marcel*[2], *F. Rösch*[2], *A. Rominger*[1], *E. Gourni*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Chemistry-TRIGA site, Johannes Gutenberg University of Mainz, Mainz, GERMANY.*

Aim/Introduction: Targeting components of the tumor stroma offers a promising theranostic approach for cancer management. Among these components, the fibroblast activation protein (FAP) attracts attention due to its overexpression on cancer activated fibroblasts (CAFs) in various tumor types, while being largely absent in healthy tissues and most non-malignancies. This study aims at preclinical evaluation of DOTAGA.PEG$_2$.Glu.(FAPI)$_2$, a FAP-dimeric-based inhibitor, as a potential precursor for developing theranostic radiopharmaceuticals targeting FAP-positive tumors. ***Materials and Methods:*** DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ was labeled with gallium-68 and lutetium-177. Both radiotracers were evaluated in-vitro (lipophilicity, protein binding, saturation, internalization and externalization) on immortalized CAFs expressing FAP. In-vivo studies (biodistribution, metabolic stability in plasma, blood clearance kinetics, PET/SPECT/CT imaging) were performed in PC3-xenografts. ***Results:*** DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ was radiolabeled with gallium-68 and lutetium-177, in >98% radiochemical purity. The apparent molar activities (Am) ranged from 15-20 GBq/μmol for the ^{68}Ga-labeled and 10-26 GBq/μmol for the ^{177}Lu-labeled tracer. [^{68}Ga]Ga-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ and [^{177}Lu]Lu-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ demonstrated Log_D values of -3.0 and -3.3, respectively. Both radiotracers exhibited high FAP affinity (K_d: 0.9-1.2 nM). Internalization was rapid, with up to 95 % of total cell-bound activity internalized within 30 min in CAFs. Externalization studies showed that 35% of the total internalized

activity was released from the cells after 24 h of incubation. Incubation of the radiotracers with human plasma revealed that ~8% and ~4% for [^{68}Ga]Ga-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ and [^{177}Lu]Lu-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ was bound to the proteins after 30 and 60 min of incubation. Metabolic studies showed that both tracers are stable in plasma. Biodistribution studies of [^{68}Ga]Ga-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ at 1, 2, and 3 h p.i. (n=5), revealed high and consistent tumor uptake (19.2±2.7, 18.3±3.3 and 21.4±5.6 %IA/g at 1, 2 and 3 h p.i.) with low blood activity levels at all tested time points (~2.9 %IA/g). For [^{177}Lu]Lu-DOTAGA.PEG$_2$.Glu.(FAPI)$_2$, tumor uptake at 4 h p.i. was 16.1±2.6 %IA/g and decreasing to 3.7±0.2 %IA/g by 48h. Blood retention decreased from ~2.0 %IA/g at 4 h to 0.2 %IA/g at 48 h for [^{177}Lu]Lu- DOTAGA.PEG$_2$.Glu.(FAPI)$_2$. For both tracers, the accumulated activity in the kidneys and liver remained below 3% IA/g and decreased over time, leading to high tumor-to-normal organ ratios at all time points, as confirmed by the high-contrast PET/SPECT/CT images. ***Conclusion:*** The results provide strong evidence for the potential use of DOTAGA.PEG$_2$.Glu.(FAPI)$_2$ as a promising theranostic agent for targeting FAP-positive tumors. The compound demonstrated significant potential to enhance precision oncology by utilizing their ability to both identify and therapeutically address FAP-expressing malignancies.

EPS-014

Development and Evaluation of a BCMA-Targeted Bicyclic Peptide Imaging Probe for Multiple Myeloma Detection

L. Kang[1], *L. Song*[1], *Q. Yang*[1], *Y. Qiu*[1], *Z. Chen*[1], *X. Sun*[1], *W. Huang*[1], *T. Wang*[1], *Z. Wang*[2];
[1]Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA, [2]Fujian Provincial Key Laboratory of Brain Aging and Neurodegenerative Diseases, School of Basic Medical Sciences, Fujian Medical University, Fuzhou, CHINA.

Aim/Introduction: Multiple myeloma (MM) is a hematologic malignancy marked by abnormal bone marrow plasma cell proliferation and excessive monoclonal immunoglobulin production. Current diagnostic methods, such as bone marrow biopsy and imaging (X-ray, CT, MRI), face limitations in sensitivity, specificity, and non-invasiveness. Although ^{18}F-FDG is widely used for MM diagnosis and monitoring, its lack of specificity remains a challenge. This study aims to develop a BCMA-targeted bicyclic peptide imaging probe to improve stability, specificity, and imaging performance for MM detection. ***Materials and Methods:*** A bicyclic peptide (BCP1) targeting BCMA was synthesized using a 1,3,5-tris(bromomethyl)benzene (TBMB) scaffold, forming a stable structure via cysteine thiol residues. BCP1 was radiolabeled with ^{68}Ga to produce [^{68}Ga]Ga-DOTA-BCP1, with radiochemical purity and stability assessed by HPLC. In vitro uptake experiments in H929 myeloma cells evaluated targeting specificity. PET/CT imaging in H929 (BCMA-positive) and K562 (BCMA-negative) tumor models assessed in vivo targeting efficiency. Pharmacokinetic studies in primates evaluated metabolic pathways and clearance mechanisms. ***Results:*** HPLC analysis confirmed that [^{68}Ga]Ga-DOTA-BCP1 exhibited high radiochemical purity (>95%) and remained stable in physiological saline and FBS for at least 2 hours, with no significant degradation. Cell uptake experiments demonstrated a significantly higher binding rate of [^{68}Ga]Ga-DOTA-BCP1 to H929 myeloma cells (0.497±0.06%) compared to the blocked group (0.225±0.03%, $P < 0.01$) and the BCMA-negative K562 cells (0.255±0.04%, $P < 0.01$), confirming its strong affinity and specificity for BCMA-expressing tumors. PET/CT imaging in tumor-bearing mice revealed rapid and selective accumulation of [^{68}Ga]Ga-DOTA-BCP1 in H929 tumors, with sustained uptake up to 60 minutes post-injection. In contrast, BCMA-negative K562 tumors showed no significant uptake, further validating specificity. Biodistribution analysis quantified tumor uptake, showing significantly higher retention in H929 tumors (1.38±0.08 %ID/g at 30 min, 1.05±0.04 %ID/g at 60 min) compared to K562 tumors ($P < 0.001$). Immunofluorescence staining confirmed high BCMA expression in H929 tumors, correlating with observed imaging results. Pharmacokinetic studies in non-human primates demonstrated that [^{68}Ga]Ga-DOTA-BCP1 exhibited a rapid distribution phase, predominantly renal clearance, minimal hepatic accumulation, and a favorable metabolic profile, supporting its potential for clinical translation. ***Conclusion:*** [^{68}Ga]Ga-DOTA-BCP1 demonstrated strong potential for non-invasive, MM-specific PET imaging, offering a promising alternative to repeated invasive biopsies. Its high specificity, stability, and favorable pharmacokinetics support its clinical application for MM diagnosis and monitoring, making it a viable candidate for future precision imaging of BCMA-positive malignancies.

EPS-015

How does ionizing radiation activate photosensitizers—and how can this improve radiotherapy?

B. Xu[1], *R. Eelkema*[2], *A. G. Denkova*[1];
[1]Department of Radiation Science and Technology, Delft University of Technology, Delft, NETHERLANDS, [2]Depatment of Chemical Engineering, Delft University of Technology, Delft, NETHERLANDS.

Aim/Introduction: Photosensitizers (PSs) have attracted growing attention as potential radiosensitizers due to their ability to generate reactive oxygen species (ROS) when activated by ionizing radiation[1]. Unlike conventional chemotherapeutic agents, which often cause severe systemic side effects, PSs exhibit minimal toxicity in their inactive form, reducing damage to healthy tissue. Even though clinical studies have shown promising results[2-4], the mechanism underlying their activation by ionizing radiation, rather than light, remains unknown. Obtaining an understanding of the activation mechanisms can help to improve their effectiveness when combined with radiotherapy. ***Materials and Methods:*** This study explores the radiation-induced activation of chlorin e6 (Ce6), focusing on how photon energy, dose and dose rate influence the generation of singlet oxygen ($^1O_2$). Experiments were conducted using X-rays (up to 310 kV) and ^{60}Co gamma rays (1.17 and 1.33 MeV) across a range of doses and dose rates. The formation of $^1O_2$ was measured using the singlet oxygen sensor green (SOSG) probe and the imidazole/RNO method. ***Results:*** Our results revealed that both energy and dose rate significantly impact $^1O_2$ production, with unexpectedly high yields observed at very low dose rate. Scavenger experiments further showed that the superoxide anion ($\cdot O_2^-$) is a critical intermediate in the activation pathway. ***Conclusion:*** our results suggest that the typical triplet-state mediated energy transfer involved in light activation does not play a role in ionizing radiation exposure. Instead, our data supports a radical-driven mechanism in which Ce6 radical cations together with $\cdot O_2^-$, play a key role in generating $^1O_2$. The activation at low dose rates (0.005 Gy/min) suggests that photosensitizers are best combined with radionuclide therapy or low dose brachytherapy. ***References:*** 1Owari, T. et al. 5-Aminolevulinic acid overcomes hypoxia-induced radiation resistance by enhancing mitochondrial reactive oxygen species production in prostate cancer cells. Synergistic Antitumor Effects of B-OT and ^{177}Lu-PSMA-617 in PSMA-Positive Prostate Cancer via Transketolase Inhibition

Q. Wu[1,2,3], *T. Zhao*[1,2,3], *X. Yao*[1,2,3], *R. P. Baum*[4], *X. Duan*[1,2,3], *J. Zhang*[1,2,3];

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) with ^{177}Lu-PSMA-617 has shown promise in treating PSMA-expressing tumors. However, the efficacy of ^{177}Lu-PSMA-617 RLT remains limited by intrinsic resistance mechanisms in prostate cancer. Benfo-oxythiamine (B-OT), a derivative of oxythiamine, inhibits transketolase in the non-oxidative branch of the pentose phosphate pathway (PPP), thereby reducing ribose-5-phosphate synthesis and impairing DNA repair. We hypothesized that B-OT could act as a radiosensitizer to enhance the efficacy of ^{177}Lu-PSMA-617 therapy in PSMA-positive prostate cancer. Unlike existing combination approaches that focus on DNA repair inhibition or target upregulation, our strategy employs B-OT to induce metabolic crisis through dual mechanisms, depletion of nucleotide precursors essential for radiation damage repair, and reduction of NADPH pools required for oxidative stress defense. ***Materials and Methods:*** PSMA-expressing pip-PC3 xenografts (80-100 mm^3) were randomized to: (1) PBS control, (2) B-OT alone (oral gavage, -2 d pre-RLT then dosing every 3 d), (3) ^{177}Lu-PSMA-617 alone (350 µCi), or (4) combination therapy (n=6/group). Tumor response was assessed by caliper measurements and SPECT/CT imaging (Days 1,2,3,7,14). Terminal IHC analysis evaluated Ki67, TUNEL, DNA damage (γ-H2AX), and metabolic stress markers. Safety was monitored via weight and clinical observation. ***Results:*** The BOT combination group demonstrated superior antitumor activity, achieving complete remission in 33% of mice (2/6 mice) and a 100% objective response rate by Day 14 ($p<0.001$ vs. RLT alone). Quantitatively, the combination yielded a tumor growth inhibition (TGI) of 106.9% and a tumor regression rate of 90.45%, significantly surpassing the effects of RLT monotherapy. Mechanistic studies revealed increased DNA damage, a reduction in tumor nucleotide levels and stable PSMA expression by IHC, verifying target-agnostic action. Importantly, the combination was well-tolerated with no additional toxicity over RLT monotherapy. ***Conclusion:*** B-OT enhances the therapeutic efficacy of ^{177}Lu-PSMA-617 in PSMA-positive prostate cancer by impairing nucleotide synthesis and DNA repair through transketolase inhibition. The oral bioavailability and favorable safety profile of B-OT support clinical translational potential to address RLT resistance in prostate cancer.

Efficacy of FAP-targeted radiopharmaceutical treatment: Comparing [^{177}Lu]Lu-FAP-2286 and [^{161}Tb]Tb-FAP-2286 behavior and efficacy in vitro and in vivo

C. D. van der Heide[1], *C. Ntihabose*[1,2], *H. Ma*[1], *M. Konijnenberg*[1], *Y. Seimbille*[1], *M. Doukas*[3], *D. Stuurman*[1], *C. de Ridder*[4], *E. de Blois*[1], ***S. U. Dalm***[1];
[1]*Department of Radiology & Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS,* [2]*Department of Hospital Pharmacy, Erasmus MC, Rotterdam, NETHERLANDS,* [3]*Department of Pathology, Erasmus MC, Rotterdam, NETHERLANDS,* [4]*Department of Experimental Urology, Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: Fibroblast activation protein (FAP), predominantly expressed on cancer-associated fibroblasts (CAFs), is present >90% of solid cancers, making it an ideal target for radionuclide theranostics. Imaging studies using FAP-targeting radiopharmaceuticals are promising, but it remains to be elucidated whether FAP-targeted radionuclide treatment (TRT) is effective. Regarding TRT, the beta-minus, conversion- and auger-electrons emitted by Tb-161 are potentially more cytotoxic than the beta-minus radiation emitted by Lu-177. We aimed to determine FAP-TRT efficacy using radiolabeled FAP-2286, and compared [^{177}Lu]Lu-FAP-2286 and [^{161}Tb]Tb-FAP-2286 treatment. Prior to this, we compared radiopharmaceutical behavior and potential dose-effects. ***Materials and Methods:*** FAP-2286 was labeled with luteium-177 or terbium-161, and radiopharmaceutical stability in mouse serum was determined. FAP affinity and radiopharmaceutical uptake were evaluated in vitro using the FAP-transduced human fibrosarcoma cell line HT1080-FAP. To determine affinity, cells were exposed to 1 nM [^{177}Lu]Lu-FAP-2286/[^{161}Tb]Tb-FAP-2286 (20 MBq/nmol), +/- 10^{-12}-10^{-6} M UAMC-1110. Furthermore, cells were incubated with 1 nM [^{177}Lu]Lu-FAP-2286/[^{161}Tb]Tb-FAP-2286 (20 MBq/nmol), +/- 1 mM UAMC-1110, to determine radiopharmaceutical uptake. Additionally, ex vivo biodistribution studies were performed post injection of 5 MBq/500 pmol in C57BL/6 mice xenografted with FAP-negative mouse pancreatic cancer cells, PDAC229, known to attract CAFs in vivo. Using the biodistribution data, dosimetry calculations were performed to guide subsequent efficacy studies in the same animal model. First, treatment with 4×40 MBq/500 pmol [^{177}Lu]Lu-FAP-2286 or 4×40 MBq/500 pmol [^{161}Tb]Tb-FAP-2286 was compared. Hereafter, treatment with alternating doses of 2×40 MBq/500 pmol of each radiopharmaceutical was evaluated. ***Results:*** FAP-2286 was successfully labeled with lutetium-177 and terbium-161 (RCY>98%, RCP>97%). Radiopharmaceutical stability in mouse serum decreased over time, with <13% intact [^{177}Lu]Lu-FAP-2286/[^{161}Tb]Tb-FAP-2286 present after 24 h. FAP affinity (IC_{50}: 2.9±7.2 nM (Lu-177) and 1.5±3.2 nM (Tb-161)) and in vitro radiopharmaceutical uptake (19.7±6.8% (Lu-177) and 18.5±5.2% (Tb-161) added activity/200,000 cells after 1 h) was comparable. Similarly, ex vivo biodistribution studies showed no relevant differences in radiolabeled FAP2286 uptake in blood, tumor and background organs of PDAC229-xenografted animals, e.g. tumor uptake was 1.85±0.39% and 1.39±0.45% injected dose/g for Lu-177 and Tb-161, respectively, 1 h post injection. Unfortunately, no significant survival benefit was observed in animals treated with 4×[^{177}Lu]Lu-FAP-2286 or 4×[^{161}Tb]Tb-FAP-2286. Remarkably, treatment with 2×[^{161}Tb]Tb-FAP-2286 and 2×[^{177}Lu]Lu-FAP-2286 did show a significant prolonged survival compared to animals receiving vehicle. ***Conclusion:*** We demonstrated that [^{177}Lu]Lu-FAP-2286 and [^{161}Tb]Tb-FAP-2286 have similar behavior. In our in vivo study using a clinically representative mouse model, limited FAP-TRT efficacy was observed, with only tandem treatment with Lu-177 followed by Tb-161 being beneficial.

EPS-018

Biodistribution Study of Intraperitoneally Administered Annexin A1 in Mouse Ovarian Cancer Models

L. Xu[1], *S. K. Singh*[1], *K. R. Smith*[1], *C. Mallett*[1], *D. Agnew*[1], *J. Schnitzer*[2], *K. R. Zinn*[1];
[1]*Michigan State University, East Lansing, MI, UNITED STATES OF AMERICA,* [2]*Proteogenomics Research Institute for Systems Medicine (PRISM), La Jolle, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: A humanized antibody Annexin A1 (hAnnA1) is known to target caveolae on tumor endothelium, leading to hAnnA1 accumulation in the tumor space by a pumping mechanism (1). This study assessed the potential of hAnnA1 for tumor imaging following intraperitoneal (IP) injection of the labeled antibody in immune-competent mouse ovarian cancer

models. ***Materials and Methods:*** FVB (n=8) and C57BL/6 (n=8) female mice were intraperitoneally implanted with luciferase-positive 30200 and HGS2 tumor spheroids, respectively. Bioluminescence imaging (Revvity IVIS) was used to monitor tumor growth in both groups for 3 months prior to IP injection of IRDye680-hAnnA1 mixed with Tc99m-HYNIC-hAnnA1 (HGS2, n=4) or Zr-89-DFO-hAnnA1 (30200, n=4). Strain-matched controls received IRdye680-IgG1 co-injected with Tc99m-HYNIC-IgG1 (HGS2, n=4) or Zr-89-DFO-IgG1 (30200, n=4). Fluorescence imaging (LICORbio Pearl Trilogy) was used to determine antibody localization in mice. PET/MR imaging (7T Bruker BioSpec) was performed following initial injection and 6 hours post-injection for FVB mice. Regions of interest were derived from bioluminescence images (centered on highest intensity pixels) and applied to co-registered PET (MLEM reconstruction with standard corrections) and anatomical MR (3D FISP) images in PMOD to estimate regional radiotracer concentration as %injected dose per mL of tissue (%ID/mL). Biodistribution was conducted for major tissues at 2, 6, and 24 hours to quantify tracer uptake as %injected dose per gram of tissue (%ID/g) using the Gamma Counter (Revvity Wizard2 2480). Statistical analysis (Graphpad) using two-way analysis of variance (ANOVA) with Tukey's test compared antibody uptake levels between tissue groups to assess significance ($p<0.05$). ***Results:*** For both cell lines, labeled hAnnA1 detected by fluorescence and PET were co-localized with the tumor's bioluminescence signal, but not for IgG1 controls. Significantly higher hAnnA1 uptake was observed for 30200 tumors at 2 hours (14.1±2.3 %ID/g for hAnnA1 vs 4.3±1.0 %ID/g for IgG1) and 6 hours (19.9±3.0 %ID/g for hAnnA1 vs 6.5±3.1 %ID/g for IgG1) post-injection ($p<0.05$). hAnnA1 levels (1.9±0.9 %ID/g) were the highest compared to IgG1 (0.02±0.01 %ID/g) at 2 hours post-injection for HGS2 tumors ($p<0.05$). Blood levels of hAnnA1 were highest at 6 hours post-injection (24.5±3.2 %ID/g for 30200 and 22.8±1.4 %ID/g for HGS2). Larger tumors exhibited higher hAnnA1:IgG1 ratios, possibly due to more mature blood vessel formation. hAnnA1/IgG ratios and trends observed in PET data agree with biodistribution results. ***Conclusion:*** hAnnA1 antibody is a promising targeting agent for ovarian cancer, showing high tumor uptake in immune-competent mouse models with minimal off-target binding. ***References:*** 1. Nat Med. 2014 Sep 1; 20(9):1062-8.

EPS-019

Design and Preclinical Evaluation of a Small-Molecule Diagnostic and Therapeutic Radionuclide Probe Targeting Tumor Extracellular Nucleotidase CD73

C. Zhao, *L. Li, X. Wu;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: CD73 (Ecto-5'-Nucleotidase, NT5E) inhibits anti-tumor immune responses and promotes tumor immune evasion, metastasis, and drug resistance. Therefore, accurate evaluation of CD73 expression level in tumor tissues is of great significance for tumor targeted therapy and treatment efficacy prediction. This study aims to develop a novel non-nucleotide small-molecule radiotracer targeting CD73 for accurate in vivo PET imaging of CD73 expression. Additionally, radionuclide-labeled therapeutic agents were prepared to achieve integrated diagnosis and therapy targeting CD73. ***Materials and Methods:*** Based on the crystal structure of CD73 protein reported in the literature, we synthesized a series of non-nucleoside small-molecule inhibitors targeting CD73 and screened the test compounds through in vitro enzymatic activity assays. The selected optimal compound was radiolabeled with ^{68}Ga, and its targeting specificity was validated via cellular uptake and competitive binding assays. Then, biodistribution and micro-PET/CT imaging studies were conducted to investigate the in vivo metabolic characteristics and imaging performance of the probe. Subsequently, the compound was radiolabeled with ^{177}Lu to evaluate its antitumor efficacy in LS174T and EMT6 tumor-bearing mice. ***Results:*** Through enzymatic activity assays, the newly synthesized compound HX-6 was selected from seven candidates as having the highest inhibitory activity (IC_{50} = 0.07 μM) and the capability for radioisotope labeling. ^{68}Ga-HX-6 rapidly binds to CD73-positive cells, and this binding can be effectively blocked by the corresponding non-radiolabeled compound, with inhibition rates of 62.5% in LS174T cells and 75.9% in EMT6 cells. Biodistribution studies indicated that ^{68}Ga-HX-6 is primarily metabolized through the liver. Micro-PET/CT imaging demonstrated that ^{68}Ga-HX-6 possesses favorable imaging performance for CD73-positive tumors, with peak tumor uptake reaching 6.98 ± 0.74 %ID/g in LS174T tumors and 6.92 ± 0.65 %ID/g in EMT6 tumors. Moreover, tumor uptake could be effectively blocked by the corresponding non-radiolabeled compound. 177Lu-HX-6 exhibited favorable antitumor efficacy. In LS174T tumor-bearing mice, the best therapeutic outcome was observed with the 37 MBq ^{177}Lu-HX-6 (×4) treatment group, achieving a tumor growth inhibition (TGI) rate of 67.7 ± 5.0%. In EMT6 tumor-bearing mice, the most effective antitumor response was observed with the combination therapy of 37 MBq ^{177}Lu-HX-6 and anti-PD-1, with a TGI of 64.9 ± 4.2%. ***Conclusion:*** ^{68}Ga-HX-6 has a good specific binding power for CD73 and can effectively visualize the content of CD73 in tumor tissues in vivo. ^{177}Lu-HX-6 is a safe and effective radionuclide therapeutic agent, which can significantly delay the growth of CD73-positive tumors.

EPS-020

The absorbed dose-response relationship of the Auger electrons from La-135

M. Crabbe, *K. Spoormans, T. Opsomer, C. Segers, S. Rodriguez Pérez, K. Vermeulen, C. Saldarriaga Vargas, L. Struelens, M. Ooms;*
Belgian Nuclear Research Centre, Mol, BELGIUM.

Aim/Introduction: Auger electron (AE) therapy is expected to be highly efficient for metastatic disease, leading to lower risks of radiotoxicity in healthy tissues. Lanthanum-135 (La-135) has been proposed as a potential candidate for AE therapy, moreover, its production was recently up-scaled to reach a yield and purity suitable for preclinical research (1). In this proof-of-principle study, we assessed the differential dose-response correlation of internalizing (DOTA-TATE) and non-internalizing vectors (DOTA-LM3) labeled with La-135 in in vitro models of neuroendocrine tumors. ***Materials and Methods:*** Quantitative equipment for activity measurements was cross-calibrated based on gamma spectrometry, taking into account relevant geometry and volume effects. Radiochemical conversion (RCC) and purity (RCP) were assessed at molar activities 5-100 MBq/nmol. CA20948 cells (2) were treated with an activity range of 0.31-1.25 MBq/mL of [^{135}La]La-DOTA-TATE and [^{135}La]La-DOTA-LM3 to evaluate the effects on clonogenic potential (CFU) and metabolic activity (MTS). Saturation binding assays were executed for both radioligands at a 0.025-2.5 MBq/mL activity range to verify the subcellular biodistribution parameters. Kinetic uptake data was retrieved from previously published radiolanthanide data (3). To calculate the absorbed dose to the nucleus, the S-values for AE particle emissions were computed via Monte Carlo simulations, while considering a concentric CA20948 sphere model. SPECT imaging of homogeneity and Derenzo phantoms was performed. ***Results:*** Activity calibrations were challenging due to poor reproducibility and extensive non-linearity and measurement geometry effects, which was attributed to substantial low-energy X-ray yield of La-135. The maximum achievable molar activity was 50 MBq/nmol with a RCC and RCP of >99% for [^{135}La]La-DOTA-TATE while this was ~97% and 93%, respectively, for [^{135}La]La-DOTA-LM3. Qualitative SPECT imaging was feasible based on preliminary phantom imaging. The cellular biodistribution pattern of both radioligands corresponded to previous reports with radiolanthanides albeit that K_d and B_{max} of [^{135}La]La-DOTA-LM3 were different in this

study (3). The absorbed dose to the nucleus for both radioligands was very low (<0.15 Gy at 1.25 MBq/mL concentration). No statistically significant biological effects were detected with the CFU or MTS assay. ***Conclusion:*** We conclude that La-135 offers limited therapeutic potential in combination with the respective internalizing and membrane-bound ligands DOTA-TATE and DOTA-LM3 in vitro. Future studies may explore DNA-binding vectors to enable the close-range therapeutic effects of its Auger electrons. ***References:*** 1) Pedersen et al. Applied Radiation and Isotopes. 2023 2) Bernard et al. Nucl Med Commun. 2000 3) Spoormans et al. JNM. 2024

Development of a ^{64}Cu/^{67}Cu theranostic radioligand for imaging and therapy in CXCR4-expressing cancers

I. Astiazaran-Rascon[1], *M. Jaraquemada-Pelaez*[2], *H. Merkens*[1], *N. Colpo*[2], *K. Lin*[2], *F. Benard*[2];
[1]*BC Cancer/UBC, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA.*

Aim/Introduction: The chemokine receptor 4 (CXCR4) is a G protein-coupled receptor overexpressed in multiple cancers. In recent years, ^{68}Ga and ^{177}Lu-labelled theranostic ligands have been developed for imaging and therapy of CXCR4-expressing cancers. However, their clinical success is limited by biokinetic differences and on-target bone marrow toxicity. The development of copper-based theranostics offers potential advantages due to their identical chemical properties and half-lives optimal for both late timepoint imaging and therapy. A cyclic peptide targeting CXCR4, previously developed in our group, was selected for preclinical evaluation of ^{64}Cu/^{67}Cu-labelled CXCR4 radioligands. ***Materials and Methods:*** A CXCR4-targeting cyclic peptide was chosen for coupling to 1,4,7-triazacyclononane-based chelators (p-SCN-Bn-NOTA and NODAGA). In vitro binding affinity to CXCR4 was evaluated in a competition binding assay. Our lead candidate (NODAGA-BL34) was labelled with [^{64}Cu/^{67}Cu]Cl_2 for in vitro and in vivo characterization. The time-course biodistribution of [^{64}Cu]Cu-NODAGA-BL34 was evaluated by PET imaging and biodistribution studies in two tumour models (Z138 and LTL331R) with different CXCR4 expression levels. Specific binding was confirmed by blocking with unlabeled CXCR4-targeting peptide. [^{67}Cu]Cu-NODAGA-BL34 specific binding was validated through cell uptake and internalization studies. ***Results:*** The BL34 pharmacophore was successfully coupled to three different 1,4,7-triazacyclononane-based chelators. The cold standard, ^{nat}Cu-NODAGA-BL34, showed high in vitro binding affinity to human CXCR4 (IC_{50}= 12.2±3.4 nM). NODAGA-BL34 was radiolabelled with ^{64}Cu and ^{67}Cu with a radiochemical purity of >95%. Moreover, both radioligands resulted in similar partition coefficients. [^{64}Cu]Cu-NODAGA-BL34 showed high tumour uptake at 1h post-injection in Z138 (12.5±1.5 %IA/g) and LTL331R-tumour bearing mice (7.2±2.3 %IA/g). After 24h, tumour uptake values decreased by 48% (6.5±0.3 %IA/g) and 82% (1.3±0.2 %IA/g) in Z138 and LTL331R, respectively. In both models, the tracer was cleared mainly through the renal pathway and the maximum tumour uptake correlates to the CXCR4 protein expression levels observed by western blot. [^{67}Cu]Cu-NODAGA-BL34 resulted in >60% cell uptake after 3 hours in CXCR4-expressing cells. ***Conclusion:*** The results presented show that [^{64}Cu]Cu-NODAGA-BL34 accumulates in the tumour site at high levels in CXCR4-expressing tumour models. Minimal uptake in major organs such as kidneys and liver was observed with time. Currently, in vivo characterization of [^{67}Cu]Cu-NODAGA-BL34 is being performed to design a dose-escalation therapy study.

^{68}Ga-NY104 PET/CT for the Detection of Clear Cell Renal Cell Carcinoma in Presurgical Patients With Renal Masses: A Prospective Phase II Study

X. Yan[1], *G. Zheng*[2], *M. Liu*[1], *Y. Zhang*[1], *Y. Xie*[1], *W. Zhu*[1], *L. Huo*[1];
[1]*Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA,* [2]*Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA.*

Aim/Introduction: Presurgical detection of clear cell renal cell carcinoma (ccRCC) remains challenging with conventional imaging. Contrast-enhanced CT demonstrates suboptimal specificity due to overlapping enhancement patterns with other renal masses. Carbonic anhydrase IX (CAIX) overexpression in clear cell renal cell carcinoma (ccRCC). We developed ^{68}Ga-NY104, a novel small-molecule PET tracer with high affinity to CAIX, and conducted this prospective study to evaluate its ccRCC detection performance in presurgical patients with renal masses. ***Materials and Methods:*** This prospective single-center phase II trial enrolled 51 patients with renal masses scheduled for surgical resection. All patients underwent intravenous injection of ^{68}Ga-NY104 followed by PET/CT imaging at 45-75 minutes post-injection. Surgical specimens were evaluated for histopathological diagnosis and CAIX expression. Diagnostic metrics including sensitivity, specificity, positive and negative predictive values were calculated against pathological results. ***Results:*** A total of 51 patients with renal masses were evaluated, all of whom underwent surgical resection. Histopathological analysis confirmed 36 ccRCC and

15 non-ccRCC cases. At the patient level, ^{68}Ga-NY104 PET/CT demonstrated 91.7% sensitivity (33/36 ccRCC correctly identified) and 60.0% specificity (9/15 non-ccRCC correctly classified). The positive and negative predictive values were 84.6% (33/39) and 75.0% (9/12), respectively. Six false-positive cases included 3 chromophobe RCCs and 2 oncocytomas and 1 FH-deficient RCC. Two of three false-negative cases were CAIX-negative ccRCC (both with extensive hemorrhage and necrosis) showing limited tracer uptake (SUVmax=4.0 and 0.8). The third case was pathologically confirmed as ccRCC (CAIX-positive by immunohistochemistry), showed moderate uptake (SUVmax=9.0, tumor-blood pool ratio=7.5) but was visually interpreted as negative due to high-uptake of normal renal cortex (SUVmax=28.6,). ***Conclusion:*** ^{68}Ga-NY104 PET/CT demonstrates promising diagnostic performance for ccRCC lesion detection in presurgical patients with renal masses.

OP-067

Relationship between [^{18}F]PSMA-1007 PET parameters and biochemical recurrence-free survival in high-risk prostate cancer patients receiving neoadjuvant hormonal treatment

N. Ahmadi Bidakhvidi[1], *A. Giesen*[2], *G. Devos*[2], *A. Laenen*[3], *M. Baldewijns*[4], *M. Koole*[1], *C. M. Deroose*[1], *W. Everaerts*[5], *S. Joniau*[2], *K. Goffin*[1];
[1]*Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM,* [2]*Urology, University Hospitals Leuven; Urogenital, Abdominal and Plastic Surgery, Department of Development and Regeneration, KU Leuven, Leuven, BELGIUM,* [3]*Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Leuven, BELGIUM,* [4]*Pathology, University Hospitals Leuven, Leuven, BELGIUM,* [5]*Urology, University Hospitals Leuven; Laboratory of Ion Channel Research, Department of Cellular and Molecular Medicine, KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: To investigate the relationship between [^{18}F]PSMA-1007 PET parameters and biochemical recurrence-free survival (BCR-FS) in high-risk primary prostate cancer patients receiving neoadjuvant hormonal treatment. ***Materials and Methods:*** This prospective randomized, double-blind, placebo-controlled phase II trial included 89 high-risk primary prostate cancer patients who received a pelvic [^{18}F]PSMA-1007 PET/MRI prior to and following neoadjuvant hormonal treatment. Patients were randomly assigned to neoadjuvant hormonal treatment with degarelix + apalutamide (n=45) or degarelix + matching placebo (n=44) for 3 months followed by radical prostatectomy and extended pelvic lymph node dissection. The following [^{18}F]PSMA-1007 parameters were determined on the pre- and posttreatment [^{18}F]PSMA-1007 PET: (i) semi-quantitative [^{18}F]PSMA-1007 PET parameters such as SUV_{max}, SUV_{mean}, PSMA-expressing volume and total lesion activity, and their absolute and relative differences; (ii) number of pelvic lymph node, distant and extraprostatic metastases determined on [^{18}F]PSMA-1007 PET; (iii) [^{18}F]PSMA-1007 PET-based response criteria (aPERCIST and RECIP 1.0); (iv) molecular imaging TNM-stage as determined by PROMISE version 2. ***Results:*** Thirty-five percent of included patients developed BCR within a median follow-up time of 38 months. Multivariate regression analyses revealed that PSMA-expressing volume posttreatment, the number of distant metastases pretreatment and miN1+miN2 vs. miN0 pretreatment were significant predictors of BCR-FS with hazard ratios of 1.184 (95% CI 1.070-1.309, p=0.0010), 5.820 (95% CI 2.498-13.561, p<0.0001) and 4.024 (95% CI 1.740-9.307, p=0.0011), respectively. ***Conclusion:*** Our results indicate that [^{18}F]PSMA-1007 PET can be a tool to monitor response to neoadjuvant hormonal treatment and that [^{18}F]PSMA-1007 PET can be used to aid in patient stratification for determining which patients would benefit from additional (neo)adjuvant treatment.

OP-068

Integrating PSMA PET with mpMRI Enhances Specificity and Reduces Unnecessary Biopsies in Suspected Prostate Cancer: Interim Results of the BIOPSTAGE Trial

M. Celli[1], *R. Gunelli*[2], *F. Ferroni*[1], *M. Costantini*[2], *A. Prochowski Iamurri*[1], *E. Fragalà*[2], *L. Fantini*[1], *I. Marini*[1], *D. Bezzi*[3], *V. Rossetti*[1], *I. Grassi*[1], *S. Nicolini*[1], *E. Giunta*[1], *S. Bellia*[1], *V. Di Iorio*[1], *F. Foca*[1], *F. Matteucci*[1], *P. Caroli*[1];
[1]*IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola (FC), ITALY,* [2]*Morgagni Pierantoni Hospital, Romagna Local Health Service, 47100 Forlì, Italy, Forlì (FC), Italy, Forlì (FC), ITALY,* [3]*Bufalini Hospital, Romagna Local Health Service, 47100 Cesena, Italy, Cesena (FC), Italy, Cesena (FC), ITALY.*

Aim/Introduction: mpMRI is widely used to guide prostate biopsies but suffers from limited specificity. PSMA PET may complement mpMRI by improving lesion characterization. The BIOPSTAGE trial evaluates whether combining the two modalities enhances diagnostic accuracy and biopsy triage in suspected prostate cancer (PCa). ***Materials and Methods:*** In this single-center prospective study, 96 men with clinical suspicion of PCa underwent [^{68}Ga]Ga-PSMA-11 PET/CT and mpMRI prior to prostate biopsy. Clinically significant PCa (csPCa) was defined as ISUP grade group ≥2. ROC analysis determined optimal semiquantitative PET thresholds (SUVmax ≥9.1; SUVratio ≥3.6). Diagnostic performance and biopsy burden were compared for mpMRI alone, PSMA PET alone, and their integration. ***Results:*** mpMRI alone identified 74 lesions (PI-RADS ≥3), achieving 93.8% sensitivity, 54.6% specificity, PPV of 20.3%, and NPV of 98.6%. PSMA PET identified 25 positive lesions in 21 patients using predefined thresholds, with a sensitivity of 85.7%, specificity of 86.3%, PPV of 48.0%, and NPV of 97.6%. Fourteen lesions were concordant between PET and mpMRI, while 11 were PET-only positive. Implementing an integrated approach that targets only PET-positive lesions would reduce biopsy targets by 66.2% compared to an mpMRI-only strategy. This approach increased specificity from 54.6% (mpMRI alone) to 86.3%. Two small csPCa lesions (5 mm and 8 mm, both ISUP 2) were missed by PET but detected on mpMRI. One PET-only lesion was confirmed as csPCa (ISUP 3). Concordant PSMA PET and mpMRI positive lesions had the highest frequency of csPCa (64.3%), compared to 9.1% in PET-only positive lesions. ***Conclusion:*** The integration of semiquantitative PSMA PET with mpMRI enhances lesion-level specificity and substantially reduces biopsy burden. mpMRI remains important for detecting small or low-uptake tumors, but the combined imaging approach may improve biopsy decision-making in men with suspected PCa.

OP-069

Comparison of PET/CT images with ^{68}Ga-NY104 and ^{18}F-FDG in metastatic clear cell renal cell carcinoma

W. Zhu[1], *X. Li*[2], *G. Zheng*[3], *C. Bai*[2], *Y. Zhang*[3], *L. Huo*[1];
[1]*Department of Nuclear Medicine, Beijing Key Laboratory of Molecular Targeted Diagnosis and Therapy in Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA,* [2]*Department of Oncology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA,* [3]*Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

Aim/Introduction: To evaluate the role of ^{68}Ga-NY104 PET/CT in metastatic clear cell renal cell carcinoma(ccRCC) in comparison with ^{18}F-FDG PET/CT ***Materials and Methods:*** This prospective single-center study (NCT05879471, IRB I-23YJ610) at Peking Union Medical College Hospital (PUMCH, Beijing, China) evaluated 45 consecutive paired ^{68}Ga-NY104/^{18}F-FDG PET/CT scans via independent interpretations. Inclusion required histologically confirmed ccRCC with radiologically/histologically

proven metastases, no change in ccRCC treatment between two scans, and ≥1-week VEGF-TKI washout if applicable. All patients underwent ^{18}F-FDG PET/CT and ^{68}Ga-NY104 PET/CT within a maximum time interval of 7 days. The primary outcome assessed lesion/region-level sensitivity and specificity of ^{68}Ga-NY104 PET/CT and ^{18}F-FDG PET/CT for ccRCC detection. Secondary outcomes included PPV/NPV, SUV_{max}/TBR (stratified by lesion/region type), imaging-histopathology correlation, identification of previously undetected regions, and the clinical impact (high/medium/low/no) of ^{68}Ga-NY104 PET/CT findings on patient management. ***Results:*** 682 lesions (591 ccRCC, 91 non-ccRCC) and 175 regions were analyzed. The lesion-level sensitivity, specificity, PPV, NPV were 94.4% (95%CI, 92.6%-96.3%), 98.9% (95%CI, 96.7%-100%), 99.8% (95%CI, 99.5%-100%), 73.2% (95%CI, 65.3%-81.0%) for ^{68}Ga-NY104, and 78.2% (95%CI, 74.8%-81.5%), 5.5% (95%CI, 0.8%-10.2%), 84.3% (95%CI, 81.3%-87.3%), 3.7% (95%CI, 0.5%-6.9%) for ^{18}F-FDG. For 591 ccRCC lesions, ^{68}Ga-NY104 showed higher SUV_{max} (12.4±11.8 vs. 7.5±10.7, P<0.001) and TBR (15.3±14.6 vs. 4.7±5.5, P<0.001) than ^{18}F-FDG, whereas non-ccRCC lesions exhibited lower tracer uptake (SUV_{max}: 1.2±0.9 vs. 6.7±3.4; TBR: 1.0±0.6 vs. 3.6±2.9; both P<0.001). The region-level sensitivity, specificity, PPV, NPV were 97.0% (95%CI, 94.2%-99.9%), 97.5% (95%CI, 92.7%-100%), 99.2% (95%CI, 97.8%-100%), 90.7% (95%CI, 82.0%-99.4%) for ^{68}Ga-NY104, and 82.2% (95%CI, 75.8%-88.7%), 10.0% (95%CI, 0.7%-19.3%), 75.5% (95%CI, 68.6%-82.5%), 14.3% (95%CI, 1.3%-27.2%) for ^{18}F-FDG. ^{68}Ga-NY104 demonstrated superior lesion/region-level sensitivity and specificity over ^{18}F-FDG (both P<0.001). Of 99 regions previously identified via other imaging, 90 were detected by either PET. ^{68}Ga-NY104 and ^{18}F-FDG PET identified 47 and 32 additional ccRCC regions, respectively. ^{68}Ga-NY104 PET/CT provided additional radiographic information versus ^{18}F-FDG PET/CT in 37 (37/45, 82%) patients, impacting clinical management in 11 (11/45, 24%: 6 high, 5 medium impact) patients. In the remaining 26 patients, added ^{68}Ga-NY104 data revealed no management changes despite supplementary radiographic information. ***Conclusion:*** ^{68}Ga-NY104 PET/CT demonstrates superior diagnostic accuracy, lesion characterization, and clinical utility compared to ^{18}F-FDG PET/CT in metastatic ccRCC, with significantly higher sensitivity and specificity. Its ability to detect occult lesions and influence clinical management underscores its potential as a transformative tool for staging, therapeutic monitoring, and personalized decision-making in ccRCC, particularly in scenarios where ^{18}F-FDG underperforms.

Influence of the injected peptide mass on imaging of prostate cancer: Phase I clinical study with the GRPR-antagonist [^{99m}Tc]Tc-DB8

A. Orlova[1], *V. Chernov*[2], *T. Maina*[3], *B. A. Nock*[3], *P. Kanellopoulos*[1], *M. Larkina*[2], *L. Tashireva*[2], *A. Rybina*[2], *R. Varvashenya*[2], *R. Zelchan*[2], *O. Bragina*[2], *A. Medvedeva*[2], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Cancer Research Institute, Tomsk, RUSSIAN FEDERATION,* [3]*NCSR "Demokritos", Athens, GREECE.*

Aim/Introduction: The gastrin-releasing peptide receptor (GRPR) is highly expressed in many human tumors, including prostate cancer (PCa). Its expression in the early stages of PCa, but not in prostate hyperplasia, allows the discrimination of early neoplastic events from common hyperplasia. [^{99m}Tc]Tc-DB8 is a GRPR-antagonist, demonstrating favorable biodistribution in PCa models in mice1. In the present study, we investigated the diagnostic value of [^{99m}Tc]Tc-DB8 in PCa patients, including tolerability and safety assessments and dosimetry calculations. We also performed a mass escalation study for the first time in PCa patients, aiming to improve diagnostic accuracy. ***Materials and Methods:*** A Phase I clinical study was conducted as a single-center diagnostic open-label exploratory study (ClinicalTrials.gov ID NCT05940298). Single intravenous injections of [^{99m}Tc]Tc-DB8 were performed in a 10 ml solution of 40, 80, or 120 µg of peptide. Patients (n=16 with clinically and radiologically diagnosed and histologically verified naïve hormone-sensitive or castration-resistant PCa) underwent whole-body planar imaging and SPECT-CT acquisition 2, 4, 6, and 24 h post-injection (pi). ***Results:*** The safety and tolerability of single intravenous administration of [^{99m}Tc]Tc-DB8 was confirmed for all tested peptide masses injected. The overall activity distribution was characterized by rapid activity excretion via kidneys. Elevated activity uptake was found in the kidneys and pancreatic tissue in the patients injected with 40 µg of peptide. Activity uptake in other normal tissues was low. Increased injected peptide mass led to faster whole-body activity elimination and blood clearance. The effective doses for individual peptide masses did not differ significantly and were in the range of 0.0038-0.0066 mSv/MBq, which corresponded to 1.6-3.0 mSv/procedure. High contrast images were obtained already 2 h pi of [^{99m}Tc]Tc-DB8 for all tested masses of peptide. Primary PCa lesions were visualized in 14 of 15 patients (93.3%, one patient underwent prostatectomy). The highest activity uptake in primary lesions and the highest tumor-to-background ratios were found for [^{99m}Tc]Tc-DB8 injections with 120 µg. Notably, increase of injected mass resulted in 3-fold lower activity uptake in pancreas and 2.5-fold lower activity uptake in kidneys. ***Conclusion:*** [^{99m}Tc]Tc-DB8 turned out to be a promising tracer in the diagnosis of PCa with SPECT/CT and its diagnostic value improved by increasing injected peptide dose. This concept warrants further clinical validation as a new versatile tool to improve image contrast (and potentially also therapeutic efficacy) of other receptor antagonist radioligands. ***References:*** 1. Nock et al. J Med Chem 2018,61:3138.

OP-071

Deep Learning for Automated Whole-Body Tumor Quantification and Prognostic Stratification of Prostate Cancer on ^{68}Ga-PSMA-11 PET/CT

P. Yang[1], *Q. Pan*[2], *L. Jiang*[1], *Z. Zhao*[1], *L. Li*[1], *Q. Guo*[3], *H. Cai*[1];
[1]*West China Hospital of Sichuan University, ChengDu, CHINA,* [2]*Machine Intelligence Laboratory, College of Computer Science, Sichuan University, ChengDu, CHINA,* [3]*School of Artificial Intelligence,Guangxi Minzu University, Nanning, CHINA.*

Aim/Introduction: To develop a deep learning (DL) approach for fully automated, whole-body tumor quantification on ^{68}Ga-PSMA-11 PET/CT and validate its value in prognostic stratification for prostate cancer (PCa). ***Materials and Methods:*** A total of 782 patients with PCa from two independent medical centers were included in this retrospective study, comprising a training cohort (n = 656), an internal testing cohort (n = 73), and an external testing cohort (n = 53). A whole-body tumor segmentation model of ^{68}Ga-PSMA-11 PET was developed based on a transformer-driven framework MedNeXt. Segmentation performance was evaluated by the Dice similarity coefficient (DSC), intersection over union (IoU), sensitivity, and positive predictive value (PPV). DL-based whole-body quantitative PET metrics, including SUVmax, SUVmean, total tumor volume (TV), and total lesion uptake (TLU) were extracted from the automated segmentations and then utilized to predict overall survival (OS) in another 94 patients with Castration-Resistant Prostate Cancer (CRPC). Furthermore, the prognostic performance of these metrics was further compared with that of the miTNM staging system using Harrell's concordance index (C-index). ***Results:*** For the internal testing cohort, the mean DSC, IoU, Sensitivity, and PPV were 0.75±0.24, 0.64±0.24,0.73±0.26, and 0.81±0.21, respectively. For the external testing cohort, the mean DSC, IoU, Sensitivity, and PPV were 0.81±0.17, 0.71±0.19,0.83±0.18, and 0.82±0.18, respectively. DL-based TV (HR: 4.291, p<0.001) and TLU (HR: 3.215, p<0.001) were significantly associated with poor OS. Among all evaluated features, distant lymph node metastasis (M1a), multiple or diffuse bone metastases [M1b (diss or dmi)], organ metastasis (M1c), and DL-based TV together achieved the highest C-index of

0.800 (95%CI: 0.708-0.892) for OS risk prediction. ***Conclusion:*** The proposed approach demonstrated accurate tumor segmentation on ^{68}Ga-PSMA-11 PET/CT scans. Moreover, DL-based TV and TLU showed potential for improving OS prognostic stratification in patients with CRPC.

OP-072

Comparative diagnostic utility and quantification of PSMA-avid lesions on 99mTc-HYNIC-PSMA-11 SPECT/CT with 68Ga-PSMA PET/CT in metastatic prostate cancer patients.

M. Hooda[1], *B. Singh*[1], *R. Mavuduru*[2], *H. Singh*[3], *A. P. Sharma*[2];
[1]*Department of Nuclear Medicine, Post-graduate institute of medical education and research (PGIMER), Chandigarh, INDIA,* [2]*Department of Urology, Post-graduate institute of medical education and research, (PGIMER), Chandigarh, INDIA,* [3]*Department of Nuclear Medicine, Post-graduate institute of medical education and research, (PGIMER), Chandigarh, INDIA.*

Aim/Introduction: In this study, we assessed the diagnostic-efficacy of ^{99m}Tc-HYNIC-PSMA-11(whole-body and regional-SPECT/CT) and compared it with the 'standard-of-care' ^{68}Ga-PSMA-PET/CT, for the detection of primary and metastatic lesions in prostate cancer (PCa) patients. Additionally, we analysed the correlation between semi-quantitative-parameters i.e. the percentage-quantitative-lesion-uptake (%QLU-SPECT) and (SUVmax-PET) of these techniques. Prior studies have highlighted the potential of ^{99m}Tc-HYNIC-PSMA-11 as a cost-effective alternative to ^{68}Ga-PSMA imaging in clinical management of PCa(1). ***Materials and Methods:*** This prospective study included forty-six male-patients (mean-age 67.2±8.41years) with histologically confirmed PCa and raised PSA-levels. Each patient underwent ^{68}Ga-PSMA-PET/CT followed within-one-week by ^{99m}Tc-HYNIC-PSMA-11 scintigraphy. Patients received an intravenous dose of ^{99m}Tc-HYNIC-PSMA-11 (mean-activity 12.3±1.8mCi). The whole-body anterior& posterior at 2h & 4h and regional SPECT/CT at-3h of the involved/suspected sites were acquired using the dual-headed-gamma-camera (Symbia-T16-Siemens, Erlangen, Germany). The comparative data analysis of the two techniques included the number of metastatic-lesions detected on ^{99m}Tc-HYNIC-PSMA-11 in comparison to ^{68}Ga-PSMA-PET/CT imaging. Further, the correlation between the SPECT and PET-based quantitative-parameters i.e. %quantitative-lesion-uptake (%QLU) and SUV_{max} for the matched PSMA-avid lesions detected on both modalities was also evaluated. The method for SPECT-based quantitative analysis has been described by us elsewhere(2). ***Results:*** The mean PSA-levels among patients was 136.10±447.34ng/mL, with a Median Gleason-score of 4.0+3.0 and an ISUP grade of 4.0. Both imaging modalities detected PSMA-avid lesions in 45/46 patients with no disease evidence in one patient on either scan. The primary lesions (n=45) were detected in all the patients on both the imaging techniques. ^{68}Ga-PSMA-PET/CT detected 252 metastatic lesions (5.6-lesions/patient), while ^{99m}Tc-HYNIC-PSMA-11-SPECT/CT identified 209 lesions (4.6-lesions/patient), including 48/68 pelvic nodes; 45/59 distant nodes; 115/124 skeletal lesions; 1/1 visceral lesion. On 165 matched lesions (45 primary;50 lymph nodes(pelvic & distant) and 69 skeletal lesions) detected on both the modalities, the semi-quantitative analysis provided mean-%QLU of 7.76±9.01 and mean-SUV_{max} of 18.30±12.69 respectively. A highly significant-correlation (r=0.61;p<0.001) was noted with the SUV_{max} values. ***Conclusion:*** With the comparative detection efficiency, ^{99m}Tc-HYNIC-PSMA-11 demonstrates 83% lesion-detection and strong-correlation with SUV_{max}, supporting its use as a cost-effective alternative for evaluating metastatic-PCa when ^{68}Ga-PSMA-PET/CT is unavailable(3). ***References:***

OP-073

Radionuclide Therapy with FAP-2286 in FAP expressing Relapsed / Refractory Malignancies - Proof of Concept and Up-to-date Single Centre Experience

S. Dash*, V. Malasani, R. Vatsa, A. Raj, V. Hari, D. Pendharkar; Sarvodaya Hospital, Faridabad, INDIA.*

Aim/Introduction: Fibroblast activation proteins (FAP) expressed in specific subtypes of "cancer associated fibroblasts (CAF)" are seen in the tumor microenvironment of several cancer types like pancreatic ductal adenocarcinoma, aggressive subtypes of breast cancers, colorectal& gastric cancers, non-small cell lung cancers, ovarian cancer, sarcomas, hepatocellular, and head & neck squamous cell carcinomas· In addition to increased cell migration, angiogenesis, epithelial-to-mesenchymal transition, immune evasion, FAP expression is also linked to chemotherapy resistance and poor prognosis· Recently FAP targeted radiopharmaceuticals have demonstrated promising potential for diagnosis and therapy· This study shares the experience of FAP-2286 theranostics in a tertiary cancer care center in India, establishing proof of concept, safety for palliation, and survival benefits ***Materials and Methods:*** It is an ongoing interventional study comprising 60 patients with relapsed or refractory disease on established standard treatment with ≥80% positive lesions on FAP-2286 PET- CT scan· Patients who had received two or more doses were included (n¦56) for analysis· Depending upon the tumor subtypes & biological behaviour, genetic studies, and clinical profile, patients received either monotherapy (radiolabeled FAP-2286) or combination therapy (radiolabeled FAP-2286 with targeted/Immunotherapy)· The objective response rate (ORR), progression free survival rate (PFSR) and radiopharmaceutical safety were analyzed· Patients with mixed response and progressive disease were excluded from the study ***Results:*** Of the 56 patients (34M,22F) 14 vs 42 received monotherapy and combination therapy, respectively· 37 patients received 4 radionuclide therapy cycles and are under long-term follow up (Table-1)· 177-Lu-FAP-2286, 225-Ac-FAP-2286, and both (tandem) were administered in n≡46, n≡8, and n≡2 patients, respectively· After 2 cycles, 4/14 and 2/14 of monotherapy arm and 6/42 and 3/42 of combination therapy arm were excluded due to mixed response and disease progression, respectively· The ORR, disease control and mean PFSR for monotherapy vs combination therapy were noted to be 42.9%, 14.2%, and 3.5 months vs 57%, 21.4%, and 8.9 months· Patients with combination therapy also experienced other drug-related adverse effects, notably fatigue, skin reactions, and various GI symptoms ***Conclusion:*** FAPI Theranostics with FAP-2286 seems to be a viable alternative for patients failing on all standard lines of management in FAP expressing malignancies· There is definite evidence of improved quality of life, reduction in disease burden, and survival benefit.

Aim/Introduction: [^{203}Pb]/[^{212}Pb]Pb-PSV359 is a novel theranostic radiopharmaceutical targeting Fibroblast Activation Protein alpha (FAP-α), which can be overexpressed on tumour or stromal cells in the tumour microenvironment. PSV359 is designed for the delivery

of targeted alpha particle therapy, combining [^{203}Pb]Pb-PSV359 for SPECT imaging and [^{212}Pb]Pb-PSV359 for targeted radiotherapy. Preliminary human imaging data using [^{203}Pb]Pb-PSV359 demonstrated specific and sustained tumour uptake across multiple cancer types, supporting the advancement of this agent into therapeutic studies. We present the design of a first-in-human Phase I/IIa study evaluating safety, dosimetry, and preliminary efficacy in patients with FAP-α-positive tumours. ***Materials and Methods:*** Phase I of the trial follows a modified Toxicity Probability Interval version 2 design. Patients will first undergo [^{203}Pb]Pb-PSV359 imaging to confirm FAP-α expression. [^{212}Pb]Pb-PSV359 will then be administered in dose cohorts ranging from 2.5 mCi to ≤ 10 mCi (92.5 to 370 MBq). A dosimetry sub-cohort will receive scans at multiple time points to characterise biodistribution and radiation exposure. Safety, pharmacokinetics, and efficacy data will be collected at baseline and at regular intervals (every 8 weeks for the first 6 months, then every 12 weeks up to 12 months). Dose-limiting toxicities will be evaluated during cycle 1 as part of the primary objective of the study to determine the recommended Phase 2 dose (RP2D). Imaging assessments to evaluate antitumour efficacy will include FDG PET/CT and MRI or CT scans. Safety will be assessed according to the Common Terminology Criteria for Adverse Events, version 5.0 and efficacy by Response Evaluation Criteria in Solid Tumours v1.1. Expansion cohorts at the RP2D will further characterise the agent's benefit-risk profile across multiple tumour types where FAP-α may play a role in tumourigenesis and/or progression, such as in sarcoma, mesothelioma, colorectal, ovarian, and head and neck cancers. ***Results:*** The study is now actively enrolling. The[PH1] main inclusion criterion of FAP-α expression will be determined by SPECT imaging. Main exclusion criteria include active brain metastasis, the presence of another active secondary malignancy, and known hypersensitivity to the active agent or a history of life-threatening allergic reactions. ***Conclusion:*** [^{203}Pb]/[^{212}Pb]Pb-PSV359 represents a promising approach to targeted alpha therapy in FAP-α-overexpressing solid tumours through selective FAP-α targeting, tumour accumulation, and retention, combined with rapid clearance from normal organs. The ongoing clinical study is designed to rigorously evaluate safety, dosimetry, and initial efficacy outcomes, with the goal of advancing a pan-cancer theranostic agent.

Hydrophobic F-base engineering augments aptamer pharmacokinetics for precision oncology: A PET imaging study
S. Yang[1], *Q. Chen*[1], *D. Ding*[2], *X. Lan*[1], *D. Jiang*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Institute of Molecular Medicine (IMM), Renji Hospital, State Key Laboratory of Oncogenes and Related Genes, Shanghai*

Jiao Tong University School of Medicine, and College of Chemistry and Chemical Engineering, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: Aptamers, oligonucleotide sequences with a specific spatial conformation, hold immense potential as cancer-targeting agents but suffer from rapid clearance that compromises tumor accumulation. While hydrophobic F-base engineering have been proposed to enhance aptamer circulation, systematic pharmacokinetic evaluations across tumor models remain lacking. This study addresses this gap by comprehensively assessing the impact of F-base engineering on Sgc8 pharmacokinetics and tumor uptake using positron emission tomography (PET) imaging across multiple tumor models. ***Materials and Methods:*** The Sgc8 aptamer and its F-base derivatives (FSgc8, 2FSgc8) were radiolabeled with Zr-89, with radiochemical purity (>90%) validated by radioactive instant thin layer chromatography (radio-iTLC). Dynamic PET imaging (0-168 h) was conducted in murine MC38 and CT26 colon carcinoma models. Time-activity curves for blood pools and tumors were quantified via the region of interest (ROI) analysis in MC38 models, followed by the area under the curve (AUC) comparisons and tumor-to-blood (T/B) ratio calculations. ***Results:*** F-base modification conferred dose-dependent pharmacokinetic enhancements: 1 h post-injection blood retention increased from 0.05 ± 0.01%ID/g (native Sgc8) to 1.05 ± 0.23%ID/g (FSgc8) and 2.93 ± 0.25%ID/g (2FSgc8), with sustained detection of 2FSgc8 until 168 h. Tumor uptake of 2FSgc8 surpassed FSgc8 until 72 h ($p < 0.05$), achieving 33.2-fold and 1.5-fold increases over Sgc8 and FSgc8, respectively. Despite superior bioavailability (AUC_{blood}: 38.8× Sgc8; 2.4× FSgc8), 2FSgc8 exhibited a declining T/B ratio at 72 h (1.99 vs. 2.58 for FSgc8), suggesting prolonged circulation may reducing tumor-specific enrichment by decreasing intact 2FSgc8 at tumor sites. ***Conclusion:*** Hydrophobic F-base engineering significantly enhances aptamer pharmacokinetics and tumor targeting, positioning it as a transformative strategy for oligonucleotide therapeutics. Ongoing optimization focuses on balancing serum stability and tumor accumulation kinetics to maximize clinical translatability.

OP-087

Linker Modifications in Radiolabeled Rm26-based Antagonists to Gastrin-releasing Peptide Receptor (GRPR) Improved Pharmacokinetics

E. Bezverkhniaia*, A. Abouzayed, P. Kanellopoulos, V. Tolmachev, U. Rosenström, A. Orlova;*
Uppsala university, Uppsala, SWEDEN.

Aim/Introduction: Radionuclide targeting of gastrin-releasing peptide receptor (GRPR) holds significant diagnostic and therapeutic potential. Recently, our group reported the results of the Phase I clinical evaluation of [^{99m}Tc]Tc-maSSS-PEG2-RM26, an antagonist GRPR-targeting SPECT imaging agent [1]. The present study aimed to develop the next generation of RM-26-based GRPR antagonists with enhanced metabolic stability and improved pharmacokinetics. Four new agents containing a sarcosine (Sar) at position 11 to improve the in vivo stability and with more hydrophilic linkers were designed: Pep1 - maSSS-PEG2-[Sar^{11}]RM26, Pep2 - maSSS-PEG6-[Sar^{11}]RM26, Pep3 - maSSS-PEG2-Pip-[Sar^{11}]RM26, Pep4 - maSSS-EEE-[Sar^{11}]RM26. These analogues were compared in vitro and in vivo with [^{99m}Tc]Tc-maSSS-PEG2-RM26. ***Materials and Methods:*** Constructs were radiolabeled with ^{99m}Tc using transchelation from gluconate. In vitro GRPR-binding specificity, cellular processing, and binding kinetics were evaluated using PC-3 cells. Biodistribution and in vivo stability (for the best-performing constructs) were assessed in NMRI mice. Tumor targeting, in vivo specificity, and SPECT/CT imaging were performed in BALB/c nu/nu mice. ***Results:*** All constructs were radiolabeled with radiochemical yields over 95%. The label was stable during 1h in 300-molar excess of L-cysteine and PBS at room temperature. In PC-3 cells, [^{99m}Tc]Tc-Pep1, [^{99m}Tc]Tc-Pep2 and [^{99m}Tc]Tc-Pep3, but not [^{99m}Tc]Tc-Pep4, specifically bound to GRPR and exhibited low nanomolar affinity. When compared in vivo in NMRI mice, new peptides had significantly reduced activity uptake in the liver: [^{99m}Tc]Tc-Pep1 had a 2.3-fold reduction, [^{99m}Tc]Tc-Pep2 - 10-fold reduction, [^{99m}Tc]Tc-Pep3 - 3-fold reduction compared to [^{99m}Tc]Tc-maSSS-PEG2-RM26. This was also reflected in the octanol-water coefficient. Both [^{99m}Tc]Tc-Pep2 and [^{99m}Tc]Tc-Pep3 showed improved metabolic stability (≈ 62% and ≈ 73% of intact radiopeptide respectively) compared with [^{99m}Tc]Tc-maSSS-PEG2-RM26 (≈ 31% of intact radiopeptide), bound specifically to GRPR in vivo, and demonstrated a tendency (not statistically significant) for higher tumor activity uptake compared to the reference. Biodistribution data were confirmed by SPECT/CT imaging. ***Conclusion:*** This study demonstrated the promising impact of linker modification on refining the pharmacokinetic profile of ^{99m}Tc-labeled GRPR-antagonists. Based on the obtained results, the introduction of a hydrophilic PEG2-pip linker or a PEG6 linker, as pharmacokinetic modifiers, has a profound impact on the shift from hepatobiliary excretion towards renal excretion compared to the reference [^{99m}Tc]Tc-maSSS-PEG2-RM26. The use of a PEG6 linker decreased activity uptake in the liver by 10-fold and by 1.3-fold in the gastrointestinal tract. The use of a PEG2-pip linker decreased activity uptake in the liver by 3-fold and by 1.4-fold in the gastrointestinal tract. ***References:*** 1. Chernov et al. Cancers. 2023,15(6):1631.

OP-088

[^{18}F]F-FPy prosthetic group lowers kidney accumulation while retaining tumor uptake in a Glypican-3 targeted nanobody

S. Fayn*[1,2], F. Basuli[1], H. Makala[1], W. Lee[1], M. Ho[1], R. E. Swenson[1], P. L. Choyke[1], O. Jacobson[1], F. E. Escorcia[1];*
[1]National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA, [2]University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Nanobodies (Nbs), or single-domain antibodies (sdAbs), have become a promising tool in helping augment cancer treatment. These sdAbs have good tumor penetration, a half-life amenable to same-day imaging, and renal clearance, making them attractive scaffolds for building radiotheranostics for liver cancer. One limitation of nanobodies for radiopharmaceutical therapy is their high kidney retention, which could result in significant nephrotoxicity. Strategies to reduce kidney uptake of Nbs have been underway, including manipulating prosthetic groups used for labeling. Here, we used a fluorine-18-based labeling strategy with our previously developed Glypican-3 targeted nanobody, ssHN3, with the aim of minimizing kidney retention. ***Materials and Methods:*** We made two new versions of our ssHN3 LPETG-tagged nanobody, including direct lysine-based labeling of [^{18}F]F-FPy, and sortase-based site-specific labeling using triglycine-[^{18}F]F-FPy. Direct labeling was done by combining [^{18}F]F-FPy-TFP with ssHN3 and incubating for 20 min at 37 °C. Site-specific labeled nanobody was prepared by combining H-GGGK-[^{18}F]F-FPy-NH_2, sortase, and ssHN3 and incubating at 4°C for 30 min. Ex vivo biodistribution studies were done in nude athymic mice inoculated with HepG2 GPC3+ and GPC3- tumors. Organs were collected at 1, 2, and 3 h post-injection (p.i.), and activity was measured on a gamma counter to determine conjugate uptake (n = 4-5 per time point). ***Results:*** Radioconjugates were synthesized at high purity (>99%). ssHN3-[^{18}F]F-FPy and ssHN3-GGGK-[^{18}F]F-FPy demonstrated specificity for GPC3+ tumors with 10% and 6% injected activity/gram (IA/g) in HepG2 GPC3+ vs 1.13 and 1.38 %IA/g in HepG2 GPC3- tumors 1 h p.i., respectively (n = 5 for ssHN3-[^{18}F]F-FPy, n = 4 for ssHN3-GGGK-[^{18}F]F-FPy). More importantly, kidney uptake was ~40-fold lower between the two tracers in HepG2 GPC3+ tumors 3 h p.i. (2.37% IA/g for ssHN3-[^{18}F]F-FPy and 3.35% IA/g for ssHN3-GGGK-[^{18}F]F-FPy) compared to our previously developed version ssHN3-Al[^{18}F]F-RESCA (113.36% IA/g 3 h p.i.), and ~62 fold lower compared to our previously developed version ^{89}Zr-ssHN3 (173.77% IA/g 3 h p.i.). ***Conclusion:*** Altogether,

we demonstrated the ability to significantly reduce renal uptake of a nanobody by replacing metal-based chelators with a nonmetal [^{18}F]F-FPy construct. This allows for a higher signal-to-noise in PET/CT imaging of liver tumors, lowers the amount of radioactivity that normal tissue is exposed to, and underscores the approach of using nonmetal-based therapeutic radionuclides (e.g., Iodine-131, Astatine-211). Furthermore, this strategy could be extended to other smaller molecules and antibody fragments with similar challenges and ultimately provide a much-needed library of targeted tools for cancer diagnosis and treatment.

OP-089

Selection of the optimal format of albumin-binding domain-fused CAECAM5-specific affibody for targeted delivery of cytotoxic payload to malignant tumours

V. Tolmachev[1], *E. Papalanis*[1], *R. Li*[2], *M. Oroujeni*[1], *A. J. Herlina*[1], *Y. Liu*[1], *A. Orlova*[3], *E. Bezverkhniaia*[3], *P. Nygren*[2], *T. Gräslund*[2];
[1]*Department of Immunology, Genetics and Pathology (IGP), Uppsala University, Uppsala, SWEDEN,* [2]*KTH-Royal Institute of Technology, Stockholm, SWEDEN,* [3]*Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: A cell surface protein CEACAM5 is overexpressed in colorectal, pancreatic, ovarian and lung carcinomas, but shows low postnatal expression. Thus, CEACAM5 is a potential molecular target for cancer therapy. Affibodies are engineered affinity proteins based on non-immunoglobulin scaffold. They demonstrated capacity of specific delivery of cytotoxic substances to malignant tumours. A dimeric affibody C9-9 binding to CEACAM5 with an apparent affinity of 2 nM has been reported. Fusing affibodies with the albumin-binding domain (ABD) reduces their renal clearance and reabsorption, increases residence in blood and enhances tumour accumulation. This study aimed to characterise fusions of C9-C9 with albumin-binding domain ABD_{035} and select the best variant for development of targeting system. ***Materials and Methods:*** Two variants of the fusion were created, ABD_{035}-C9-C9-EYEC (ABD at the N-terminus) and C9-C9-ABD_{035}-EYEC (ABD at the C-terminus). The chelating sequence -EYEC was incorporated at C-termini of both constructs for labelling with ^{99m}Tc. In vitro binding specificity and internalisation were evaluated using BxPC3, LS174T and HT-29 cells, having high, intermediate and low CEACAM5 expression, respectively. Apparent affinity of interaction with caner cells was measured using LigandTracer. Biodistribution was measured in nude mice bearing human CEACAM5-expressing xenografts 4, 24 and 48 h post- injection (p.i.). ***Results:*** Both constructs showed radiochemical purity >95%, and labels were stable under cysteine challenge. Both [^{99m}Tc]Tc-C9-C9-ABD_{035}-EYEC and [^{99m}Tc]Tc-ABD_{035}-C9-C9-EYEC bound specifically to CEACAM5-expressing cells in vitro, and binding was proportional to the expression level. InteractionMap analysis of the LigandTracer data showed two types of interaction with CEACA5-expressing cells, one with apparent dissociation constant of 550-850 pM and another with 14-19 nM. The strongest interaction was more abundant for [^{99m}Tc]Tc-ABD_{035}-C9-C9-EYEC. After 24-h incubation at 37°C, the internalised fraction was 50-55% for both constructs. The retention of ABD-fused variants in blood 4 h p.i. was >50-fold higher than the retention of non-fused control [^{99m}Tc]Tc-C9-C9-EYEC. Their tumour uptake was six-fold higher and renal uptake was 10-fold lower compared with the uptake of [^{99m}Tc]Tc-C9-C9-EYEC. The blood half-lives were 20.6 and 12.3 h for [^{99m}Tc]Tc-ABD_{035}-C9-C9-EYEC and [^{99m}Tc]Tc-C9-C9-ABD_{035}-EYEC, respectively. The maximum uptake in BxPC3 xenografts (48 h) of [^{99m}Tc]Tc-ABD_{035}-C9-C9-EYEC (59±20 %ID/g) was significantly higher than the uptake of [^{99m}Tc]Tc-C9-C9-ABD_{035}-EYEC (22±7 %ID/g). ***Conclusion:*** Targeting properties of fusions of C9-C9 with ABD depend on the position of domains binding to CEACAM5 and albumin. ABD_{035}-C9-C9-EYEC provides more efficient targeting compared with the counterpart with the C-terminal positioning of ABD_{035}.

OP-090

Oligonucleotide modification minimizes renal uptake of nanobodies

S. Yang[1], *X. Long*[1], *W. Wei*[2], *X. Lan*[1], *D. Jiang*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: Nanobodies, single-domain antibody fragments, are valuable in precision medicine for their superior tumor-targeting ability and rapid clearance from the bloodstream. However, their high renal retention complicates cancer diagnosis, especially in renal metastasis, and radioimmunotherapy. To address this limitation, we developed a novel oligonucleotide-based modification strategy to reduce radioactive retention of nanobodies. ***Materials and Methods:*** A nanobody targeting CD70 (namely B6) was site-specifically conjugated to a 20-base double-stranded nonsense oligonucleotide (dsODN) via a two-step reaction. The B6-dsODN conjugates were purified via size-exclusion chromatography (SEC) and confirmed by polyacrylamide gel electrophoresis (PAGE). The serum stability was assessed by agarose gel electrophoresis after incubation in 90% fetal bovine serum (FBS) at 37°C for 4 hours. The nanobody and ODN components of B6-dsODN were radiolabeled with F-18, respectively (i.e., [^{18}F]B6-dsODN and [^{18}F]dsODN-B6). The renal uptake was compared to [^{18}F]B6 by PET/CT imaging and biodistribution studies in healthy mice. ***Results:*** The PAGE electrophoresis confirmed the conjugation of B6 to dsODN with >95% purity. B6-dsODN showed excellent serum stability, with the majority remaining intact after 4 hours in FBS due to the nuclease resistance of the double-stranded structure. PET/CT imaging in healthy mice showed significantly lower renal uptake of [^{18}F]dsODN-B6 compared to [^{18}F]B6, with a 187-fold reduction. Biodistribution studies at 2 h after injection revealed a >200-fold reduction in renal uptake for [^{18}F]dsODN-B6. However, no difference in renal uptake was observed between [^{18}F]B6-dsODN and [^{18}F]B6. Further analysis confirmed that the F-18 labeled dsODN detached in the kidneys, resulting in reduced renal radioactivity uptake. ***Conclusion:*** This dsODN-based modification strategy effectively reduces renal radioactive uptake of nanobodies, offering a convenient and efficient approach for developing nanobody-derived drugs. Future work will validate the universal applicability of the strategy and evaluate its efficacy in tumor-bearing mice.

OP-091

Assessing the generalizability of a preclinical PBPK model for DOTA-TATE-based radiopharmaceuticals: application to ^{161}Tb, ^{177}Lu, ^{153}Sm and ^{68}Ga

J. Henriot[1], *L. Struelens*[2], *M. Andersson*[3], *S. Rodriguez Pérez*[2], *M. Koole*[4], *C. Saldarriaga Vargas*[2];
[1]*SCK CEN & KU Leuven, Mol, BELGIUM,* [2]*SCK CEN, Mol, BELGIUM,* [3]*SCK CEN & ULB, Mol, BELGIUM,* [4]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: [177Lu]Lu-DOTA-TATE combined with [68Ga]Ga-DOTA-TATE is current the theragnostic approach of choice for Peptide Receptor Radionuclide Therapy (PRRT) of Neuro-Endocrine Tumors (NETs). Several research groups are exploring the potential of DOTA-TATE labelled with other radionuclides, such as 161Tb. Considering that pharmacokinetics are predominantly driven by the peptide moiety, we propose a generic preclinical physiologically-based pharmacokinetic (PBPK) model to accurately predict the uptake of various DOTA-TATE-based radiopharmaceuticals in both tumor and organs at risk. ***Materials and Methods:*** A murine whole-body PBPK model for [161Tb]Tb-DOTA-TATE was implemented using MATLAB Simbiology based on a published model (1). The model was initially developed in healthy mice, incorporating novel in vitro binding data (2), plasma protein binding, and competition between labeled and unlabeled DOTA-TATE for receptor targeting. Kinetic parameters and SSTR2

densities were fitted to [161Tb]Tb-DOTA-TATE preclinical biokinetic data. The model was then verified using an independent [161Tb]Tb-DOTA-TATE dataset (3) and further developed and verified using biokinetic data of mice bearing a CA20948 rat pancreatic tumor (4). The generalizability of the model was assessed using preclinical literature biodistribution studies for DOTA-TATE radiolabeled with [68Ga]Ga and various β-emitters. ***Results:*** The developed PBPK model successfully described the pharmacokinetics of [161Tb]Tb-DOTA-TATE both in healthy and tumor-bearing mice. The relative errors for time-integrated activities ranged from -1% to +22% in the kidneys, while a value of -15% was obtained for the tumor. SSTR2 densities emerged as a strain-specific parameter such that fitting was essential to accurately match experimental data. Still, relative SSTR2 levels between organs remained reasonably constant across mice strains with relative simulated expressions of 19 ± 3% for the pancreas, 2 ± 1% for the liver, 1 ± 0% for the spleen, and 10 ± 5% for the lungs (mean ± SD), using kidneys expression levels as reference. Our findings also indicated that our PBPK model can be applied to other DOTA-TATE-based radiopharmaceuticals labeled with [177Lu]Lu, [153Sm]Sm, [68Ga]Ga, showing the potential of a generic model for DOTA-TATE-based PRRT and supporting its clinical translation to predict tumoral and organ uptake of [161Tb]Tb-DOTA-TATE and [177Lu]Lu-DOTA-TATE in NET patients. ***Conclusion:*** These preclinical results constitute a first step towards the broad clinical application of a generalized PBPK model to support dosimetry-based PRRT personalization with radiolabeled DOTA-TATE. ***References:*** (1) Zaid et al. 2021. https://doi.org/10.3390/pharmaceutics13122132. Association of different forms of non-conjugated astatine-211 to albumin

E. Aneheim[1,2], *S. Lindegren*[1], *H. J. Jensen*[3], *T. Bäck*[1];
[1]*University of Gothenburg, Göteborg, SWEDEN,* [2]*Sahlgrenska University Hospital, Göteborg, SWEDEN,* [3]*Copenhagen University Hospital, Copenhagen, DENMARK.*

Aim/Introduction: Astatine-211 is one of the alpha-particle emitting nuclides investigated for use within Targeted Alpha Therapy (TAT) of disseminated cancer. In previous studies, a difference in blood clearance has been observed when comparing astatinated compounds with their iodinated counterparts. This has been explained by a potentially prolonged retention in the blood by present free astatine. In this work, the spontaneous association of non-conjugated, so called "free" astatine to albumin has been investigated and compared to iodine in vitro under physiological conditions. In addition, the in vivo blood circulation behavior of free astatine was evaluated in comparison to iodine. ***Materials and Methods:*** Astatine solutions were formulated following dry distillation and evaporation to dryness of astatine solvated in $CHCl_3$. In vitro evaluation of astatine and iodine association to albumin was mainly performed using size exclusion chromatography applying both disposable columns (PD10 and NAP10) as well as an FPLC system (ÄKTA) with online UV detection and activity fraction collection. Also methanol precipitation and radio-TLC methods were used for analysis. In vivo evaluation was performed using furry BALB/C mice (3 / group) with both i.v. and i.p. injection of activity, followed by sequential blood sampling from the tail vein and biodistribution. ***Results:*** Oxidized and unmodified forms of free astatine display a significantly higher and more rapid association to albumin in vitro compared to reduced forms, with >97 % compared to <25 % associated after 10 minutes. Both the corresponding oxidized and reduced forms of iodine display a very low and slow association to albumin with < 5% associated after 40 minutes. Oxidized, unmodified and reduced astatine show very similar blood profiles over time as well as a similar uptake in biodistribution after 20-22 h following i.p. injection. Upon i.v. injection a larger difference in blood profiles between the species could be observed, which in turn was different compared to the curve obtained after i.p. injection. In addition an unexpected uptake of Astatine in PBS/1% Asc. in stomach was found. In all cases the blood profile and biodistribution of astatine was significantly different compared to iodine, which displayed a greater and more rapid blood clearance and specific accumulation in thyroid. ***Conclusion:*** Different forms of unbound astatine differ in their association to albumin. However, all investigated forms of free astatine associates to albumin to a much higher degree than iodine. This behavior could explain the prolonged blood circulation of free astatine compared to iodine.

Kinetic modelling of [^{89}Zr]Zr-DFO-anti-VEGF PET at different stages of glioblastoma progression

E. Ramos-Docampo[1,2], *M. Muñoz-González*[1], *J. Codesido*[1], *X. García-Otero*[1], *C. Domínguez-Borrero*[1], *S. Groba-de Antas*[1], *N. Gómez-Lado*[1], *P. Aguiar*[1,2], *L. García-Varela*[1,2];
[1]*Molecular Imaging and Pharmacokinetic Modelling Group, Center for Research in Molecular Medicine and Chronic Diseases (CiMUS), University of Santiago de Compostela, Santiago de Compostela, SPAIN,* [2]*Nuclear Medicine and Molecular Imaging Group, Health Research Institute of Santiago de Compostela (IDIS), University Hospital Santiago de Compostela, Santiago de Compostela, SPAIN.*

Aim/Introduction: Kinetic modelling offers a detailed quantification of the radiotracer, enhancing our understanding of tumor antigen dynamics during disease progression and treatment. While standardized uptake values (SUVs) are simple to compute, they are highly variable and influenced by body weight and dose injected estimation errors 1,2. To overcome these limitations, we performed kinetic modelling analysis to characterize the pharmacokinetics of [89Zr]Zr-DFO-anti-VEGF (vascular endothelial growth factor) PET radiotracer during glioblastoma (GBM) development, a highly aggressive brain tumor with poor prognosis 3. This approach may reveal VEGF changes during tumor growth and treatment, which are linked to pharmacoresistance and reduced therapeutic efficacy. ***Materials and Methods:*** GBM models were induced on Sprague-Dawley rats by implanting F98 cells into the frontal cortex and injected with [89Zr]Zr-DFO-anti-VEGF (bevacizumab), following previously described methods 4. Multiple PET/CTs were performed on two groups: rats with 1-week tumor development (n=4) (1W) were scanned at 0, 48, 168, and 240 hours post-injection, and rats with 2-week tumor development (n=2) (2W) were scanned at 0, 5, 9, 14, 23, 26, 30, 48, 72, 144, and 216 hours. Blood and plasma samples were collected before each scan for radioactivity analysis. Tumor volumes of interest were delineated using MRI images acquired one day before PET/CTs. Mean and maximum SUVs, as well as the Patlak influx rate constant (Ki), were calculated for each subject. Differences in SUVs and Ki between groups were assessed using independent t-tests. Correlations between SUV and Ki were also evaluated. ***Results:*** [89Zr]Zr-DFO-anti-VEGF showed >95% purity and a specific activity of 74 MBq/mg. The average tumor volume was 0.0141 cm3 in 1W and 0.092 cm3 in 2W. SUV values showed high variability, especially at early time points and in animals with 1W animals. SUVmean at the final time point was higher in the 2W group ($p = 0.031$), with no significant differences in SUVmax. Ki values were 1.5 times higher in 2W group ($p = 0.036$) and strongly correlated with SUVmean ($R^2 = 0.878$), but not with SUVmax ($R^2 = 0.096$). These changes may reflect increased VEGF expression over tumor progression and/or altered blood-brain barrier (BBB) penetrability at more advanced stages. Further kinetic modeling studies are currently being conducted to better address this issue. ***Conclusion:*** Our findings provided higher Patlak-derived Ki values in the 2W compared to 1W group, supporting significant stage-dependent changes in the pharmacokinetics of the [89Zr]Zr-DFO-anti-VEGF. ***References:*** (1) https://doi.org/10.2967/

Pharmacokinetics, Tumour and Normal Tissue Uptake, SPECT/CT and Cerenkov Imaging of Radiolabeled Hybrid Gold-Lipid Nanoparticles vs. Gold Nanoparticles in a Human Breast Cancer Xenograft Mouse Model

Z. Cai[1], *A. Momeni*[2], *M. K. Brown*[1], *L. Messier*[2], *M. H. Y. Cheng*[2], *C. A. Brimacombe*[3], *P. R. Cullis*[2], *R. M. Reilly*[1];
[1]University of Toronto, Toronto, ON, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA, [3]Polymorphic BioSciences, Vancouver, BC, CANADA.

Aim/Introduction: Hybrid gold-lipid nanoparticles (AuNP-LNP) enable triggered drug release in tumours by laser irradiation of the encapsulated AuNP. Our aim was to evaluate the pharmacokinetics (PK) and biodistribution (BOD) of AuNP-LNP vs. AuNP in tumour-bearing mice. ***Materials and Methods:*** [^{198}Au]AuNP (^{198}AuNP) or AuNP were synthesized by H[^{198}Au]$AuCl_4$ or $HAuCl_4$ reduction in Na citrate and tannic acid, then conjugated to PEG_{2k}-lipoic acid (LA) or DOTA-PEG_{2k}-OPSS, respectively. DOTA-PEG_{2k}-OPSS-AuNP were complexed to [^{177}Lu]$LuCl_3$. LNP encapsulating ^{198}AuNP or [^{177}Lu]Lu-DOTA-PEG_{2k}-OPSS-AuNP (^{177}LuAuNP) were synthesized at 2.2 x 10^{13} AuNP/µmol lipid. AuNP and AuNP-LNP were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). NRG mice with s.c. 164/8-1B/H2N.Luc+ and MDA-MB-231 human breast cancer tumours were injected intravenously with 3.8-6.3 MBq (2.1-4.8 x 10^{13} AuNP) of ^{177}LuAuNP, ^{177}LuAuNP-LNP, ^{198}AuNP or ^{198}AuNP-LNP. Blood samples were collected up to 120 h post-injection (p.i.). The percent injected dose/g (%ID/g) in the blood vs. time curves were fitted to 2-compartment PK models. SPECT/CT and Cerenkov imaging was performed at 6, 24 and 96 h p.i. BOD was determined ex vivo at 120 h p.i. ***Results:*** The diameter of AuNP by DLS was 7.5±0.7 nm [polydispersity index = 0.13±0.02]. TEM showed a spherical shape with diameter = 5.8±0.9 nm. The diameters of ^{177}LuAuNP, ^{177}LuAuNP-LNP, ^{198}AuNP-LNP were 19±2, 73±1 and 87±25 nm, respectively. Elimination from the blood was slowest for ^{198}AuNP ($t_{1/2}\beta$=36.9 h), then ^{177}LuAuNP (14.9 h), ^{177}LuAuNP-LNP (10.4 h) and ^{198}AuNP-LNP (3.4 h). Uptake in MDA-MB-231 at 120 h p.i. was higher for ^{198}AuNP than ^{198}AuNP-LNP (15± 4 vs 2±1 %ID/g, p=0.046). Uptake (%ID/g) in 164/8-1B/H2N.Luc+ was higher for ^{198}AuNP (6.1±2.7) than ^{198}AuNP-LNP (0.9±0.5), ^{177}LuAuNP (0.40±0.08) and ^{177}LuAuNP-LNP (0.26±0.05). The highest normal tissue uptake (%ID/g) was observed in the spleen and liver for each NP: ^{198}AuNP -LNP (136±6 and 76±5), ^{198}AuNP (19 ± 2 and 15 ± 4), ^{177}LuAuNP-LNP (29±13 and 6.0±0.6) and ^{177}LuAuNP (14±4 and 5.1±0.4), respectively. The kidney uptake of each NP was <2 %ID/g (p=0.769). The tumour uptake of ^{198}AuNP and ^{198}AuNP-LNP were visualized by Cerenkov imaging at 6, 24 and 96 h p.i. and by SPECT/CT at 24 and 96 h p.i. Images by both imaging modalities correlated well. ***Conclusion:*** ^{198}AuNP exhibited the longest blood circulation time and highest tumor uptake. In contrast, ^{198}AuNP-LNP had shortest circulation time, but second highest tumour uptake. ^{198}AuNP would be superior to ^{177}LuAuNP for guiding laser irradiation of AuNP-LNP in tumours by SPECT/CT or Cerenkov imaging.

Aim/Introduction: Fractionated molecular radiotherapy with 177Lu-DOTATATE is an effective treatment option for patients with generalized neuroendocrine tumors. Absorbed dose (AD) calculations to solid organs have been suggested to optimize the treatment. The uncertainty of the calculated absorbed doses is both dependent on how well the activity concentrations are determined and at what time-point (after therapy) the activity concentration is determined. This study aims to determine the accuracy of measuring activity concentrations in a kidney phantom using two different methods, for eight different observers. ***Materials and Methods:*** A 3D printed kidney phantom described earlier [Jessen et al, 2024] was prepared blindly for the eight observers. The phantom was scanned in two different SPECT/CT systems, GE Discovery 670 with photomultipliers (PMT) and GE 870 CZT (CZT). The activity concentration in the kidneys was determined using two methods, 4 ml VOI (one VOI) and 2.21 ml VOIs (the mean of three 2.21 mL VOIs, non-overlapping). The VOI(s) were placed in area with homogenous uptake. The activity concentrations determined by the observers were compared with the known activity concentration and the accuracy of each activity concentration determination was established. ***Results:*** Across all observers irrespective of method and system, the determined activity concentrations showed an accuracy better than 10%. For the 2.21 ml VOI method, the CZT system yielded a more pronounced underestimation in the left kidney (median, min to max, -6.0%, -8.9 to -1.1) compared to the PMT system (-4.3%, -9.3 to 0.0). In contrast, both systems showed positive deviations in the right kidney, with PMT slightly higher (5.2%, 1.3 to 6.8) than CZT (4.0%, 0.0 to 6.5). For the 4 ml VOI, both systems showed small differences in the left kidney (CZT: -0.9%, -2.9 to 0.4; PMT: -0.4%, -2.0 to 1.5) and identical median values (4.7%) in the right kidney, with overlapping ranges (CZT: 1.0 to 6.0; PMT: 1.9 to 5.4). ***Conclusion:*** The activity concentration was determined with an accuracy better than 10 % for the eight observers. Overall, the 2.21 ml VOI method yielded larger variability and greater differences between kidneys and systems compared to the 4 ml VOI method, which provided more consistent results across both systems and kidneys. ***References:*** Jessen L, Gustafsson J, Ljungberg M, CurkicKapidzic S, Imsirovic M and SjögreenGleisner K. 3D printed non-uniform anthropomorphic phantoms for quantitative SPECT. Towards harmonised quantitative SPECT imaging: experiences from the EARL ^{177}Lu SPECT/CT Accreditation pilot study

L. Vávrová[1], *W. Claeys*[2], *A. Denis-Bacelar*[3], *I. Hristova*[4], *M. Lassmann*[1], *M. Koole*[2], *J. Dickson*[5], *J. Tran-Gia*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*KU Leuven, Leuven, BELGIUM,* [3]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [4]*EANM Forschungs GmbH, Vienna, AUSTRIA,* [5]*Institute of Nuclear Medicine, University College London Hospitals, London, UNITED KINGDOM.*

Aim/Introduction: Quantitative ^{177}Lu SPECT/CT is increasingly important for dosimetry, treatment verification, and clinical research. However, a lack of harmonised protocols and standardisation limits the comparability of results across centres. The EARL Accreditation Programme aims to provide a framework for harmonisation in ^{177}Lu SPECT/CT. Within this effort, this study evaluates differences in reconstruction approaches and highlights challenges of multi-centre harmonisation. ***Materials and Methods:*** In the ^{177}Lu SPECT/CT Accreditation pilot, data from 29 systems across 25 European sites have been collected to date. Of these, 16 datasets are pending resubmission due to non-compliance with EARL protocol (e.g., phantom mispositioning, inappropriate reconstruction parameters, or data transfer issues). Two Siemens Symbia Pro.specta datasets were excluded due to limitations in exporting scatter projections, required for manufacturer-independent reconstruction. The remaining 11 datasets (5 Siemens, 6 GE) were analysed. Alongside the mandatory manufacturer OSEM reconstructions, data were centrally reconstructed using the vendor-neutral PyTomography platform [1] (20 iterations, 4 subsets, no post-filtering, attenuation correction, triple-energy-window scatter correction, resolution modelling). Images were processed in Python (v3.12.4) to derive image calibration factors (ICFs, Jaszczak phantom) and recovery coefficients (RCs, NEMA phantom with 6 spheres, no background). RCs were calculated using SPECT-based segmentation with a centre-of-mass method and spherical volumes of interest (VOI) defined by the nominal lesion volume. Recovery curves were compared across systems and methods. ***Results:*** ICFs showed strong correlation ($R^2 = 0.999$) between manufacturer and PyTomography reconstructions. Siemens systems yielded higher ICFs (mean ± SD: 19.76 ± 0.43 cps/MBq) than GE (11.80 ± 0.92 cps/MBq), with minimal intra-manufacturer variation. In contrast, RCs showed greater variability, with percentage deviations of 3-14% (Siemens) and 4-54% (GE) for vendor reconstructions, and 4-19% (Siemens) and 4-60% (GE) for Pytomography reconstructions. For manufacturer reconstructions, Siemens generally showed better recovery than GE, while PyTomography showed the opposite trend. Normalising recovery curves to a single manufacturer-specific reference site reduced inter-system variability for both reconstruction methods. Differences may reflect inaccuracies in activity concentration (e.g., lack of traceable activity measurements and/or volume uncertainties in stock solution preparation). Residual discrepancies likely arise from segmentation inconsistencies, particularly for the smallest sphere. ***Conclusion:*** These preliminary findings suggest that harmonisation of quantitative imaging across different SPECT/CT systems and reconstruction methods is achievable but challenging. Scaling recovery curves shows promise for improving consistency, though activity measurement and segmentation issues must still be addressed. Resolving these factors is essential for reliable multicentre dosimetry in ^{177}Lu radiopharmaceutical therapy. ***References:*** [1] Polson et al. arXiv:2309.01977

Aim/Introduction: Following the recent successes of radionuclide therapies for treating neuroendocrine tumors and prostate cancer, the use of ^{177}Lu has grown considerably, with more and more centers performing quantitative ^{177}Lu-SPECT imaging. However, due to a lack of standardization, ^{177}Lu-SPECT image quality can differ significantly across hospitals, making data pooling or reproducible dosimetry estimates challenging. The goal of this study was to assess variability in quantitative ^{177}Lu SPECT-imaging across different systems and hospitals. ***Materials and Methods:*** A uniform cylindrical phantom (6.3l) and a NEMA IEC body phantom containing six hot spheres (13-60mm) and a cold background, were prepared centrally at UZ/KU Leuven. These phantoms were measured during 2 weeks at 8 different sites across Belgium using a representative set of NaI(Tl) and CZT SPECT/CT systems from different manufacturers. Each site scanned the phantoms using their own clinical protocol and a standardized acquisition protocol (TEW, 60 views, 256 matrix) using the 208 keV photopeak. The acquisition duration was adapted to preserve the total number of counts per acquisition. Similarly, reconstructions were performed using each site's clinical protocol as well as a standardized protocol (OSEM, 40 iterations 2 subsets). Most sites used vendor-specific reconstruction software, only two sites reconstructed the images using third-party software. All images were analyzed centrally: based on the uniform cylinder, the calibration factor for each system was determined, which was then used to calculate the recovery coefficients (RCs) from the NEMA IEC body phantom. ***Results:*** The calibration factor was fairly constant across systems from the same manufacturer, (12 or 20 cps/MBq for NaI(Tl) systems, 100 cps/MBq for CZT), regardless of acquisition/reconstruction protocol. The RC curves were little affected by the acquisition protocol but changed significantly with reconstruction settings like number of updates and post filter. Additionally, pre-filtering of the scatter windows turned out to have a major impact on the image quality by improving the scatter estimates. When using standardized acquisition and reconstruction settings, scanners from the same manufacturer had similar RC curves, but differences between manufacturers remained large. In particular, CZT systems had lower RCs than NaI(Tl) systems. ***Conclusion:*** The current diversity in quantitative ^{177}Lu-SPECT protocols leads to significant differences in the SPECT-images generated with different SPECT/CT systems at various hospitals. Standardizing the reconstruction protocol, rather than the acquisition protocol, could more effectively reduce differences between systems from the same vendor, while additional post-filtering would help harmonize systems across different manufacturers.

OP-098

Dual-Peak Image Reconstruction for 177Lu SPECT with CZT Gamma-Camera: Phantom-Based Optimization of Acquisition Time for 177Lu-DOTATATE and 177Lu-PSMA617 Protocols

Y. Cras, *H. Noamen, A. Benhamla, G. Rovera, P. Lacassagne, L. Ferreol, D. Deandreis;*
Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: Specific Semiconductor CZT-based gamma-camera are able to reconstruct images using both main photopeaks of Lutetium-177 (113 keV and 208 keV). The aim of this

study was to optimize in a NEMA phantom the acquisition time for 177Lu-DOTATATE and 177Lu-PSMA617 protocols by comparing current single-peak reconstructions (113 keV) with dual-peak reconstructions by a CZT gamma-camera. ***Materials and Methods:*** A NEMA IEC image quality phantom was used for this study, with hot background, cold lung insert, and six hot spheres (10-37 mm in diameter). The phantom was filled using a single calibrated syringe (total activity 637 MBq; sphere-to-background ratio: 10.3). It was acquired once using single standardized protocol: 30 minutes for 177Lu DOTATATE and 20 minutes for 177LuPSMA617. A dedicated tool on the CZT system was applied to simulate reduced acquisition times by resampling the raw projection data at 20, 15, and 10 minutes for DOTATATE and 15, 10, and 5 minutes for PSMA617. The standard Single-Peak reconstruction applied 4 iterations, 8 subsets, 2.46 mm voxel size, CT-based attenuation correction, scatter correction, intra-filter convolution and median post-filter for both protocols. Image quality metrics were first assessed on all Time-Points for single-peak reconstructions: background variability, contrast recovery for each sphere, total activity recovery, and sphericity (top 3 spheres). Then, the same variables were compared with dual-peak reconstructions. ***Results:*** For 177Lu-PSMA617, the dual-peak reconstruction (8 iterations, 8 subsets for the 113 keV, 6 iterations, 16 subsets for the 208 keV) at 15 minutes (25% time reduction) preserved image noise, improved contrast for all 6 spheres, provides a total activity recovery of +4%, and maintained sphericity compared to the 20-minute single-peak reference. For 177Lu-DOTATATE, the dual-peak reconstruction (8 iterations, 8 subsets for the 113 keV, 8 iterations, 8 subsets for the 208 keV) at 18 minutes (40% time reduction), found with continuous interpolation of Time-Points by a quadratic trend curve, preserved image noise, improved contrast in 1 sphere, maintained unchanged contrast in 4 out of 6 spheres, provides a total activity recovery of +5%, and preserved sphericity compared to the 30-minute single-peak reference. ***Conclusion:*** Dual-peak image reconstruction using the CZT gamma-camera allowed significant acquisition time reduction for both 177Lu-DOTATATE and 177Lu-PSMA617 protocols without degrading image quality. This phantom-based study supports clinical implementation of shortened protocols. Clinical validation is underway via blinded qualitative and quantitative assessments compared to current routine reconstructions.

OP-099

Evaluation of modified window-based scatter correction in quantitative ^{177}Lu-SPECT for a ring-configured CZT SPECT

I. Ceric Andelius[1,2], *A. Stenvall*[1], *E. Nilsson*[1], *E. Larsson*[1], *J. Gustafsson*[3];
[1]*Radiation Physics, Department of Haematology, Oncology, and Radiation Physics, Skåne University Hospital, Lund, SWEDEN,* [2]*Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN,* [3]*Medical Radiation Physics, Lund, Lund University, Lund, SWEDEN.*

Aim/Introduction: The aim was to experimentally evaluate ^{177}Lu-activity estimation for a ring-configured CZT gamma camera using a modified window-based scatter correction (MSC) that accounts for the tailing affects seen in CZT gamma cameras. While the original correction addressed tailing in the 208 keV peak only [1], separating primary and scatter photon within the scatter window, the current adaption extents to the 113 keV peak. In the modified version, the primary photons can be added back to the main window (MSC+P). We aim to assess the quantitative effects at 113 keV and 208 keV with respect to bias and precision using TEW, MSC and MSC+P. ***Materials and Methods:*** Phantom experiments with a NEMA-PET body phantom filled with ^{177}Lu were performed on a ring-configured CZT system. The NEMA phantom with six spheres (1.2 mL to 113 mL) had a non-radioactive background. Projections were acquired for 1 h and divided into six 10-minute frames. Reconstruction was performed using OS-EM 2-30 iterations (10 subsets) with compensation for attenuation, scatter (TEW for 113 keV, MSC and MSC+P), distance-dependent spatial resolution, and penetration at 208 keV. Total activity within the entire phantom and volumes-of-interest following the physical size of the spheres were defined and activity-concentration mean relative errors and coefficients-of-variation (CVs) over timeframes were computed for the different number of iterations. ***Results:*** MSC and MSC+P showed similar mean relative errors and CVs for 208 keV. For the smallest and largest NEMA-sphere at 20 iterations, the mean relative errors/CVs were -74 %/17% (MSC) and -78%/20% (MSC+P) and -25%/0.6% (MSC) and -24%/0.7% (MSC+P). At 113 keV, corresponding results for the 113 keV peak were -50%/12% (TEW), -60%/9% (MSC) and -70%/6% (MSC+P) for the smallest sphere (and -10%/0.75% (TEW), -16%/0.6% (MSC) and -22/0.2% (MSC+P) for the largest sphere. Mean relative in total activity at 20 were -4% (MSC) and -2.0% (MSC+P) for the 208 keV peak. Corresponding results for 113 keV were 21% (TEW), -5% (MSC) and 4% (MSC+P). ***Conclusion:*** The MSC and MSC+P resulted in improved signal to noise ratios for the NEMA phantom spheres resulting in reduced coefficient of variation for 113 keV peak and considerably better preservation of total activity. MSC and MSC+P improves the accuracy of quantitative ^{177}Lu-SPECT. ***References:*** Stenvall A, Ceric Andelius I, Nilsson E, Lindvall A, Larsson E, Gustafsson J. Recovery coefficients in Lu-177-SPECT-CT are reduced as a function of activity concentration

V. Reijonen[1], *S. E. A. Kokkonen*[2], *M. Tenhunen*[1];
[1]*Helsinki University Hospital, Helsinki, FINLAND,* [2]*University of Helsinki, Helsinki, FINLAND.*

Aim/Introduction: Quantitative SPECT-CT imaging is used to determine absorbed dose distributions in molecular radiotherapy (MRT). There are initiatives for harmonization of this process, such as EARL Lu-177 Quantitative SPECT accreditation. It is acknowledged that resolution recovery is a key factor to consider, especially due to the importance of tumor dosimetry. Resolution recovery coefficients (RCs) are usually measured using a standardised phantom with fillable inserts, and a constant target activity concentration may be used and established along the harmonization: a level of 2 MBq/ml has been suggested [1]. Subsequently, the acquired RC correction curve is applied to the patient dose calculation. There are several factors contributing to the uncertainty of the RC curve. In this study we evaluated whether activity concentration level affects the RCs. ***Materials and Methods:*** We prepared a solution using left-over no-carried-added Lu-177 from MRT treatments at the activity concentration level of 10 MBq/ml. The six standard sphere inserts (diameters 10, 13, 17, 22, 28 and 37 mm) of a NEMA IEC Body Phantom Set were filled with this solution. A quality assurance sample was taken from each fill syringe to ensure homogeneity of the solution. The background compartment of the phantom was filled with distilled water. The phantom was imaged with our site's clinical Lu-177 SPECT-CT protocol (parameters otherwise as in [1] except for a fixed imaging time, 10 s per projection, and automated quantification reconstruction with i=8, s=4) repeatedly over a period of eight half-lives. Volumes of interest (VOIs) were outlined for the inserts along their external wall on the first-day CT image,

and the RCs were determined based on the first-day imaging, accordingly. The VOIs were transferred to the other time-points with an automated alignment tool (CT-to-CT fusion). ***Results:*** The RCs determined at the initial activity concentration (9.7 MBq/ml) appeared to work within 5% down to 1 MBq/ml scale for the three largest inserts. At 0.5 MBq/ml, the recovered activity concentration in the inserts was 71%, 82%, 84%, 93%, 90% and 99%, respectively. At the lowest activity concentration measured in this series, 0.04 MBq/ml, the recovered activity of the largest insert had declined to 93%. ***Conclusion:*** There appears to be activity concentration dependence in the RC curve behaviour, which starts to manifest at clinically relevant activity concentration levels. This effect should be further studied, especially to improve tumor dosimetry. ***References:*** 1. EANM Forschungs GmbH: Lu-177 EARL Quantitative SPECT prototype, 15 Mar 2022 (update Feb 2025).

OP-101

Assessment of an ultra-fast dual-energy whole-body 360° ^{177}Lu-CZT-SPECT recording developed for the monitoring of ^{177}Lu-PSMA therapy

C. Boursier, *T. Zaragori, A. Zouaoui, A. Verger, P. Marie, L. Imbert; CHRU Nancy, Vandoeuvre-les-Nancy, FRANCE.*

Aim/Introduction: The ^{177}Lu-PSMA therapy monitoring of prostate cancer patients may be performed with high-speed whole-body 360° ^{177}Lu-CZT-SPECT recordings of only 18 min, based on the single 113 keV ^{177}Lu energy peak. However, count sensitivity is two to three times higher for SPECT recorded with dual 113 / 208 keV ^{177}Lu energy peaks. This study assesses the feasibility of an ultra-fast dual-energy whole-body 360° ^{177}Lu-CZT-SPECT recording of only 9 min. Such a short recording time would improve patient comfort and facilitate ^{177}Lu-SPECT scheduling. ***Materials and Methods:*** We selected the list-mode data of high-speed (18 min) whole-body 360° ^{177}Lu-CZT-SPECT recordings acquired the day after injection of 7.4 GBq of ^{177}Lu-PSMA in 20 prostate cancer patients (median age 73 years [interquartile range: 69 - 75 years]) referred to our nuclear medicine department between March and April 2025. SPECT images were reconstructed (i) as previously validated on the single 113 keV ^{177}Lu energy peak on the entire 18-min recording (SINGLE) and (ii) using a new dual 113 / 208 keV ^{177}Lu energy peak-based method applied on only the initial 9-min recording period. We compared SINGLE and DUAL reconstructions, using the parameters for tumor monitoring (SUVmax, SUVmean, and bone tumor volume determined using the standard 3 SUV threshold level), and background activity on a large region-of-interest encompassing the thigh muscles. Reconstruction parameters were previously optimized separately for 113 keV, 208 keV and dual 113 / 208 keV from an IEC body phantom filled in with a 12.7 ratio of ^{177}Lu between hot spheres and background. ***Results:*** Of these patients, 15 were considered to have metastatic bone lesions. SINGLE and DUAL reconstructions provided comparable levels of tumor SUVmax (38.7 [13.0-120.1] vs. 41.2 [10.9-143.0]), tumor SUVmean (7.8 [4.6-11.4] vs. 7.7 [4.3-12.9]), and background SUVmean (0.59 [0.043-0.079] vs. 0.59 [0.038-0.075]). However, tumor volume was lower with DUAL than with SINGLE reconstructions (70.9 [46.4-658.2] ml vs. 115.5 [61.1-550.2] ml, p=0.009), with a median decrease of 21.5 % [15.6-26.6 %] between SINGLE and DUAL reconstructions. ***Conclusion:*** Ultra-fast dual-energy whole-body 360° ^{177}Lu-CZT-SPECT recordings of only 9 min are feasible in cancer patients treated by ^{177}Lu-PSMA, although are associated with smaller tumor volumes than the previous single-energy peak recording method. Therefore, these two methods are not interchangeable when analyzing tumor changes during follow-up.

OP-102

Optimal SPECT Acquisition Settings for Quantitative Ac-225 Dosimetry

L. Polson[1], *S. Kurkowska*[2], *C. Li*[1], *P. Esquinas*[3], *C. Uribe*[1], *A. Rahmim*[1];
[1]*University of British Columbia, Vancouver, BC, CANADA,* [2]*Pomeranian Medical University, Szczecin, POLAND,* [3]*BC Cancer, Vancouver, BC, CANADA.*

Aim/Introduction: Patient specific dosimetry in radiopharmaceutical therapy requires accurate activity maps from SPECT images for personalization of treatment. The isotope Ac-225 is difficult to image with a SPECT system due to (i) a low count rate and (ii) a complex decay chain with contamination from multiple daughter isotopes in each photopeak. This work explores simulation and real phantom experiments to determine the optimal acquisition settings for accurate quantitative imaging of Ac-225. ***Materials and Methods:*** Monte Carlo (MC) simulations from SIMIND and real acquisitions from a Siemens Symbia T2 scanner were considered; the simulation represented the real system. MC simulations: to identify the optimal calibration method, (i) point source scans were acquired and (ii) uniform cylindrical phantoms of varying diameters were imaged and reconstructed. Optimal acquisition and reconstruction parameters were determined using a three-sphere phantom (10:1 source-to-background ratio, 40 min scan time), evaluated across different activity concentrations (0.2, 1, 10 kBq/mL), projection counts (8-128), photopeak/scatter windows (centered on 218 and 440 keV), scatter prefilter widths (0.0, 0.5, 1 cm FWHM), radial distances (15-25 cm), and reconstruction settings (up to 200 iterative updates). Multiple noise realizations were included for each condition, and both calibration methods were compared for converting to activity units. Real acquisitions: optimal settings were then used for a real phantom with spheres containing 10 kBq/mL. All reconstructions used OSEM, considering (i) attenuation and (ii) the collimator detector response, including septal penetration and septal scatter. The triple energy window (TEW) was used for scatter correction. ***Results:*** The optimal calibration was uniform cylinder reconstruction with ≥1 MBq total activity and cylinder diameter <10 cm; the point-source method was suboptimal due to sensitivity variation with source-detector distance. Convergence in a 40 mm sphere required ~100 (218 keV) and ~200 (440 keV) iterations; smaller VOIs required more. RCs in the 72 mm sphere declined with increasing source-detector distance by 18.0% (440 keV) and 10.3% (218 keV) from 15-25 cm. Scatter window width (5% vs. 10%) had little impact, but ≥0.5 cm TEW prefiltering greatly improved accuracy, especially at low activity (e.g., 186.0% vs. 87.3% RC at 200 Bq/mL). Thirty-two projections (in 40 min) balanced angular sampling and TEW precision. In the real phantom, optimal settings achieved RCs of 84.6% (218 keV) and 87.4% (440 keV) in a 60 mm sphere. ***Conclusion:*** Optimal acquisition, calibration, and reconstruction parameters for Ac-225 imaging were established through simulations and validated with a real phantom.

OP-103

Comparative Ac225 performance evaluation for a dual-collimator 3D CZT Camera

R. Zananiri, *A. Devir-Wolfman, L. Tsukerman, J. Bouhnik; GE HeathCare, Haifa, ISRAEL.*

Aim/Introduction: With the growing prominence of theragnostic isotopes in nuclear medicine (NM), Ac225 has emerged as a promising candidate, thanks to its unique combination of alpha and gamma emission properties. The Ac225 decay cascade incorporates gamma emissions from its daughters peaking at 440, 218 and 79 keV. Due to alpha toxicity, the injection doses are generally 10-100 folds less than nominal NM practices. The wide imaging peak ranges and the low activity pose a challenge on imaging Ac225. In this report, we compare the performance of a newly designed CZT-based multi-detector dual collimator 3D camera; deonted as dual-collimator StarGuide (DCS). DCS is equipped with two collimators optimized for high sensitivity (HS) and low penetration (LP) fulfilling the wide energy range needed for NM theragnostic scans. Ac225 performance of this DCS with LP collimators is compared to general purpose NaI based camera (870DR-GEHC) equipped with HEGP. To the best of our knowledge, this study reports the first Ac225 study on a multi-headed, CZT based detector imaging its all three peaks. ***Materials and Methods:*** Camera Design: DCS detectors were mounted on the StarGuide™ gantry. Notably, the detectors accounted for and corrected the Compton scattered photos within the CZT detector throughout the acquisition. Ac225 Phantom Test: A NEMA IEC phantom with spheres filled with 2.7µCi/ml and water background was scanned on both cameras; with LP collimator on DCS and HEGP on 870DR. The net acquisition time for both cases was 60 min. Images for the three peaks were assessed visually and quantitatively: separately and as a summed image of the reconstructions. ***Results:*** DCS possesses an overall equivalent or better image quality for all Ac225 peaks. Specifically, the background around the spheres is better on DCS in comparison to HEGP. The Spheres appear sharper on DCS as opposed to Dual-Head with sizes accurately reflecting the ground truth. The sum of the three Ac225 peaks marks a potential solution to increase the acquisition statistics and/or reduce the scan times for Ac225 patients. ***Conclusion:*** Using LP collimator on DCS provides a great potential to scan Ac225 gaining from the improved camera ring design as well as the ability to acquire all three Ac225 with accuracy. More studies on scan duration and phantoms possessing activity in their background are needed to fully develop an Ac225 patient protocol.

Aim/Introduction: Triple-negative breast cancer (TNBC) is defined by the absence of ER, PR, and HER2 expression. However, androgen receptor (AR) and low HER2 expression have emerged as potential therapeutic targets. Literature suggests that AR-positive TNBC is associated with lower [18F]FDG uptake than AR-negative, while HER2-zero and HER2-low TNBC show similar uptake patterns. We thus aimed to validate the association between pre-treatment [^{18}F]FDG PET/CT parameters and HER2/AR expression, and to identify metabolic and histopathological biomarkers predictive of pathological complete response (pCR), recurrence-free survival (RFS), and breast cancer-specific survival (BCSS) in early-stage TNBC (eTNBC). ***Materials and Methods:*** We analyzed 176 patients with biopsy-proven eTNBC of no special type and other subtypes, prospectively enrolled in the SCANDARE trial (NCT03017573) at Institut Curie between 2017 and 2021. All underwent pre-treatment [^{18}F]FDG PET/CT (~62 min post-injection, median 194 MBq), using three different scanners. Tumours were segmented with a semi-automatic 41% SUVmax threshold, and PET biomarkers were tumor SUVmax and total metabolic tumor volume (TMTV). HER2-low was defined as IHC 1+ or 2+ with negative FISH; AR positivity as >10% nuclear staining. Patients received either neoadjuvant or adjuvant chemotherapy with surgery and radiotherapy. Associations between imaging and histopathological biomarkers with pCR, recurrence-free survival (RFS), and breast cancer-specific survival (BCSS) were assessed . ***Results:*** HER2 status was available for all patients: 76% were HER2-zero and 24% HER2-low. AR status was available for 53% of patients, with 23% AR-positive. No significant differences in clinicopathological features, tumor SUVmax, or TMTV were observed between AR or HER2 subgroups. Neither AR nor HER2 expression was associated with pCR (AR-positive: 22.6% vs. 18.2%, p=0.86; HER2-low: 30.0% vs. 27.8%, p=0.93), RFS (AR: HR=1.0, p=0.95; HER2: HR=0.7, p=0.48), or BCSS (AR: HR=0.7, p=0.66; HER2: HR=1.2, p=0.74). Median follow-up was 5 years; median tumor SUVmax and TMTV were 12.4 and 4.6 cm^3, respectively. High tumor SUVmax (>median) was strongly associated with pCR (p<0.001), while high TMTV predicted poorer RFS (HR=2.5, p=0.02) and BCSS (HR=6.9, p=0.002). ***Conclusion:*** Pre-treatment tumor SUVmax and

TMTV on [18F]FDG PET/CT were predictive of response and survival respectively, while HER2-low and AR-positive phenotypes showed no impact on outcomes. These results align with previous HER2 data. For AR, discrepancies may stem from differing positivity thresholds—1% in prior studies, reflecting the commonly used cutoff in the US, versus 10% in our study, in line with European practice. Further validation in larger cohorts is needed, along with international consensus on AR threshold definition.

Aim/Introduction: triple-negative breast cancer (TNBC) is an aggressive malignancy, and its management remains challenging due to limited therapeutic options. As such, accurate diagnosis is crucial to ensure timely and effective treatment decisions. TNBC is known to be an [18F]-FDG-avid tumor; however, [18F]-FDG PET/CT is still employed in only a limited number of clinical scenarios. TRINE-PET is a large, retrospective, real-world multicenter Italian study designed to investigate the correlation between [18F]-FDG PET/CT findings and survival outcomes in TNBC patients across different clinical stages of the disease. This sub-analysis of the TRINE-PET study aims to assess the clinical impact of [18F]-FDG PET/CT in influencing the changes in patient therapeutic management. ***Materials and Methods:*** data on [18F]-FDG PET/CT in TNBC patients were retrospectively collected from 24 Italian centers. Scans were categorized into four clinical settings: (a) baseline, (b) post-neoadjuvant chemotherapy (NAC), (c) suspected disease recurrence, and (d) patients undergoing systemic therapies. For inclusion, a minimum follow-up of two years was required. Clinical decisions made following [18F]-FDG PET/CT were recorded, and the percentage of changes in patient therapeutic management was calculated for each clinical setting. ***Results:*** a total of 707 [18F]-FDG PET/CT scans from 389 patients (mean age = 54 ± 13 years) were analyzed. The distribution of scans across clinical settings was as follows: baseline = 257, post-NAC = 111, suspected recurrence = 144, and systemic therapy = 195. [18F]-FDG PET/CT led to a change in therapeutic management in 22 (8.6%) baseline cases, 15 (13.5%) post-NAC cases, 42 (29.2%) cases with suspected recurrence, and 68 (35%) cases in patients receiving systemic therapies. ***Conclusion:*** the clinical impact of [18F]-FDG PET/CT in guiding treatment decisions increased with the progression of the stages of disease. A lower influence on patients therapeutic management was observed when PET/CT was performed at baseline or after NAC. In contrast, [18F]-FDG PET/CT significantly influenced therapeutic decisions in patients with suspected recurrence and in those undergoing systemic therapy. ***References:*** DOI: 10.1007/s00259-024-06866-9Acknowledgements: De Rimini M.L., Frega N., Filippi L. and Mattoli M.V.

The PET/CT Response Monitoring in Oncology (PREMIO) criteria: A first suggestion to adapt the PERCIST criteria for patient-centric response monitoring of solid tumors in PET/CT scans

S. Hein[1], *N. M. Jakobsen*[2], *M. Naghavi-Behzad*[2], *W. A. Weber*[1], *W. Vach*[3], *M. Grubbe Hildebrandt*[2,4], *M. Vogsen*[5,4];
[1]*Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY,* [2]*Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK,* [3]*Basel Academy for Quality and Research in Medicine, Basel, SWITZERLAND,* [4]*Department of Clinical Research, University of Southern Denmark, Odense, DENMARK,* [5]*Department of Oncology, Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: As PERCIST was originally designed for pharmaceutical trials using a study-centric framework, its application in clinical response monitoring may overlook disease progression due to baseline-focused comparisons and may yield false-positive results owing to its generalized definition of new lesions[1]. To address the need for objective response criteria in an international clinical trial, we adapted PERCIST towards a more patient-centric approach for better individual assessment: the PREMIO (PET/CT Response Monitoring In Oncology) criteria. ***Materials and Methods:*** Evolving from the one-lesion PERCIST, we further developed the criteria based on a prospectively acquired dataset of [18F]-FDG-PET/CT response monitoring cases of 87 metastatic breast cancer patients with a median of 6 follow-up scans without therapy change and without influence of the [18F]-FDG-PET on therapy decisions[1]. To determine the suitable SULpeak increase for progression in the PREMIO criteria, the probability for false progression was minimized based on an analysis of SULpeak variation in stable periods. Ideal ground truth time point of progression was determined by consent of two nuclear medicine physicians after validation of progression in the follow-up scans. ***Results:*** The PREMIO criteria are based on three pillars: quantitative assessment, new lesion assessment, and visual assessment. Major changes in PREMIO with respect to PERCIST are: the usage of the nadir scan with the lowest malignant SULpeak as the reference scan for progression in the quantitative assessment; the definition of measurability and assessability on scan level and between current scan and reference scan; a 50% SULpeak increase criterium for progression; definitions for the progression based on visual assessment; the integration of a classification system for new lesions for the examined cancer entity - e.g. the mBI-RADS (metastatic Breast cancer Imaging Reporting and Data System, presented at EANM24); and the introduction of the new category EMD (Equivocal Metabolic Disease), which demands a re-evaluation of a new equivocal lesion (mBI-RADS 3) in the following scan. PREMIO proved better suited for clinical response monitoring than PERCIST, with a positive predictive value of 94% vs. 84% and a negative predictive value of 100% vs. 63%. ***Conclusion:*** The new PREMIO criteria fill the gap for an objective and patient-centric response monitoring system of solid tumors in PET/CT scans, demonstrating promising accuracy results for response monitoring in metastatic breast cancer. The modular approach with possible different molecular imaging RADS also suggests the application in other tumor entities for future perspectives. ***References:*** [1] Vogsen et al. HER2-Targeted^{68}Ga-ABS011 positron emitted tomography (PET) in Metastatic Breast Cancer: Intermediate analysis of the HERMIA study.

G. Gebhart[1], *R. Lhommel*[2], *H. Everaert*[3], *O. De Winter*[4], *M. Lonneux*[5], *K. Goffin*[6], *D. Frijns*[7], *E. De Azambuja*[1];
[1]*Hôpital Universitaire de Bruxelles (HUB)-Institut Jules Bordet, Brussels, BELGIUM,* [2]*Cliniques Universitaires Saint-Luc, Brussels, BELGIUM,* [3]*Universitair Ziekenhuis Brussel, Brussels, BELGIUM,* [4]*Onze Lieve Vrouw Ziekenhuis, Aalst, BELGIUM,* [5]*CHIREC AZ Delta, Brussels, BELGIUM,* [6]*Universitair Ziekenhuis Gasthuisberg, Leuven, BELGIUM,* [7]*ABSCINT NV/SA, Liège, BELGIUM.*

Aim/Introduction: The 2016 ZEPHIR study introduced the concept of HER2 tumor heterogeneity, raising concerns about the reliability of HER2 immunohistochemistry (IHC) [1]. The IMPACT-MBC study, presented at ASCO 2024 [2], assessed whole-body HER2 heterogeneity using ^{89}Zr-trastuzumab PET in 200 metastatic breast cancer patients and showed that in a 21% of HER2-negative patients, HER2 PET led to treatment adjustments and improved survival outcomes. However, the clinical use of ^{89}Zr-labeled antibodies is limited due to challenges such as high cost, slow pharmacokinetics, and relatively high radiation doses [3]. Single-domain antibodies (sdAbs) are stable small proteins (12-15 kDa), with high nanomolar affinity, and low immunogenicity [4-7]. When radiolabeled, sdAbs target their antigen rapidly, enabling same-day imaging (i.e. 90 min after administration). Additionally, labeling with gallium-68 significantly reduces the radiation exposure [6-7]. ***Materials and Methods:*** After the successful completion of the Phase I and IIa trials, confirming safety and scan repeatability, the HERMIA Phase IIb study (EU-CT20245114192200) was designed to assess the diagnostic performance of ^{68}Ga-ABS011 PET in determining HER2 expression status and its potential to guide treatment decisions. ^{68}Ga-ABS011 is being compared to current standard diagnostic methods, including IHC/ISH, ^{18}F-FDG PET, and contrast-enhanced CT. Secondary objectives evaluate tumor heterogeneity and correlate the HER2 full body PET/CT images with early metabolic response, and tumor shrinkage after two cycles of T-DXd treatment. ***Results:*** To date, the positive safety profile of the ABS011 tracer was confirmed for 27 trial subjects. Based on intermediate data, temporal and inter-lesion heterogeneity was observed. A preliminary evaluation was performed on 8 out of 27 patients that were eligible for T-DXd treatment, and for which a follow-up ^{18}F-FDG-PET/CT after 2 treatment cycles was available. Positive lesions on HER2 PET/CT with Ga68-ABS011 showed treatment response, assessed via RECIST and PERCIST criteria. ***Conclusion:*** Upon completion of the full HERMIA dataset and confirmation of the diagnostic performance of Ga68-ABS011 PET tracer, a phase III trial evaluating of clinical utility, i.e relationship between HER2 PET/CT and long-term treatment outcomes, is envisioned. ***References:*** 1. Al^{18}F-HER2-BCHImaging as a Non-invasive Approach to Assess Whole-Body HER2 StatusinHER2-Negative, -Low, and -PositiveBreast Cancer

X. Guo[1], *N. Zhou*[1], *J. Liu*[1], *H. Zhu*[2], *Z. Yang*[1];
[1]*Beijing Cancer Hospital, Beijing, CHINA,* [2]*Beijing Cancer Hospital, Beijing, CHINA.*

Aim/Introduction: Understanding which patients with human epidermal growth factor receptor 2 (HER2)-negative or -low metastatic breast cancer benefit from HER2-targeted strategies is urgently needed. We assessed the whole-body heterogeneity of HER2 expression on Al^{18}F-NOTA-HER2-BCH PET and the diagnostic performance in a large series of patients, including HER2-negative and -low breast cancer. ***Materials and Methods:*** In this prospective study conducted from June 2020 to March 2025, participants with newly diagnosed or relapsed breast cancer underwent both Al^{18}F-NOTA-HER2-BCH and ^{18}F-FDG PET/CT. HER2 status was determined by immunohistochemistry and in situ hybridization. Uptake was quantified by maximum standardized uptake value (SUVmax). HER2 immunohistochemistry was related to the quantitative Al^{18}F-NOTA-HER2-BCH uptake of corresponding biopsied lesions and all metastases, uptake heterogeneity, and qualitative scan evaluation. A prediction algorithm for HER2 immunohistochemistry positivity based on uptake was developed. ***Results:*** In 185 participants, HER2 status were positive (3+ or 2+/FISH+), low (1+ or 2+/FISH-), negative (0) in 98, 63, and 24 participants. With increasing HER2 immunohistochemistry status, the uptake of Al^{18}F-NOTA-HER2-BCH was higher (median SUVmax of 12.7, 7.2, and 4.0 for a HER2-positive, -low, -negative, respectively; P< 0.001) in 318 biopsied metastases. High uptake exceeding 10 was observed in 72.6% of HER2-positive participants, and low uptake below 4 predicted 50% of HER2 negative participants. Al^{18}F-NOTA-HER2-BCH uptake in the biopsied metastases with the predefined SUVmax threshold of 2.85 predicted HER2 IHC with a sensitivity of 95.2%, a specificity of 87.1%, of 98.6%, a PPV of 98.6%, and a NPV of 65.9%. The sensitivity, specificity, PPV and NPV of ^{18}F-FDG PET/CT was 84.6%, 83.9%, 97.9%, and 38.2%. Additionally, clear interindividual and intraindividual differences on Al^{18}F-NOTA-HER2-BCH uptake was noted between participants, different metastases in the same participants, even within different organ systems. ***Conclusion:*** Al^{18}F-NOTA-HER2-BCH had good diagnostic performance in breast cancer, showing considerable whole-body HER2 heterogeneity and uptake above background in HER2-negative and -low patients. This provides novel insights into HER2-negative and -low metastatic breast cancer compared with standard HER2 IHC on a single biopsy for identifying patients who may derive clinical benefit from HER2-targeted therapies. ***References:*** 1. Diagnostic Accuracy of 99mTc-FAPI-46 SPECT/CT in Differentiating Malignant and Benign Breast Masses Classified as BIRADS IV and V: A Prospective Clinical Study

S. Barashki, *K. Aryana, N. Raeisi, R. Sabzi, A. J. Noughabi, H. Soleimani Bami, M. Emadzadeh;*
Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Breast cancer is the most common malignancy among women worldwide, and early, accurate diagnosis is crucial for optimal treatment. The Breast Imaging Reporting and Data System (BIRADS) categorizes lesions based on malignancy risk, with BIRADS IV and V indicating high suspicion. However, many BIRADS IV lesions are benign, leading to unnecessary biopsies. Fibroblast activation protein (FAP), highly expressed in cancer-associated fibroblasts, is a promising target for molecular imaging. 99mTc-FAPI-46 is a novel SPECT radiotracer that may improve diagnostic accuracy while offering wider accessibility compared to PET tracers. We evaluate the diagnostic accuracy of 99mTc-FAPI-46 SPECT/CT in differentiating benign from malignant breast lesions classified as BIRADS IV and V, using histopathology as the reference. ***Materials and Methods:*** Thirty patients (mean age 45 ± 9.1 years, range 30-65) with BIRADS IV or V breast masses

were prospectively enrolled. The cohort included 7 BIRADS 4a, 7 BIRADS 4b, 6 BIRADS 4c, and 10 BIRADS 5 cases. After informed consent, patients received 20 mCi 99mTc-FAPI-46 intravenously. Imaging was performed 1 hour post-injection, including static chest, whole-body, and SPECT/CT scans. Images were interpreted by nuclear medicine specialists blinded to pathology. All patients underwent biopsy, and pathology results served as the gold standard. Tumor-to-contralateral breast and tumor-to-liver uptake ratios were calculated. ROC curve analysis assessed diagnostic performance. ***Results:*** Pathology confirmed 11 benign and 19 malignant lesions. The tumor-to-contralateral breast uptake ratio was significantly higher in malignant lesions (6.2 ± 4.1, range 1.6-17.4) than benign ones (1.1 ± 0.27, range 0.65-1.64; P < 0.001). The tumor-to-liver uptake ratio was also higher in malignant lesions (2.4 ± 1, range 0.9-5.0) compared to benign (0.64 ± 0.32, range 0.23-1.21; P < 0.001). Uptake ratios increased progressively from BIRADS 4a to 5. ROC analysis showed excellent accuracy: tumor-to-contralateral breast ratio had an AUC of 0.995 (95% CI: 0.979-1.000), and tumor-to-liver ratio had an AUC of 0.985 (95% CI: 0.950-1.000), both p < 0.001. A tumor-to-contralateral breast ratio >1.5 yielded 100% sensitivity and 91% specificity; a tumor-to-liver ratio >1.2 showed 94% sensitivity and 100% specificity. ***Conclusion:*** 99mTc-FAPI-46 SPECT/CT offers high sensitivity and specificity in distinguishing malignant from benign BIRADS IV and V breast lesions. Its accessibility and diagnostic performance support its potential as a valuable adjunct in breast cancer evaluation. Further studies are recommended to validate these findings and explore broader clinical applications.

OP-110

The Contribution of Ga-68 FAPI PET/CT in Newly Diagnosed Breast Cancer Patients Receiving Neoadjuvant Chemotherapy

M. Oflas[1], *D. Has Simsek*[1], *R. Yilmaz*[2], *N. Cabioglu*[3], *S. Onder*[4], *E. Isik*[1], *Z. Ozkan*[1], *A. Aydiner*[5], *Y. Sanli*[1], *S. Kuyumcu*[1];
[1]*Istanbul Faculty Of Medicine Department Of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*istanbul Faculty Of Medicine Department Of Radiology, Istanbul, TÜRKIYE,* [3]*istanbul Faculty Of Medicine Department Of General Surgery, Istanbul, TÜRKIYE,* [4]*Istanbul Faculty Of Medicine Department Of Pathology, Istanbul, TÜRKIYE,* [5]*Istanbul University Institute Of Oncology, Department Of Clinical Oncology, Istanbul, TÜRKIYE.*

Aim/Introduction: This study primarily aims to evaluate the utility of Ga68-FAPI PET/CT in combination with MAMMI PET for assessing pathological response to neoadjuvant chemotherapy (NACT) in breast cancer patients. ***Materials and Methods:*** We retrospectively reviewed breast cancer patients who underwent NACT and had pre/post-therapy imaging with F18-FDG PET/CT, Ga68-FAPI-FAPI PET/CT, and Ga68-FAPI MAMMI PET. Radiological and histopathological findings before and after treatment were documented. Quantitative PET parameters were calculated, and the post-therapy diagnostic performance of PET imagings were assessed using ROC analysis. Threshold values for detecting residual lesions were calculated, and univariate-multivariate analyses were performed for the breast and axilla. ***Results:*** A total of 21 breasts from 20 female patients were included in the study. Residual tumor was detected in 11 breasts (52.4%), while pathological complete response (pCR) was achieved in 10 breasts (47.6%). In visual assessment, the sensitivity, specificity and accuracy for detecting residual tumor in the breast after NACT were 73%, 70% and 71% for of F18-FDG PET/CT; 73%, 80% and 76% for Ga68-FAPI PET/CT; 64%, 70% and 67% for Ga68-FAPI MAMMI PET (including all lesions); 70%, 70% and 70% for Ga68-FAPI MAMMI PET (including the lesions in the field of view); and 100%, 50% and 76% for MRI, respectively. In quantitative analysis, the primary tumor TBR SUVmax value derived from post-therapy Ga68-FAPI MAMMI PET images had the highest diagnostic performance in detecting residual tumor in the breast. A threshold value of 1,35 for the TBR SUVmax value had 91% sensitivity, 80% specificity ,83% PPV, 89% NPV and 86% accuracy. In visual assessment, the sensitivity, specificity and accuracy for detecting residual tumor in the axilla were 33% ,91% and 71% for F18-FDG PET/CT, 50%,100% and 82% for of Ga68-FAPI PET/CT, and 50%,70% and 63% for MRI, respectively. None of the quantitative parameters have been found statistically significant in detecting residual tumor on the axilla. Ga68-FAPI PET/CT downstaged TNM in 15% of patients and upstaged TNM in 5% of the patients. ***Conclusion:*** The diagnostic performance of quantitative parameters derived from Ga68-FAPI PET/ BT combined MAMMI PET was found superior to current diagnostic methods in determination of pathological response of primary tumor, which may prevent unnecessary surgeries by accurate assessment of pCR. The contribution of Ga68-FAPI PET/CT for determination of NACT response in the axilla is limited. Moreover, it is predicted that Ga68-FAPI PET/CT may significantly impact the treatment approach in breast cancer by altering the TNM stage.

Prostate-specific membrane antigen expression in patients with metastatic triple negative breast cancer: Final results of the PRISMA study

M. Manley[1], *G. Nader Marta*[2], *A. Arcay Ozturk*[1], *M. Kassas*[1], *L. Taraji*[1], *P. Aftimos*[1], *Z. Wimana*[1], *P. Flamen*[1], *G. Gebhart*[1];
[1]*Institute Jules Bordet, Anderlecht, BELGIUM,* [2]*Dana-Farber Cancer Institute, Boston, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Radioligand therapy (RLT) targeting prostate-specific membrane antigen (PSMA) prolongs survival in patients with prostate cancer. Immunohistochemistry-based studies suggest that PSMA is highly expressed in the tumor-associated neovasculature of triple-negative breast cancer (TNBC). In this study, we aimed to assess PSMA expression in patients with metastatic TNBC (mTNBC) via [^{68}Ga]Ga-PSMA-11 positron-emission tomography/computed tomography (PSMA PET/CT) to evaluate the feasibility of PSMA-targeted RLT for mTNBC. ***Materials and Methods:*** PRISMA is a prospective, single-center study that enrolled 22 patients with progressive mTNBC. Patients undergoing FDG-PET/CT with PET Response Criteria in Solid Tumors (PERCIST)-evaluable disease underwent PSMA PET/CT. For qualitative analysis, healthy liver uptake was used as a patient-specific reference. Patients were classified as PSMA-positive if PSMA uptake was higher than healthy liver uptake in the majority of lesions. For semi-quantitative analysis, target-lesions (TLs) were segmented and defined as ≥1.5 cm in diameter and PERCIST measurable on FDG PET/CT. TL volumes were propagated to the PSMA PET/CT and anatomically matched to measure maximum standard uptake value corrected for body weight (SUVmax) for each TL. Mann-Whitney U test was used to compare mean SUVmax between subgroups based on age, prior therapy and androgen receptor status. ***Results:*** Twenty patients were evaluable for analysis. On qualitative analysis, 10 (50%) patients were classified as PSMA positive. Semi-quantitatively, the mean SUVmax on PSMA PET/CT of all TLs (total 106) was 6.5 (range 1.4 - 28.0). Overall, 71 (67%) of TLs had PSMA SUVmax greater than their respective healthy liver. In 7 (35%) patients, all TLs showed PSMA uptake higher than healthy liver. In 13 (65%) patients, the majority of TLs demonstrated PSMA SUVmax higher than healthy liver. All TLs exhibited an SUVmax above the patient specific blood pool. Tumor histopathology is available for 16/20 patients, of which 15/16 expressed PSMA in endothelial cells. Mean PSMA SUVmax was higher in patients having received < 3 lines of prior therapy, having undergone immunotherapy and with negative androgen receptor status. ***Conclusion:*** PSMA expression in mTNBC exhibits substantial intra-

and interpatient heterogeneity with frequent mismatching with FDG-avidity. In approximately one third of progressing mTNBC patients all FDG-positive target lesions demonstrated PSMA-expression higher than normal liver on PSMA PET/CT. For this specific subset of patients, who currently have limited therapeutic alternatives, ^{177}Lu-PSMA RLT might become a new therapeutic opportunity.

OP-112

Integrin $\alpha_v\beta_6$-Targeted ^{68}Ga-Trivehexin PET/CT in Breast Cancer: A Prospective Comparison with ^{18}F-FDG

Z. Liu[1], *L. Li*[1], *H. Wu*[1], *Q. Chen*[2], *C. Li*[1], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Pathology, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

Aim/Introduction: Breast cancer has become the most commonly diagnosed malignancy worldwide. While ^{18}F-FDG PET/CT is widely used in clinical practice, its limitations—such as reduced sensitivity in low-metabolic tumors and false positives in inflammatory lesions—scan hinder accurate assessment. ^{68}Ga-Trivehexin, an integrin $\alpha_v\beta_6$-targeted tracer, has shown promising results in various tumors but remains unexplored in breast cancer. In this prospective study, we aimed to compare the diagnostic performance of ^{68}Ga-Trivehexin and ^{18}F-FDG PET/CT in breast cancer patients, and to analysis the correlation between tracer uptake and $\alpha_v\beta_6$ expression. ***Materials and Methods:*** Patients with clinically suspected or biopsy-confirmed, treatment-naïve breast cancer were enrolled in this prospective study and underwent both ^{18}F-FDG and ^{68}Ga-Trivehexin PET scans within one week. The primary endpoint was the diagnostic efficacy, using the histological findings from primary tumors and regional lymph nodes, as the gold standard. The secondary endpoint was the comparison of uptake parameters (SUVmax and TBR:tumor-to-background ratios) between the two imaging modalities. Integrin $\alpha_v\beta_6$ expression was evaluated via immunohistochemistry in available surgical specimens. A $p< 0.05$ was considered as statistically significant. ***Results:*** A total of 26 patients (mean age 50.7 ± 9.5 years) were included, comprising 4 triple-negative (TNBC), 4 HER2-positive, 3 Luminal A, and 15 Luminal B cases. Among 46 primary tumors, ^{68}Ga-Trivehexin PET/CT achieved a detection rate of 100% (46/46), compared to 97.83% (45/46) for ^{18}F-FDG ($p=0.317$). Notably, ^{68}Ga-Trivehexin detected a 5-mm ductal carcinoma in situ that was confirmed by postoperative histology but missed by ^{18}F-FDG. Semiquantitative analysis revealed significantly higher TBR with ^{68}Ga-Trivehexin (11.76 vs. 8.61; $p<0.001$). Among 177 regional lymph nodes evaluated, ^{68}Ga-Trivehexin detected 172 metastatic nodes (93.99%) versus 174 (95.08%) with ^{18}F-FDG ($p=0.527$). In 4 TNBC patients (28 nodes), ^{68}Ga-Trivehexin exhibited significantly higher uptake compared to ^{18}F-FDG (SUVmax: 6.72 vs. 4.44; TBR: 10.60 vs. 3.68; all $p<0.001$). Immunohistochemistry confirmed integrin $\alpha_v\beta_6$ expression in 5/6 surgically resected primary tumors. ***Conclusion:*** ^{68}Ga-Trivehexin PET/CT provides superior tumor-specific contrast compared to ^{18}F-FDG, particularly in $\alpha_v\beta_6$-overexpressing subtypes like TNBC. These findings support further clinical validation of ^{68}Ga-Trivehexin for subtype-specific imaging and management of breast cancer.

TROP Session - Thyroid Committee: Nuclear Medicine Imaging in Thyroid Disorders: From Thyroid Nodule to Advanced/Refractory Cancer

OP-113

A non-invasive approach integrating PET/CT radiomics and ultrasound to improve risk stratification of thyroid incidentalomas detected on FDG PET/CT.

M. Roncali*, G. Ferrulli, R. Durmo, A. Frasoldati, A. Ghidini, S. Piana, M. Bertolini, L. Braglia, A. Filice;*
AUSL-IRCCS di Reggio Emilia, Reggio Emilia, ITALY.

Aim/Introduction: Thyroid incidental uptake (TIU) on FDG PET/CT is a relatively common finding in clinical practice, yet its clinical significance remains controversial. This study aimed to develop an integrated predictive algorithm combining conventional parameters and radiomic features to better assess the risk of malignancy in TIU. ***Materials and Methods:*** We retrospectively analyzed patients who underwent FDG PET/CT between January 2010 and December 2024 for non-thyroid indications, had reported TIU and have fine-needle aspiration cytology available. Patients were classified as positive or negative based on cytological results. Collected covariates included demographics, comorbidities, ultrasound (US) classification, PET/CT semi-quantitative parameters (SUVmax, SUVmean, MTV, TLG) and radiomic features (for a subset of patients) extracted using LifeX software. Statistical analysis was performed by estimating linear and quadratic discriminant analysis classifiers, with previous variable selection according to both a forward (Wilks' lambda based) and bidirectional (prediction accuracy based) stepwise procedure. Accuracies and diagnostic tests performance measures were calculated using a jackknife approach. Statistical analysis was performed using R 4.3.0. ***Results:*** A total of 208 patients (65.4% female; median age 67 years, IQR 58-73) were included. Among them, 68.8% (143/208) had benign nodules, while 31.2% had positive cytology. US categorized nodules as benign in 32.4%, indeterminate in 52.5%, suspect in 14.4%, and malignant in 0.7% of cases rspectively. Median SUVmax was 6.04 (IQR 4.15-8.93), SUVmean 3.56 (IQR 2.32-5.45), MTV 3.09 cm^3 (IQR 1.63-6.94), and TLG 11.34 (IQR 5.80-22.59). In the discriminant analysis on all the sample only US features were consistently selected in all stepwise procedures, with best performance obtained using only suspect/malignancy (with a moderate predictive performance: accuracy 74.4%, positive predictive value 77.3%). Radiomic analyses were available for 96 patients. Among the extracted textures, a geometric feature (NHOpeak) was selected in using the forward procedure, not with the bidirectional (accuracy prediction based) one. The model combining ultrasound and NHOpeak didn't overperformed, in terms of prediction accuracy, if compared with model with US feature only, bothhaving an accuracy of 84.9%, specificity and positive predictive value of 100%, a negative predictive value of 84.2%, and a sensitivity of 21.4%. Further evaluations are in progress. ***Conclusion:*** Ultrasound classification remains the cornerstone for initial TIU risk stratification. However, the integration of radiomic features from FDG PET/CT may enhance diagnostic accuracy, particularly by increasing specificity and PPV, thus minimizing false-positive findings.

OP-114

Diagnostic ^{131}I whole-body scans in the Detection of Differentiated Thyroid Cancer: Comparison with different doses

T. Ming, *f. Kang, w. Ma, j. Wang;*
Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.

Aim/Introduction: Compare the diagnostic efficacies of different low-dose diagnostic ^{131}I whole-body scans (Dx-WBS) in differentiated thyroid cancer (DTC). ***Materials and Methods:*** We reviewed data from 1146 consecutive patients with DTC who had total thyroidectomy and were referred for Radioactive iodine (RAI) therapy between April 2022 and April 2025 in Xijing Hospital. They were divided into three groups according to doses of Dx-WBS(353 patients with 5mCi, 609 patients with 3mCi, and 184 patients with 1mCi). The diagnostic efficacy of Dx-WBS was calculated with post-therapy WBS (Rx-WBS) as the reference, and compare diagnostic efficacies of different low-dose Dx-WBS. ***Results:*** In total, 1146 patients [mean age, 40.1±12.0 years; range, 7-77 years; 688 (60%) Female,458 (40%)male] were evaluated. For different doses (5mCi,3mCi and 1mCi) of low-dose diagnostic whole-body scans (Dx-WBS), the detection rates for residual thyroid tissue [99.4% (328/330),91.6% (535/584) and 80.8% (139/172)], lymph node metastasis [61.2% (39/62),58.1% (61/105) and 22.7% (5/22)], and distant metastasis [72.3% (8/11), 71.4% (10/14) and 50.0% (1/2)]. In lymph node metastasis, the diagnostic efficiency of Dx-WBS at a dose of 3mCi is comparable to that of Dx-WBS at a dose of 5mCi. The detection rates are 61.2% and 58.1% respectively, and both have significantly higher detection rates than 1mCi (22.7%). ***Conclusion:*** Dx-WBS with a dose of 3mCi exhibits comparable diagnostic performance to 5mCi for lymph node metastasis. However, both significantly surpasses Dx-WBS with a dose of 1mCi. Therefore, for patients with a high suspicion of lymph node metastases, it is recommended that they undergo a Dx-WBS with a dose of 3mCi.

OP-115

[18F]AlF-NOTA-FAPI-04 PET/CT improves detection of subcentimeter recurrent lesions in differentiated thyroid cancer: acomparative study with [18F]FDG

K. Zheng, *H. Ye;*
Hunan Cancer Hospital, Changsha, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP)-targeted PET/CT has emerged as a promising tool for visualizing tumor stroma. This study aimed to validate the diagnostic efficacy of [^{18}F]AlF-NOTA-FAPI-04 PET/CT in detecting subclinical metastases in recurrent differentiated thyroid cancer (DTC), with direct comparison to [^{18}F]FDG PET/CT. ***Materials and Methods:*** Twenty-three DTC participants with biochemical recurrence (suppressed thyroglobulin [Tg] ≥1 ng/mL or Tg antibodies [Tg-Ab] >115 IU/mL) underwent [^{18}F]AlF-NOTA-FAPI-04 PET/CT, including 16 who underwent paired [18F]FDG scans. Lesion classification followed histopathology or 15.5-month clinical follow-up (median, 8-32 months). ***Results:*** [^{18}F]AlF-NOTA-FAPI-04 PET/CT demonstrated significantly higher lesion-level sensitivity (75% vs 12.5%, P = 0.002) and accuracy (80% vs 26.7%, P < 0.001) than [^{18}F]FDG. Participant-level sensitivity reached 100% (7/7 vs 14.2% [1/7], P =0.003). Notably, 7 cervical lymph node metastases (mean diameter 5.9 ± 1.4 mm) were detected exclusively by FAPI imaging. ***Conclusion:*** [^{18}F]AlF-NOTA-FAPI-04 PET/CT exhibits superior diagnostic performance over [^{18}F]FDG PET/CT in detecting small metastatic lesions in recurrent DTC, potentially enabling earlier intervention and improved patient management.

OP-116

Diagnostic value of [18F]-FDG and [68Ga]-FAPI-04 PET/MRI for lymph node metastasis in papillary thyroid cancer

T. Han[1], *Z. Quan*[1], *H. Wei*[2], *J. Wang*[1], *F. Kang*[1];
[1]*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA,* [2]*Department of Thyroid and Breast Surgery, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.*

Aim/Introduction: This study aimed to evaluate the diagnostic value of [^{18}F]-FDG PET/MRI for the diagnosis of neck lymph node metastasis (LNM) in patients with initially diagnosed papillary thyroid cancer (PTC) and to compare it with [^{68}Ga]-FAPI-04 PET/MRI. ***Materials and Methods:*** Thirty patients with PTC confirmed by thyroid fine-needle aspiration biopsy were prospectively enrolled and underwent [^{18}F]-FDG PET/MRI; of which, 6 additionally underwent [^{68}Ga]-FAPI-04 PET/MRI within 3 days. According to surgical guidelines, the neck lymph node (LN) was divided into three macroscopic regions: central (VI) and left/right lateral neck (II-V). Images were semi-quantitatively and visually interpreted, and lesions' quantity, location, and uptake values were noted. Diagnostic performance of [^{18}F]-FDG PET/MRI versus US and MRI in N-staging of PTC patients based on regional analysis using postoperative histopathology as the gold standard. Whether the $BRAF_{V600E}$ mutation or not affects metastatic LN radioactivity uptake. Exploring the relevance of dual tracer imaging of metastatic LN radioactivity uptake and its head-to-head comparison for diagnostic efficacy. ***Results:*** A total of 48 macroscopic regions were surgically dissected. The diagnostic efficacy of [^{18}F]-FDG PET/MRI for detecting LNM was higher than that of US and MRI, overall sensitivity, specificity, and accuracy were 71.1% vs. 60.5% vs. 65.8%, 90.0% vs.80.0% vs. 80.0%, and 75.0% vs. 64.6% vs. 68.8%, respectively (all P > 0.05). For the central region (n=30), the sensitivity, specificity, and accuracy of US, MRI, and [^{18}F]-FDG PET/MRI for detecting LNM were 42.9% vs. 47.6% vs. 52.4%, 77.8% vs. 88.9% vs. 88.9%, and 53.3% vs. 60.0% vs. 63.3%, respectively (all P > 0.05). For the lateral region, the sensitivity and accuracy of [^{18}F]-FDG PET/MRI for detecting LNM were significantly superior to those of US (94.1% vs. 82.4%; 94.4% vs. 83.3%; all P < 0.05), while demonstrating comparable specificity. SUV_{max} of metastatic LNs on [^{68}Ga]-FAPI-04 PET/MRI was positively correlated with [^{18}F]-FDG PET/MRI (r=0.8564,95%CI:0.7208-0.9289; P<0.0001). The positive lesion detection rate of dual tracer imaging in 6 patients with PTC is consistent, and the degree of radioactivity uptake of [^{68}Ga]-FAPI-04 was higher than that of [^{18}F]-FDG in both primary lesion and LNM (12.3±5.7 vs. 6.9±5.3;4.5±3.7 vs. 3.4±1.8; all P > 0.05). ***Conclusion:*** [^{18}F]-FDG PET/MRI demonstrated marginally superior diagnostic performance for LNM detection compared to US and MRI, but all three modalities exhibited suboptimal sensitivity, particularly in the central region. Small sample populations revealed no significant differences in [^{68}Ga]-FAPI-04 and [^{18}F]-FDG uptake levels in primary lesion and LNM of PTC.

OP-117

Trop2-Targeted PET/CT with ^{68}Ga-MY6349 for Detecting Metastatic Lesions in Recurrent/Metastatic Thyroid Cancer: Prospective Comparison of Diagnostic Efficacy with ^{18}F-FDG PET/CT

H. Fu[1], *J. Huang*[1], *W. Guo*[1], *H. Wu*[1], *F. Wang*[2], *H. Chen*[1];
[1]*The First Affiliated Hospital of Xiamen University, Xiamen, CHINA,* [2]*Peking University, Beijing, CHINA.*

Aim/Introduction: Trophoblast cell surface antigen 2 (Trop2) targeted molecular imaging with ^{68}Ga-MY6349 has been proposed as a potential modality for visualizing cancerous lesions, but its utility for identifying recurrent/metastatic thyroid cancer (TC) is not well-established in the literature. This study

aims to evaluate the clinical utility of ^{68}Ga-MY6349 PET/CT for detecting metastatic TC and to compare the results with those of ^{18}F-fluorodeoxyglucose (FDG) PET/CT. ***Materials and Methods:*** This was a prospective, single-center, open-label, single-arm comparative imaging trial. Patients with clinically suspected or confirmed recurrent/metastatic TC were prospectively enrolled and underwent paired ^{68}Ga-MY6349 and ^{18}F-FDG PET/CT from November 2023 to March 2024. Histopathology and clinical follow-up (mean 12 months ± 0.7 [standard deviation] (range: 11-13 months) were used as reference standards for the final diagnosis. ^{18}F-FDG and ^{68}Ga-MY6349 uptake were compared by using the Wilcoxon signed-rank test. The McNemar test was used to compare the diagnostic efficacy of the two techniques, and the influence of various clinicopathological characteristics on ^{18}F-FDG and ^{68}Ga-MY6349 uptake was evaluated by Mann-Whitney and Kruskal-Wallis tests. ***Results:*** In total, 113 participants (median age, 51 years [interquartile range, 35-61 years]; 17 men) were evaluated. Among the 113 patients, 89 had papillary thyroid cancer (PTC). The other tumor entities were follicular thyroid cancer (9), Hürthle cell cancer (3), poorly differentiated thyroid cancer (4), differentiated high-grade thyroid cancer (4), medullary thyroid cancer (3), and anaplastic thyroid cancer (1), respectively. In all 113 participants, the ^{68}Ga-MY6349-derived SUV_{max} was higher than the ^{18}F-FDG-derived SUV_{max} in all the lesions (6.43 vs. 2.46, P<0.001), the local recurrence (24.9 vs. 10.7, P = 0.026), metastatic central compartment (12.7 vs. 4.9, P < 0.001), metastatic lateral compartment (11.0 vs. 5.4, P < 0.001), and mediastinal lymph nodes (LNs) (9.5 vs. 4.6, P = 0.012). In PTC lesions, the ^{68}Ga-MY6349-derived SUV_{max} was higher than the ^{18}F-FDG-derived SUV_{max} (8.26 vs. 2.09, P< 0.001). Besides, the ^{68}Ga-MY6349-derived SUV_{max} in PTC lesions was higher than that of non-PTC lesions (8.26 vs. 3.38, P< 0.001). ^{68}Ga-MY6349 PET/CT had a higher sensitivity than ^{18}F-FDG PET/CT for detecting neck lesions (90% vs. 58%; P < 0.001). ***Conclusion:*** ^{68}Ga-MY6349 PET/CT had high screening sensitivity in PTC metastatic lesions, and was superior to ^{18}F-FDG PET/CT for detecting metastatic TC, especially in local recurrence and LNs metastases of PTC.

OP-118

Diagnostic Utility of ^{68}Ga-PSMA PET/CT in Differentiated Thyroid Cancer Patients with Biochemical Recurrence and Negative Conventional Imaging.

C. Sgro[1], *E. Greco*[1], *G. Fuso*[1], *G. Bianciardi*[1], *L. Carrara*[1], *G. Cuzzani*[1], *E. Fortunati*[2], *L. Zanoni*[2], *R. Mei*[2], *L. Vetrone*[2], *A. Golemi*[2], *E. Lodi Rizzini*[3], *L. Calderoni*[2], *E. Tabacchi*[2], *S. Fanti*[1,2];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Radiation Oncology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Differentiated thyroid cancer(DTC) generally exhibits a favourable prognosis following total thyroidectomy and radioactive iodine(I-131)ablation. However, a subset of patients develops biochemical recurrence-elevated thyroglobulin (Tg) or anti-Tg antibodies(AbTg)-with negative or equivocal findings on conventional imaging(ultrasound or CT).In these cases,^{18}F-FDG-PET/CT may be used,although the results may be equivocal. ^{68}Ga-PSMA-PET/CT, although primarily used in prostate cancer, has shown promising results in detecting neoplastic lesions by targeting tumour neovascularisation in other malignancies, including DTC. ***Materials and Methods:*** This study enrolled patients with DTC who underwent thyroidectomy followed by I-131 therapy.All patients had evidence of biochemical progression,defined as increasing Tg or AbTg levels,but negative or indeterminate findings on ultrasound and CT.Each patient underwent an ^{18}F-FDG PET/CT scan,which either failed to localise the disease or was inconclusive.^{68}Ga-PSMA-PET/CT was then performed. PSMA-avid lesions, SUVmax values and uptake distribution were analysed.Histological or radiological follow-up (when available) was used as a reference standard to validate PET results. ***Results:*** 17 patients were included(mean age: 60y.o.):12/17(70%)patients had papillary variant DTC,4/17(26%) had follicular variant and 1/17(6%) had hurtle-cell carcinoma.BRAF, RAS and TERT mutations were tested in 11 patients:8/11(73%) had BRAF mutations, 2/11(18%)had RAS and 4/11(36%)had TERT mutations.Mean basal Tg and Ab-Tg were 32 ng/mL and 42 UI/mL,respectively,at the time of ^{68}Ga-PSMA-PET/CT. 4/17(24%) patients had equivocal CT, 7/17(41%) had equivocal ultrasound, while 6/17(35%) had evidence of biochemical progression with negative imaging. All patients underwent^{18}F-FDG-PET/CT: 12/17(70%) resulted FDG-negative, 4/17(24%) FDG-positive and only 1/17(6%) had equivocal scan.Regarding the ^{68}Ga-PSMA-PET/CT scans:9/17(53%) resulted PSMA-positive while 8/17(47%) PSMA-negative.Two patients had both FDG-PSMA-positive-PET-scan and one resulted FDG-positive but PSMA-negative.SUVmax values of 11 PSMA-positive lesions showed a mean of 2.65, a median of 2.4 and a range of 1.5-3.7. Of the 9 patients with PSMA-positive findings, lymph node metastases were histologically confirmed in 2/9 patients, while 4/9 patients had radiological evidence of metastatic disease(bone, lung, abdominal-lymph nodes); data were not available for the other patient. In patients with negative-scans, the absence of detectable disease supported ongoing surveillance strategies.No clear association was observed between PSMA-expression and histological variants of DTC nor with the presence of BRAF, RAS or TERT mutations. ***Conclusion:*** ^{68}Ga-PSMA-PET/CT appears to be a useful imaging modality in selected DTC patients with biochemical progression and negative or inconclusive conventional imaging.While ^{18}F-FDG-PET/CT remains an important imaging modality for the evaluation of dedifferentiated or radioiodine-refractory thyroid cancer, PSMA-based imaging may serve as a valuable adjunct.Future prospective studies should investigate its diagnostic accuracy, prognostic relevance and potential in theranostic applications.

OP-119

Diagnostic accuracy of ^{18}F-FDG PET/CT compare to 18F-PSMA PET/CT in Radioiodine-Refractory Differentiated Thyroid Carcinoma Patients

A. J. S. Portilho, *M. O. Cerci, S. Kuba, N. T. T. P. Silva, R. N. Tineo, C. A. de Souza, D. E. Zantut-Wittmann, C. D. Ramos;
University of Campinas (UNICAMP), Campinas, BRAZIL.*

Aim/Introduction: While differentiated thyroid carcinoma (DTC) typically has excellent prognosis (10-year survival: 98.4%), 5-15% of cases progress to radioiodine-refractory disease (rRIT), necessitating alternative diagnostic approaches. Emerging evidence suggests prostate-specific membrane antigen (PSMA)-targeted PET/CT may complement ^{18}F-FDG imaging in rRIT-DTC [1], potentially enabling theranostic applications. This study aimed to perform a head-to-head comparison of 18F-PSMA-1007 and ^{18}F-FDG PET/CT for lesion detection and metabolic characterization in rRIT-DTC patients. ***Materials and Methods:*** This cross-sectional study enrolled rRIT-DTC patients with suspected locoregional or metastatic disease. All underwent both ^{18}F-FDG and 18F-PSMA-1007 PET/CT within 7 days. Lesion detection rates and maximum standardized uptake values (SUVmax) were compared across anatomical sites. ***Results:*** Among 23 enrolled patients (16 female, mean age 55.6 ± 18 years), a total of 91 lesions were identified by ^{18}F-FDG PET/CT compared to 87 lesions detected with 18F-PSMA-1007 PET/CT. Both tracers demonstrated similar localization of metastases, with concordant findings in the thyroid bed (6 vs. 5 lesions), cervical lymph nodes (17 vs. 17), thoracic lymph nodes (12 vs. 12), lungs (17 vs. 16), and liver (1 vs. 1). Discrepancies were observed in abdominal lymph nodes (3 detected by ^{18}F-FDG vs. 0 by 18F-PSMA) and bone lesions (4 vs. 6). The median SUVmax across all lesions was higher for ^{18}F-FDG (24.2; range 5.6-80.9) than for 18F-PSMA (17.3; range 4.1-73.3). Notably,

13 patients (56.5%) exhibited at least one lesion with greater 18F-PSMA uptake intensity than 18F-FDG, suggesting interlesional heterogeneity in tracer avidity. ***Conclusion:*** 18F-PSMA-1007 demonstrates comparable lesion detection to ^{18}F-FDG in rRIT-DTC, with heterogeneous uptake patterns suggesting complementary roles. The superior 18F-PSMA uptake in >50% of patients supports further investigation of PSMA-targeted theranostics for selected cases. ***References:*** [1] Rizzo A, et al. Potential Role of PSMA-Targeted PET in Thyroid Malignant Disease: A Systematic Review. Diagnostics (Basel). 2023;13(3):564.

Aim/Introduction: Liquid biopsy (LB) is a promising technique for less invasive and more comprehensive molecular profiling of cancers. However, data on the use of LB in thyroid cancer, in particular metastatic/locally-advanced DTC are still limited, and LBs are not always concordant with tissue biopsies. LB is thus currently recommended to detect target mutations (BRAF/RET/NTRK fusions) only in absence of a tissue biopsy. The aim of this study was to investigate the association between the [18F]FDG-PET/CT metabolic profile and the diagnostic yield of LB in metastatic/locally-advanced DTC. ***Materials and Methods:*** A retrospective study was conducted on patients with metastatic/locally-advanced DTC who underwent LB at our center (01/2021-01/2024). The concordance between LB results and tissue biopsies was assessed using genetic data from primary-tumor/metastases (NGS/immunohistochemistry). [18F]FDG-PET/CT imaging was reviewed and semiquantitatively analyzed using MIM-v7.3.7 and a 41% SUVmax threshold. Extracted parameters included SUVmax, SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) at both lesion and whole-body level. Statistical analysis was performed using SPSS-v29, and differences in PET-derived parameters between concordant/discordant LB cases were assessed using Mann-Whitney test. ***Results:*** 76 patients (median age 61 [range:23-87]) with metastatic/locally-advanced DTC were retrospectively evaluated. At the time of LB, 85.5% of patients were radioiodine-refractory, 90.8% were M1, 40.8% were receiving treatment and 27.6% had already undergone ≥2 lines of treatment. Out of 76 patients, 30 underwent [18F]FDG-PET/CT imaging near the date of liquid biposy. In this sub-cohort, concordance between LB and tissue biopsy was observed in 26.7% (8/30) of patients, while in 73.3% (22/30) LB did not identify the same driver mutation. At [18F]FDG-PET/CT semiquantitative analysis, the median tMTV was found to be significantly higher in patients with concordant LB results (64.0ml [IQR 24.18-128.52] vs 7.6ml [IQR 1.50-18.91], p=0.008). Similarly, the median tTLG was also higher in case of informative LB (358.7 [85.0-851.5] vs 33.9 [10.8-114.3], p=0.031). These findings suggest that [18F]FDG-PET/CT may provide valuable functional information by reflecting the biological aggressiveness of disease and metabolic tumor burden, which could influence the shedding of tumor-derived genetic material into the bloodstream and therefore the rate of LB concordance. On the other hand, no significant differences were found in terms of more conventional metrics such as SUVmax (9.3 vs 11.1) and SUVmean (4.3 vs 3.8). ***Conclusion:*** Higher metabolic tumor burden on [18F]FDG-PET/CT is associated with increased diagnostic yield of liquid biopsy in advanced DTC, suggesting its potential as a complementary tool in patient selection.

OP-121

Intraoperative PET/CT imaging for thyroid cancer, parathyroid adenoma and oncological work-up of cervical lymph nodes with a high resolution mobile PET/CT-camera for surgical specimens

B. Lambert[1], *V. Vergucht*[2], *D. Berwouts*[1], *B. Van Den Bossche*[1], *J. Mertens*[1], *C. Van Haverbeke*[2], *M. Coppens*[2], *C. Gabriel*[3], *M. Rottiers*[2], *A. Decock*[2], *V. Galle*[2], *T. Van Oostveldt*[2], *K. Decaestecker*[2];
[1]*Maria Middelares Hospital - Jan Palfijn Hospital, Gent, Gent, BELGIUM,* [2]*Maria Middelares Hospital, Gent, BELGIUM,* [3]*Maria Middelares Hospital, Gent, BELGIUM.*

Aim/Introduction: This prospective exploratory trial, conducted at Maria Middelares Hospital (Ghent, Belgium), investigates the feasibility of using a mobile specimen PET/CT camera during surgery for thyroid and parathyroid disease, as well as for oncological work-up of suspicious cervical lymph nodes. Patients are injected with a PET tracer prior to surgery, and the resected specimens were scanned intraoperatively. While prior applications of this technology have been reported in breast and prostate cancer, this study explores its potential in new indications. The study is ongoing, with partial results published in a recent paper. ***Materials and Methods:*** Seventeen patients were enrolled for head-and-neck related indications: 8 thyroid cancers, 3 parathyroid explorations and 6 nodal excision biopsies of cervical suspect nodes for oncological work-up. Patients received 1h preoperatively a low activity of [18F]Choline (parathyroid), or [18F]FDG. After surgical excision, specimens were scanned using a mobile specimen PET/CT scanner (AURA10, Xeos Medical, Ghent, Belgium), with imaging completed within 12 minutes post-resection. Imaging results were compared with histopathology to evaluate correlation. ***Results:*** In the thyroid cancer group, 4 patients underwent total thyroidectomy—3 with lymphadenectomy—and 4 resection of recurrent disease. Intraoperative imaging predicted R0 status in all total thyroidectomies and correctly identified a positive margin in a local relapse. In 7/8 cases intraoperative PET/CT confirmed complete removal of all suspicious lymph nodes identified pre-operatively. In all 3 patients suspected of suffering from parathyroid adenoma, intraoperative PET/CT with [18F]Choline showed concordance with pathology.For the oncological work-up of metabolic active cervical lymph nodes of unknown origin, imaging accurately identified malignant involvement in 5/6 patients, including 4 cases of lymphoma, lymph node metastases from breast cancer. One biopsy resection of a neck node in a patient with colorectal cancer was futile: due to adherence the lymph node could not be resected and only non-suspicious tissue was removed. Pathology confirmed all intraoperative PET/CT imaging findings (6/6 concordance with 1 true negative case). ***Conclusion:*** Our initial experiences with intraoperative PET/CT demonstrate the feasibility to assess the surgical margins of tumoral specimens as well as confirmation that the correct nodes/nodules are resected in thyroid cancer, parathyroid exploration and lymph node excision biopsies. ***References:*** Lambert, B. et al. (2025). "Feasibility study on the implementation of a mobile high-resolution PET/CT scanner for surgical specimens: exploring clinical applications and practical considerations". Aim/Introduction: The use of endovascular prostheses for aortic root replacement (Bentall-Bono procedure) and aortic arch/intrathoracic aorta repair (Frozen Elephant Trunk (FET)) is increasingly common in patients with complex acute and chronic aortic disease. Infection of these devices poses significant diagnostic and therapeutic challenges. [18F]FDG-PET/CT may have a clinical impact in detecting infections and guiding their management. The objectives of this study are: to assess the utility of [18F]FDG-PET/CT in detecting aortic prosthetic vascular infections; to identify morphometabolic features that help differentiate between post-surgical inflammatory changes and true infection and to correlate PET/CT findings with clinical data. ***Materials and Methods:*** Retrospective descriptive study of patients with FET and aortic root prostheses who presented clinical suspicion of infection and underwent [18F]FDG-PET/CT between March 2016 and February 2025. Demographic data, vascular device and PET/CT study characteristics were analyzed and compared with the final diagnosis established by a multidisciplinary team. ***Results:*** A total of 18 patients with 22 PET/CT studies were included. Six patients had FET prostheses and 12 had aortic root prostheses. The cohort included 6 women and 12 men, with a mean age of 64 years (30-82). The average time between surgery and PET/CT was 26 months. Of the 22 studies, 10 were classified as positive by PET/CT, 9 of which were true positives and 1 false positive (this case was not clinically considered infected and prolonged antibiotic therapy was not initiated). All 9 studies deemed negative by PET/CT were true negatives. Three studies were considered indeterminate; among these, one was confirmed as positive for infection, the other two were negative. In 7 of the 9 true positive cases, the highest metabolic activity was observed within the prosthetic body, with a mean SUVmax of 6mg/dL. In the remaining 2, the highest uptake was at the suture sites, with a higher mean SUVmax (11mg/dL). In the negative studies, a mean SUVmax of 3mg/dL was observed, attributed to post-surgical inflammatory activity. CT imaging identified suspicious signs of infection (thickening, fat stranding, and para-aortic abscesses) in 8/10 PET/CT-positive cases. Patients with positive PET/CT findings showed higher SUVmax values and greater leukocytosis compared to negative cases. ***Conclusion:*** [18F]FDG-PET/CT is a useful, non-invasive tool for detecting infections associated with aortic endovascular prostheses. It allowed for the safe exclusion of infection in negative cases, avoiding unnecessary surgeries and prolonged antibiotic treatments. PET/CT plays a significant role in the clinical and therapeutic decision-making process for complex patients.

EPS-023
Is ^{18}F-FDG PET/CT useful in suspected Cardiac Implantable Electronic Device infection?
***R. Dobson**, D. Bartholomeusz, S. Jo, M. Bills; Royal Adelaide Hospital, SA Medical Imaging, South Australia, AUSTRALIA.*

Aim/Introduction: Positron Emission Tomography with low dose Computed Tomography (PET/CT) is an established investigation in prosthetic valve endocarditis. The role of PET/CT in the diagnosis of Cardiac Implantable Electronic Device (CIED) related infection is evolving. Diagnosis is difficult but crucial as infection, if confirmed, may result in device removal and associated morbidity. The aim of this study was to evaluate the role of PET/CT in patients with suspected CIED infection. ***Materials and Methods:*** A 12-month (January - December 2024) retrospective review was conducted of PET/CT scans performed at a quaternary public hospital, in patients referred for suspected CIED infection and/or prosthetic valve infective endocarditis (IE). 18F-Flurodeoxyglucose (18F-FDG) PET/CT was performed on Siemens Biograph MCT Flow PET scanners. All patients were instructed to follow a standardised low-carbohydrate diet for 24 hours to supress physiological cardiac uptake and fast for a minimum of 6-hours prior to scanning. Patients were intravenously injected with 285MBq of 18F-FDG. Following a 60-minute uptake period whole-body and dedicated gated cardiac scans were acquired. Scan technique, effectiveness of cardiac diet, clinical context including suspected IE, echocardiography and microbiology results were reviewed with final diagnosis based on clinical consensus. ***Results:*** 53 patients (36 male), median age 76 years (31 - 96 years) underwent PET scans for suspected CIED infection and/or IE. Adherence to the low-carbohydrate diet was noted in 85% of patients, evidenced by sufficient physiologic myocardial suppression. Of the 53 patients, 37 (70%) had CIEDs alone, the remaining 16 (30%) had both CIED and prosthetic valves. Nine cases were positive for CIED infection, and 3 cases were positive for IE. Microbiology was positive in 88%. Of the positive CIED group, 3 suggested pocket infection

and 6 lead infection. The SUVmax mean was 4.19 (range 2.9 - 7.6). Transthoracic echocardiogram (TTE) and transoesophageal echocardiogram (TOE) were performed in 5 of the 9 PET positive lead infections and positive in only 1 case. Patients were discussed at an endocarditis multidisciplinary team meeting. Antibiotic treatment was commenced in patients with results that were consistent with Duke Criteria and clinical consensus for infection. ***Conclusion:*** PET/CT is an important investigation in the diagnosis of CIED infection and has demonstrated value in the context of IE, particularly when echocardiography is inconclusive or negative despite a strong clinical indication. Thus, PET imaging can inform targeted therapeutic decisions, from conservative management to device removal.

EPS-024

Diagnostic value of [^{18}F]FDG PET/CT imaging in LVAD infection

G. Metzger[1], *C. Hosse*[2], *I. Schobert*[2], *I. Just-Lauer*[3], *J. Mulzer*[4], *J. Kolck*[2], *W. Lüdemann*[2], *E. Sodemann*[2], *T. Wallter-Rittel*[2], *E. Potapov*[4], *C. Furth*[1], *G. Böning*[2];
[1]*Charité Universitätsmedizin Berlin - Klinik für Nuklearmedizin, Berlin, GERMANY,* [2]*Charité Universitätsmedizin Berlin - Klinik für Radiologie, Berlin, GERMANY,* [3]*Charité Universitätsmedizin Berlin - Klinik für Herz-, Thorax- und Gefäßchirurgie, Berlin, GERMANY,* [4]*Charité Universitätsmedizin Berlin - Klinik für Herz-, Thorax- und Gefäßchirurige, Berlin, GERMANY.*

Aim/Introduction: Treatment of LVAD infections remains highly challenging. Accurate diagnosis, including precise localization of the affected LVAD component and reliable therapy monitoring, is essential. Current evidence on the diagnostic value of [^{18}F]FDG PET/CT is limited to small case series without clearly defined endpoints. We therefore conducted a clinical analysis with surgical and, where possible, microbiological correlation. ***Materials and Methods:*** This single-center retrospective study included patients with suspected LVAD infection who underwent FDG PET/CT between April 2016 and July 2022 with subsequent cardiac surgical correlation. Microbiological evidence—such as positive driveline swab, blood cultures, or intraoperative confirmation—served as the reference standard. CRP levels and body temperature were recorded to support clinical assessment. Quantitative PET parameters (SUVmax and SUVmean) were measured at key device sites, and concomitant thoracic lymph node involvement was analyzed. ***Results:*** Twenty PET/CT scans were included: 18 with surgical confirmation of LVAD infection and 2 without. FDG PET/CT identified LVAD-specific infections with a sensitivity and specificity of 100%. Affected regions included the cutaneous driveline entry (11%), driveline course (66%), and pump/outflow graft (11%); the inflow cannula was unaffected. The infection site was identified in all cases, with a mean SUVmax of 7.9 and a mean Deauville score of 5. Thoracic lymphadenopathy was present in 65% (n=13) of patients, most frequently with a Deauville score of 5. Notably, there was no significant correlation between C-reactive protein levels or body temperature and confirmed infection (p>0.05). ***Conclusion:*** FDG PET/CT enables accurate, noninvasive diagnosis of suspected LVAD infections, allowing precise localization of affected components and detection of associated inflammatory responses such as thoracic lymphadenopathy. Its diagnostic performance exceeds that of systemic inflammatory markers and supports its clinical use for surgical planning and therapy guidance.

EPS-025

Feasibility of Shortened Total-body ^{18}F-FDG PET/CT Dynamic Acquisition for Parametric Imaging in the Quantitative Evaluation of Takayasu's Arteritis

L. Gao[1], *Y. Ng*[2], *Y. Duan*[1], *Z. Cheng*[1];
[1]*The First Affiliated Hospital of Shandong First Medical University, Jinan, Shandong, CHINA,* [2]*United Imaging Healthcare Group Co., Ltd. Shanghai 201807, China, Shanghai, CHINA.*

Aim/Introduction: Takayasu's arteritis is a systemic inflammatory vasculitis affecting large arteries. ^{18}F-FDG PET/CT is essential for detecting active inflammation, with guidelines recommending 90-120 minute delayed acquisition optimal reliable quantification. Previous study have demonstrated that K_i parametric imaging derived from 60-min dynamic PET (dPET) exhibits superior sensitivity and detectability over 2-hour delayed imaging in visualizing and quantifying TAK-active arteries. However, the clinical implementation of prolonged dynamic acquisition is constrained by patient discomfort and feasibility concerns. This study investigates the potential of further reducing total-body ^{18}F-FDG PET/CT dynamic acquisition time while preserving the diagnostic integrity of parametric imaging in quantitative assessment of Takayasu's arteritis. ***Materials and Methods:*** A retrospective study of eight Takayasu's arteritis patients (3 males, 5 females; mean age: 33.88 ± 6.71 years) was conducted at The First Affiliated Hospital of Shandong First Medical University (March - October 2022). Patients were stratified into active and inactive inflammation groups based on the National Institute of Health (NIH) criteria. All subjects underwent a 1-hour total-body dPET scan followed by a 2-hour delayed static PET acquisition, with a 1-hour static PET image extracted from the 50-60 min dPET data. K_i parametric images were generated using 10, 20, 30, 40 and 60 min dPET data and compared with the 1-hour and 2-hour static PET images. Clinical differences between active and inactive inflammation groups were analyzed using the Chi-square test and Mann-Whitney U test. Image quality metrics, including target-to-background ratio (TBR), contrast-to-noise ratio (CNR), and active lesion detection rates were evaluated across acquisition times using the Friedman test and Fisher's exact probability tests. ***Results:*** There were no statistically significant differences among TBR_{30min}, TBR_{40min}, and TBR_{60min} (P=0.425, 0.772) but were significantly higher than at 1-h and 2-h (P<0.001). While CNR_{30min} and CNR_{40min} was lower than CNR_{60min}, both were significantly higher than at 1-h and 2-h (P<0.001). No significant difference was observed between CNR_{40min} and CNR_{60min} (P=0.460).In both active and inactive inflammation groups, K_{i30min} and K_{i40min} demonstrated significantly higher detection rates for active arteries than 1-h static PET (χ^2=17.711, P=0.001; χ^2=24.348, P<0.001). Although their detection rates also exceeded those of 2-h static PET, the differences were not statistically significant (χ^2=0.031, P=0.861; χ^2=3.396, P=0.093, respectively). ***Conclusion:*** K_i parametric imaging derived from shortened dPET acquisitions is feasible for evaluating arterial inflammation in Takayasu's arteritis, with 30-40 min dPET providing optimal image quality and lesion detectability.

EPS-026

Impact of [^{18}F]FDG PET/CT on therapeutic intent in patients with large vessel vasculitis treated with tocilizumab

N. Canchumanya Huatuco, *A. Caresia Aroztegui, J. Font-Urgelles, V. Vallejos Arroyo, M. Boronat de Ferrater, S. Lafuente Carrasco, M. Salcedo Pujantell, J. Deportós Moreno, M. Solà Suárez, I. Casafont-Solé, A. Riveros Frutos, R. Ugena-García, G. Moragas Freixa;*
Hospital Universitario Hermanos Trias I Pujol, Badalona, SPAIN.

Aim/Introduction: The role of [^{18}F]FDG PET/CT in the diagnosis of large vessel vasculitis (LVV) has been demonstrated. However, there is insufficient scientific evidence on its impact on therapeutic management in case of unclear relapse. Furthermore, it is known that tocilizumab (TCZ) treatment blocks the expression of inflammatory markers, so the use of PET/CT in these patients may be a determining factor for the correct management of LVVs. Therefore, our objective is to determine the impact of PET/CT results on therapeutic intent of patients with LVV in treated with TCZ with clinical suspicion of relapse or disease remission. ***Materials and Methods:*** 26 patients (23 females/3

males; mean age at diagnosis of 69.5 ± 10.4 years) with LVV and ongoing treatment with TCZ were included. All patients underwent contrast enhanced [18F]FDG PET/CT. Images were interpreted using qualitative visual analysis of vascular tracer uptake according to the Total Vascular Score. The change on initial pre-test therapeutic intention was also calculated. ***Results:*** In 19 patients (73%) were studied for suspicion of recurrence. The other 7 (27%) to assess discontinuation of TCZ. The average time between the start of TCZ treatment and the PET/CT scan was 20.1 months (4-63 months).Suspected recurrence group (19 patients): 11 patients (57.9%) tested positive, so treatment was escalated (increase in steroid dose, iv TCZ, or increase in sc TCZ dose). 8 patients (42.1%) had a negative scan, leading to changes in the initial therapeutic intention (mainted treatment and/or decrease in steroid dose).Clinical remission group (7 patients): 6 patients (85.7%) tested negative and clinical remission was confirmed, so the pre-established therapeutic plan of treatment optimization was maintained. Only one patient (14.3%) had a positive PET/CT and treatment was maintained, thus avoiding recurrence due to drug discontinuation.Overall, the actual change in therapeutic management was 9/26 patients, which corresponds to 34.6%. ***Conclusion:*** In our cohort of patients with LVV on active treatment with TCZ, PET/CT scans performed for suspicion of recurrence or for assessing discontinue of TCZ resulted in a 34.6% change in pre-test therapeutic intention.

EPS-027

Diagnostic value of 18F-FDG-PET/CT in detecting vascular graft infection and the role of a complementary labelled leucocyte scan

S. Georga[1], *D. Katsampoukas*[1], *A. Morfesi*[1], *N. Vavlas*[1], *A. Georgiou*[1], *D. Karamanos*[2], *V. Mpalaris*[1], *K. Lazaridis*[1], *E. Moralidis*[1], *G. Arsos*[1];

Aim/Introduction: Vascular graft infection (VGI) is a severe complication of vascular surgery, associated with high morbidity and mortality. Early diagnosis of VGI is essential for successful treatment and clinical outcome. The study aimed to assess the diagnostic value of 18F-FDG-PET/CT in detecting VGI and, furthermore, to explore the role of the additional performance of Tc-99m-HMPAO-labelled leucocyte-SPECT/CT scan. ***Materials and Methods:*** Fifty two consecutive patients with clinical suspicion of VGI underwent 18F-FDG-PET/CT. Twenty six patients had aortobifemoral grafts, 24 thoracic aorta grafts and 2 axillobifemoral grafts. Median time between graft implantation and imaging was 24 months (range 1-240 months).Vascular prostheses were visually evaluated for the presence, intensity (mild, moderate or intense uptake, using a 3-point scale comparing peri-graft uptake to blood pool activity in the ascending aorta and liver uptake) and pattern (focal/multifocal, heterogenous or homogenous diffuse) of FDG uptake. Maximum standardized uptake value (SUVmax) was also calculated. Focal/multifocal or heterogeneous diffuse, peri-graft intense FDG uptake was suggestive of VGI. A Tc-99m-HMPAO-labelled leucocyte-SPECT/CT scan (LS-SPECT/CT) was additionally performed in 14 patients with equivocal 18F-FDG-PET/CT findings. LS-SPECT/CT was performed and interpreted according to the EANM guidelines. Increased over time leucocyte uptake in the region of vascular graft, in terms of intensity and/or extension, indicated VGI. Final diagnosis was based on surgical/histopathological findings or long-term clinical follow-up. ***Results:*** Twenty nine out of 52 vascular grafts investigated were confirmed as infected. All infected vascular grafts showed intense focal/multifocal or heterogeneous FDG uptake. SUVmax was significantly higher in infected than uninfected vascular grafts (10.3 ± 2.6 vs 3.9 ± 3.7, $p < 0.05$).18F-FDG-PET/CT results were as follows: TP 28, TN 19, FP 6 and FN 0. False positive 18F-FDG-PET/CT results were attributed to inflammation/foreign body reaction, even years after graft implantation, and were reduced by the additional performance of LS-SPECT/CT. Sensitivity, specificity, accuracy, PPV and NPV of 18F-FDG-PET/CT for diagnosing VGI were 100 %, 76%, 90 %, 82% and 100 %, respectively. LS-SPECT/CT showed 100% specificity and PPV and helped to discriminate infection from sterile inflammation/foreign body reaction in patients with equivocal 18F-FDG-PET/CT findings, leading to the correct diagnosis. ***Conclusion:*** FDG-PET is a highly sensitive non-invasive imaging modality for detection of VGI. A negative study excludes VGI. LS-SPECT/CT is a more specific method for diagnosing VGI. Thus, in cases of equivocal FDG-PET findings, the additional performance of LS-SPECT/CT scan helps to discriminate infection from sterile inflammation/foreign body reaction and establish the correct diagnosis.

EPS-028

The post-therapy follow-up of [F[18]]FDG PET in vasculitis

R. Park*, J. McCormick, S. Olson, R. Staff;*
NHS Grampian, Aberdeen, UNITED KINGDOM.

Aim/Introduction: There is little clarity regarding using [18F] FDG PET/CT to monitor the response to treatment for patients with vasculitis[1]. The Scottish guidance states that [18F]FDG PET imaging currently has no role in routine response monitoring. This is likely due to an absence of evidence rather than evidence of its value. This retrospective audit investigated the patient cohort returning for imaging mid/post-treatment. ***Materials and Methods:*** Of the patients (n=93) referred for an [18F]FDG PET/CT scan due to a vasculitis indication between July 2023 and June 2024, 11 patients were imaged as part of mid/post-treatment follow-up. All patients underwent some form of therapy, including steroids and immunosuppressants. To analyse each patient's response to their treatment, the Target to Background Ratio (TBR) was calculated for both imaging sets. This was calculated using the SUV_{max} of the most visually avid area of the aorta and a defined region from the right lobe of the liver. In addition, the extent of the vasculitis was quantified by assessing the uptake in 7 vascular regions, providing a Total Vascular Score (TVS) that was compared before and after treatment. Two blind observers performed scoring, and the inter-rater agreement was found. ***Results:*** Patients had follow-up imaging either once (5), twice (4) or three times (2) after their initial baseline images. The mean interval between baseline and subsequent follow-up was 18 months (range 5-35 months). Nine of those with baseline and follow-up were positive at the first visit. After treatment, the observed TVS for all positive patients had reduced. However, only 4 cases were resolved. Of the positive patient cohort, the calculated TBR reduced (6), stayed the same (2) or increased (1) after treatment. In both instances where a positive repeat scan followed a negative baseline, the TVS and TBRS increased. ***Conclusion:*** For patients with an initial positive diagnosis, the extent of the vasculitis reduced after treatment in all cases, as expected; however, the avidity of the aortic uptake had a mixed response. For patients with a negative to positive disease progression, both the avidity and extent of the uptake increased. The heterogeneity of the follow-up suggests that [18F]FDG PET/CT may have a role in monitoring vasculitis treatment. ***References:*** [1] R.H.J.A. Slart et al. "FDG-PET/CT imaging in large vessel vasculitis and polymyalgia rheumatica: joint procedural recommendation of the EANM, SNMMI, and the PET Interest Group (PIG), and endorsed by the ASNC." EPS-029

Tailored Management of Non-Typhoid Salmonella Bacteremia: Insights from 2-[^{18}F]FDG PET/CT Imaging

P. Chuang[1], *C. Huang*[2], *T. Hong*[1], *M. Chiang*[3], *C. Hung*[2], *C. Lu*[1];
[1]*National Taiwan University Cancer Center, Taipei, TAIWAN,* [2]*National Taiwan University Hospital, Taipei, TAIWAN,* [3]*Taipei Medical University Hospital, Taipei, TAIWAN.*

Aim/Introduction: Non-typhoid Salmonella (NTS) bacteremia is associated with significant morbidity and mortality, particularly in high-risk populations such as the elderly and immunocompromised patients. Metastatic infections are not uncommon and may require prolonged antibiotic therapy or surgical intervention to ensure pathogen eradication and prevent recurrence. This study evaluates the utility of 2-[^{18}F]fluorodeoxyglucose (FDG) PET/CT in detecting metastatic foci and guiding individualized treatment strategies. ***Materials and Methods:*** We retrospectively reviewed consecutive patients with NTS bacteremia who underwent 2-[^{18}F]FDG PET/CT between 2018 and 2023. Imaging findings, including visual interpretation and semiquantitative measurements, were analyzed alongside clinical parameters to assess their impact on treatment decisions, such as the duration of antibiotic therapy or surgical management. Recurrence of NTS bacteremia following treatment cessation was recorded and correlated with initial PET/CT findings. ***Results:*** Thirty-three patients (25 men, 8 women; mean age 66.5 ± 13.1 years) were included, with group D Salmonella isolated in 30 cases (90.9%). 2-[^{18}F]FDG PET/CT revealed metastatic infections in 27 patients (81.8%), including mycotic aneurysms (9/27, 33.3%), septic arthritis or spondylodiscitis (9/27, 33.3%), soft tissue abscesses (9/27, 33.3%), and visceral abscesses (7/27, 25.9%). Patients with metastatic infections received significantly longer antibiotics treatment compared to those without (median 10.6 vs. 3.2 weeks, p=0.012), and were more likely to undergo surgery (29.6% vs. 0%, p=0.131). Despite aggressive treatment, 4 of 27 patients (14.8%) with metastatic disease identified on initial PET/CT experienced recurrence within two years after discontinuing antibiotic therapy. The recurrent cases included one mycotic aneurysm, one soft tissue abscess, and two visceral abscesses. The median time to recurrence was 12.1 months. In contrast, no recurrences were documented during follow-up in patients without PET-detected metastatic disease. ***Conclusion:*** 2-[^{18}F]FDG PET/CT effectively detects metastatic foci in NTS bacteremia and plays a pivotal role in tailoring treatment duration and identifying candidates for surgical intervention. Its use may reduce recurrence by supporting evidence-based, personalized management strategies.

Preliminary diagnostic evaluation of CROhn's disease with DYNamic total-body pOsitron emission tomography/computed tomography (CRODYNO) - A single-center prospective study

A. Farolfi[1], *G. Calini*[2,3], *I. Brusa*[1], *D. Dall'Olio*[3], *C. Nanni*[1], *L. Romagnoli*[1], *V. Lucidi*[4], *B. Spencer*[5], *G. Wang*[5], *L. Nardo*[5], *S. Fanti*[1], *A. Di Giorgio*[6];
[1]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Surgery of Alimentary Tract, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Department of Medical and Surgical Sciences, Alma Mater Studiorum - University of Bologna, Bologna, ITALY,* [4]*Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria Di Bologna, Bologna, ITALY,* [5]*Department of Radiology, University of California Davis Health, Sacramento, CA, UNITED STATES OF AMERICA,* [6]*Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Bologna, Italy, Bologna, ITALY.*

Aim/Introduction: Crohn's Disease (CD) is a chronic inflammatory disease with rising global prevalence. Magnetic resonance enterography (MRE) excels in surgical indications but is limited in disease staging, particularly regarding activity, mesenteric involvement, and extraintestinal manifestations. Dynamic total-body PET/CT with ^{18}F-fluorodeoxyglucose (FDG-TBPET), with its high sensitivity and ability to quantify kinetic parameters (FDG delivery rate K_1, phosphorylation rate k_3, net influx rate K_i, volume of distribution DV) across the entire body, offers a novel approach for characterizing inflammatory diseases like CD. This study explores its potential in CD assessment and in distinguishing CD from aspecific bowel FDG uptake. ***Materials and Methods:*** Prospective study enrolling CD patients undergoing restaging with MRE and 60-minute dynamic FDG-TBPET (FOV=194cm). Healthy controls (n=10) from UC Davis, California, were stratified based on the presence (n=5) or absence (n=5) of diffuse aspecific FDG bowel uptake. Images were analyzed qualitatively, semiquantitatively (SUV-metrics) and quantitatively using two-tissue compartment models with model selection (2TC, 2TiC; mean absolute scaled error-MASE and the Akaike Information Criterion-AIC for selection). Kinetic parameters were compared between MRE and/or histopathology-positive lesions, healthy intestine/mesentery in CD patients, and intestine/mesentery in healthy controls. VOIs included non-diseased bowel and mesentery in CD patients compared to healthy controls. ***Results:*** Three patients experiencing a CD flare-up underwent MRE and dynamic FDG-TBPET prior to surgery. MRE findings were positive for ileal involvement in two patients and large bowel involvement in one patient. Histological examination of surgical specimens revealed CD in the anal canal and rectum in 1 patient, the ileo-cecal tract in 2 patients, and the ileal mesentery in 1 patient. Across the 3 patients, a total of 8 areas positive for CD were identified via MRE/histology, and corresponding VOIs were generated. While SUV values alone did not discriminate disease from physiological bowel uptake (p=0.147), significant differences in k_3 and K_i values were observed between CD patients and healthy controls (both p<0.001), even in the subgroup of healthy controls with diffuse aspecific bowel uptake (p<0.001), suggesting altered glucose metabolism in CD. Within CD patients, confirmed lesions tended to exhibit a kinetic profile characterized by lower K_1 and higher k_3, particularly in the ileum, but not statistically significant (p>0.05). ***Conclusion:*** These preliminary findings suggest that dynamic FDG-TBPET, by enabling simultaneous assessment of metabolic activity throughout the body, may differentiate pathological inflammation from healthy tissue in CD. Kinetic modeling, particularly k_3 and K_i, may offer a pathophysiological signature of active inflammation beyond SUV-metrics.

Clinical impact of [^{18}F]FDG PET/CT in the assessment of incidental findings related to aesthetic procedures: implications for complication detection and oncological management.

M. Pudis[1], *P. Notta*[1], *C. S. Salomón-Duhalde*[2], *C. Cases-Pellise*[3], *L. Rodríguez-Bel*[1], *L. M. Gracia-Sánchez*[1], *V. A. Carrero-Vasquez*[1], *J. J. Robles-Barba*[1], *A. I. Fritsch-Medina*[1], *P. Perlaza-Jiménez*[1], *A. Tapias-Mesa*[1], *M. Suarez-Piñera*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Nuclear Medicine, Hospital Universitari Son Espases, Palma de Mallorca, SPAIN,* [3]*Nuclear Medicine, Hospital Universitario Virgen del Rocío, Sevilla, SPAIN.*

Aim/Introduction: Aesthetic procedures are increasingly common and often undocumented in medical records. [^{18}F]FDG PET/CT may incidentally detect related findings, which can pose diagnostic challenges in oncological settings. This study aims to assess the role of [^{18}F]FDG PET/CT in identifying such findings and to evaluate their clinical relevance in differential diagnosis, complication detection, and therapeutic decision-making. ***Materials and Methods:*** This retrospective study included 17 aesthetic procedures identified in 15 female patients (mean age: 60 years) who underwent [^{18}F]FDG PET/CT for oncological

evaluation. Incidental findings suggestive of prior aesthetic interventions were identified based on characteristic metabolic activity and morphological alterations observed during image interpretation.As most procedures were not documented in the institutional medical records, confirmation was obtained through structured telephone interviews. Patients were asked to confirm the type of procedure, material used, anatomical location, approximate date, and any associated or persistent symptoms. Only findings with both patient-confirmed history and concordant PET/CT features were included in the analysis. ***Results:*** The most frequent intervention was silicone breast implantation (n=9; eight bilateral). Post-surgical inflammatory changes with low-to-moderate [^{18}F]FDG uptake were observed in seven cases, with five patients reporting persistent postoperative pain. One patient presented an intracapsular rupture requiring explantation, and another showed axillary siliconomas with mild discomfort.Two cases of autologous fat grafting (lipofilling) to the breast revealed areas of fat necrosis, both asymptomatic.Four patients had facial or mandibular fillers: three in the zygomatic region (hyaluronic acid, calcium hydroxyapatite, and biopolymers) and one in the mandible (calcium hydroxyapatite). All demonstrated increased FDG uptake associated with local erythema or warmth. One patient with permanent biopolymers presented with an active infection requiring antibiotic therapy.Two asymptomatic patients with gluteal biopolymer fillers exhibited moderate-to-intense FDG uptake consistent with granulomatous inflammatory reaction. All 17 aesthetic procedures exhibited PET-detectable metabolic alterations, ranging from benign post-procedural inflammation to infectious or granulomatous reactions. In five patients (33%), these findings prompted additional clinical evaluation or therapeutic intervention. ***Conclusion:*** [^{18}F]FDG PET/CT can reveal clinically relevant findings associated with prior aesthetic procedures, even when undocumented in medical records. Recognising these characteristic uptake patterns is essential to avoid misinterpretation—particularly in oncological patients—and to prevent unnecessary biopsies or delays in management. Increased awareness among nuclear medicine specialists is crucial as the prevalence of such interventions continues to rise.

EPS-032

[^{18}F]FAPI Total-Body PET in Metabolic-Dysfunction Associated Steatotic Liver Disease: Preliminary Results

S. Shivani[1], *Y. G. Abdelhafez*[1], *B. A. Spencer*[1], *V. Medici*[1], *V. Lyo*[1], *M. T. Corwin*[1], *K. Chung*[1], *X. Duan*[1], *O. R. Vigil*[1], *I. Tunali*[2], *P. Lacor*[2], *A. T. Hoye*[2], *M. Flitter*[2], *A. McGeehan*[2], *M. Johnson*[2], *E. C. Collins*[2], *G. Wang*[1], *R. Badawi*[1];
[1]*University of California at Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [2]*Eli Lilly, Inc., Indianapolis, IN, UNITED STATES OF AMERICA.*

Aim/Introduction: Fibrosis staging plays a critical role in assessing disease progression and prognosis in metabolic dysfunction-associated-steatotic liver disease (MASLD). Existing non-invasive tests (NITs) including MRI elastography, ultrasound transient elastography, and blood-based scores (Fibrosis-4) have known limitations and invasive liver biopsy remains the gold standard. This highlights the unmet need for reliable NITs to accurately stage liver fibrosis. Fibroblast activation protein (FAP) expression has been shown to correlate with fibrosis severity and staging. This study aims to investigate the potential of quantitative [^{18}F] FAPI PET imaging as an NIT to assess liver fibrosis in MASLD subjects relative to biopsy-confirmed fibrosis stage. ***Materials and Methods:*** This ongoing study has so far recruited eight participants (7 females, 1 male): one healthy volunteer (HV, age: 27), and seven MASLD participants who had undergone liver biopsy within 90 days of PET imaging (fibrosis stages F1/F2 [n=3] and F3/F4 [n=4], age range: 39-69). Fibrosis pathological staging was determined using MASH Clinical-Research-Network criteria. Dynamic total-body PET/CT imaging was performed between 0-60 minutes post-intravenous administration of 215-236 MBq [^{18}F]FAPI-74. Volumes-of-interest (VOIs) were placed on eight liver segments and descending aorta. Liver VOI values were averaged. Liver SUVmean ratio (SUVR) was calculated using descending aorta as reference region. Kinetic modelling was conducted using a dual-input two-tissue compartment model to estimate the net influx rate (K_i). No statistical tests were performed due to the small sample size. ***Results:*** Liver SUVmean, SUVR, and K_i values showed differences between HV and MASLD participants. SUVmean and SUVR measured at 4 mins post-injection (240s to 300s), 20 mins (20 min to 23 min), and 55 mins (55 min to 60 min) were compared. The 4 min data were shown to best separate the groups and are reported here. Participants with stage F3/F4 exhibited a higher median SUVmean of 4.53 [range: 4.12-4.85] and SUVR of 0.64 [0.61-0.68] compared to those with stage F1/F2 (SUVmean: 3.89 [3.79-4.57], SUVR: 0.53[0.48-0.54]) and HV (SUVmean: 3.62, SUVR: 0.48). Similarly, median K_i values reflected differences in tracer retention across groups: HV (0.009), F1/F2 (0.021[0.017-0.023]), and F3/F4 (0.035 [0.027-0.040]). ***Conclusion:*** [^{18}F]FAPI PET demonstrates potential as an imaging NIT For staging liver fibrosis that may be more accurate than existing NITs and avoid the need for liver biopsy. The observed association between liver SUVmean, SUVR, and K_i values and pathology-confirmed fibrosis stages supports its potential for disease stratification in MASLD. These preliminary results warrant validation in larger cohorts.

EPS-033

A Prospective Study on the Diagnosis and Severity Assessment of Interstitial Lung Disease Complicated by Dermatomyositis in Adults Using ^{68}Ga-FAPI PET/CT

J. Hu[1], *X. Sun*[1], *X. Shao*[2], *Q. Qu*[1], *J. Hu*[2], *Q. Zhao*[2], *Y. Jin*[1], *Z. Cheng*[3], *W. Hai*[1], *B. Li*[1], *H. Cao*[2];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Department of Dermatology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [3]*Department of Radiology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: Dermatomyositis is a heterogeneous disease characterized primarily by muscle weakness and multi-organ involvement (e.g., lungs, heart, gastrointestinal tract, kidneys, or associated malignancies). Its common complication and leading cause of death is rapidly progressive interstitial lung disease (RP-ILD). Currently, the early specific screening methods used in clinical practice still have certain limitations. Based on this, this study employs a novel fibroblast activation-targeting tracer—^{68}Ga-FAPI PET/CT—to explore its clinical utility in dermatomyositis patients complicated by interstitial lung disease. ***Materials and Methods:*** Prospective study including 140 dermatomyositis patients who underwent 68Ga-FAPI PET/CT, PFTs and autoimmune blood analysis. Four groups were created: non-ILD subjects and ILD patients with or without infection. For normally distributed continuous data, unpaired t-tests or analysis of variance (ANOVA) were used, while for non-normally distributed continuous data, the Mann-Whitney test or Kruskal-Wallis test was employed to compare variable differences. Pearson or Spearman correlation coefficients were used to analyze associations with clinical indicators. ***Results:*** The sensitivity and specificity of ^{68}Ga-FAPI PET/CT for diagnosing dermatomyositis with non-infectious ILD reached 97.67% and 97.83%, respectively, while for dermatomyositis with infectious ILD, both sensitivity and specificity were 100%. The results showed that in the non-infection group, the maximum value of SUVmax in lung lesions (SUVlung) in patients with anti-synthetase syndrome and MDA5-positive dermatomyositis was significantly higher than in TIF-1γ-positive dermatomyositis patients (P=0.0514). Additionally, SUVlung in MDA5 and Ro-52 double antibody-positive dermatomyositis patients was higher than in MDA5-positive but

Ro-52-negative patients (P=0.0216). In the non-infection state, SUVlung exhibited significant correlations with KL-6 and FVC (r=0.4941, P<0.0001; r=-0.4651, P=0.0001). These correlations strengthened in the infection state (r=0.6529, P<0.0001; r=-0.5020, P=0.0029). ***Conclusion:*** In conclusion, ^{68}Ga-FAPI PET/CT enables accurate diagnosis and severity assessment of interstitial lung disease complicated by dermatomyositis, thereby potentially guiding therapeutic decisions and improving patient prognosis.

EPS-034

[99mTc]DTPA aerosol clearance as an assessment of pulmonary alveolar permeability in long COVID

T. Biggans, *J. Asogan Vaishnavi, P. Guntur Ramkumar; NHS Tayside, Dundee, UNITED KINGDOM.*

Aim/Introduction: Individuals experiencing ongoing symptoms four weeks since onset of Coronavirus disease 2019 (COVID-19) are widely described as suffering from long COVID. Breathlessness is one of the most common of these symptoms. The physiological cause of this breathlessness is unknown with unremarkable findings on CT and lung function tests. The aim of this study was to determine if the clearance rate of 99mTc-diethylenetriaminepentaacetic acid ([99mTc]DTPA) aerosol from the lungs is abnormal in patients suffering from long COVID. This objective marker is representative of alveolar epithelial membrane integrity. Any change in clearance rate would indicate that membrane permeability may have been affected and could be involved in the underlying cause of long COVID symptoms. ***Materials and Methods:*** Participants were recruited from patients who were referred for ventilation/perfusion lung scintigraphy (V/Q scan) at Ninewells Hospital, Dundee, Scotland from July 2022 to June 2023. Participants completed a questionnaire to ascertain smoking habits and any history of lung disease. Dynamic lung scintigraphy was performed following inhalation of [99mTc]DTPA aerosol. Regions of interest (ROIs) were drawn around each lung with corresponding background regions. Background corrected geometric mean time activity curves were generated from these ROIs and the clearance half time was determined from least squares exponential fit of the data. The mean of the clearance half time from both lungs was calculated. Participants were grouped into smokers and non-smokers before being clinically sub-grouped using the questionnaire, relevant clinical history and the final V/Q scan report. The sub-groups were defined as history of interstitial lung or airways disease, history of long COVID and controls. ***Results:*** In total 125 participants were recruited with 21 subsequently excluded for technical reasons. Only 7 of the remaining 104 were smokers which did not allow for subgroup analysis of the smoking group. The mean clearance half time (SD - standard deviation) for non-smokers was 56 min (SD 24), 72 min (SD 23) and 71 min (SD 22) for interstitial lung or airways disease, long COVID and control subgroups respectively. For smokers, the mean clearance half time was 35 min (SD 12). ***Conclusion:*** This study indicates pulmonary alveolar permeability is maintained in long COVID sufferers.

EPS-035

Emotional Stress During the COVID-19 Lockdown: How Negative X/Twitter Posts Correlated with Changes in the Brain's Fear Network

E. Guedj[1], *J. Y. Campion*[2], *T. Horowitz*[1], *F. Barthelemy*[3], *S. Khalfa*[4], *W. El-Hage*[2];
[1]*Aix-Marseille University, Marseille, FRANCE,* [2]*CHRU Tours, Tours, FRANCE,* [3]*APHM, Marseille, FRANCE,* [4]*CNRS, Marseille, FRANCE.*

Aim/Introduction: The COVID-19 pandemic has profoundly affected mental health, with the lockdown period particularly exacerbating negative emotions such as fear, sadness, and uncertainty. This study examines brain metabolic changes associated with the psychological context of the French COVID-19 lockdown. ***Materials and Methods:*** As a proxy measure of this psychological context, we utilized a composite negative-emotion score from an open-source X/Twitter dataset ("The First French COVID-19 Lockdown Twitter Dataset"), previously designed to capture the overall public sentiment during the 55-day lockdown. Using statistical parametric mapping (SPM), this composite negative-emotion score was day-by-day correlated to the whole-brain voxel-based [18F]FDG PET imaging in 95 patients with neurological conditions (p-voxel < 0.001, k > 108). ***Results:*** Results showed a significant negative correlation between daily negative-emotion scores and metabolism in the right ventromedial prefrontal cortex (vmPFC) and anterior cingulate cortex (ACC), key regions within the brain fear circuit. Inter-regional correlation analysis (IRCA) of metabolic connectivity from the right vmPFC/ACC subsequently revealed a right limbic-dominant network encompassing the amygdala, hippocampus, thalamus, and basal ganglia. ***Conclusion:*** These findings highlight the sensitivity of the right vmPFC/ACC to societal emotional stressors, suggesting a potential cerebral substrate for the increase in psychological and psychiatric disorders observed during the pandemic. Future research is required to validate these results in broader populations and explore their longitudinal implications to better understand the neurological and psychiatric impacts of collective stress.

EPS-036

TSPO PET relates to blood markers of vascular regulation, immune cell survival and brain damage in post-COVID syndrome

D. Visser[1], *H. L. D. M. Willemen*[2], *S. S. V. Golla*[1], *R. Boellaard*[1], *H. Knoop*[3], *B. N. M. van Berckel*[1], *J. Bosch*[3], *J. den Dunnen*[4], *N. Eijkelkamp*[2], *N. Tolboom*[5];
[1]*Department of Radiology & Nuclear Medicine, Amsterdam Neuroscience, Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*Center for Translational Immunology, UMC Utrecht, Utrecht, NETHERLANDS,* [3]*Department of Medical Psychology, Amsterdam UMC, Amsterdam, NETHERLANDS,* [4]*Center for Experimental and Molecular Medicine, Amsterdam UMC, Amsterdam, NETHERLANDS,* [5]*Department of Radiology & Nuclear Medicine, UMC Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: The pathophysiology of post-COVID syndrome is still unclear. We previously showed that a subset of post-COVID individuals show neuroinflammatory activity on TSPO PET, indicating pathophysiological heterogeneity of the syndrome(1). Further validation of this neuroinflammatory subtype using blood based biomarkers would greatly aid unravelling the pathophysiology of post-COVID. Therefore, we aimed to identify which blood-based biomarkers associate with neuroinflammatory activity as measured with TSPO PET in post-COVID syndrome patients. ***Materials and Methods:*** We included 31 post-COVID patients (mean age 50±9, 55% female, 26±8 months after initial SARS CoV2 infection) who underwent a 60-minute dynamic [^{18}F] DPA-714 PET with arterial sampling, MRI, and blood-collection on the day of, and prior to, the PET scan. [^{18}F]DPA-714 binding was quantified using binding potential in the global grey matter. Blood samples were analysed using NULISA (Alamar's 120-plex Central Nervous System disease Panel)(2). Regression models and Spearman's correlation were employed to evaluate the the association between neuroinflammatory activity on PET and blood-based markers. Additionally, we compared blood-based markers between patients with high (>mean+1.5SD of a control population) and those with low neuroinflammatory activity on PET using ANOVA and Wilcoxon tests. ***Results:*** Increased [^{18}F] DPA-714 binding on PET associated with higher levels of Vascular endothelial growth factor A (VEGFA; Spearman's rho 0.50, p=0.007), a protein with an important role in angiogenesis and vascular permeability including blood brain barrier permeability, but which also supports neuroprotection and glial growth(3). Post-COVID patients with high binding on PET compared to those with low binding on PET had higher levels of Ficolin-2 (FCN2; p=0.040), a lectin pathway initiator linked to the severity of brain damage(4),

and lower levels of Interleukin-7 (IL7; p=0.049), a cytokine essential for immune cell survival(5). ***Conclusion:*** We identified VEGFA, FCN2, and IL7 to be associated with neuroinflammatory activity as measured with TSPO PET in post-COVID syndrome patients. This might reflect altered vascular regulation, complement activation, and immune dysregulation, which were previously hypothesized as central to the pathophysiology of post-COVID syndrome. These findings reinforce the concept of a distinct neuroinflammatory subtype within post-COVID syndrome. Further validation in larger cohorts is required to confirm and expand upon these results. ***References:*** (1) Visser, D, et al. Varying levels of inflammatory activity in brain and body of patients with persistent fatigue and difficulty concentrating after COVID-19: a TSPO PET study; submitted (2) DOI:10.1038/s41467-023-42834-x (3) DOI:10.4161/org.6.2.11687 (4) DOI:10.1177/0271678X18758881 (5) DOI:10.1016/j.cyto.2022.156049

Synergistic FAPI and PSMA PET/CT Imaging in Primary Sjögren's Syndrome: Comprehensive Evaluation of Inflammatory Burden and Functional Parameters for Clinical Translation

J. Wang, *J. Xiang, R. Wang, X. Peng, Y. Wang, Z. Zhu;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disorder characterized by immune-mediated glandular destruction and sicca symptoms. Pro-inflammatory fibroblasts drive glandular damage, quantifiable via fibroblast activation protein (FAPI) PET/CT, which maps inflammatory activity. Prostate-specific membrane antigen (PSMA) PET/CT, traditionally used in oncology, reveals salivary gland dysfunction in pSS through reduced physiological uptake. Combining these modalities offers a dual-perspective approach to evaluate inflammation and functional decline in pSS. ***Materials and Methods:*** Thirty-five pSS patients underwent paired [^{68}Ga]Ga-FAPI-04 and [^{68}Ga]Ga-PSMA PET/CT imaging (February 2024-March 2025). Salivary gland uptake was compared to 35 age-/sex-matched breast cancer controls. Standardized uptake values (SUVmax/mean), salivary gland ultrasonography (SGUS) scores, and clinical indices (ESSDAI, ESSPRI, IgG, RF, ESR) were analyzed. Histopathological validation was performed using FAPI/PSMA immunohistochemistry on labial gland biopsies. ***Results:*** pSS patients exhibited higher FAPI uptake (SUVmax: 3.42 ± 1.25 vs. 2.08 ± 0.42, $p < 0.001$) and reduced PSMA uptake (SUVmean: 5.39 ± 2.77 vs. 10.60 ± 2.02, $p < 0.0001$) compared to controls. The functional-to-inflammatory ratio (FPR = FAPI SUVmax/PSMA SUVmean) correlated with SGUS scores (parotid: $r = 0.58$, $p < 0.05$; submandibular: $r = 0.63$, $p < 0.01$), disease activity (ESSDAI: $r = 0.3$; ESSPRI: $r = 0.4$), and serologic markers (IgG/RF/ESR, $p < 0.05$). FAPI PET strongly correlated with fibroblast activation on immunohistochemistry ($r = 0.72$, $p < 0.001$), while PSMA PET moderately aligned with glandular function ($r = 0.51$, $p < 0.05$). ***Conclusion:*** The functional-to-inflammatory ratio (FPR) integrates FAPI PET/CT (inflammation) and PSMA PET/CT (glandular function) into a novel biomarker for stratifying pSS severity and guiding therapy. Histopathological validation reinforces its biological relevance, supporting future applications in precision management.

EPS-038

Imaging Phenotypes of Idiopathic Inflammatory Myositis using ^{18}F-FDG PET/MR

Y. Zhang, *B. Zhang, B. Li, X. Zhang;*
The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, CHINA.

Aim/Introduction: Idiopathic inflammatory myositis (IIM) comprises a heterogeneous group of autoimmune disorders involving muscle inflammation and increased malignancy risk. ^{18}F-FDG PET/MR imaging shows promise for evaluating muscle involvement. This study aimed to derive novel imaging phenotypic clusters of muscle involvement using ^{18}F-FDG PET/MRI. ***Materials and Methods:*** This retrospective study included patients fulfilling classification criteria for IIM who underwent ^{18}F-FDG PET/CT with whole-body MRI or ^{18}F-FDG PET/MRI. Muscle enzyme levels were collected. Muscle oedema (scores 0-2), fatty infiltration (0-1), and atrophy (0-1) were evaluated across 42 muscle groups. Fasciitis (0-1) and subcutaneous oedema (0-1) were assessed in 8 regions. Muscle ^{18}F-FDG uptake was measured via target-to-background ratio (TBR: muscle SUVmax / liver SUVmean). Mean scores for each parameter were calculated per patient. Hierarchical clustering analysis using z-transformed mean TBR, oedema, fatty infiltration, atrophy, fasciitis, and subcutaneous oedema scores identified patient subgroups. ***Results:*** Seventy-two IIM patients (n=48 female [66.7%]; median age 51.0 [IQR 34.5, 59.5] years) were included. Subtypes were antisynthetase syndrome (11/72, 15.3%), dermatomyositis (DM, 47/72, 65.3%), immune-mediated necrotizing myopathy (IMNM, 8/72, 11.1%), and polymyositis (PM, 6/72, 8.3%). Four clusters emerged. Cluster 1 (n=32) showed moderate ^{18}F-FDG uptake, severe muscle oedema, mild fatty infiltration/atrophy, and moderate fasciitis/subcutaneous oedema; DM was most frequent (22/32, 68.8%), CK levels were moderately elevated (255.5 [IQR 66.0, 910.0] U/L), and 3/32 (9.4%) had malignancy. Cluster 2 (n=26) exhibited mild muscle involvement on PET/MRI with mild fasciitis/subcutaneous oedema; DM (15/26, 57.7%) and antisynthetase syndrome (6/26, 23.1%) were common, CK levels were not evidently elevated (82.0 [IQR 57.0, 188.0] U/L), and 3/26 (11.5%) had malignancy. Cluster 3 (n=9) displayed high ^{18}F-FDG uptake, severe muscle oedema, severe fatty infiltration/atrophy, and moderate fasciitis/subcutaneous oedema; IMNM (4/9, 44.4%) and PM (3/9, 33.3%) were frequent, CK levels were significantly elevated (2,094.0 [IQR 318.0, 2,899.0] U/L), with no malignancies detected. Cluster 4 (n=5) had high ^{18}F-FDG uptake, severe muscle oedema, mild fatty infiltration/atrophy, and severe fasciitis/subcutaneous oedema; all patients had DM, CK levels were elevated (398.0 [IQR 229.0, 860.0] U/L), and 2/5 (40.0%) had malignancy. ***Conclusion:*** Distinct imaging phenotypes within IIM can be identified using ^{18}F-FDG PET/MR biomarkers and clustering analysis. These clusters exhibit different patterns of muscle inflammation, damage, and extramuscular involvement, potentially reflecting different underlying pathologies or disease stages and showing varied associations with specific IIM subtypes and malignancy risk. ^{18}F-FDG PET/MR shows promise in characterizing the heterogeneity of IIM.

EPS-039

Role of ^{68}Ga-FAPI PET/CT in assessing liver fibrosis in chronic liver disease

S. Singh, *M. Ora, S. Gambhir;*
SGPGIMS, Lucknow, INDIA.

Aim/Introduction: Chronic liver disease (CLD) is a global health burden and it requires accurate fibrosis staging, but liver biopsy's invasiveness and non-invasive methods limited resolution create diagnostic gaps. Fibroblast activation protein (FAP), expressed in hepatic stellate cells during fibrogenesis, offers a novel target. ^{68}Ga-FAPI PET/CT enables whole-liver quantification of fibrotic activity via SUV measurements, potentially detecting early fibrosis before structural changes occur. This study evaluates its role versus traditional methods. ***Materials and Methods:*** This prospective study was conducted in the Department of Nuclear Medicine at SGPGIMS, enrolling 30 chronic liver disease (CLD) patients (stratified into Child-Pugh classes A, B, and C; n=10 each) and 10 healthy controls. Inclusion criteria comprised adults (≥18 years) with confirmed CLD who provided informed consent, while exclusion criteria eliminated patients with liver masses/malignancy, pregnancy/lactation, or inability to cooperate. All participants underwent baseline evaluation including medical

history, CBC, liver function tests, viral markers, APRI, and FIB-4 scoring. Each patient received ^{68}Ga-FAPI PET/CT imaging following standardized protocols (150 MBq IV, 60-minute uptake period), with qualitative (visual assessment) and quantitative (SUVmax) analysis performed by an experienced nuclear medicine physician blinded to clinical data. Statistical analysis included correlation of FAPI uptake with Child-Pugh class and non-invasive biomarkers, along with group comparisons. ***Results:*** The study included 30 CLD patients (Child-Pugh A/B/C: 10 each) and 10 controls. ^{68}Ga-FAPI PET/CT demonstrated significantly higher hepatic uptake in CLD patients versus controls (mean SUVmax 4.8 (2.7-5.7) vs 1.0 (0.8-1.2), p<0.001). FAPI avidity correlated strongly with disease severity, showing progressive SUVmax increases across Child-Pugh classes (A: 3.0 (2.0-3.8), B: 5.5 (3.9-6.8), C: 5.3 (4.6-6.1); p<0.001). ***Conclusion:*** ^{68}Ga-FAPI PET/CT emerges as a transformative, non-invasive tool for liver fibrosis assessment, demonstrating strong correlation with disease severity and superior diagnostic accuracy to conventional biomarkers. Its ability to quantify fibrotic activity through SUVmax measurements and detect regional heterogeneity offers distinct advantages over current standards, potentially reducing reliance on invasive biopsies. These findings position FAPI-PET as a promising technique for personalized management of chronic liver disease, particularly for monitoring progression and therapeutic response.

[18F]FDG-PET/CT value in the assessment of treatment response in patients with extrapulmonary tuberculosis

M. Tormo Ratera[1], *M. Cortés-Romera*[1], *M. Santin*[2], *A. Fritsch-Medina*[1], *S. Pérez-Recio*[2], *M. Grijota-Camino*[2], *P. Perlaza-Jiménez*[1], *J. Diaz-Moreno*[1], *A. Bagán-Trejo*[1], *J. Robles-Barba*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Infectious Diseases Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: The aim of this study is to evaluate the utility of [18F]FDG-PET/CT in assessing the response to antituberculosis treatment in patients with extrapulmonary tuberculosis (TB-E). ***Materials and Methods:*** Retrospective cohort study, including 20 patients diagnosed with TB-E, all of whom underwent a baseline [18F]FDG-PET/CT prior to treatment and another for assessment of the response to antituberculosis treatment.Demographic and diagnostic data (IGRA, PPD, cultures, and biopsies) were collected. [18F]FDG-PET/CT semi-quantitative (SUVmax, ΔSUVmax) and visual parameters were analysed. Lesions with activity greater than the hepatic reference were considered pathological, and a complete metabolic response (CMR) was defined as a reduction in uptake (≤hepatic). ***Results:*** The median age at diagnosis was 49 years (7 women). At diagnosis, 90% (18/20) of the patients had a positive IGRA, 10% (2/20) a positive PPD, 20% (4/20) positive cultures, and 35% (7/20) compatible biopsies.Baseline [18F]FDG-PET/CT images showed pathological findings in 100% of the patients: 75% (15/20) showed only lymph node involvement, 20% (4/20) both lymph node and extranodal involvement, and 5% (1/20) only extranodal involvement. The mean baseline SUVmax was 9.03 ± 4.8. The median duration of antituberculosis treatment was 6 months (range 3-9 months), and the interval between the start of treatment and the post-treatment [18F]FDG-PET/CT was 6 months (range 2-18). The mean post-treatment SUVmax was 3.37 ± 3.12. CMR was observed in 50% of the patients. Moreover, 95% of the patients showed a reduction in SUVmax, with a mean ΔSUVmax of 61.3% (range 6%-86%). One patient exhibited an increase in both SUVmax and the number of lesions, which led to a concomitant diagnosis of urothelial carcinoma. ***Conclusion:*** [18F]FDG-PET/CT has proven to be useful in assessing the response to antituberculosis treatment in patients with TB-E, showing a good correlation between semi-quantitative and visual parameters and clinical response.

EPS-041

FDG-PET/CT Patlak Parametric Imaging in Patients with Alveolar Echinococcosis

B. Sah[1], *L. Husmann*[1], *F. Kotasidis*[2], *A. Maurer*[1], *C. Meyer zu Schwabedissen*[1], *A. Deibel*[1], *M. Huellner*[1];
[1]*University Zurich/University Hospital Zurich, Zurich, SWITZERLAND,* [2]*University Zurich/GE Healthcare, Zurich/Waukesha,USA, SWITZERLAND.*

Aim/Introduction: To determine the role of whole-body dynamic (WBD) / Patlak parametric ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) in patients with alveolar echinococcosis (AE). This technique allows separating metabolized from unmetabolized FDG in the blood pool and tissue, potentially providing complementary qualitative information and superior quantification to standard static PET/CT images. ***Materials and Methods:*** We prospectively analysed 20 PET/CT datasets performed for staging or therapy monitoring in patients with confirmed AE. Dynamic and standard static PET/CT datasets were acquired in all patients, and quantitative imaging parameters were measured in the lesion with the highest uptake (i.e., maximum standardized uptake value (SUVmax) and Patlak parameters) and compared to normal liver tissue (SUVratio and Patlak ratio). ***Results:*** Mean SUVmax in AE manifestations was 5.7±3.1 (3.2-13.9), compared to 3.2±0.4 (2.5-4.2) in non-infected liver tissue, respective values for Patlak were 13.0±8.6 (2.7-35.5) and 4.9±2.8 (0.6-12.1). SUVratio (1.8±1.1; 1.0-5.2) was significantly lower (P<0.001) than Patlak ratio (3.2±3.2; 1.1-15.6). Both ratios correlated significantly with E. granulosus hydatid fluid (EgHF) antibodies (SUVratio r=0.73, P<0.001; Patlak ratio r=0.85, P<0.001). ***Conclusion:*** WBD PET/CT yields higher lesion-to-background contrast and may therefore have the potential to increase sensitivity in the assessment of hepatic AE.

EPS-042

Neuroimmune activation in temporal lobe epilepsy patients with worsening seizure following the COVID-19 pandemic: A [^{18}F]DPA-714 PET/MR study

L. Xiao[1], *L. Feng*[1], *Y. Tang*[1], *S. Hu*[1], *K. Shi*[2];
[1]*Xiangya Hospital Central South University, Changsha, CHINA,* [2]*University Hospital Bern, Bern, SWITZERLAND.*

Aim/Introduction: Temporal lobe epilepsy (TLE) patients frequently experience worsening epilepsy following COVID-19, referred to as post-COVID-19 active TLE. While neuroinflammatory changes are suspected in these patients, measurements of both central and systemic inflammation in the brain remain unexplored. To investigate whether the translocator protein standardized uptake value ratio (TSPO SUVr), a quantifiable marker of neuroinflammation using positron emission tomography (PET), is elevated in the brains of patients with post-COVID-19 active TLE. Additionally, we examine correlations between TSPO SUVr and inflammatory factors to identify potential peripheral blood inflammatory predictors of post-COVID-19 active epilepsy. ***Materials and Methods:*** This prospective single-center study was conducted at Xiangya Hospital of Central South University from June 2023 to May 2024. It included 24 TLE patients (12 with post-COVID-19 active TLE, 12 with post-COVID-19 non-active TLE) and 9 healthy controls (HCs), comparing serum inflammatory factors and TSPO SUVr across participants. TSPO SUVr was measured using the TSPO radioligand fluorine [^{18}F]DPA-714 PET, and the serum inflammatory factors levels were quantified using enzyme-linked immunosorbent assay (ELISA) kits. ***Results:*** The study involved 33 participants. In comparison to non-active TLE patients and HCs, the active TLE group exhibited significantly higher levels of IL-1β, IFN-γ, TNF-α, IL-5, and IL-10 ($P < 0.05$). Notable increases in TSPO SUVr were observed in specific regions, including the left temporal gyrus, right inferior frontal gyrus, and right cingulum ($P < 0.001$ uncorrected, clusters of ≥ 200 voxels). IL-1β, IL-10, and IFN-γ demonstrated the strongest associations with TSPO SUVr in the left temporal gyrus. ***Conclusion:*** Our study highlights

the presence of widespread neuroinflammation in the brain and increased levels of inflammatory cytokines in the plasma of individuals with post-COVID-19 active TLE. Furthermore, strong correlations between plasma levels of IL-1β, IL-10, and IFN-γ and neuroimmune activation suggest the potential for integrating plasma inflammatory factors with TSPO PET as a dependable approach for clinical diagnosis, dynamic monitoring, and assessment of immune-based therapeutic efficacy in TLE-associated neuroinflammation. ***References:*** 1.Depressive and Cognitive Symptoms. Tumour Heterogeneity in FAP Expression Exposes a Dual Role for FAP-Expressing CAFs in FAP-Targeted Radionuclide Therapy
***C. Wu**, A. Kurniawan, Z. Ming, G. Li, W. Noordzij, A. W. J. M. Glaudemans, I. F. Antunes, B. Cornelissen;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Despite promising therapeutic efficacy in preclinical studies, fibroblast activation protein-targeted radionuclide therapy (FAP-TRT) has shown limited clinical benefit. This study aims to clarify the dual role of FAP-expressing cancer-associated fibroblasts (CAFs) as therapeutic targets and potential tumour-promoting components during FAP-TRT with [^{161}Tb]Tb-FAPI-46, using 2D and 3D co-culture models of pancreatic ductal adenocarcinoma (PDAC). ***Materials and Methods:*** Immunofluorescence staining of alpha-smooth muscle actin (α-SMA) and FAP was performed on tumour sections from 10 PDAC patients, and the proportions of FAP-positive CAFs and tumour cells were enumerated. FAP expression in PSN-1 cells (human PDAC) and CAFs was measured by immunofluorescence. Uptake, internalisation, efflux, and specific binding of [^{161}Tb]Tb-FAPI-46 (40 MBq/nmol) were assessed in PSN-1 and CAFs at low (10 kBq) and high (4000 kBq) activities. Therapeutic effects of [^{161}Tb]Tb-FAPI-46 at various activities (0-4000 kBq) were evaluated in 2D clonogenic assays and 3D spheroid models, both in monoculture and co-culture conditions with different tumour-to-CAFs ratios (1:2 and 1:5). Spheroid growth was monitored for up to 13 days. ***Results:*** FAP expression varied widely among PDAC samples, with FAP-positive stromal and tumour cells ranging from 38-88% and 6.8-30%, respectively. PSN-1 cells showed lower uptake of [^{161}Tb]Tb-FAPI-46 than CAFs. High and low-added activities displayed distinct uptake/internalisation patterns in both PSN-1 and CAFs. In 2D clonogenic assays, no significant cytotoxicity to PSN-1 cells was observed in either mono- or co-culture models. In 3D spheroids, a paradoxical tumour-growth-promoting effect was seen at intermediate added activities (2000 kBq), especially in the 1:2 PSN-1: CAFs spheroid, where tumour growth temporarily accelerated markedly (P=0.002) (Table 1). This suggests that sublethal irradiation of CAFs may (transiently) stimulate tumour proliferation. By day 13, representing the long-term treatment response, all models exhibited activity-dependent growth inhibition, with 4000 kBq achieving the strongest effect ($P < 0.001$). However, the extent of inhibition decreased with increasing CAFs proportion, indicating that CAFs abundance may attenuate the long-term efficacy of FAP-TRT on tumour cell growth, even at high doses. The discrepancy between 2D and 3D model responses emphasises the importance of spatial architecture and tumour-CAFs interactions in mediating FAP-TRT efficacy. ***Conclusion:*** FAP expression and CAFs proportions critically influence FAP-TRT efficacy. While they enhance tracer uptake in cancerous tissue as a whole, excessive CAFs may promote tumour growth when exposed to subtherapeutic amounts of FAP-TRT. These findings highlight the importance of patient selection, dose optimisation, and CAFs composition and spatial arrangement for effective FAP-TRT.

OP-150
Investigating Fibroblast Activation Protein Binding of the dimeric DOTAGA.Glu.$(FAPI)_2$ labelled with Terbium-161 in Ovarian Cancer Models Incorporating the Tumor Microenvironment
***S. Van Mechelen**[1,2], K. Vermeulen[1], T. Opsomer[1], Z. Janssen[1], J. Buset[1], M. Ooms[1], F. Rösch[3], A. Coosemans[2], K. Tabury[1], I. Primac[1];*
[1]SCK CEN, Mol, BELGIUM, [2]KU Leuven, Leuven, BELGIUM, [3]Johannes Gutenberg University, Mainz, GERMANY.

Aim/Introduction: Radiotheranostics targeting the tumour stroma, particularly cancer-associated fibroblasts (CAFs) expressing fibroblast activation protein (FAP), offer a promising pan-cancer approach for the treatment of various malignancies, including ovarian cancer (OC). High-affinity, long-retention FAP-targeting radioligands are essential to maximise tumour uptake and therapeutic impact. This study preclinically evaluates the potential of a dimeric FAP inhibitor, DOTAGA.Glu.$(FAPi)_2$, labelled with the β- and Auger/conversion electron-emitting radionuclide Terbium-161 (^{161}Tb) in FAP-expressing OC models. ***Materials and Methods:*** A panel of OC cell lines and CAFs was characterized for FAP expression using Western blotting and immunofluorescence imaging. DOTAGA.Glu.$(FAPi)_2$ was radiolabelled with ^{161}Tb (100

MBq/nmol), achieving radiochemical purities exceeding 98%. Radioligand uptake was measured in CAF and OC monocultures at different timepoints (0.5-4 hours), while binding affinities were determined at one hour in co-culture models of FAP-positive CAFs and OC cells. A comparison with the clinically established monomeric analogue FAPI-46 was also included. Ex vivo tissue binding was analyzed by autoradiography on OC-CAF xenograft sections, and data were correlated to FAP histology. ***Results:*** Significantly elevated FAP expression was detected in CAFs compared to OC cell lines, as confirmed by both Western blotting and immunofluorescence. Correspondingly, radioligand uptake in CAFs peaked at 1 hour (38.9% ± 0.6% added activity (AA)/10^5 cells), while uptake in OC cells remained minimal (0.92% ± 0.01% AA/10^5 and 2.4% ± 0.1% AA/10^5 for OC cells). [161Tb]Tb-DOTAGA.Glu.$(FAPi)_2$ demonstrated a 3.1-fold increase in cellular uptake relative to [^{161}Tb]Tb-FAPI-46 and exhibited high FAP-binding affinity, with nanomolar dissociation constants in OC-CAF co-culture models. Autoradiographic analysis of OC-CAF xenograft tissues revealed a significantly greater tumour-associated specific binding for the dimeric radioligand (18.1 ± 1.7 DLU/mm^2) compared to the monomeric counterpart (6.0 ± 0.8 DLU/mm^2, $p < 0.0001$), alongside minimal non-specific uptake in healthy organs. These findings were consistent with FAP expression patterns observed in tumour histology. ***Conclusion:*** [^{161}Tb]Tb-DOTAGA.Glu.$(FAPi)_2$ exhibits markedly improved tumour targeting and binding in biologically relevant FAP-expressing ovarian cancer models. These findings support its further development as a potent radioligand for the targeted treatment of FAP-positive tumours, including ovarian cancer.

Safety, Biodistribution, and Dosimetry of Fibroblast Activation Protein and Integrin $\alpha_v\beta_3$ dual Targeting radioligand ^{177}Lu-DOTA-FAPI-RGD: Preclinical and First-in-Human Results

J. Xiang[1,2], *X. Wen*[3], *R. Wang*[1,2], *J. Wang*[1,2], *X. Peng*[1], *Y. Wang*[1,2], *Z. Zhu*[1], *J. Zhang*[4];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*Peking Union Medical College, Beijing, CHINA,* [3]*Theranostics Center of Excellence (TCE), Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [4]*Department of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: Fibroblast activation protein (FAP) and integrin αvβ3 are promising targets for cancer theranostics. We developed a novel dual-targeting radiotheranostic agent, ^{177}Lu-DOTA-FAPI-RGD, and conducted a first-in-human study to evaluate its safety, biodistribution, dosimetry, and preliminary therapeutic efficacy in patients with advanced adenocarcinomas. ***Materials and Methods:*** DOTA-FAPI-RGD was synthesized by conjugating a FAPI inhibitor, an RGDfK peptide and a DOTA chelator. The biodistribution and preclinical pharmacokinetics of ^{177}Lu-DOTA-FAPI-RGD were determined in HT1080-FAP and U87MG xenograft models. Nine patients with advanced adenocarcinomas and positive ^{68}Ga-FAPI-RGD PET/CT underwent treatment with 2.0±0.3 GBq (range, 1.6-2.4 GBq) of ^{177}Lu-DOTA-FAPI-RGD. ***Results:*** ^{177}Lu-DOTA-FAPI-RGD showed high radiochemical purity and stability (≥96 h). It demonstrated strong dual-target binding in vitro and sustained tumor uptake with favorable tumor-to-background ratios in vivo. ^{177}Lu-DOTA-FAPI-RGD was well-tolerated in humans. The whole-body effective dose was 0.08±0.02 Sv/GBq. Mean absorbed doses were: red marrow, 0.04±0.01 Gy/GBq; liver, 0.50±0.31 Gy/GBq; and kidneys, 0.31±0.11 Gy/GBq. Tumor-absorbed doses reached 6.10±1.42 Gy/GBq (lung metastases) and 4.20±0.84 Gy/GBq (lymph nodes). No grade 4 adverse events occurred. Grade 3 adverse events included thrombocytopenia (n=3), leukopenia (n=2), and anemia (n=1). Preliminary therapeutic outcomes showed a partial response in 2 patients (22.2%), stable disease in 6 (66.7%), and progression in 1 (11.1%), resulting in an objective response rate of 22.2% and disease control rate of 88.9%. ***Conclusion:*** ^{177}Lu-DOTA-FAPI-RGD showed adequate radiochemical purity and stability, persistent tumor uptake and high tumor-to-background ratios during the preclinical evaluation. ^{177}Lu-DOTA-FAPI-RGD also demonstrated acceptable safety, significant tumor uptake, and promising efficacy in patients, supporting further investigation in dose-escalation and multi-cycle trials.

OP-152

Head-to-head comparison of FAP-targeting single domain antibody 4AH29 vs peptide FAP-2286

N. Dumauthioz*, L. Navarro, M. Berdal, S. Nagachinta, S. Massa, A. R. Pombo Antunes, J. Dewulf, D. Mantzilas, M. D'Huyvetter;*
Precirix, Brussels, BELGIUM.

Aim/Introduction: The FAP-targeting sdAb 4AH29 was developed previously, with exceptional binding kinetics and sustained tumour retention, which translates in proper therapeutic efficacy as a single agent[1]. ^{177}Lu-labelled FAP-2286 is generally considered as most clinically advanced[2], however its perceived limited tumour retention might impact its effectiveness. This study head-to-head compares sdAb 4AH29 and peptide FAP-2286 for their in vitro and in vivo tumour retention, resulting dosimetry, and eventual therapeutic efficacy in U87 (FAP expression on tumour cells) and HT29 (FAP expression in stroma) tumour bearing mice. ***Materials and Methods:*** In vitro cell retention of [^{177}Lu]Lu-DOTA-4AH29 or [^{177}Lu]Lu-DOTA-FAP-2286 was assessed until 24h on U87 cells. Their biodistribution was evaluated in U87 and HT29 tumour xenografted mice, by i.v. injecting both ^{177}Lu-labelled compounds (3.9±0.1MBq, 1nmol) and assessing radioactive uptake in relevant organs and tissues until 168h p.i. The obtained data was used for dosimetry calculations. Finally mice with established U87 tumours were treated with a single administration of ~60 MBq (1 nmol) of [^{177}Lu]Lu-DOTA-4AH29 or [^{177}Lu]Lu-DOTA-FAP-2286, after which animals are monitored for general wellbeing and tumours volume until end of study. Statistics are done via one-way ANOVA (Tukey correction). ***Results:*** In vitro, [^{177}Lu]Lu-DOTA-4AH29 showed sustained cell-associated activity until 24h, whereas it dropped to baseline within the first hours for [^{177}Lu]Lu-DOTA-FAP-2286, indicating a rapid dissociation from U87 cells for the latter. In vivo, U87 tumour uptake was 2.8±1.0%IA/g for [^{177}Lu]Lu-DOTA-4AH29 and 9.8±2.3%IA/g for [^{177}Lu]Lu-DOTA-FAP-2286 at 1h. In the case of [^{177}Lu]Lu-DOTA-4AH29 this was retained up to 72h (2.3±0.8%IA/g), whereas for [^{177}Lu]Lu-DOTA-FAP-2286, uptake dropped to 0.96±0.4%IA/g by 24h and 0.44±0.14%IA/g at 72h. The prolonged retention resulted in a threefold higher absorbed dose to the tumour [^{177}Lu]Lu-DOTA-4AH29. Similar retention trends were obtained in HT29 tumours, however at lower absolute uptake given the lower FAP-expression in this model. HT29 tumour uptake measured rather similar for both [^{177}Lu]Lu-DOTA-4AH29 and [^{177}Lu]Lu-DOTA-FAP-2286 (1.14±0.35 vs 1.10±0.4%IA/g) early after administration in line with the results obtained in U87 tumours, improved tumour retention was observed for [^{177}Lu]Lu-DOTA-4AH29 over time, resulting in a twofold higher absorbed dose to tumour. Treatment with [^{177}Lu]Lu-DOTA-4AH29 significantly delayed tumour development vs vehicle (p=0.0124), and showed superior anti-tumour effects over treatment with [^{177}Lu]Lu-DOTA-FAP-2286 (p=0.0362) at 43 days after U87 tumor cell inoculation. ***Conclusion:*** These preclinical results underline the potential benefit of radiolabelled 4AH29 over radiolabelled FAP-2286 because of its improved tumour retention and more pronounced anti-tumour effect, and warrants its translation into the clinic. ***References:*** 1. Dekempeneer,JNM,64,1941-1948,(2023). 2. NCT04939610,ClinicalTrials.gov.

OP-153

eFAP-51: a promising dimeric FAP inhibitor with prolonged tumor retention for cancer radionuclide therapy

H. Ma, *L. Li, A. Piet, C. de Ridder, D. Stuurman, P. Paraiso, Y. Seimbille;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Fibroblast activation protein (FAP) is a membrane-bound serine protease highly expressed in cancer-associated fibroblasts but minimally present in normal tissues, making it a promising bio-target for cancer. Although small-molecule FAP inhibitors have shown utility in tumor imaging, their short residence time limits therapeutic use. To address this limitation, we tested two quinoline-based monomeric FAP inhibitors—eFAP-9 and eFAP-12—from our in-house library. eFAP-9 exhibited tumor uptake comparable to the clinical reference FAPI-46, while eFAP-12 demonstrated a 1.7-fold longer tumor half-life. Building on these results, we designed dimeric analogs—eFAP-51 and eFAP-52—to enhance tumor retention through multivalency. ***Materials and Methods:*** eFAP-9 and eFAP-12 were synthesized using an 8-quinolinecyanopyrrolidine (8-QCP) scaffold. Dimers eFAP-51 and eFAP-52 were constructed by linking the respective monomers via a triazine-based platform. All compounds were radiolabeled with indium-111 and/or lutetium-177 and we evaluated their stability in PBS/mouse serum. Enzymatic inhibition was assessed against human/murine FAP, prolyl endopeptidase (PREP), and dipeptidyl peptidase-4 (DPP4). Cellular uptake was determined in HT-1080.hFAP cells. SPECT/CT imaging and biodistribution were performed in HT-1080.hFAP tumor-bearing NMRI-Foxn1^nu/nu mice. ***Results:*** All compounds were synthesized and radiolabelled with high RCY (>95%) and RCP (>96%). Both monomers and dimers exhibited potent FAP inhibition (IC_{50} < 3 nM), strong selectivity over PREP (SI >10), or DPP4 (IC_{50} > 1 mM). eFAP-9 (26.6 ± 2.3% AD) and eFAP-12 (12.0 ± 4.1% AD) showed comparable uptake in HT-1080.hFAP cells to FAPI-46 (17.2 ± 4.3% AD). eFAP-51 achieved the highest uptake (33.7 ± 4.0% AD), resulting in a 1.3-fold increase over eFAP-9, while eFAP-52 (12.5 ± 0.5% AD) performed similarly to eFAP-12. In vivo, eFAP-9 and eFAP-12 displayed tumor uptake similar to FAPI-46 at 1 h p.i., but retention declined over 24 h. In contrast, high tumor uptake (3.2% ID/g) of eFAP-51 remained over 48 h, 9-fold higher than eFAP-9 (0.35% ID/g). eFAP-52 also outperformed its monomer eFAP-12 (1.8 vs. 0.4% ID/g). Both dimers exhibited 2-4-fold higher retention than FAPI-46 (0.71% ID/g) at 48 h and showed minimal off-target accumulation with renal clearance profiles similar to monomers. ***Conclusion:*** Dimeric eFAPs demonstrated high FAP affinity, in vitro stability, and specificity, comparable to their monomeric analogs. While monomers showed modest pharmacokinetic improvement over FAPI-46, dimerization significantly enhanced tumor uptake and retention. eFAP-51, in particular, stands out as a strong candidate for FAP-targeted radioligand therapy. These findings pave the way for multivalent FAP inhibitors in next-generation cancer theranostics. ***References:*** Fibroblast activation protein, dimeric small-molecule analog, radionuclide theranostic application.

OP-154

^{67}Cu-, ^{161}Tb- and ^{177}Lu-radiolabeled antibody derivatives addressing fibroblast activation protein for radionuclide therapy

C. Neuber, *M. Kubeil, L. Loureiro, S. Brühlmann, N. Berndt, C. Arndt, A. Feldmann, K. Kopka, M. Bachmann, J. Pietzsch;*
Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY.

Aim/Introduction: Fibroblast activation protein alpha (FAP) is expressed on the surface of cancer-associated fibroblasts (CAFs) but, in contrast, is mostly absent in healthy adult tissue. Therefore, imaging of this promising tumor marker provides an excellent tumor-to-background contrast. Various attempts have been made to exploit this property also for development of (radionuclide) therapeutics. In our previous preclinical study, a human IgG4-based, FAP-specific target module (anti-FAP-IgG4) was shown to be not only effective in universal chimeric antigen receptor (UniCAR) T-cell immunotherapy but also, when radiolabeled with ^{64}Cu, to be a highly specific diagnostic PET tracer for the detection of human FAP in vivo [1]. Subsequently, we aim at the use of radiolabeled anti-FAP-IgG4 for targeted radionuclide therapy (TRT). ***Materials and Methods:*** To be labeled with the beta particle emitting radionuclides ^{67}Cu, ^{161}Tb, and ^{177}Lu, anti-FAP-IgG4 was modified with the complexing agent NODA-GA (for ^{67}Cu) or DTPA-CHX-A" (for ^{161}Tb or ^{177}Lu). Pharmacokinetics of the radiolabeled compounds were determined by SPECT/CT imaging and ex vivo biodistribution experiments, which also allow for dosimetry. Therapeutic effects of different activity amounts of [^{67}Cu]Cu-, [^{161}Tb]Tb-, and [^{177}Lu]Lu-anti-FAP-IgG4 (3.2-18 MBq per mouse) on tumor growth and potential adverse side effects, e.g. on the hematopoietic system, were assessed by regular tumor size and weight monitoring for 120 days as well as by blood and urine analysis, respectively. ***Results:*** Radiolabeling with ^{67}Cu, ^{161}Tb, and ^{177}Lu showed high radiochemical yields and purities as well as good molar activities ≥40 GBq/µmol. SPECT/CT imaging revealed an excellent FAP-specific tumor uptake 24 hours post i.v. injection in mice bearing genetically modified HT1080 tumor xenografts overexpressing human FAP (HT1080-hFAP). In line with this, all radioligands caused a significant tumor growth inhibition within 72 hours retaining for up to 120 days. Nevertheless, clear differences between [^{67}Cu]Cu-, [^{161}Tb]Tb-, and [^{177}Lu]Lu-anti-FAP-IgG4 could be observed with regard to long-term tumor control and adverse side effects, requiring the need for individual activity amount adjustments. ***Conclusion:*** In conclusion, we demonstrated in the HT1080-hFAP model the suitability of anti-FAP-IgG4 not only for immunotherapeutic approaches using UniCAR T-cells but, after radiolabeling with appropriate radionuclides, also for diagnostic PET and SPECT imaging as well as TRT. ***References:*** [1] Loureiro LR, Hoffmann L, Neuber C, Rupp L, Arndt C, Kegler A, Kubeil M, Hagemeyer CE, Stephan H, Schmitz M, Feldmann A, Bachmann M. A Phase I Clinical Study of Evaluating the Safety and Preliminary Efficacy of ^{177}Lu-FAPI-XT in Advanced Solid Tumors with Fibroblast Activation Protein Expression

H. Liu[1], *R. Guo*[2], *X. Zhang*[1], *H. Ji*[1], *S. Sun*[1], *S. Sun*[3], *J. Liu*[4], *Z. Yang*[2], *R. Wang*[1];
[1]*Department of Nuclear Medicine, the First Medical Center of Chinese PLA General Hospital, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA,* [3]*Sinotau Pharmaceutical Group, Beijing, CHINA,* [4]*Department of Bone and Soft Tissue Tumor, Peking University Cancer Hospital & Institute, Beijing, CHINA.*

Aim/Introduction: To investigate the safety profile, radiation dosimetry characteristics, and preliminary therapeutic potential of ^{177}Lu-FAPI-XT in patients of advanced solid tumors with fibroblast activation protein (FAP)-positive. ***Materials and Methods:*** Fourteen patients with histologically confirmed FAP-positive advanced malignancies who had progressed on standard therapies received intravenous administration of ^{177}Lu-FAPI-XT. Quantitative dosimetric analysis was performed to determine the percentage of injected activity (%ID), residence time, absorbed dose of per organ, and total effective dose using hybrid SPECT/CT imaging. Tumor response was assessed according to RECIST 1.1 criteria. ***Results:*** Peak organ uptake (%ID) occurred at 1-hour post-injection, with pulmonary parenchyma (3.878±1.331%) and red marrow (2.014±1.843%) demonstrating the highest accumulation. Prolonged tracer retention was observed in lungs (0.853±0.339 h) and hematopoietic system (0.659±0.373 h). Mean absorbed doses of per unit activity were kidney 0.13±0.047 Gy/GBq, lung 0.103±0.077 Gy/GBq, and red marrow 0.05±0.015 Gy/GBq. Tumor-absorbed doses ranged from 0.063 to 3.089 Gy/GBq. The treatment demonstrated favorable safety profiles with no

grade ≥3 adverse events. Six-month disease control rate (DCR) was 21.4% (3/14 partial responses), with fibroblastic sarcoma subgroup showing 37.5% DCR (3/8). Notably, one malignant solitary fibrous tumor case maintained stable disease for 9.4 months, while two myo-fibroblastic sarcoma cases exhibited significant reduction in FAPI PET/CT uptake activity. ***Conclusion:*** ^{177}Lu-FAPI-XT exhibits manageable toxicity and promising disease control efficacy in treatment-refractory and FAP-expressing malignancies. The favorable dosimetric profile supports further clinical investigation, particularly dose-escalation studies in mesenchymal neoplasms.

Increasing the Residence Time of FAP Radioligands Using a Ketoamide FAPI

A. de Groot[1], *P. Brzeminski*[2], *D. Wilocx*[3], *E. Verhulst*[1], *S. Peeters*[2], *A. Fabisiak*[2], *I. De Meester*[1], *P. Van Der Veken*[2], *F. Elvas*[3];
[1]*Laboratory of Medical Biochemistry (LMB), University of Antwerp, Antwerp, BELGIUM,* [2]*Laboratory of Medicinal Chemistry (UAMC), University of Antwerp, Antwerp, BELGIUM,* [3]*Molecular Imaging and Radiology (MIRA), University of Antwerp, Antwerp, BELGIUM.*

Aim/Introduction: Fibroblast activation protein alpha (FAP) is a promising pan-tumor target, with diagnostic radiotracers demonstrating significant success across various cancer types. However, therapeutic translation remains a major challenge, primarily due to suboptimal radiation doses. Limited radioligand retention in the tumor has been identified as one of the potential causes[1]. We hypothesized that increasing FAP residence time could improve tumor retention and efficacy. In this study, we present a novel FAP-targeting radioligand, [^{177}Lu]Lu-DOTA-UAMC5947, featuring an alpha-ketoamide warhead and a quaternary ammonium linker to optimize both pharmacokinetics and pharmacodynamics. The goal is to enhance tumor retention to improve the efficacy of FAP-targeted radiotherapeutics. ***Materials and Methods:*** A novel ketoamide-FAP ligand derivatized with DOTA (UAMC5946) was radiolabelled with Lu-177 to generate [^{177}Lu]Lu-DOTA-UAMC5947. Inhibition and kinetic enzyme assays determined binding specificity, affinity and kinetic parameters. The lipophilicity and stability were evaluated. Cellular uptake, binding specificity and distribution were determined in CT-5.3-hTERT cancer-associated fibroblasts (CAFs) up to 48h. SPECT/CT imaging and ex vivo biodistribution were performed from 4h up to 96h p.i. in U-87 MG xenografts. ***Results:*** ^{Nat}Lu-complex (UAMC5947) exhibited potent FAP inhibition, with an IC_{50} of 1.6 nM and an exceptionally slow dissociation rate (k_{off} = 0.00006 s^{-1}), corresponding to an in vitro FAP-residence time of 286 minutes. Moreover, it exhibited high selectivity (SI > 625) over DPP2, DPP4, DPP8 and DPP9 and an SI over prolyl oligopeptidase of 2. The Lu-177 labeled ligand was obtained with a radiochemical purity >95%, and exhibited very good stability in PBS, and mouse plasma (>69% intact after 96h). In cell-based assays using CAFs, [^{177}Lu]Lu-DOTA-UAMC5947 showed specific binding, sustained cellular retention over 48h, and minimal efflux. SPECT/CT imaging revealed fast clearance via the kidney resulting in low background and good tumor visualisation from 4h until 96h p.i.. Accordingly with the hydrophilicity profile (logD = -2.5), the radioligand showed fast blood clearance (1.99±0.08%IA/g at 4h p.i.) with excretion through the kidneys (4.39±2.99%IA/g at 4h p.i.). [^{177}Lu]Lu-DOTA-UAMC5947 showed high and persistent tumor uptake from 4h p.i. (18.92±1.99%IA/g) with negligible tumor washout 96h p.i. (22.31±3.82%IA/g at 4h p.i.). ***Conclusion:*** [^{177}Lu]Lu-DOTA-UAMC5947 demonstrated strong FAP binding, excellent stability, and prolonged tumor retention with low background uptake, making it a promising candidate for FAP-targeted radiotherapy. Its ability to enhance intratumoral residence time may help overcome current limitations in radioligand therapy. In vivo efficacy studies in murine tumor models are currently underway to further assess its therapeutic potential. ***References:*** [1]Mori et al, npj imaging, 2024.

OP-157

An MAE_3-DOTA-Conjugated FAP Inhibitor for TargetedRhenium-188 Radionuclide Therapy

M. Xu*, Z. Liu;*
Changping Laboratory, Beijing, CHINA.

Aim/Introduction: Rhenium-188 (^{188}Re) is a promising radionuclide for targeted radionuclide therapy due to its cost-effectiveness, high-energy β^- emissions for therapeutic efficacy, and γ emissions enabling SPECT imaging. However, the complex coordination chemistry of rhenium poses significant challenges in developing stable bifunctional chelators. Here, we designed four fibroblast activation protein (FAP)-targeted radiotracers: ^{188}Re-labeled MAS_3-FAPI, MAS_3-DOTA-FAPI, MAE_3-FAPI, and MAE_3-DOTA-FAPI, aiming to offer synergize therapeutic precision with diagnostic capabilities. ***Materials and Methods:*** Radiolabeling was achieved using triamidomonothiol (N_3S) chelator framework, mercaptoacetyl-Ser-Ser-Ser (MAS_3) and mercaptoacetyl-Glu-Glu-Glu (MAE_3). The 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) was used to modulate the pharmacokinetic properties. Radiolabeling efficiency, in vitro stability, and hydrophilicity were systematically compared. The tracers were further evaluated through FAP protein/cell binding assays, SPECT/CT imaging, biodistribution studies, and therapeutic efficacy assessments in HT1080-FAP xenograft model. ***Results:*** All the radiotracers exhibited efficient radiolabeling with yields exceeding 80%. MAE_3-based chelators demonstrated good stability (radiochemical purity >96% at 6 h). In vitro studies confirmed FAP-specific binding, while in vivo SPECT imaging revealed distinct pharmacokinetic profiles: DOTA-modified tracers (MAS_3-DOTA-FAPI and MAE_3-DOTA-FAPI) showed enhanced tumor uptake and prolonged retention, with significantly reduced hepatic/intestinal accumulation. Notably, [^{188}Re]Re-MAE3-DOTA-FAPI achieved potent tumor growth inhibition (100% reduction vs. controls) with negligible off-target toxicity. ***Conclusion:*** In this study, the potential of ^{188}Re-targeted radionuclide therapy was evaluated through the development and in vitro and in vivo assessment of ^{188}Re-labeled radiopharmaceuticals. This study establishes [^{188}Re]Re-MAE_3-DOTA-FAPI as an optimized therapeutic agent, combining MAE_3's robust chelation stability with DOTA-driven pharmacokinetic refinement. Its high tumor specificity, sustained intralesional retention, and potent therapeutic efficacy underscore strong potential for clinical translation.

Towards reliable automation of anatomical segmentation in whole-body bone scintigraphy using deep learning

I. Correia[1,2], *F. Oliveira*[1], *C. S. Constantino*[1], *L. C. Silva*[1], *J. Castanheira*[1], *Â. Ferreira*[1], *R. Teixeira*[1], *D. C. Costa*[1];
[1]*Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*Faculdade de Ciências, Universidade de Lisboa, Lisbon, PORTUGAL.*

Aim/Introduction: This project aims to assess the performance of deep-learning-based (DL) automatic anatomical segmentation of bone scintigraphy (BS) images. In combination with lesion segmentation and classification models, it can be used to generate lesion location reports to support clinical interpretation. Therefore, interpretation time and inter-reader variability are reduced to

improve clinical workflows. ***Materials and Methods:*** 255 total-body BS (anterior and posterior projections) from 189 patients were retrospectively collected for training and testing. Patients were injected with 99mTc-HDP (677±51.55 MBq) and scanned 2-4 hours post-injection using a Philips BrightView® dual-head gamma camera with LEHR collimators. Scans were acquired continuously at 14 cm/min, resulting in 512×1024 resolution images (2×2 mm^2 pixels). Patients (107 female, 82 male, mean age 70±13 years) were diagnosed with breast (N=99), prostate (N=66), or other cancers (N=24). Scans were acquired for staging or reassessment of bone metastases. From the full dataset, 50 patients were randomly selected for testing, ensuring no patient testing-training overlap and balanced sex distribution. The remaining scans (N=205) were used for network training. Both anterior and posterior projections were manually segmented under the supervision of an experienced nuclear medicine physician, covering the entire skeleton. The resulting masks contained 31 bones/bone structures for the anterior and 28 for the posterior projections. The training and inference were done using the nnU-Net framework [1], with one input channel per projection segmentation. Model performance was evaluated using manual segmentation as the ground truth. The Dice similarity coefficient (DSC) was computed per patient, weighted by label size. Bones/bone-structures-wise DSC across patients were also calculated. ***Results:*** The average DSC was 0.970 (range: 0.928-0.983) for anterior and 0.969 (range: 0.851-0.987) for posterior projections. Regarding bones/bone-structures-wise DSC, the skull achieved the highest mean score (0.993) in both projections. The lowest mean values were observed for the left radius (0.788 for anterior, and 0.781 for posterior projections), likely due to high variability in arm positioning and frequent partial cropping, rather than low uptake. The lowest score per patient resulted from the model mislabelling of symmetrical structures (left/right swap) despite the segmentation itself being anatomically correct, requiring potential architectural or input refinements. ***Conclusion:*** The proposed DL approach effectively identifies the skeletal structures in BS images, achieving high segmentation accuracy. While further validation is still needed across broader clinical scenarios to validate this tool and promote its integration in lesion detection models, it potentially paves the way for clinically meaningful automation. ***References:*** [1] Isensee, et al., (2021). doi:10.1038/s41592-020-01008-z

Deep Learning Segmentation for Myocardial Perfusion Imaging SPECT

T. Huxohl[1], *M. Günter*[2];
[1]*Heart and Diabetes Center NRW, Bad Oeynhausen, GERMANY,* [2]*Bielefeld University, Bielefeld, GERMANY.*

Aim/Introduction: Segmentation of the myocardium in myocardial perfusion SPECT images is an important preprocessing step. It facilitates downstream tasks such as reorientation and polar map generation required for clinical interpretation. In this work, a deep learning approach is implemented, and evaluated on three different SPECT scanners. ***Materials and Methods:*** Using a dataset of 437 SPECT/CT scans acquired with a Siemens Symbia Intevo scanner, initial segmentation masks were generated from attenuation maps using TotalSegmentator [1]. To deal with registration errors, the masks were shifted to maximize the activity under the mask. Furthermore, all masks were dilated, smoothed, manually refined and checked. With about 20% of the scans retained for testing, this dataset is used to train an nnU-Net [2] to segment the myocardium in MPI SPECT scans. The resulting model is evaluated qualitatively and using the Dice coefficient. In addition, the model is evaluated qualitatively on data from two other scanners: 64 scans acquired with a GE Discovery 530c and 47 scans acquired with a Philips Cardio-MD scanner. ***Results:*** The trained model achieves a Dice coefficient of 0.83±0.04 on the Siemens Symbia Intevo test data. In a qualitative evaluation, the segmentation masks for the other two scanners show a very good fit. ***Conclusion:*** An nnU-Net performs well for the segmentation of the myocardium in myocardial perfusion SPECT images across multiple scanners. In future work, we want to evaluate the segmentation masks with respect to two downstream tasks: (1) reorientation, and (2) image registration by comparing SPECT segmentation masks with CT segmentation masks generated with TotalSegmentator. ***References:*** [1] J. Aim/Introduction: Precise delineation of the left ventricle (LV) enables advanced analyses of endo-to-epicardium blood perfusion patterns and their gradients in PET, which can support various clinical applications, including coronary microvascular dysfunction. Approaches like simple thresholding or semi-automatic curve fitting often fall short in accurately capturing the LV boundaries in dynamic ^{82}Rb PET/CT. They also require expert manual input. This study presents a reliable manual, multi-modal LV delineation strategy, and a fully automatic segmentation algorithm using deep convolutional neural networks (CNNs). ***Materials and Methods:*** We manually segmented 40 non-gated dynamic PET/CT volumes from 20 patients, acquired under both rest and stress examinations. The cohort consists of patients who underwent ^{82}Rb PET/CT examinations for revascularization and includes several cases with evident apex thinning and hypoperfused septal and lateral walls. To support accurate delineation, multiple time frames—including early and late uptake phases—were used to segment the LV while excluding the blood pool. Additionally, computed tomography (CT) scans were used as a sanity check to ensure that the contours remained within the LV muscle tissue. This dataset was then used to train and evaluate an nnU-Net architecture [1] using a 5-fold cross-validation. The results are compared to a simple semi-automatic baseline thresholding method. ***Results:*** Best segmentation performance using semi-automatic baseline thresholding was achieved with a threshold equal to 35% of the highest photon count inside the LV, which achieved a mean Dice of 0.7452 and a balanced accuracy of 0.9101. The fully automatic nnU-Net outperformed this baseline by a large margin, achieving a Dice of 0.8701 and a balanced accuracy of 0.9392. Thresholding especially fails to contour the LV in ischaemic patients in the presence of hypoperfused septal and lateral walls or apex thinning. In such cases, the performance gap between the best nnU-Net and thresholding is even more pronounced, with nnU-Net achieving a Dice of 0.8525 compared to 0.7026 for thresholding. This performance gap is also more evident in stress examinations compared to rest, where nnU-Net boosts the Dice from 0.7387 (using thresholding) to 0.8696 for stress. ***Conclusion:***

Deep CNNs enable fully automated segmentation of ^{82}Rb dynamic PET sequences. It eliminates the need for human expert intervention in segmentation and achieves a relative improvement of 21% for patients with hypo-perfused tissues compared with the baseline thresholding algorithm. ***References:*** [1] Isensee F, Jaeger PF, Kohl SA, Petersen J, Maier-Hein KH. nnU-Net: a self-configuring method for deep learning-based biomedical image segmentation. Aim/Introduction: Clinical guidelines (PIOPED/EANM) for pulmonary embolism (PE) diagnosis rely on qualitative assessment of segmental/subsegmental perfusion defects in ventilation-perfusion (V/Q) scintigraphy. Annotation of segmental defects is limited by interobserver variability and is labor-intensive, so is seldom performed clinically, undermining communication of findings. To address this, we trained and validated three AI 2.5D models—nnUnet, SwinUnet, and Bottle neck transformer Unet (BTUnet)—for automated, reproducible defect segmentation in planar V/Q scans. ***Materials and Methods:*** Planar lung V/Q image data were sources from The Ottawa Hospital (TOH) and University Health Toronto (UHT). Both using a 256x256 grid with a ^{99m}Tc energy peak of 140±7.5% [129-150] keV, across six standard projections: anterior, posterior, and left/right anterior/posterior obliques. Ventilation at TOH was performed using Technegas, while UHT used various aerosolized agents. Both centers used ^{99m}Tc-MAA for perfusion. Models were trained on data from 1,313 patients (7,878 projections) and validated on 329 patients (1,974 projections) group-wise split by patient IDs and equally stratified by PIOPED categories. The BTUnet model was in-house developed and incorporated a lightweight transformer block within the bottleneck of the Unet architecture. Each model was trained on 6 consecutive paired V/Q images stacked channel-wise and corresponding annotated masks using a combined cross-entropy and Dice loss. Model performance was assessed on a hold-out test set of 46 images (276 projections), using FROC analysis and calculating sensitivity at 1 and 0.5 false positive rate (FPR) and Dice scores. Predicted defects were considered true positives if their centroids were within 1.95 cm (10 pixels) of the ground truth. Model results were compared to annotations by seven nuclear medicine physicians of the same images. ***Results:*** BTUnet, SwinUnet, and nnUnet mean ± std Dice scores were 0.51±0.37, 0.48±0.36, 0.48±0.40, respectively. BTUnet, SwinUnet, nnUnet, and for physicians mean ± std sensitivity at 1 FPR were 0.495±0.028, 0.462±0.030, 0.386±0.028, 0.572±0.058 and at 0.5 FPR were 0.400±0.041, 0.374±0.045, 0.374±0.044, and 0.459±0.057, respectively. Thus, BTUnet was the only model whose performance approached that of human readers, but did not reach the same level ($p<0.001$). ***Conclusion:*** Our top-performing AI model, BTUnet, robustly segmented vascular perfusion defects on V/Q scintigraphy, approaching the performance of expert physician assessments, but not matching it. Its ability to provide rapid and consistent segmentation marks its potential to enhance diagnostic efficiency and support the integration of AI-driven tools into standard clinical workflows for PE evaluation. Future work may aim to improve model performance by using all projections concurrently.

Improved Differential Diagnosis of Parkinsonian Syndromes Using Quantitative Dual-Phase [^{18}F]FP-CIT PET

H. Yoon[1], *D. Kim*[2], *S. Lee*[2], *S. Lee*[1], *M. Park*[3], *M. Yun*[1];
[1]*Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Yonsei University, Seoul, KOREA, REPUBLIC OF,* [3]*UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Dual-phase [^{18}F]FP-CIT PET/CT has proven valuable for the differential diagnosis of parkinsonian syndromes. Early-phase images resemble [^{18}F]FDG PET scans, reflecting cerebral perfusion and neuronal activity, while delayed-phase images depict striatal dopamine transporter binding. With increasing interest in artificial intelligence (AI)-based diagnostic tools, we hypothesized that combining early- and delayed- phase imaging would allow diagnosis and differential diagnosis of Parkinsonism. This study aimed to quantitatively analyze and classify dual-phase [^{18}F]FP-CIT PET/CT images using a machine learning algorithm, and to evaluate whether the inclusion of early-phase features improves the accuracy of differential diagnosis. ***Materials and Methods:*** We retrospectively collected dual-phase [^{18}F]FP-CIT PET/CT images from 435 subjects (normal = 188, idiopathic Parkinson's disease (IPD) = 111, atypical Parkinson's disease (APD) =136) at a single center. To measure regional uptake, segmentation masks of the ventral striatum, putamen and caudate were obtained from CT images using a deep learning model. Based on anterior commissure (AC)-posterior commissure (PC) landmarks, the mask was divided into 12 regions of interest (ROIs): anterior putamen, anterior caudate, posterior putamen, posterior caudate, ventral putamen, and ventral striatum (left and right). Binding potential (BPnd) and standardized uptake value ratios (SUVRs) were extracted from delayed and early-phase images, respectively, using the occipital cortex (delayed) and cortical white matter (early) as reference regions. In addition to BPnd and SUVRs for each ROI, 18 inter-regional ratios were derived and included as features. For early-phase features, SUVRs from 26 regions outside the basal ganglia were also incorporated. Two XGBoost classifiers were trained to categorize patients into normal, IPD, or APD groups using 10-fold stratified cross-validation. One model was trained using delayed-phase features only, while the other utilized both delayed- and early-phase features. Model performance was evaluated based on accuracy and F1 score. ***Results:*** The model trained solely on delayed-phase features achieved an accuracy of 0.834 ± 0.057 and an F1 score of 0.823 ± 0.063 (mean ± standard deviation). The model incorporating both delayed- and early-phase features demonstrated higher performance, with an accuracy of 0.917 ± 0.039 and an F1 score of 0.915 ± 0.041 (mean

± standard deviation). ***Conclusion:*** Incorporating early-phase features alongside delayed-phase features significantly improves machine learning-based differential diagnosis of parkinsonian syndromes. The enhanced accuracy and F1 scores highlight the added value of dual-phase [^{18}F]FP-CIT PET/CT as a more informative and comprehensive imaging modality for AI-assisted diagnosis.

Seg V/Q: Building a Large-Scale Database of Lung Ventilation-Perfusion Scintigraphy Annotated for Pulmonary Embolism Mismatch Defects (VQ4PEDB) With the Help of AI

A. Jabbarpour[1], *S. Kaviani*[2,3], *E. Moulton*[3,4], *S. Ghassel*[5], *W. Zeng*[6], *R. Akbarian*[7], *A. Couture*[8], *A. Roy*[9], *R. Liu*[9], *Y. A. Lucinian*[8], *N. Hejji*[6], *S. AlSulaiman*[6], *F. Shirazi*[6], *E. Leung*[6], *R. Klein*[6];
[1]*Carleton University, Ottawa, ON, CANADA,* [2]*Division of Nuclear Medicine and Molecular Imaging, Faculty of Medicine, University of Ottawa, Ottawa, Ontario, Canada., Ottawa, ON, CANADA, Ottawa, ON, CANADA,* [3]*Jubilant DraxImage, Montreal, QC, CANADA, Montreal, QC, CANADA,* [4]*Electrical Engineering and Computer Science, University of Ottawa, Ottawa, Ontario, Canada., Ottawa, ON, CANADA,, Ottawa, ON, CANADA,* [5]*Electrical Engineering and Computer Science, University of Ottawa, Ottawa, Ontario, Canada, Ottawa, ON, CANADA,* [6]*Department of Nuclear Medicine and Molecular Imaging, The Ottawa Hospital, Ottawa, Ontario, Canada, Ottawa, ON, CANADA,* [7]*Electrical Engineering and Computer Science, University of Ottawa, Ottawa, Ontario, Canada, Ottawa, ON, CANADA,* [8]*Hôpital Maisonneuve-Rosemont, Montreal, QC, CANADA, Montreal, QC, CANADA,* [9]*McGill University Faculty of Medicine, Montreal, QC, CANADA,, Montreal, QC, CANADA.*

Aim/Introduction: Pulmonary embolism (PE) can be reliably diagnosed using ventilation-perfusion (V/Q) scintigraphy, yet subjective interpretation and labor-intensive annotation impede both clinical consistency and the development of AI-driven image processing tools. To overcome these limitations, we have been constructing VQ4PEDB, the first large-scale annotated database of V/Q studies, leveraging Seg V/Q, a hybrid AI-human workflow to enhance the scalability of high-quality PE defect annotation. ***Materials and Methods:*** We analyzed 2,137 planar V/Q studies from The Ottawa Hospital, classified by modified PIOPED criteria. In phase one, 1,485 studies were manually annotated by 10 nuclear medicine physicians using the V7 Darwin platform, segmenting perfusion defects across six standard projections: anterior, left anterior oblique, left posterior oblique, posterior, right posterior oblique, and right anterior oblique. In phase 2, the remaining 652 studies were annotated using Seg V/Q software, an in-house developed GUI incorporating a Bottle Neck Transformer Unet (BTUnet) segmentation model. The model, pre-trained on phase 1 data, generated preliminary defect masks that annotators refined to finalize the segmentations. Annotation times were compared between phases. Furthermore, the proportion of BTUnet annotations requiring human corrections were also evaluated. ***Results:*** The phase 1 cohort included 669 normal studies and 816 with perfusion defects (138 high, 168 intermediate, 266 low, 244 very low probability). The distribution of PIOPED scores were similar between phases. AI integration reduced mean annotation time by 65% (1.24 ± 1.67 vs. 3.50 ± 4.20 minutes; $p < 0.0001$). Critically, 25% of cases required extensive corrections to BTUnet generated defect annotations, 20% of cases required moderate boundary corrections, 35% required only minor boundary edits, with no significant accuracy loss (<2 cm border deviations), and 20% did not require adjustment. ***Conclusion:*** Seg V/Q using AI-generated initial annotations significantly shortened the time required to annotate lung V/Q mismatch defects in planar scintigraphy, while preserving label fidelity. The resulting VQ4PEDB enables the development and validation of diagnostic clinical tools for the accurate detection of PE.

OP-165

Long-term surveillance of an AI segmentation tool in clinical practice

J. Taylor*, P. Metherall;*
Sheffield Teaching Hospitals, Sheffield, UNITED KINGDOM.

Aim/Introduction: Ongoing surveillance of AI tools is a requirement of EU legislation. Such procedures ensure that software performance remains consistent and that user behaviour does not shift significantly over time (e.g. due to automation bias). The aim of this study was to evaluate the long-term performance of a clinically implemented AI tool for automated segmentation of Multi-Gated Acquisition (MUGA) scans. We assessed: • Time required for users to check/edit auto-generated regions • Extent of user editing • Evidence of performance drift or automation bias over time ***Materials and Methods:*** All stages of MUGA scan processing were automatically recorded in a bespoke local database, with associated timestamps. Records between November 2022 to April 2025 were analysed. Tool performance and user editing were evaluated by comparing the ejection fraction (EF) result generated from fully automated regions to the final EF result after human quality checking. To further assess human intervention, 20 cases from two time points (Feb 2023 and Feb 2025) were selected. Left ventricular segmentation areas were measured across all 24 frames of each acquisition, comparing automated vs. manually adjusted results. ***Results:*** Full dataset: Across 625 samples, the mean absolute EF difference between automated and final results was 2.2% (SD 2.6%), suggesting small underestimation by the AI. The mean time for quality checking/editing was 13.5 minutes (SD 22.3 mins), with the high variability likely reflecting workflow interruptions. Frame-by-frame analysis showed systematic overestimation of left ventricular area by the AI, most notably at end-systole (mean difference 0.5 cm^2 across all frames; 1.2 cm^2 at end-systole). Timeline analysis: EF data split into 6-month periods showed no significant trend in absolute EF difference, suggesting stable performance and no increase in automation bias. Similarly, comparing 2023 and 2025 cohorts for per-frame segmentation areas revealed no significant change over time. ***Conclusion:*** This clinically implemented AI tool showed consistent long-term performance in MUGA scan segmentation. A small underestimation of EF was observed, likely due to systematic overestimation of end-systolic size. However, no evidence of performance drift or automation bias was found since implementation.

OP-166

Deep Learning-Based Segmentation of Carotid Arteries for Reliable PET Metric Extraction on a Clinical Dataset of 192 [^{64}Cu]Cu-DOTATATE PET/CT Scans

A. Kristensen Vølund*, V. M. B. Frederiksen, J. S. Madsen, M. E. K. Jensen, A. Clemmensen, R. S. Ripa, A. Kjaer;*
Cluster for Molecular Imaging, Copenhagen University Hospital - Rigshospitalet, Department of Biomedical Sciences, University of Copenhagen, Copenhagen, DENMARK.

Aim/Introduction: The carotid artery bifurcation is a common and critical location for atherosclerotic plaques to develop. If such a plaque becomes unstable, it may lead to stroke. Positron emission tomography (PET) has shown potential in imaging atherosclerotic cardiovascular disease [1], however assessing the radiotracer uptake requires manual annotation of the arteries, which is a time-consuming task. The aim of this study was to train a deep learning model to perform segmentation of the carotid arteries for reliable PET metric extraction ***Materials and Methods:*** In total, 192 clinical [^{64}Cu]Cu-DOTATATE PET/CT scans were included. First, all carotid arteries were manually annotated by trained raters. Second, a 3D nnU-Net model [2] was trained on 154 of the CT scans and the corresponding human annotations of both left and right carotid artery. The performance of the model was evaluated on a test

set consisting of 38 PET/CT scans not used for training. Four PET metrics were extracted: SUV_{max}, $mSUV_{max}$, TBR_{max} and $mTBR_{max}$. In addition, intra- and inter-rater reliability of the manual annotation method was assessed. ***Results:*** The model obtained a Dice score of 0.86±0.11 and 0.88±0.04 for, respectively, the left and right carotid artery on the test set compared to the human annotations. For all four PET metrics, the intraclass correlation coefficient (ICC) was ≥0.96. Bland-Altman analysis showed that the bias ± limits of agreement (LoA) between the model and the human annotations were 0.07±0.64, 0.05±0.15, 0.07±0.89 and 0.07±0.24 for SUV_{max}, $mSUV_{max}$, TBR_{max} and $mTBR_{max}$, respectively. For the intra-rater reliability, the bias ± LoA were 0.10±0.57, 0.00±0.08, -0.06±0.94 and -0.10±0.32, and for the inter-rater reliability bias ± LoA were 0.00±0.94, 0.04±0.09, -0.01±1.52 and 0.03±0.27. The model segments the carotid arteries in just 63 seconds per scan, while the manual annotation takes 14.5 minutes on average per scan. ***Conclusion:*** The width of the LoA for the model was comparable to that of the human intra- and inter-rater variability for all four PET metrics. This, in addition to high ICCs, indicates that the model's ability to create reliable segmentations for PET metric extraction is excellent. A 93% reduction in segmentation time compared to the manual annotation underscores the potential in applying automated segmentation in cardiovascular nuclear imaging. ***References:*** [1] Maier, A. et al. Integrin $\alpha_v\beta_6$ Targeting ^{68}Ga-Trivehexin PET/CT for Imaging Non-Small Cell Lung Cancer: A Prospective Study

W. Hq[1], *C. Li*[1], *L. Li*[1], *Q. Chen*[2], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Pathology, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

Aim/Introduction: This study aimed to investigate and compare the diagnostic performance of ^{68}Ga-Trivehexin and ^{18}F-FDG PET/CT for detecting mediastinal and hilar lymph node metastasis in non-small cell lung cancer (NSCLC), and further explore their impacts on patients' therapeutic management. ***Materials and Methods:*** Forty patients with histologically confirmed NSCLC were prospectively enrolled and underwent paired ^{68}Ga-Trivehexin and ^{18}F-FDG PET/CT within one week (NCT05835570). The maximum standardized uptake value (SUVmax), target-to-background ratio (TBR) and target-to-liver ratio (TLR) were accessed for paired positive lesions. The diagnostic performance of ^{68}Ga-Trivehexin and ^{18}F-FDG was compared for the detection of primary tumors, lymph nodes and distant metastases. The reference standard was based on histopathological findings, typical radiological manifestations, clinical imaging follow-up of no less than 3 months. Wilcoxon signed-rank test or Mann-Whitney U test was used to compare these indicators between the two groups. ***Results:*** For regional lymph nodes, ^{68}Ga-Trivehexin exhibited higher diagnostic sensitivity (61.5% vs. 53.8%), specificity (98.4% vs. 81.5%), and accuracy (94.9% vs. 78.8%) compared to ^{18}F-FDG (all $p < 0.05$). For primary tumors, the detection efficiency of ^{18}F-FDG and ^{68}Ga-Trivehexin PET/CT is equal (100%). For distant metastases, ^{68}Ga-Trivehexin detected more lesions than ^{18}F-FDG (27 vs. 21), and with higher TLR for liver (22.57 vs 10.07, $p = 0.016$) and bone metastases (13.64 vs 6.65, $p < 0.001$). In particular, for brain metastases, the TBR of ^{68}Ga-Trivehexin was 89.1 times that of ^{18}F- FDG (96.23 vs 1.08, $p = 0.004$). For N-staging, ^{68}Ga-Trivehexin PET/CT showed that 84.2% (16/19) of the patients were consistent with pathological N-staging. A total of 16 patients changed their therapeutic regimens according to ^{68}Ga-Trivehexin PET/CT compared with ^{18}F-FDG PET/CT. ***Conclusion:*** Our study demonstrated that ^{68}Ga-Trivehexin PET/CT is significantly superior to ^{18}F-FDG PET/CT in identifying lymph node metastasis in NSCLC. ^{68}Ga-Trivehexin PET/CT showed a comparable diagnostic performance with ^{18}F-FDG for detecting primary tumors and distant metastases except for brain metastasis.

Aim/Introduction: To evaluateT&N-staging diagnostic performances of [68Ga]Ga-FAPI-46 (FAPI) and [18F]F-FDG-PET/CT (FDG) in a suspected/confirmed lung cancer (LC) non-surgical cohort. ***Materials and Methods:*** Among patients with suspected/confirmed LC enrolled in a prospective-monocentric-trial (EudraCT:2021-006570-23;concluded)to perform additional FAPI over conventional-staging-flow-chart(including FDG), only non-surgical patients were included. Results on surgical cohort(n=50) were already published. Visual-positivity-criteria was defined forT&N as uptake higher than mediastinal-blood-pool(MBP). Agreement(%) between FAPI/FDG and histopathology was assessed byTNM-StagingAJCC8thEdition. PET-semiquantitative-parameters were measured forT&N: SUVmax,target-to-background-ratios(TBRs:SUVmaxLesion/SUVmeanBackground) using MBP, liver(L) and pulmonary-parenchyma(P), as backgrounds. FAPI-PET/CT visual&semiquantitative-performances(ROC-AUC forSUVmax and TBRs) were analysed per-patient and per-T&N-regions, compared to FDG. Transthoracic-needle-biopsy(TTNB) and endobronchial-ultrasound-guided-transbronchial-needle-aspiration(EBUS-TBNA)results were considered as standard-of-reference; without TTNB/EBUS-TBNA, radiological/clinical follow-up(FU;1year) were considered to validate PET results. ***Results:*** 63FAPI were performed out of 64patients enrolled(26May22-30Nov23). 3/63patients(mean-age:67y[52-83];M:F=8:5) did not undergo surgery and were included in this subgroup-analysis: 46%(6/13)T0N0-benign, 15%(2/13)T2N2, 15%(2/13)T3N2, 8%(1/13) T3N1(drop out from surgery), 8%(1/13)T1N3, 8%(1/13)T1N0(RT-treated). 92%of patients(12/13)underwentTTNB/EBUS-TBNA: biopsies results were present forT in 77%of patients(10/13) and for N in69%(9/13). Subsequent clinical-imaging-FU was used to validate PET results in the remaining 3/13-T patients and 4/13-N patients. Agreement(%) with histopathological-T&N-results(FAPIvsFDG) was: T-60%vs60%, N-95%vs75%; Cohen's k were also measured

0.29vs0.23 and 0.90vs0.51 respectively.Among the13 patients of the non-surgical cohort, 77%(10/13) presented 10lesions(T) which were examined(1Tfor each patient). 60%resulted benign(6/10): 83%(5/6)inflammatory nodules (3/5concordantFDG&FAPI-FP, 1/5discordantFDG-VN/FAPI-FP, 1/5concordantFDG&FAPI-VN) and 17%(1/6)mycotic infection-concordantFDG&FAPI-TN.40%(4/10) resulted malignant: 75%(3/4)adenocarcinoma(2/3concordantFDG&FAPI-TP, 1/3dicordantFDG-FN/FAPI-TP) and 25%(1/4) adeno-squamous-carcinoma(concordantFDG&FAPI-TP). The remaining 23%of patients(3/13) were judged concordant for T with the N-biopsy results(2/3adenocarcinoma,concordantFDG&FAPI-TP) or with radiological/clinical-FU(1/3absence of tumour,concordantFDG&FAPI-TN).Among the 69%of patients(9/13) with N-biopsies results, 56%of patients(5/9) showed lymph node metastases of adenocarcinoma(2/5N2 concordantFDG&FAPI-TP, 1/5discordantN2FDG-TP/N1FAPI-FN, 1/5N1concordantFDG&FAPI-TP, 1/5discordantN0FDG-FN/N3FAPI-TP)and 11%(1/9)metastases of adeno-squamous carcinoma(concordantFDG&FAPI-TP). 33%of patients(3/9) resulted negative for N-metastases:2/3concordantFDG&FAPI-TN, 1/3discordantFDG-FP/FAPI-TN. 31% of patients(4/13)did not undergo N-biopsies and were judged negative for metastases with radiological/clinical-FU(all concordantFDG&FAPI-TN).20 lymph-nodal stations were analysed(EBUS-TBNA): 55%(11/20) resulted positive for metastases. 82%(9/11)were adenocarcinoma metastases: 4/9concordantFDG&FAPI-TP, 1/9discordantFDG-TP/FAPI-FN, 4/9discordantFDG-FN/FAPI-TP. 18%(2/11)were adeno-squamous carcinoma metastases:2/2concordantFDG&FAPI-TP. 45%of lymph nodal station(9/20)resulted negative for metastases:8/9concordantFDG&FAPI-TN and 1/9discordantFDG-FP/FAPI-TN.AnalysesT-per-patient(n=13) and per-region(n=13),Visual(FAPIvsFDG): TN3vs4, FN0vs1, TP7vs5, FP3vs3; sensitivity100%vs83%, specificity50%vs57%, PPV70%vs63%, NPV100%vs80%, accuracy77%vs69%.AnalysesN-per-patient(n=13);Visual(FAPIvsFDG): TN7vs6, FN1vs1, TP5vs5, FP0vs1; sensitivity83%vs45%, specificity100%vs86%, PPV100%vs83%, NPV88%vs86%, accuracy92%vs85%.AnalysesN-per-region(n=20);Visual(FAPIvsFDG): TN9vs8, FN1vs4, TP10vs7, FP0vs1; sensitivity91%vs54%, specificity100%vs89%, PPV100%vs88%, NPV90%vs67%, accuracy95%vs75%.SUVmax, TBRs parameters performed similarly, better for N(AUCs p< 0.001 in all cases) than forT, not significantly different between the two tracers although slightly in favour of FAPI for N (N-AUCs FAPI>0.90 vs FDG>0.78); T-AUCs ranging from0.83 of FAPI-TBR-L to0.90 of FAPI-SUVmax). ***Conclusion:*** In a suspected/confirmed LC-non-surgical cohort, diagnostic performances forT&Nstaging were slightly in favour of FAPI in all cases (except for T-specificity).

FAPI PET/CT response assessment in non-small cell lung cancer (NSCLC) patients: interim results of a prospective exploratory imaging study

A. Deleu, *T. Berghmans, M. Brandão, A. Goudsmit, K. Stathopoulos, A. Arçay Öztürk, C. Marin, L. Taraji, S. Nisar, Z. Wimana, S. Vercauteren, B. Vanderlinden, P. Flamen;*
Jules Bordet Institute - H.U.B., Brussels, BELGIUM.

Aim/Introduction: Fibroblast activation protein inhibitor (FAPI) PET/CT is emerging as promising pan-cancer molecular imaging technique.(1) In non-small cell lung cancer (NSCLC), FAPI outperforms [^{18}F]FDG PET/CT in mediastinal lymph node staging and the detection of brain, pleural, and bone metastases. (2) However, current evidence remains insufficient for clinical implementation of FAPI PET/CT, particularly regarding its potential for evaluating treatment response.Therefore, the aim of this interim analysis is to evaluate tumor response assessment with FAPI PET/CT, as secondary objective of a prospective study (ClinicalTrials.gov; NCT06107608). Moreover, we aimed to validate the immune PET response criteria in solid tumors (iPERCIST) using [^{18}F]FDG PET/CT in NSCLC. ***Materials and Methods:*** Stage III/IV NSCLC patients underwent both [^{68}Ga]Ga-FAPI-46 and [^{18}F]FDG PET/CT at baseline and after 2 cycles of (chemo)immunotherapy. Response was evaluated according to iRECIST. PET parameters were assessed quantitatively on both [^{18}F]FDG and FAPI PET/CT. A correlation analysis of the relative change in [^{18}F]FDG and FAPI PET parameters in the primary tumor after 2 treatment cycles was performed. The difference in the kinetics of FAPI PET imaging biomarkers between the iRECIST response categories was analyzed using an unpaired T-test. ***Results:*** In the 25 patients included so far, a high FAPI uptake was observed with a mean SUVmax of 14.8 in the primary lung tumor on the baseline FAPI PET/CT (range 5.9 - 23.4). After two treatment cycles, both iRECIST and iPERCIST evaluations were available for 17 patients, revealing a near-complete concordance in response categories (Table 1). Regarding the SUVmax changes of the primary tumor after 2 treatment cycles, a significant strong correlation was found between [^{18}F]FDG and FAPI PET/CT ($n = 15$; $r = 0.76$; $p=0.001$). There was a significant difference in relative FAPI ΔSUVmax between the iRECIST partial response (iPR; mean ΔSUVmax -49%) and stable disease (iSD; mean ΔSUVmax -3%) response categories ($p=0.001$). ***Conclusion:*** FAPI PET/CT demonstrates significant potential as a sensitive and reliable imaging modality for assessing treatment response in patients with NSCLC, as evidenced by this interim analysis showing a strong correlation with established response evaluation criteria. Additionally, the analysis highlights the validation of the iPERCIST response criteria in this small cohort of NSCLC patients. Further inclusion is needed to confirm these findings in a larger cohort of patients. ***References:*** 1.Kratochwil C et al. (68)Ga-FAPI PET/CT:Tracer Uptake in 28 Different Kinds of Cancer. Imaging tumor-infiltrating CD8+ T-cells upon neo-adjuvant treatment with aPD-L1 in non-small cell lung cancer patients

E. Van Genugten[1], *B. Piet*[1], *I. A. E. van der Hoorn*[1], *K. Schmiedehausen*[2], *F. Ciompi*[1], *C. Jacobs*[1], *M. M. van den Heuvel*[1], *J. J. M. de Vries*[1], *E. H. J. G. Aarntzen*[1];
[1]*Radboud UMC, Nijmegen, NETHERLANDS,* [2]*ImaginAb, Calabasas, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Presence, localisation and function of CD8 T-cells has prognostic and predictive impact in numerous cancer types[1]. [89Zr]Zr-crefmirlimab berdoxam[2] targeting human CD8a has been introduced to non-invasively detect and monitor CD8 T-cell tumor infiltration[3]. Taking advantage of the neoadjuvant setting, we characterized [89Zr]Zr-crefmirlimab berdoxam as imaging biomarker in early-stage non-small lung cancer patients(NSCLC) upon anti-PD-L1 immune therapy. ***Materials and Methods:*** Eight early-stage NSCLC patients enrolled in a prospective study(NCT03853187) underwent PET/CT imaging 24h p.i. of [89Zr]Zr-crefmirlimab berdoxam(1.5mg protein dose, 37±10%MBq radioactivity dose) and CT-perfusion imaging 4 weeks after start of anti-PD-L1 immune therapy and within 3 days prior to curative resection. Standardized uptake values(SUV) were determined on tumor, tumor-draining lymph nodes(TDLN), distant lymph nodes(LN), spleen and bone marrow. CT images were coregistered and analyzed with the help of a perfusion model to extract hemodynamic parameters of the tumor. Whole-tumor sections were used for autoradiography while consecutive tissue slides were stained immune histochemical(IHC) for CD8 and quantified using Hover-Net algorithm[4] and density maps. A multiplex IHC panel to simultaneously detect multiple lymphocyte populations developed in-house[5] and CODEX[6] stained tissue microarrays were used to characterize tumor-infiltrating CD8 cell

populations. ***Results:*** Tracer uptake in T1b-2bN0-1M0 resectable NSCLC tumors ranged from SUVmean 0.7-2.7 while uptake in lymphoid structures such as TDLN SUVmean exceeded that of the tumor, ranging 1.5-12.3. IHC revealed prominence of different subsets of CD8 cells in the tumor and TDLN, suggesting different subsets contributing to the PET signal. CT-perfusion of the tumor revealed no limitations in [89Zr]Zr-crefmirlimab uptake due to perfusion or permeability, and autoradiography demonstrated good spatial correlation between signal and localization of CD8 lymphocytes. Except for one subject(DON430) with exceptional high CD8 density(2604 cells/mm2) and small tumor(0.5mL), tracer uptake correlates with IHC CD8 cell densities. Tumor SUV was associated with proportion of CD103-negative CD8 cells, concluding that non-tissue resident CD8 cells contribute most to tumor-related PET-signal. ***Conclusion:*** [89Zr]Zr-crefmirlimab berdoxam tumor uptake colocalizes and correlates with CD8 cell density and is independent of perfusion, but high cell density and partial volume effect may have impact on quantification. Tracer uptake in the tumor is determined by non-tissue resident CD8 cells, suggesting that distant labeling and subsequent infiltration is a dominant mechanism of tracer accumulation. Further analysis of CD8 distribution patterns beyond the tumor will help increase our understanding of the complex anti-tumor immune response. ***References:*** [1]Bruni, NatRevCancer,2020[2] Farwell, JNuclMed2022[3]Krekorian, Theranostics2019[4] Graham, MedImageAnal2019[5]Gorris, JVisExp2023[6]Black, NatureProtocols2021

OP-171

Integrating PET/CT Radiomics from Primary Tumors and Metastatic Lymph Nodes for Enhanced Survival Prediction in NSCLC Patients Undergoing Radical Radiotherapy

K. Albattat;
Cardiff University, Cardiff, UNITED KINGDOM.

Aim/Introduction: Lymph node (LN) metastasis is a critical prognostic factor in non-small cell lung cancer (NSCLC), yet survival prediction models often rely solely on primary tumor characteristics [1]. This study aims to determine whether integrating radiomic features from metastatic lymph nodes with those from the primary tumor can significantly improve survival prediction in NSCLC patients undergoing radical radiotherapy. We further evaluated whether incorporating lymph node burden (LN station count) and spatial spread (average nodal distance from the tumor) could enhance prognostic performance. We hypothesized that a combined radiomic model would outperform models based on primary tumor or lymph node features alone. ***Materials and Methods:*** This retrospective study included 147 NSCLC patients with mediastinal or hilar LN metastases. Three cohorts were analysed: (1) Primary Tumour Cohort (n=147), (2) LN Cohort (224 metastatic LNs), and (3) Combined Cohort (n=294 lesions). Patients were stratified into training (70%) and test (30%) sets while maintaining event/non-event balance to reduce validation bias. Radiomic features were extracted from PET/CT images using standardised lesion segmentation protocols. LASSO regression with 10-fold cross-validation was applied separately to each cohort's training set to select predictive features for four survival endpoints: overall survival (OS), progression-free survival (PFS), 2-year OS, and 2-year PFS. Features selected in at least 3 of the 4 LASSO runs were retained. Cox regression was used for OS and PFS, and logistic regression for 2-year outcomes. ***Results:*** Calibration curves indicated the primary tumor cohort had the best alignment with the reference line, suggesting reliable probability estimates. The LN cohort showed the greatest deviation, while the combined cohort had reasonable calibration with greater fluctuation at higher probabilities. Cox regression analysis showed the combined model yielded the best overall fit ($\chi^2 = 30.981$, $p = 0.002$), significantly improving survival prediction. The primary-only model was marginally significant ($p = 0.018$), and the LN-only model was not significant ($p = 0.077$). ***Conclusion:*** Combining radiomic features from primary tumors and metastatic lymph nodes enhances the predictive accuracy of survival models in NSCLC. Despite slightly better calibration in the primary-only model, the combined approach provides a more comprehensive, statistically robust, and clinically valuable prediction of patient outcomes, supporting its potential integration into personalized treatment planning ***References:*** [1] Hellwig D, et al. All you need is Δ SUVmax! Response prediction of preoperative immune checkpoint inhibition by dual time point FDG PET/CT in patients with resectable NSCLC in a prospective setting.

H. Hautzel[1], *M. Wiesweg*[2], *T. Plönes*[3,4], *D. Theegarten*[5], *D. Kersting*[1], *C. Aigner*[3,6], *K. Herrmann*[1], *M. Schuler*[2];
[1]*Department of Nuclear Medicine, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [2]*Department of Medical Oncology, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [3]*Department of Thoracic Surgery, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [4]*Department of Surgery, Division of Thoracic Surgery, University Hospital Carl Gustav Carus, Technical University Dresden, Dresden, GERMANY,* [5]*Institute for Pathology, University Hospital Essen, University Duisburg - Essen, Essen, GERMANY,* [6]*General Hospital Vienna, Department of Thoracic Surgery, Medical University Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Immune checkpoint inhibition (ICI) is increasingly used as neoadjuvance prior to surgery in resectable non-small-cell-lung-cancer (NSCLC). A prospective, randomized, multicenter study, NEOpredict-Lung, explores the potential of short-term preoperative ICI with nivolumab (anti PD-1 antibody) with/without relatlimab (anti-LAG-3 antibody) in patients with NSCLC stages I B, II or III A (1). Aim of the present analysis was to explore various parameters derived from two subsequent ^{18}FDG PET/CT scans for the non-invasive prediction of an ICI induced major pathological response. ***Materials and Methods:*** NEOpredict-Lung (NCT04205552) required imaging-based staging at initial NSCLC diagnosis and immediately prior to surgery. ^{18}FDG PET/CT at baseline (PET1) and pre-surgically (PET2) after two cycles of ICI was prospectively included at our center. The pathological response rates (IASLC criteria) in the resected tumors served as reference standard. A major pathological response (MPR) with viable tumour cells ≤10% was regarded as clinically relevant response to ICI (1). In that trial, PERCIST1.0 and RECIST1.1 were used to separate ICI responders from non-responders. Here, the predictive value of additional PET-derived parameters were tested by ROC analyses: single PET/CT scan variables (PET1-SUVmax, PET1-MTV, PET1-TLG, PET2-SUVmax, PET2-MTV, PET2-TLG) and comparative parameters (ΔSUVmax in %, ΔMTV in %, ΔTLG in %). The area-under-the-curves (AUC) were compared to those of PERCIST1.0 and RECIST1.1. ***Results:*** 31 patients with baseline ^{18}FDG PET/CT (median 22 days before ICI inititation) were included. The second ^{18}FDG PET/CT was performed at a median of 4 days before surgery. MPR was achieved in 8/31 patients. ROC of PERCIST1.0 revealed a high AUC of 0.913 while the ROC of RECIST1.1 demonstrated an AUC of 0.541. Taking that PERCIST1.0 AUC as cutting point which indicates a comparable or better prediction capability all single PET/CT parameters (from PET1-SUVmax: AUC 0.408 to PET2-SUVmax: AUC 0.877) and the dual time point PET parameter ΔMTV (AUC 0.85) failed. However, the dual time point PET parameters ΔTLG (AUC 0.931) performed non-inferior and ΔSUVmax (AUC 0.983) better than PERCIST1.0. ***Conclusion:*** ^{18}FDG

PET/CT PERCIST1.0 is recommended in scientific trials as a robust strategy for non-invasive response prediction. This holds true in neoadjuvant ICI before NSCLC resection as well. However, from our prospective data one might infer that the less elaborate and faster to achieve parameter ΔSUVmax is at least comparable in this specific setting and therefore qualifies as straightforward analytical approach in the clinical routine setting of neoadjuvant ICI and NSCLC. ***References:*** Schuler M et al.: Nat Med. 2024. doi: 10.1038/s41591-024-02965-0

Aim/Introduction: To develop a clinico-radiomic signature to predict treatment duration under tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer (NSCLC) patients. ***Materials and Methods:*** Pre-treatment [18F]FDG-PET/CT scans from 184 advanced NSCLC patients treated with TKIs before 2021 were retrospectively collected in 9 centers (training cohort), along with 57 patients treated from 2021 onward (testing cohort). All lesions were segmented by an expert using a 4 SUV threshold. The brain was segmented using TotalSegmentator on the CT, and copied onto the PET. Using LIFEx (www.lifexsoft.org, v7.8.0) [1], four PET features were extracted: Total Metabolic Tumor Volume (TMTV), the largest distance between two lesions (Dmax), the maximum uptake across all lesions (maxSUVmax), and the whole-brain average FDG uptake ($SUVmean_{Brain}$). For the training cohort, a conditional inference tree [2] was constructed to predict treatment duration under TKIs using the PET-derived features, patient age, gender, BMI, and the presence of an EGFR exon 19 mutation. Model performance was evaluated using Kaplan-Meier analysis and log-rank tests based on TKI treatment duration. ***Results:*** In the training cohort, the decision tree identified three key variables: $SUVmean_{Brain}$, EGFR exon 19 mutation status, and maxSUVmax. Patients were stratified into two groups (log-rank test: p<0.0001): low-risk group (n=42) - characterized by high $SUVmean_{Brain}$ (>5.9 SUV), the presence of an EGFR exon 19 mutation, and a maxSUVmax less than 18.3 SUV units, versus high-risk group (n=142), corresponding to all other patients. At 1 year, 93% of low-risk patients remained on TKI treatment compared to 64% of high-risk patients; at 3 years, these rates were 58% and 18%, respectively. In the testing cohort, the model identified 12 low-risk patients and 45 high-risk patients, with a significant difference in treatment duration curves between the two groups (log-rank test: p=0.019): 92% remained on TKI therapy at 1 year in the low-risk group, compared to 66% in the high-risk group. No significant association was found between $SUVmean_{Brain}$ values and the presence of brain metastases (Wilcoxon test: p=0.631 and 0.546, respectively). ***Conclusion:*** The three-factor decision tree developed and subsequently validated on a testing cohort enables identification of patients likely to benefit from TKI. This signature requires further validation on a larger scale and deeper understanding of the predictive value of $SUVmean_{Brain}$. It could help to guide treatment intensification strategies for patients classified as high-risk. ***References:*** [1] Nioche et al. Cancer Res 2018. [2] Hothorn & Zeileis J Mach Learn Res 2015.

OP-174

PET/CT Metabolic Parameters Correlation of Invasive Lung Adenocarcinoma Histological Grading to Optimize Surgical Decisions

X. Shen*, T. Chen, J. Wen, J. Deng, Y. She, D. Xie, C. Chen; Shanghai Pulmonary Hospital, Shanghai, CHINA.*

Aim/Introduction: The International Association for the Study of Lung Cancer (IASLC) has proposed a grading system for invasive lung adenocarcinoma which has been validated as being a reliable prognostic biomarker. However, given the reliance of this grading system on comprehensive histological evaluation, preoperative grading remains indeterminate. In the present study, we examined the substantial relationship between positron emission tomography/computed tomography (PET/CT) metabolic parameters and the IASLC proposed grading system, while also investigating its potential clinical utility. ***Materials and Methods:*** This study included a total of 1,837 patients who underwent preoperative PET/CT scan and complete resection for clinical stage IA lung adenocarcinoma. A logistic regression model was implemented to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) for clinical and pathological variables. Furthermore, we employed receiver operating characteristic curve analysis to ascertain optimal cutoff values for PET/CT metabolic parameters. Survival analysis was conducted using the Kaplan-Meier method. ***Results:*** The multivariate logistic regression analysis of Grade 3 tumors revealed that male gender, pure solid radiological types, and maximum standardized uptake value (SUVmax) were significant predictive factors (p<.001 for all). The interaction between radiological type and SUVmax was significant (OR 1.31, 95% CI 1.27-1.34, p<.001), indicating that the optimal cutoff value of SUVmax for predicting grade 3 tumors may vary among subsolid and solid nodules. The optimal cutoff value for grade 3 tumor prediction was determined to be 3.35 for the entire cohort, 4.25 for pure solid nodules, and 2.30 for subsolid nodules, with area under the curve values of 0.852, 0.791, and 0.795, respectively. The violin plots demonstrated that the proportion of high-grade patterns in Grade3 lung adenocarcinoma was notably higher in pure solid nodules than in subsolid nodules, which partly explains the potential reason for the different prediction cutoff values. Survival analysis revealed that sublobar resection was associated with a markedly worse prognosis than lobectomy for patients with pure solid nodules and an SUVmax greater than 4.25 (p<.01 for both recurrence-free survival and overall survival). Conversely, the survival rate of sublobar resection and lobectomy was comparable in the entire cohort and subsolid nodules (p>.05 for all). ***Conclusion:*** The SUVmax harbors the potential to predict the histological grade, and the predicted cutoff value varies by radiological nodule type. Preoperative prediction of histologic type facilitates individualized surgical decision-making for clinical stage IA invasive lung adenocarcinoma. The clinical versatility of PET/CT metabolic parameter prediction contributes to further validation for replication.

OP-175

Added Value of Zero-Time Echo (ZTE) Sequence in Evaluating ^{18}F-FDG Positive Pulmonary Nodules on ^{18}F-FDG PET/MRI in Oncologic Patients: Preliminary Findings

S. Gulbahar Ates, *U. Aydos, S. B. Kucukali, S. Demir, U. O. Akdemir, L. O. Atay;*
Gazi University Faculty of Medicine, Ankara, TÜRKIYE.

Aim/Introduction: This study aimed to evaluate the effectiveness of zero-time echo (ZTE), T1-weighted water (T1_W), in-phase (T1_IP), and out-of-phase (T1_OP) MR sequences in identifying anatomical correlates of FDG-avid pulmonary nodules, and to optimize PET/MRI protocol for lung nodules. ***Materials and Methods:*** Patients who underwent FDG PET/MRI for oncologic indications, had either simultaneous thoracic PET/CT or a diagnostic CT within one month, and had at least one FDG-avid pulmonary nodule were included. The number of FDG-avid nodules, the localization, SUVmax, detectability of nodules, and sizes of the two largest and the smallest nodules on each sequence and CT were recorded. The presence and size of nodules on CT were accepted as the reference. The detection rates of nodules across sequences were compared using Cochran's Q and McNemar tests, while nodule sizes were compared using Friedman and Wilcoxon tests. The relationship between nodule detectability on MR sequences and their location or SUVmax was evaluated using Mann-Whitney U test. ***Results:*** 112 nodules from 65 patients (42 males (64.6%), 23 females (35.4%); median age 63 (53.5-68.5)) were included. The mean number of FDG-avid nodules per patient was 2.9±3.2. The median size of nodules on CT was 8 mm (3-27). Nodule detection rates for MR sequences were calculated as 33.9% for T1_W, 64.3% for T1_IP, 73.2% for T1_OP, and 97.3% for ZTE ($p<0.001$). ZTE demonstrated a significantly higher detection rate than other T1-weighted MR sequences ($p<0.001$). Among the three nodules not visualized on ZTE, two were ≤4 mm, and one, despite being 13 mm, was perihilar and indistinguishable from bronchovascular structures. When the T1-weighted sequences were compared with each other, the detection rate of T1_OP was significantly higher than the others, and T1_IP was significantly superior to T1_W ($p<0.05$). For nodules ≤ 4 mm in size, the detection rates were 5.9% for T1_W, 23.5% for T1_IP, 41.2% for T1_OP, and 88% for ZTE. When nodule sizes measured on MR sequences were compared to CT, no significant difference was observed between ZTE and CT ($p=0.083$), while T1 sequences underestimated nodule sizes ($p<0.001$). SUVmax of nodules detectable on T1 sequences were significantly higher than those of undetectable ones($p<0.001$). No significant association was found between nodule localization and detectability ($p>0.05$). ***Conclusion:*** The ZTE sequence outperforms other T1-weighted MR sequences in detecting FDG-avid pulmonary nodules on PET/MRI, with detection rates similar to CT, thereby reducing the need for additional thoracic CT scans.

Preclinical development of novel AR-targeted PET radioactive probe in prostate cancer

S. Lin, *B. Gu, X. Wang, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Prostate cancer is an androgen-dependent malignancy. Therefore, patients with prostate cancer receive endocrine therapy as a routine treatment. However, the heterogeneous expression of androgen receptor (AR) in prostate cancer patients presents significant challenges for the selection of appropriate anti-androgen therapies. Thus, in this study, we aimed to develop AR-targeted ^{68}Ga-IsosilybinB-FZAR PET radiotracer for detecting AR expression in prostate cancer. ***Materials and Methods:*** An AR-targeted radioactive probe ^{68}Ga-IsosilybinB-FZAR was synthesized, and the radiochemical purity and stability were evaluated by radio-HPLC. The positive or negative expressing-AR cell lines were screened by western blot assay. The targeting performance of ^{68}Ga-IsosilybinB-FZAR was characterized in vitro and in vivo. PET/CT imaging of tumor-bearing mouse models was used to assess the distribution and metabolism of ^{68}Ga-IsosilybinB-FZAR in vivo. Tumor autoradiography and immunohistochemistry were employed to validate the expression of AR in tumor tissues. ***Results:*** The radiochemical purity of ^{68}Ga-IsosilybinB-FZAR was more than 95%, and exhibited high stability in saline and fetal bovine serum for 2 h. IsosilybinB-FZAR showed a high binding affinity to AR with an excellent K_d value of 23.34 nM. PET/CT imaging of the tumor-bearing mice showed that ^{68}Ga-IsosilybinB-FZAR could specifically aggregate in AR-positive LNCaP tumors (0.5 h: 8.10 ± 0.44 %ID/g; 1 h: 6.83 ± 0.55 %ID/g; 2 h: 5.80 ± 0.46%ID/g) and 22RV1 tumors (0.5 h: 5.33 ± 0.91 %ID/g; 1 h: 3.23 ± 0.95 %ID/g; 2 h: 2.13 ±0.47 %ID/g), whereas the AR-negative PC-3 tumors revealed significantly lower uptake of ^{68}Ga-IsosilybinB-FZAR (0.5 h: 1.50 ± 0.20 %ID/g; 1 h: 0.20 ± 0.17 %ID/g; 2 h: 0.50 ± 0.36 %ID/g, P all < 0.05). Furthermore, ^{68}Ga-IsosilybinB-FZAR was mainly metabolized through liver and urinary system in vivo. Moreover, immunochemistry demonstrated the high expression of AR for LNCaP tumor, intermediate expression for 22RV1 tumor, and negative expression for PC-3 tumor, which in consistent with the results of the tumor autoradiography. The results of H&E staining confirmed the biocompatibility of ^{68}Ga-IsosilybinB-FZAR in vivo. ***Conclusion:*** As the first ^{68}Ga-labelled AR inhibitor, ^{68}Ga-IsosilybinB-FZAR exhibited high affinity and strong specificity to AR-positive cells, suggesting it's a promising PET imaging agent for the management of patients with prostate cancer.

Uncovering the Mechanisms of Action of 212Pb-based PSMA-targeting Radioligand Therapies

F. Liu, *A. Prior, M. E. Monterosso, D. Boucher, S. Shakti, K. Li, A. Sydes, A. Jones, J. Hesse, C. Kim, A. Horsfall, K. Kuan, W. Tieu, S. Rose, A. Karmann, S. Puttick, G. Li, T. Kryza;*
AdvanCell Pty Ltd, Brisbane, AUSTRALIA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) with lutetium-177 (^{177}Lu), a beta-emitter, has been clinically proven to be efficacious for the treatment of prostate cancer (PC). Although emerging clinical data indicate better efficacy with alpha-emitters, the toxicities associated with actinium-225 (^{225}Ac) may limit its broad application, and application in earlier lines of treatment. Lead-212 (^{212}Pb), is a promising isotope for targeted alpha therapy with high linear energy transfer, a half-life of 10.6 hours, and a simple decay scheme. These properties promote efficient killing of PSMA$^+$ PC cells while limiting off-target toxicities. Here we present combined in vitro and in vivo models, omics approaches, and functional assays elucidating the intrinsic cellular mechanisms of response to ^{212}Pb-PSMA RLT. ***Materials and Methods:*** ^{212}Pb-ADVC001, a novel ^{212}Pb-based PSMA-targeting RLT currently in Phase I/II clinical development (NCT05720130) for the treatment of metastatic castration-resistant prostate cancer (mCRPC), was used as ^{212}Pb RLT. The cytotoxic activity in PC cell lines was measured by cell viability assays and in vivo studies. The kinetic mechanisms associated with ^{212}Pb-ADVC001 mediated cell-death were assessed in vitro and ex

vivo using transcriptomics and proteomics approaches, and their impact on the PC cell cycle by flow cytometry. ***Results:*** ^{212}Pb-ADVC001 displayed potent cytotoxic activity with an average EC50 of 2.7, 7.2 and 3.3 kBq/mL in PC cell lines PC-3-PIP (PSMA^{high}), C4-2 (PSMA^{int}) and LNCaP (PSMA^{int}), respectively. Transcriptomic analysis of in vitro treated PC cells and proteomic analysis of tumors harvested longitudinally revealed multiple mechanisms of action involving DNA damage, cell cycle arrest and cell death, and immune response modulation. In vitro cell cycle experiment further confirmed that ^{212}Pb-ADVC001 caused significant DNA damage, and reduced DNA content in the S-phase of the cell cycle with a concomitant increase in the G1 and G2/M-phase arrest compared to ^{177}Lu-PSMA-I&T ($p<0.05$). ***Conclusion:*** Transcriptomic and proteomic analyses indicate multiple ^{212}Pb-PSMA treatment mechanisms of action collectively resulting in effective cancer cell kill. Mechanistic studies furthered the understanding of PC radiobiology and cellular responses to beta- and alpha-based RLT with the identification of a cell cycle arrest in PC specifically induced by ^{212}Pb-PSMA.

OP-178

First-in-human study of novel PSMA-targeted agents, [^{68}Ga]Ga-AAZTA-PSMA-093 and [^{68}Ga]Ga-AAZTA-NI-PSMA-093: dosimetry and initial evaluation in prostate cancer patients

G. Wang[1], *Y. Lai*[1], *W. Jin*[2], *Y. Luo*[2], *H. F. Kung*[3], *L. Zhu*[2], *W. Miao*[1];
[1]*the First Affiliated Hospital, Fujian Medical University, Fuzhou, CHINA,* [2]*Beijing Normal University, Beijing, CHINA,* [3]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Our team previously designed two novel PSMA-targeted compounds, AAZTA-PSMA-093 and AAZTA-NI-PSMA-093 (incorporating a hypoxia-sensitive nitroimidazole[NI]-moiety). Preclinical studies had confirmed their favorable tumor uptake and retention characteristics. This prospective trial aimed to further evaluate the clinical application value of both agents in prostate cancer (PCa) patients. ***Materials and Methods:*** A total of 60 patients were enrolled in the study, 30 patients underwent a head-to-head comparison between [^{68}Ga]Ga-AAZTA-PSMA-093 and [^{68}Ga]Ga-PSMA-11/[^{68}Ga]Ga-PSMA-617 PET/CT, while another 30 patients were compared between [^{68}Ga]Ga-AAZTA-NI-PSMA-093 and [^{68}Ga]Ga-AAZTA-PSMA-093 PET/CT. The number of tumors and the maximum standardized uptake value (SUV_{max}) for tumors were measured and recorded. Besides, we calculated the SUV_{max} differences of (ΔSUV_{max}) between [^{68}Ga]Ga-AAZTA-NI-PSMA-093 minus [^{68}Ga]Ga-AAZTA-PSMA-093 PET/CT for further analysis. ***Results:*** The patients tolerated [^{68}Ga]Ga-PSMA PET/CT scans well. Both [^{68}Ga]Ga-AAZTA-PSMA-093 and [^{68}Ga]Ga-AAZTA-NI-PSMA-093 showed human biodistribution similar to other PSMA-targeting radiopharmaceuticals. [^{68}Ga]Ga-AAZTA-PSMA-093 PET/CT exhibited higher tumor uptake compared to [^{68}Ga]Ga-PSMA-11 (SUV_{max}: 22.2 ± 10.8 vs. 20.4 ± 14.8, P = 0.025) and [^{68}Ga]Ga-PSMA-617 PET/CT (SUV_{max}: 20.1 ± 12.7 vs. 10.8 ± 8.7, P < 0.001), with a comparable detected number of tumors. [^{68}Ga]Ga-AAZTA-NI-PSMA-093 showed further improved tumor uptake relative to [^{68}Ga]Ga-AAZTA-PSMA-093 PET/CT (SUV_{max}: 17.8 ± 14.0 vs. 16.3 ± 11.5, P = 0.009), particularly in large-volume intraprostatic lesions (ΔSUV_{max} for tumor with diameter of ≥ 2.5 cm and < 2.5 cm, median 0.7 [IQR -2.2 - 8.0] vs. median -2.7 [IQR -5.4 - -0.4], P = 0.039) and primary PCa with high Gleason Score (Gleason Score ≥ 8 and < 8, median 1.1 [IQR -2.5 - 7.3] vs. median -2.4 [IQR -5.9 - -0.1], P = 0.041). However, within the limited sample size, there was no statistically significant difference in prostate cancer lesion detection rates between the two agents. ***Conclusion:*** Both AAZTA-PSMA-093 and AAZTA-NI-PSMA-093 represent promising PSMA-targeted radiopharmaceuticals with high clinical potential. The uptake of [^{68}Ga]Ga-AAZTA-NI-PSMA-093 in high tumor burden prostate cancer and metastatic lesions than that of [^{68}Ga]Ga-AAZTA-PSMA-093 may be attributed to its hypoxia-responsive moiety, which may provide new direction for precision imaging and therapy of PCa in the future. Further research is required to validate these findings.

Preclinical Assessment of Novel [^{99m}Tc][Tc(N)(PNP3OH)]$^{2+}$-labelled PSMA inhibitor with Improved Pharmacokinetics for Enhanced Prostate Cancer Detection

C. Bolzati[1], *J. Kleynhans*[2], *C. Gobbi*[1], *I. Hawala*[3], *S. Ghiani*[4], *A. Maiocchi*[5], *F. Cleeren*[2], *N. Salvarese*[1];

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is an optimal biotarget for prostate cancer (PCa) diagnosis and therapy due to its overexpression in PCa lesions. PSMA also appears to play an important role in triple negative breast cancer and renal cancer, opening the possibility of broadening the application to non-prostatic tumors. Although ^{68}Ga-labelled small molecular weight PSMA inhibitors (PSMAi) have proved high specificity in PCa detection by PET, limited availability and high cost of PET equipment hinder their use in routine clinical practice, especially in remote areas. Recently, several ^{99m}Tc-labelled PSMAi derivatives have been evaluated as more cost-effective analogues of ^{68}Ga- or ^{111}In-tracers for PCa diagnosis. Although these offer advantages over ^{111}In-PSMAi, none outperform the corresponding PET agents. Drawbacks are due to their kidney accumulation and unfavourable clearance from hepatobiliary and intestinal tracts. However, the low-cost and easily available SPECT technique, which predominantly utilizes technetium-99m, could provide a viable alternative for large-scale clinical implementation. Exploiting the advantages of the [TcN(PNP)]-system (PNP=bisphosphino-amine), our aim is to develop a novel ^{99m}Tc-labelled PSMAi with enhanced pharmacological/pharmacokinetic properties to improve lesion detection in primary tumours and metastases during SPECT imaging and surgical procedures. ***Materials and Methods:*** [^{99m}Tc][Tc(N)(PNP3OH)]$^{2+}$-labelled PSMAi (PNP3OH=N,Nbis[(di-hydroxymethylphosphinoethyl)]methoxyethylamine), ^{99m}Tc1 (WO2018109164A1), was prepared, preclinically evaluated, and compared with the clinically tested [^{99m}Tc][Tc-HYNIC]-iPSMA. Log $D_{7.4}$, stability, and target affinity in PSMA(+) (PC3-PIP, LNCaP) and PSMA(-) PC3 cell lines were assessed. Biodistribution and imaging studies of ^{99m}Tc1 were accomplished in PC3-PIP/PC3 tumour-bearing mice. ***Results:*** ^{99m}Tc1 was efficiently prepared with RCP>95% (molar activity 30 GBq/μmol). The compound showed low lipophilicity (^{99m}Tc1 $LogD_{7.4}$ = -2.38), minimal plasma proteins binding, and high in vivo stability. Internalization in PSMA(+) cells was high (13.70±1.0 - 12.49±0.5 %/10^6 cells). Uptake was reduced by lowering the temperature and also effectively blocked with H3NSCys-PSMAi excess. Biodistribution studies display a high and specific tumor uptake of ^{99m}Tc1, the positive-to-negative ratio was 4.37 vs 2.87 of [^{99m}Tc][Tc-HYNIC]-iPSMA. The clearance from the non-target organ was faster for ^{99m}Tc1 than [^{99m}Tc][Tc-HYNIC]-iPSMA, and accordingly a higher target-to-background ratio was reached. No uptake was evident in spleen, and, more importantly, at 1 h after injection a negligible kidneys accumulation was found, which became undetectable at 4 h. ***Conclusion:*** The high tumour uptake and unprecedent clearance of ^{99m}Tc1 from blood and non-target tissues make it a promising new radioligand for PSMA SPECT imaging and RGS. Mouse digital twin for [^{177}Lu]Lu-PSMA10.1 to enable individualised therapy.

G. Costa[1,2], *E. Yousefzadeh-Nowshahr*[1], *V. Vasic*[1], *B. Sun*[3], *L. Nagel*[3], *A. Wurzer*[3], *F. Schilling*[3], *A. Beer*[2], *W. Weber*[3], *S. Kossatz*[3], *G. Glatting*[1,2];
[1]*Uni Ulm, Ulm, GERMANY,* [2]*Uniklinik Ulm, Ulm, GERMANY,* [3]*Technische Universität München, Munich, GERMANY.*

Aim/Introduction: Although prostate-specific membrane antigen (PSMA) labelled with Lutetium-177 (^{177}Lu) is a well-established therapy for prostate cancer, the variability in the effectiveness of treatments is not fully understood. Exploring the pharmacokinetics through a physiologically based pharmacokinetic (PBPK) model may assist in understanding this variation which could, help individualising the therapy. Among different PSMA ligands, the radiohybrid rhPSMA-10.1 has the advantage of identical pharmacokinetics when used for PET imaging as [^{18}F]-^{nat}Lu-rhPSMA-10.1 and for therapy as ^{nat}F-[^{177}Lu]rhPSMA-10.1. The ligand also shows low kidney uptake and fast blood pool excretion while maintaining high tumour accumulation. This work aims to develop a digital twin with PBPK models and define an optimal SPECT imaging schedule for imaging-based dosimetry for mice after rhPSMA-10.1 infusion. ***Materials and Methods:*** The digital twins were developed by adapting an available human PBPK model [1] and fitting its parameters (e.g. receptor densities, blood flows, glomerular filtration rate, etc.) to biodistribution studies from 5 mice that received [^{177}Lu]Lu-PSMA10.1. The time-activity curves were generated for typical clinical schedules (4 h to 7 d), and assuming a human-to-mouse time scaling factor of about 7 and restrictions under animal welfare and working hours. Schedules with 2, 3, 4, and 5 time points were evaluated with combinations of 30 min, 3 h, 6 h, 24 h, and 48 h after injection, where the kidneys, tumour, and liver activities were simulated using the digital twin with an added 20% Gaussian noise to mimic measurement errors. The parameters of the PBPK model were fitted to these measurements. This process was replicated 1000 times, and the time-integrated activity (TIA) was calculated and compared with the digital twin. The relative root mean squared error (rRMSE) with the lowest value was ranked as the best schedule. ***Results:*** 20,000 replications were computed, and the rRMSE was the lowest for the schedule (3h, 6h, 24 h) when compared to all two- or three-timepoint schedules, with rRMSE being 11.0%, 11.4%, and 6.8% for the kidneys, tumour, and liver, respectively. The 5-timepoint schedule (not allowed for this project) yielded the lowest rRMSE for the organs mentioned above, with 8.6%, 9.4%, and 4.0%, respectively. ***Conclusion:*** A therapy measurement protocol at 3h, 6h, and 24 h after injection yielded optimal imaging-based dosimetry. By adding a 30-minute time point, a similar or worse rRMSE was found, suggesting that an (difficult to obtain) early time point is not necessary. ***References:*** [1] Kletting et al., J Nucl Med 2019

OP-181

A Preclinical Evaluation on the Radiohybrid Tandem [^{18}F]La- and [^{225}Ac]Ac-rhPSMA-10.1 for Targeted Alpha Therapy of Prostate Cancer

B. Sun[1,2], *A. Morgenstern*[3], *F. Bruchertseifer*[3], *S. Kossatz*[1,2], *M. Eiber*[1], *W. Weber*[1], *C. D'Alessandria*[1], *A. Wurzer*[1];
[1]*Department of Nuclear Medicine, TUM University Hospital, School of Medicine and Health, Technical University of Munich, Munich, GERMANY,* [2]*Central Institute for Translational Cancer Research (TranslaTUM), Technical University of Munich, Munich, GERMANY,* [3]*European Commission, Joint Research Centre, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted alpha therapy emerged as a promising treatment option for advanced metastatic castration-resistant prostate cancer. Imaging and dosimetry of ^{225}Ac-PSMA ligands remain challenging because of suboptimal decay properties for SPECT. Radiohybrid (rh) ligands can be labelled with a radiometal for therapy or ^{18}F for imaging. The ^{18}F-labelled ligand, complexed with the natural metal, displays the identical chemical structure and pharmacokinetics compared to the therapeutic agent. In the present study, we therefore evaluated a rh ^{225}Ac-labelled PSMA-targeted ligand ([^{225}Ac]Ac-rhPSMA-10.1). [^{18}F]La-rhPSMA-10.1, complexed with natural lanthanum, mimicking the complex structure of ^{225}Ac, was investigated as a corresponding PET imaging agent. ***Materials and Methods:*** Cell studies (affinity, internalization, externalization) of [^{225}Ac]Ac-rhPSMA-10.1 and [^{18}F]La-rhPSMA-10.1 were performed on LNCaP and PC3Pip cells in comparison to the references [^{225}Ac]Ac-PSMA-I&T and [^{225}Ac]Ac-PSMA-617. For evaluation of the efficacy, LNCaP tumour-bearing mice (groups n=6) received a single injection of different doses of [^{225}Ac]Ac-rhPSMA-10.1 (20, 30 and 40 kBq; 0.2-0.4 nmol), [^{225}Ac]Ac-PSMA-I&T (20 kBq; 0.2 nmol), versus non-radioactive rhPSMA-10.1 (control; 1 nmol) and were followed for 60 days. The pharmacokinetics of [^{18}F]La-rhPSMA-10.1 were determined via PET-imaging and ex-vivo biodistribution analysis (10 min-4 h p.i.). ***Results:*** [^{225}Ac]Ac-rhPSMA-10.1 (4-7 MBq, 0.1-0.2 MBq/nmol) and [^{18}F]La-rhPSMA-10.1 (1-4 GBq, 50±4% radiochemical yield, 10-30 MBq/nmol) were prepared with ≥95% radiochemical purity. [^{225}Ac]Ac-rhPSMA-10.1 and [^{18}F]La-rhPSMA-10.1 displayed nearly identical cellular uptake and retention, falling in a similar range as the references. For all injected activities, tumour volumes declined in a similar way from day 7 p.i. onwards. At day 28, mean tumour volume relative to baseline had decreased by 39±17% for [^{225}Ac]Ac-PSMA-I&T; and 44±25%, 54±21%, 54±12% for 20, 30 and 40 kBq [^{225}Ac]Ac-rhPSMA-10.1, respectively. Median survival was 12 d in the control group and was not reached for the 20 and 30 kBq [^{225}Ac]Ac-rhPSMA-10.1 groups. In the 20 kBq [^{225}Ac]Ac-PSMA-I&T and 40 kBq [^{225}Ac]Ac-PSMA-rhPSMA-10.1 groups, two and three mice, respectively, had to be sacrificed due to low body condition scores, resulting in median survival of 59 and 60 days. [^{18}F]La-rhPSMA-10.1 demonstrated fast clearance from background tissues via renal excretion and tumour uptake of 12.8±4.2 %ID/g at 10 min, which was maintained over 4 h (12.7±3.1 %ID/g). ***Conclusion:*** [^{225}Ac]Ac-rhPSMA-10.1 revealed high anti-tumour efficacy with low side effects at 20 and 30 kBq, highlighting its potential for targeted alpha therapy of prostate cancer. [^{18}F]La-rhPSMA-10.1 showed favourable pharmacokinetics for PET-imaging and further studies on its suitability as a PET-surrogate for [^{225}Ac]Ac-rhPSMA-10.1 have been initiated.

Aim/Introduction: Efficient targeting of disseminated solid tumors remains a critical challenge in oncology. While selective monoclonal antibodies can be easily raised against tumor targets, their size hinders rapid and homogeneous tumor penetration [1]. Small organic ligands with ultra-high affinity for tumor-specific markers offer superior pharmacokinetics and tumor penetration [1,2]. Here, we report the discovery of OncoACP3 (ProX1), the first-in-class high-affinity small molecule ligand for prostatic acid phosphatase (ACP3), a promising, underexplored prostate cancer target for radioligand theranostic applications with minimal expression in healthy organs [3]. ***Materials and Methods:*** OncoACP3 was identified through high-throughput screening of DNA-encoded chemical libraries (DELs) [4]. Binding affinity to ACP3 was assessed via surface plasmon resonance. OncoACP3 was conjugated to Lutetium-177 (^{177}Lu) for in vivo evaluation. Tumor targeting, pharmacokinetics, biodistribution, and therapeutic efficacy were investigated in mouse models bearing ACP3-

positive tumors. ***Results:*** OncoACP3 demonstrated picomolar affinity for ACP3 and negligible off-target binding. Radiolabeled ^{177}Lu-OncoACP3 selectively accumulated in ACP3-positive tumors with exceptionally high tumor-to-blood ratios (>148 at 2 h) and prolonged tumor residence time ($t_1/_2$ > 72 h). In in vivo therapy experiments, low-dose administration (5-20 MBq/injection) of ^{177}Lu-OncoACP3 led to complete tumor regression in mice, without observable toxicity. Notably, no significant uptake was detected in kidneys or salivary glands, suggesting a more favorable safety profile than PSMA-targeting agents [5]. ***Conclusion:*** OncoACP3 represents a potent and selective tumor-targeting ligand for prostate cancer, offering advantages over existing PSMA-targeted therapies. These findings highlight the potential of DEL-derived ligands for targeting tumor-specific antigens with high precision and minimal off-target effects. OncoACP3 may pave the way for new targeted radiopharmaceuticals against local and metastatic prostate cancer. ***References:*** (1) Thurber, G. M., Schmidt, M. M. & Wittrup, K. D. Radiolabeling of PSMA-functionalized Gold Nanoparticles with Terbium-161 for prostate cancer theranostics

A. Apostolopoulou*[1], D. Bajwa[1], E. Salvanou[1], S. Koelewijn[2], P. van Overeem[2], C. Liolios[1], S. Xanthopoulos[1], P. Koźmiński[3], P. Bouziotis[1]; [1]National Center for Scientific Research "Demokritos", Athens, GREECE, [2]Terthera b.v., Breda, NETHERLANDS, [3]Centre of Radiochemistry and Nuclear Chemistry, Institute of Nuclear Chemistry and Technology, Warsaw, POLAND.*

Aim/Introduction: Gold nanoparticles (AuNPs) have been widely used in cancer diagnosis and therapy since their nanoscale size offers several advantages such as low toxicity, satisfactory biocompatibility and enhanced permeability due to the EPR effect. By introducing targeting moieties, AuNPs can go directly to tumor sites and remain there, thus minimizing side effects. Terbium-161 (^{161}Tb) is a radiolanthanide with a half-life of 6.9 days that decays to stable Dysprosium-161 (^{161}Dy) through beta– (β^-) emission. This isotope emits a considerable number of conversion and Auger electrons along with beta particles, which deliver localized radiation within cancer cells, enhancing the damaging of the DNA of tumors. The aim of our study was to radiolabel AuNPs with and without a PSMA-targeting molecule with ^{161}Tb. Radiolabeling was achieved via the macrocyclic TADOTAGA chelator, which is extensively used for binding trivalent metals such as ^{161}Tb. The AuNPs were functionalized with TADOTAGA through the available thiol group which forms very strong Au-S bonds. ***Materials and Methods:*** AuNPs with the TADOTAGA chelator (AuNPs@TADOTAGA) and the PSMA-targeting molecule (AuNPs@TADOTAGA@PSMA) were radiolabeled with $^{161}TbCl_3$. Radiolabeling yield was determined by instant thin-layer chromatography (ITLC). In vitro stability studies were also carried out for both radiolabeled AuNPs in the presence of PBS (pH 7.4) at RT, as well as in Human Serum and DTPA as the competing chelating agent at 37°C, for up to 15 days. In vitro cytotoxicity studies were also carried out against LNCaP and PC3 cell lines up to 72 h using the MTT colorimetric assay. ***Results:*** The nanoparticles were radiolabeled after incubation at 70°C achieving a radiolabeling yield of more than 95% for both nanoconstructs. They also demonstrated unique in vitro stability in all solutions, as evaluated by ITLC analysis which makes them both very promising candidates for in vivo applications. The cytotoxicity studies revealed [^{161}Tb]Tb-AuNPs@TADOTAGA cause a greater reduction in cell viability in LNCaP cells, while PC3 cells display higher resistance to the ^{161}Tb-labeled AuNPs. Functionalization with PSMA ([^{161}Tb]Tb-AuNPs@TADOTAGA@PSMA) further enhances cytotoxicity in LNCaP cells, thus confirming the role of PSMA targeting. In contrast, PC3 cells (which are PSMA negative), show minimal changes in viability. ***Conclusion:*** Based on these preliminary results, we conclude that both ^{161}Tb-labeled nanocomplexes should be further investigated in athymic mice bearing LNCaP tumor xenografts, to assess their potential tumor accumulation with and without targeting. ***References:*** [1] Salvanou, E.-A. et al., Materials 2025, 18, 248. From Beta to Alpha: A Preclinical Comparison of ^{177}Lu-, ^{225}Ac- and ^{212}Pb-labeled PSMA-N139

L. Joosten*[1], G. Franssen[1], D. Löwik[2], P. Laverman[1], J. Nagarajah[1], Y. Buchatskaya[3], M. Konijnenberg[4], S. Heskamp[1], Y. Derks[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]Radboud University, Nijmegen, NETHERLANDS, [3]Nuclear Research & Consultancy Group, Petten, NETHERLANDS, [4]Erasmus University Medical Center, Rotterdam, NETHERLANDS.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) represents a promising approach for the treatment of metastatic prostate cancer (mPCa). While β-emitting radionuclides such as ^{177}Lu have been widely studied, increasing interest has turned towards more potent α-emitters, including ^{225}Ac and ^{212}Pb. Here, we compared the biodistribution and dosimetry of a novel DOTA-conjugated PSMA ligand (PSMA-N139), labeled with ^{177}Lu, ^{225}Ac and ^{212}Pb. ***Materials and Methods:*** PSMA-N139 was radiolabeled with ^{177}Lu, ^{225}Ac or ^{212}Pb. Stability in human serum was assessed up to 4h at 37 °C. PSMA-specific binding and internalization were evaluated using LS174T-PSMA cells. Tumor and normal tissue uptake were determined in BALB/c nude mice bearing subcutaneous LS174T-PSMA and LS174T-WT tumors, at multiple timepoints post injection (up to 168h p.i.). Mice received 0.3 nmol radiolabeled PSMA-N139 (^{177}Lu: 2.2 MBq, ^{225}Ac: 14 kBq, ^{212}Pb: 48 kBq). Tumor and organ absorbed doses will be calculated based on the time-activity curves extrapolated from the biodistribution data (ongoing). ***Results:*** PSMA-N139 was labeled with ^{177}Lu (molar activity (MA): 7.35 MBq/nmol, radiochemical purity (RCP): 100%), ^{225}Ac (MA: 45.8 kBq/nmol, RCP: 89.1%) and ^{212}Pb (MA: 160.1 kBq/nmol, RCP: 95.2%), which remained stable up to 4h. PSMA-specific binding and internalization was observed for all three radiopharmaceuticals. In vivo, all radiolabeled PSMA-N139 showed rapid blood clearance and low accumulation in non-target organs. High uptake in the PSMA-positive tumor was observed for PSMA-N139 labeled with ^{177}Lu, ^{225}Ac or ^{212}Pb, with prolonged retention. For example, tumor uptake of ^{177}Lu-, ^{225}Ac-, and ^{212}Pb-PSMA-N139 was 15.9 ± 4.3, 17.2 ± 5.3, and 18.0 ± 5.2 %ID/g, respectively (4h p.i.), and 13.8 ± 3.1, 15.9 ± 5.2, and 14.9 ± 2.4 %ID/g, respectively (24h p.i.). Tumor uptake was still high 7 d p.i. for ^{225}Ac (9.0 ± 2.6 %ID/g) and appreciable for ^{177}Lu (3.3 ± 0.9 %ID/g). As expected, accumulation in the kidney was observed, which decreased rapidly over time. However, kidney accumulation differed significantly between radionuclides: 25.9 ± 8.6, 32.0 ± 5.1, and 67.6 ± 9.4 %ID/g for ^{177}Lu-,^{225}Ac-, and ^{212}Pb-PSMA-N139, respectively (1h p.i.), and 1.8 ± 0.3, 2.6 ± 0.4, and 8.8 ± 3.1 %ID/g, respectively (24h p.i.). ***Conclusion:*** This study presents a direct preclinical comparison of ^{177}Lu-,^{225}Ac-, and ^{212}Pb-

labeled PSMA-N139 and is the first head-to-head comparison of these three isotopes. All three radiopharmaceuticals showed PSMA-specific tumor uptake with good retention. These results show that PSMA-N139 can be used as a versatile platform for PSMA-targeted RLT using β- or α-emitters.

Aim/Introduction: The Neurokinin-1 receptor (NK1R), a member of the G-protein-coupled receptor family, is activated by Substance P. It exists in two isoforms: a full-length (407 amino acids) and a truncated form (lacking 96 residues). NK1R is often overexpressed in cancers, with isoform patterns varying by tumor type—for example, neuroblastoma and breast cancer mainly express the truncated form, while NSCLC may express both. NK1R promotes tumor growth, angiogenesis, metastasis, and inhibits apoptosis, making it a promising theranostic target. ***Materials and Methods:*** Over sixty novel, stable, iodine-containing small molecules were synthesized as potential NK1R-targeting agents. LigandTracer technology was used to screen compounds and assess their binding affinity through competition studies, where FAM-labeled Substance P (FAM-SP) was displaced by an equimolar concentration of molecules. The binding kinetics of FAM-SP to NK1R-transfected cells served as reference molecule. Pharmacokinetic properties were evaluated through in-vitro ADME profiling. Based on these results, top candidates were selected, radioiodinated with [125I], and were isolated using HPLC. Binding of the lead compound was validated on cells transfected with both the full-length and truncated forms of NK1R. Biodistribution studies were carried out in mice bearing NK1R-positive tumors to assess distribution profile of lead molecule. Additionally, in-vivo specificity was evaluated using mice bearing both NK1R-positive and NK1R-negative tumor-xenografts to confirm selective targeting. ***Results:*** Compounds were ranked based on their ADME profiles and ability to displace FAM-SP in competitive binding assays. FAM-SP binding studies to NK1R demonstrated two binding affinities of 171nM and 17nM. Radioiodination of the top candidate was successfully achieved, and post-purification, the compound demonstrated a purity ≥98%. Successful binding of the lead compound was confirmed in cells transfected with either the full-length or truncated form of NK1R. The top candidate exhibited a binding affinity in the picomolar range[UY1] [MN2] , that could be blocked by an excess of the known NK1R inhibitor Aprepitant. In-vivo biodistribution studies revealed a tumor-to-blood ratio exceeding 70 at 24 hours p.i.. Furthermore, selective accumulation was observed in NK1R-positive tumors compared to NK1R-negative tumors. ***Conclusion:*** The lead radioiodinated small molecule demonstrated excellent in vitro binding properties, high specificity for NK1R, and favorable pharmacokinetics. It successfully bound to both full-length and truncated isoforms of NK1R in-vitro, with significantly higher tumor accumulation observed in vivo in NK1R-positive tumors compared to NK1R-negative controls. These findings highlight its strong potential as a promising theranostic agent for imaging and targeted therapy of NK1R-expressing cancers.

Preclinical and first-in-human study of dosimetry and safety for a novel radiopharmaceutical targeting the EGFR mutation in patients with non-small cell lung cancer (NSCLC)

S. Jedidi[1,2], *A. Courteau*[1,2], *B. Presles*[2], *P. S. Bellaye*[1], *B. Collin*[1,2], *N. Isambert*[3], *M. Chafai El Alaoui*[1], *A. Daoust*[4], *C. Berthet*[4], *A. Cochet*[1,2], *J. M. Vrigneaud*[1,2];
[1]*Centre Georges-François Leclerc, Dijon, FRANCE,* [2]*Institut de Chimie Moléculaire de l'Université de Bourgogne (ICMUB), UMR CNRS6302, Université Bourgogne Europe, Dijon, FRANCE,* [3]*CHU Poitiers, Poitiers, FRANCE,* [4]*Oncodesign Precision Medicine, Dijon, FRANCE.*

Aim/Introduction: [18F]-Florepizol is a novel fluorinated PET radiopharmaceutical for imaging of mutated EGFR in non-small cell lung cancer (NSCLC). Biodistribution and absorbed doses of normal organs were quantified in rats and subsequently evaluated in a Phase 0/1 firstinhuman dosimetry study, to determine its safety for clinical use. ***Materials and Methods:*** In the preclinical study, 42 Sprague-Dawley rats (21 males, 21 females) received [18F]-Florepizol intravenously (4.0±0.4 MBq). Animals were sacrificed at 5, 15, 30, 60, 120, 240, and 360 min post-injection. Organs were harvested, weighed, and radioactivity was quantified using a gamma counter. In the clinical study, eight NSCLC patients (4 males, 4 females; 70 ±9 years; 64 ±10 kg) received 300.8 ±36.3 MBq of [18F]-Florepizol as a single intravenous bolus. Eight serial whole-body PET/CT scans were acquired over 4 h, with urine and blood samples collected between or after each scan. Source organs were segmented on CT images using the AI-based tool TotalSegmentator. For both datasets, time-activity curves were fitted and optimised based on the Akaike Information Criterion. Time-integrated activity coefficients of human and animal (with allometric scaling) were then computed and processed in OLINDA/EXM 2.0 for confrontation. ***Results:*** For the preclinical study, the highest fractions of injected activity were found in the colon (20.1% in males, 17.4% in females), bladder (21.3% in males, 15.9% in females), and liver (10.6% in males, 10.4% in females). The corresponding absorbed doses per injected activity were highest in the bladder (0.16 mGy/MBq in females, 0.13 mGy/MBq in males), followed by the colon (0.08 mGy/MBq in females, 0.09 mGy/MBq in males) and liver (0.01 mGy/MBq in both sexes). In patients, the liver retained the highest fraction of injected activity (64.9% in males, 50.6% in females), followed by the small intestine (18.3% in males, 31.9% in females) and gallbladder (12.9% in males, 12.1% in females). The absorbed doses per injected activity reached 0.19±0.02 mGy/MBq in males and 0.20±0.01 mGy/MBq in females for the liver, 0.16±0.05 and 0.16±0.10 mGy/MBq for the gallbladder, and 0.03±0.01 and 0.09±0.04 mGy/MBq for the small intestine. No serious adverse events were recorded across the patient study. ***Conclusion:*** Substantial differences were observed between absorbed doses in human and animal studies. For patients, the

liver and gallbladder were the two dose-critical organs. The mean effective dose was 0.024±0.001 mGy/MBq, supporting its clinical use as a safe molecular imaging tool for EGFR-driven NSCLC.

EPS-045

Design, Synthesis and Preclinical Evaluation of Small Molecular Radiotracers Targeting AVPR2 for PET Imaging in Renal Cell Cancer Xenograft Mice

S. Huang, *T. Tian, R. Huang;*
West China Hospital of Sichuan University, Chengdu, Sichuan, CHINA.

Aim/Introduction: Arginine vasopressin receptor 2 (AVPR2) is a G-protein-coupled receptor expressed in the renal collecting ducts, distal tubules, and nephrons. Its primary function is to regulate water and electrolyte homeostasis through interaction with arginine vasopressin. However, recent studies have shown that AVPR2 activation promotes the proliferation of renal cell carcinoma, and AVPR2 is highly expressed in renal cancer cells. Importantly, AVPR2 antagonists have demonstrated potential in suppressing tumor growth. Therefore, the aim of this study is to develop radiotracers targeting AVPR2 for PET imaging of renal cancer. ***Materials and Methods:*** Radiotracers of ^{68}Ga-HX01, ^{68}Ga-HX02, ^{68}Ga-HX03 were synthesized based on benzodiazepine derivative and tolvaptan. The stability of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 after incubation in 0.9% saline and fetal bovine serum (FBS) at 37 °C for 0 h, 1 h, 2 h and 4 h were measured by radioactive thin layer chromatography. ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were partitioned between 500 µl n-octanol and 500 µl deionized water to evaluate the lipophilicity of them. Cellular uptakes and blocking in Caki-1cell were performed to confirm their specificity for AVPR2. ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were used for PET imaging in Caki-1cell xenograft mice to evaluate the expression of AVPR2. ***Results:*** The radiochemical yields of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were all > 99.0%. The Log P of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were respectively -1.77 ± 0.01, -1.90 ± 0.04 and -2.77 ± 0.05, which indicated ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were hydrophilic. As for the stability of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 in FBS and 0.9% saline, the radiochemical purities of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 were still over 95.0% after 4h. In vitro, the uptake rates of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 in Caki-1 cells continuously increased at 15min, 30min, 60min and 120min. Blocking studies found the uptake rates of ^{68}Ga-HX01, ^{68}Ga-HX02 and ^{68}Ga-HX03 in 60min declined from 1.24 ± 0.07 %, 0.69 ± 0.02 %, 0.36 ± 0.02 % to 0.44 ± 0.03 %, 0.28 ± 0.04 %, 0.21 ± 0.04 % with statistically significant. In vivo, preclinical PET/CT found ^{68}Ga-HX02 and ^{68}Ga-HX03 showed fast excretion from tumor and ^{68}Ga-HX01 had excellent retention capacity in tumor. The ^{68}Ga-HX01 uptake of tumor at 30 min, 60 min and 120 min were 5.36 ± 2.03 %ID/g, 4.51 ± 1.23 %ID/g and 4.20 ± 1.48 %ID/g, respectively. ***Conclusion:*** PET imaging with ^{68}Ga-HX01 is an effective tool to evaluate the expression of AVPR2.

EPS-046

Replacing Ahx with Pip-Lys and the C-terminal Pro with Tic for [^{68}Ga]Ga-Z01115 to improve its bradykinin B1 receptor-targeting capability for positron emission tomography

F. Radnia, *S. Jozi, C. Chen, L. Wang, H. Merkens, P. Ng, F. Bénard, K. Lin;*
BC Cancer Research Institute, Vancouver, BC, CANADA.

Aim/Introduction: Bradykinin B1 receptor (B1R), a G protein-coupled receptor, has minimal expression in healthy tissues but is overexpressed in many cancers, making it a promising diagnostic target. Our previous studies showed that the B1R-targeted agonist PET tracer [^{68}Ga]Ga-Z01115 (^{68}Ga-DOTA-Ahx-Lys-Arg-Pro-Hyp-Gly-Cha-Ser-Pro-D-Phe) had good binding affinity (K_i = 25.4 nM) and tumor uptake in B1R-expressing HEK293T::hB1R xenografts (5.65 %ID/g at 1 h post-injection). This study explored the impact of (1) replacing the Ahx linker with a cationic Pip-Lys, and (2) substituting the C-terminal Pro with the unnatural amino acid Tic on its B1R-targeting capability. ***Materials and Methods:*** Two B1R-targeted peptides, AR-B1R-D (DOTA-Pip-Lys-Lys-Arg-Pro-Hyp-Gly-Cha-Ser-Pro-D-Phe) and AR-B1R-E (DOTA-Pip-Lys-Lys-Arg-Pro-Hyp-Gly-Cha-Ser-Tic-D-Phe), were synthesized via solid-phase synthesis. ^{nat}Ga and ^{68}Ga complexations were performed in sodium acetate buffer (0.1 M, pH 4.5) and HEPES buffer (2 M, pH 5.0), respectively. B1R binding affinities were measured via in vitro competition assays using B1R-expressing CHO-K1 cell membranes and [^{3}H]-[Leu^{9},des-Arg^{10}]Kallidin as the radioligand. Intracellular calcium release was measured in HEK293T::hB1R cells using the FLIPR Calcium 6 Assay Kit. The agonist and antagonist controls were Lys-[des-Arg^{9}] Bradykinin and Lys-[Leu^{8},des-Arg^{9}]Bradykinin, respectively. PET/CT imaging and biodistribution studies were conducted at 1 h post-injection in NRG mice bearing both B1R-positive HEK293T::hB1R and B1R-negative HEK293T tumor xenografts. ***Results:*** AR-B1R-D and AR-B1R-E were synthesized in 6% and 11% yields, respectively. ^{nat}Ga-AR-B1R-D and ^{nat}Ga-AR-B1R-E were obtained in 50% and 80% yields, respectively. ^{68}Ga-labeled tracers were obtained in 37-50% decay-corrected radiochemical yields with >98% radiochemical purity. Binding assays showed that Ga-AR-B1R-D and Ga-AR-B1R-E effectively inhibited binding of [^{3}H]-[Leu^{9},des-Arg^{10}]Kallidin to B1R-expressing CHO-K1 cell membranes with K_i values of 2.30 and 1.67 nM, respectively. Ga-AR-B1R-D induced strong calcium release similar to the agonist control, while Ga-AR-B1R-E showed a moderate response, resembling the antagonist control. Both [^{68}Ga] Ga-AR-B1R-D and [^{68}Ga]Ga-AR-B1R-E enabled clear visualization of HEK293T::hB1R tumors, but not the B1R-negative HEK293T tumors in PET images, and their excretion was mainly via the renal pathway. The tumor uptake values of [^{68}Ga] Ga-AR-B1R-D and [^{68}Ga] Ga-AR-B1R-E were 8.02 ± 2.09 and 11.2 ± 4.83 %ID/g, respectively. The uptake values of collected normal organs/tissues except kidneys were minimal (<1 %ID/g) for both tracers. ***Conclusion:*** Our data demonstrate that replacing Ahx in [^{68}Ga]Ga-Z01115 with a cationic linker Pip-Lys improves B1R binding affinity and tumor uptake. Further improvement in B1R binding affinity and tumor uptake could also be achieved by replacing the C-terminal Pro with Tic. However, this additional replacement converts an agonist to an antagonist.

EPS-047

Radiosynthesis and evaluation of a novel ^{68}Ga labeled B7-H3 targeted peptide

F. Zhang, *J. Li, S. Song;*
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, shanghai, CHINA.

Aim/Introduction: B7 homolog 3 protein (B7-H3, also known as CD276), a recently identified immunoregulatory protein member of the B7 family, is overexpressed in various tumors and within the tumor mircroenvironment (TME). Several therapeutic agents targeting B7-H3 have advanced to clinical trials, demonstrating promising efficacy. To enable precise and non-invasive monitoring of B7-H3 expression in vivo, we developed a novel ^{68}Ga-labeled peptide-based radiotracer. This tracer facilitates highly specific and selective molecular imaging of B7-H3 via positron emission tomography (PET). ***Materials and Methods:*** ^{68}Ga-DOTA-B7H3 was successfully synthesized, and its radiochemical purity (RCP) was assessed by Radio-TLC and Radio-HPLC. Additional evaluations included stability testing, determination of the octanol/water partition coefficient (log P), and measurement of its biological half-life. The binding affinity of ^{68}Ga-DOTA-B7H3 to B7-H3 protein was quantified using surface plasmon resonance (SPR). Furthermore, cellular uptake assays and PET imaging studies were conducted across six tumor cell lines (5-8F, C666-1, HT29, SKOV3, PC3, H1299) with varying B7-H3 expression levels. ***Results:*** ^{68}Ga-DOTA-B7H3

exhibited high radiolabeling efficiency, with stability in saline and serum remaining above 95% over 2 hours. The log P value was determined to be -2.1 ± 0.12 (n = 5), indicating pronounced hydrophilicity. The blood half-life of the probe was 17.2 ± 1.4 min (n = 5). SPR analysis revealed a dissociation constant (K_D) of 83.22 nM, while the half-maximal inhibitory concentration (IC_{50}) in 5-8F cells was 73.5 nM. Cellular uptake was significantly higher in non-blocked groups compared to blocked controls and exhibited a positive correlation with B7-H3 expression across different cell lines. PET imaging demonstrated differential tumor uptake at 30 minutes post-injection, with the highest accumulation observed in the 5-8F model (2.53 ± 0.06 %ID/g_{max}), followed by HT-29 (2.07 ± 0.06 %ID/g_{max}), SKOV3 (1.93 ± 0.23 %ID/g_{max}), C666-1 (1.67 ± 0.38 %ID/g_{max}), PC-3 (1.57 ± 0.25 %ID/g_{max}), and H1299 (0.99 ± 0.01 %ID/g_{max}) (n = 3). These findings were consistent with Western blot (WB) analysis of B7-H3 expression levels. ***Conclusion:*** The successful synthesis of ^{68}Ga-DOTA-B7H3 was achieved with high radiochemical purity. The probe demonstrated strong binding affinity for B7-H3, and tumor uptake correlated with B7-H3 expression, confirming its specificity. These results suggest that ^{68}Ga-DOTA-B7H3 represents a promising diagnostic tool for the non-invasive detection of B7-H3-expressing malignancies in clinical settings.

EPS-048

Preclinical evaluation of a novel click-cleavable radioimmunoconjugate for improved therapy of HER2 expressing tumours

M. H. M. E. van Stevendaal[1], *K. E. de Roode*[1], *L. H. M. Zijlmans*[1], *B. Matthee*[1], *M. W. Konijnenberg*[2], *M. S. Robillard*[1], *R. Rossin*[1];
[1]Tagworks Pharmaceuticals, Nijmegen, NETHERLANDS, [2]Erasmus Medical Center, Rotterdam, NETHERLANDS.

Aim/Introduction: Radioimmunotherapy (RIT) is hampered by the long circulation of mAbs, resulting in dose-limiting toxicity. Tagworks' TGW211 program aims at solving this issue for HER2+ tumours. A trastuzumab conjugate, TGW211-DC, functionalized with DOTA via a cleavable trans-cyclooctene (TCO) linker, releases the radiolabel in circulation upon a bioorthogonal click-to-release reaction with a cell-impermeable tetrazine trigger (TRG001), boosting target-to-nontarget ratios. ***Materials and Methods:*** Release of [^{111}In]In-DOTA from [^{111}In]In-TGW211-DC upon addition of a trigger was measured in PBS and serum. [^{111}In]In-TGW211-DC binding and internalization were characterized using HER2-expressing BT-474 cells. In vivo pharmacokinetics and biodistribution were determined in nude mice +/- BT-474 xenografts, alone or in combination with a trigger. The toxicity of a single i.v. TGW211-DC dose, with or without TRG001, was evaluated in mice with a 1- and 14-day observation period. Safety of TRG001 alone was evaluated in rat and cynomolgus monkey in a repeat-dose 5-week toxicology study. Clinical data for [^{89}Zr]Zr-trastuzumab were used to estimate dosimetry of TGW211-DC +/- TRG001 for different long-lived nuclides (^{177}Lu and ^{225}Ac) using IDAC-Dose 2.1 and OLINDA. ***Results:*** [^{111}In]In-TGW211-DC showed strong in vitro binding (KD = 8.4 nM), and internalization. The trigger rapidly released the [^{111}In]In-DOTA-fragment in plasma (91.8% in 5 min). In healthy mice, [^{111}In]In-TGW211-DC was highly stable (>20d isomerization half-life for the TCO linker) while it gave fast and efficient release of the short-circulating radioactive fragment (64.5 min mean residence time) upon reaction with trigger in blood. In mice bearing BT-474 xenografts, maximal tumour internalization was reached at 72 hrs p.i. TGW211-DC +/- TRG001 and TRG001 alone were well tolerated: the no-observed-adverse-effect-level (NOAEL) of i.v. dosed TGW211-DC +/- TRG001 (62.78 mg/kg) in mouse was 55 mg/kg (TGW211-DC), and the NOAEL of TRG001 alone was 700 mg/kg/dose and 300 mg/kg/dose in rat and cynomolgus monkey, respectively. Dosimetry modelling projected that future clinical cleavable HER2-RIT could afford a maximal decrease in effective dose in bone marrow, kidney and liver when TRG001 is administered 24 hrs after dosing radiolabelled TGW211-DC (up to 92% for ^{225}Ac and 88% for ^{177}Lu). TRG001 administration after 72 hrs was projected to result in effective dose reductions of up to 80% and 72% for ^{225}Ac and ^{177}Lu respectively. ***Conclusion:*** Click-cleavable [^{111}In]In-TGW211-DC improved tumour-to-blood ratios in mice. Extensive toxicological evaluation of TGW211-DC and TRG001, alone or in combination, revealed no significant adverse effects, demonstrating safety. Dosimetry simulations illustrated the potential benefit of click-cleavable radioimmunotherapy for patients with HER2+ cancers.

EPS-049

PET imaging of PARP-1 expression using a novel ^{18}F-labeled probe based on Quinazoline-2,4(1 H,3 H)-dione Scaffold

Y. Zou, *H. Wang, M. Hu, W. Chen, R. Tian;*
Sichuan University, west china hospital, Chengdu, Sichuan, CHINA.

Aim/Introduction: Poly (ADP-ribose) polymerase-1 (PARP-1) inhibitors (PARPi) have been approved for treating cancers with homologous recombination deficiency (HRD). Although recent studies demonstrate their promising efficacy, predicting patient response is complicated by intra-tumor heterogeneity and the limited predictive power of histology-based HRD assessments. To better predict responses to PARPi treatment and stratify patients, several PARP-targeting probes, including ^{18}F-FTT and ^{18}F-PARPi, which enable noninvasive and systemic monitoring, have been reported and entered clinical trials[1]. However, limited by labeling methods, the synthesis of reported probes was cumbersome with low yields. Based on the core binding structure of Senaparib, we aimed to synthesize a novel probe targeting PARP-1 for PET with high feasibility, high binding selectivity, and a favorable tumor-to-background ratio. ***Materials and Methods:*** Based on the quinazoline-2,4(1H,3H)-dione scaffold (Senaparib), we synthesized a PARP-targeting precursor suitable for ^{18}F labeling. ^{18}F-PARP-HX-2 was synthesized using a modified photoredox-mediated ^{18}F-deoxyfluorination and radio-HPLC preparation[3]. In vitro experiments, the lipid-water partition coefficient and cellular uptake of ^{18}F-PARP-HX-2 were measured. Initial PET/CT imaging of ^{18}F-PARP-HX-2 was evaluated in U87MG xenograft models. ***Results:*** ^{18}F-PARP-HX-2 was obtained with high radiochemical purity (≥95%). The Log $D_{7.4}$ of ^{18}F-PARP-HX-2 was 1.36 ± 0.06, indicating its lipophilic nature. There was a significant reduction in cellular uptake of ^{18}F-PARP-HX-2 in the blocked group compared to the control group (7.47 ± 0.20% reduce to 3.19 ± 0.06%, $P < 0.01$). Preliminary PET/CT imaging showed a high tumor-to-muscle ratio (tumor: SUV_{max} = 0.59 ± 0.03, muscle: SUV_{max} = 0.11 ± 0.01 at 1h pi) and fast hepatobiliary excretion in U87MG xenograft models. The blocking experiment demonstrated a significant reduction of ^{18}F-PARP-HX-2 in tumor accumulation (SUV_{max} = 0.59 ± 0.03 reduce to SUV_{max} = 0.11 ± 0.03 at 1h pi, $P < 0.01$). ***Conclusion:*** Photocatalytic radiofluorination enables the facile synthesis of a PARP-1-targeted probe with high specificity and favorable contrast. Further studies on treatment response prediction will be performed in preclinical models. ***References:*** 1. Pantel AR, Gitto SB, Makvandi M, et al. EPS-050

^{177}Lu-labelled CEACAM5-binding affibody for radionuclide therapy

E. Papalanis[1], *R. Li*[2], *M. Oroujeni*[1], *A. Orlova*[1], *E. Bezverkhniaia*[1], *P. Nygren*[2], *T. Gräslund*[2], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*KTH, Stockholm, SWEDEN.*

Aim/Introduction: The carcinoembryonic antigen adhesion molecule 5 (CEACAM5) is expressed in many types of cancer including colorectal, lung, breast, ovarian, gastric and pancreatic cancer. Affibody molecules are engineered scaffold proteins that can be selected to bind specifically to desired proteins. We developed a dimeric C9-C9 affibody construct binding to CEACAM5 for delivery of cytotoxic payloads to malignant tumours. To improve targeting and reduce renal uptake, a fusion of C9-C9 with the albumin-binding domain ABD_{035} was created. We found that the N-terminal positioning of ABD_{035} (construct designated as ABD_{035}-C9-C9) provided better targeting compared with C-terminal positioning. This study aimed to evaluate the targeting properties of the ^{177}Lu-labeled ABD_{035}-C9-C9 in vitro and in vivo. ***Materials and Methods:*** Maleimido derivatives of DOTA and DOTAGA chelators were conjugated to C-terminal cysteine of ABD_{035}-C9-C9. The conjugates were labelled with ^{177}Lu and purified using size-exclusion chromatography. CEACAM5-expressing cell lines with high, intermediate and low expression levels were used (BxPC3>LS174T>>HT-29) to evaluate the constructs. The kinetics of binding to living cells was evaluated using LigandTracer. The biodistribution properties of [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA and [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTAGA were compared in nude mice with BxPC3 tumours. The best variant was selected and a biodistribution analysis was performed 4, 24, 72, 168 and 336h pi. The Area Under Curve (AUC) for decay uncorrected biodistribution data was calculated to compare absorbed doses delivered to tumours and normal organs. ***Results:*** Radiolabelling of both constructs was successful with radiochemical purities exceeding 95%. Both [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA and [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTAGA demonstrated saturable binding in vitro, which was proportional to CEACAM5 expression levels in cell lines. The internalised fraction for both variants was around 40% after 24 h. InteractionMap analysis by Ligand Tracer revealed two interactions, with higher affinity (880-1000 pM) and with lower affinity (27-41 nM). The higher affinity was more abundant for [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA. The in vivo experiments demonstrated significantly ($p<0.05$) lower kidney uptake at 48 h post-injection of [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA compared with [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTGA (19±1 and 29±2%ID/g, respectively). The DOTA-conjugated variant was selected for further studies. The uptake of [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA in BxPC3 xenografts (29±2%ID/g) was significantly higher than in HT-29 xenografts, showing CEACAM5-dependent uptake in vivo. Fusion with ABD_{035} increased tumour uptake 3.6-fold and decreased renal uptake 14-fold. AUC for the BxPC3 tumours were 4.1-, 3.4- and 23-fold bigger than AUCs for the liver, kidneys and bones, respectively. ***Conclusion:*** Conjugation of ABD_{035}-C9-C9 with DOTA leads to better targeting properties. [^{177}Lu]Lu-ABD_{035}-C9-C9-DOTA is a promising construct for therapy of CEACAM5 expressing tumours.

EPS-051

Preparation and application of novel EBNA1-targeted PET radioactive probe

B. Gu*, F. Zhang, J. Li, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: Epstein-Barr nuclear antigen 1 (EBNA1), a viral nucleoprotein encoded by EBV, plays an important role in inducing nasopharyngeal carcinoma (NPC). This study aims to develop an EBNA1-targeted PET radiotracer for detecting EBV in EBV-associated NPC tumor-bearing mouse models. ***Methods:*** An EBNA1-targeted radioactive probe ^{68}Ga-NOTA-FZEB was synthesized, and the radiochemical purity and stability were evaluated by radio-HPLC. The positive or negative expressing-EBNA1 NPC cell lines were screened by western blot assay. The targeting performance of ^{68}Ga-NOTA-FZEB was characterized in vitro and in vivo. PET/CT imaging of tumor-bearing mouse model was used to assess the distribution and metabolism of ^{68}Ga-NOTA-FZEB in vivo. ***Results:*** The radiochemical purity of ^{68}Ga-NOTA-FZEB was more than 95%, and exhibited high stability in saline and fetal bovine serum for 3 h. In vitro cell uptake studies showed that EBNA1-positive C666-1 cells revealed significantly higher uptake of ^{68}Ga-NOTA-FZEB than EBNA1-negative 5-8F cells ($P < 0.001$). PET/CT imaging of the tumor-bearing mice showed that ^{68}Ga-NOTA-FZEB could specifically aggregate in EBNA1-positive C666-1tumors, whereas the EBNA1-negative 5-8F tumors revealed significantly lower uptake of ^{68}Ga-NOTA-FZEB (%ID/g: 2.87 ± 1.10 vs. 0.97 ± 0.12, $P < 0.001$). Moreover, ^{68}Ga-NOTA-FZEB was mainly metabolized through liver and urinary system in vivo. The results of H&E staining confirmed the biocompatibility of ^{68}Ga-NOTA-FZEB in vivo. ***Conclusion:*** As the first ^{68}Ga-labelled EBNA1-tageted polypeptide, ^{68}Ga-NOTA-FZEB exhibited high affinity and strong specificity to EBNA1-positive cells, suggesting it's a promising PET imaging agent for the management of EBV-associated NPC patients.

EPS-052

PET imaging of TIM-3 enables sensitive monitoring of immunotherapy

H. Yang*, L. Feng, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: T-cell immunoglobulin and mucin domain-3 (TIM-3) is primarily expressed on CD4+ and CD8+ T cells, serving as a critical immune checkpoint. Elevated TIM-3 expression has been shown to correlate with impaired function and exhaustion of CD8+ T cells and natural killer cells, making it a highly promising target for immunotherapy. Although immunotherapy has revolutionized cancer treatment, it demonstrates significant efficacy in only a subset of patients. Early identification of responders could potentially improve patient management and treatment outcomes during immunotherapy. This study aims to develop a positron emission tomography (PET) probe for the non-invasive characterization of TIM-3 expression, thereby providing a novel approach to monitor cancer immunotherapy efficacy. ***Materials and Methods:*** We synthesized the TIM-3-targeted peptide imaging probe 68Ga-NOTA-P2 and conducted a series of in vitro and in vivo experiments to assess its biodistribution, specificity, and pharmacokinetic properties, with the aim of evaluating its potential for non-invasive imaging of TIM-3 expression in tumors. The performance of 68Ga-NOTA-P2 in targeting TIM-3 expressing tumors was validated using PET/CT imaging in mouse models of colorectal cancer, melanoma, and lung cancer, both in baseline conditions and following immune activation. Additionally, the expression levels of TIM-3 in CT26, MC38, B16F10, and LLC tumors were assessed before and after immune activation using Western blot and flow cytometry analyses to confirm the probe's targeting efficacy. ***Results:*** 68Ga-NOTA-P2 PET imaging enables the non-invasive detection of TIM-3 expression levels across various tumor models, providing insights into the distribution of TIM-3-positive cells within these tumors. Additionally, in tumor models treated with a stimulator of interferon genes (STING) agonist, this imaging modality reveals a phenotypic shift from immunologically "cold" to "hot" tumors, as evidenced by an increase in tracer uptake from 1.70 (±0.18) to 2.93 (±0.21) %ID/g in CT26 tumor models. These imaging findings are corroborated by Western blot and flow cytometry analyses, which further validate the observed changes in TIM-3

expression. ***Conclusion:*** 68Ga-NOTA-P2 PET imaging enables the non-invasive assessment of early responses to immunotherapy by targeting TIM-3 expression in colorectal cancer, melanoma, and lung cancer models. These results highlight the feasibility of employing 68Ga-NOTA-P2 PET for TIM-3 tracking and suggest new avenues for optimizing TIM-3-targeted immunotherapy through this novel imaging strategy.

EPS-053

Tissue Factor-targeted PET imaging for Early Diagnosis of Pancreatic Cancer

W. Li, *S. Cheng, R. An, Y. Zhang, X. Lan, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Pancreatic cancer (PC) is an extremely malignant tumor with a dismal five-year survival rate of 13% worldwide. Moreover, PC often remains silent until reaching late stages, making it difficult to detect, therefore resulting in delayed intervention and increased morality. Tissue factor (TF), a protein involved in coagulation, is overexpressed by many tumor cells, especially PC cells, due to its involvement in multiple signaling pathways. Herein, we developed a Fab fragment-based PET tracers targeting TF and evaluated its diagnostic performance in murine models of PC. ***Materials and Methods:*** We radiolabeled anti-TF Fab fragment (TF903) with zirconium-89 (^{89}Zr, $t_{1/2}$= 78.4 h) and gallium-68 (^{68}Ga, $t_{1/2}$=68 min) to obtain TF-targeting PET tracers [^{89}Zr]Zr-DFO-TF903 and [^{68}Ga]Ga-NOTA-TF903. We evaluated the radiolabeling yield, radiochemical purity, and in vitro stability, and tested the in vitro binding affinity of the tracer by cell uptake studies. After that, we performed PET imaging and ex vivo biodistribution studies in pancreatic tumor-bearing mice (Panc02 and ASPC-1) to evaluate imaging performance and biodistribution of radiolabeled TF903. Tumor and major tissues were collected for further immunohistochemical and immunofluorescence staining. ***Results:*** [^{89}Zr]Zr-DFO-TF903 and [^{68}Ga]Ga-NOTA-TF903 were synthesized with satisfactory radiocharacteristics: high radiolabeling yields, radiochemical purity, and stability. Both murine PC cell line Panc02 and human PC cell line AsPC-1 were found to be TF-positive and our in vitro and in vivo experiments demonstrated that TF903-based PET tracers had strong binding affinity for this target. [^{68}Ga]Ga-NOTA-TF903 PET imaging and ex vivo biodistribution studies at 2 h post-injection revealed stable circulation of the tracer in the blood pool, and the probe showed a significantly higher tumor uptake (3.54-5.38% ID/g; 2 h p.i), three times higher than the muscle (1.02-1.64% ID/g; 2 h p.i). [^{89}Zr]Zr-DFO-TF903 PET imaging at longer time points showed an upward trend of tumor accumulation over time, substantiating the specific and strong binding of the probe in vivo. Immunohistochemical analysis also proved the specific binding of TF903. ***Conclusion:*** We successfully developed a TF-targeting Fab fragment probe, which demonstrated satisfactory PET imaging results in terms of tumor uptake and specific binding affinity to PC. The demonstrated properties highlight its potential as next-generation radiopharmaceuticals, which could significantly enhance diagnostic capabilities in nuclear oncology through timely identification of pancreatic malignancies.

EPS-054

First in Man Microdose Trial of [^{68}Ga]Ga-R54, CXCR4 Targeted PET tracer. Comparison with [^{18}F]-FDG and proof of concept in lung cancer models

A. Trotta[1], *L. Portella*[1], *M. Aurilio*[1], *C. D'alterio*[1], *L. D'Ambrosio*[1], *C. Maisto*[1], *A. Morisco*[1], *F. Manna*[1], *A. Luciano*[1], *G. Palma*[1], *G. Di Maiolo*[1], *F. Bruzzese*[1], *R. De Marino*[1], *A. Esposito*[1], *A. Rossi*[1], *F. Ricci*[1], *M. Cerrone*[1], *G. De Feo*[1], *S. Di Maro*[2], *S. Lastoria*[1], *S. Scala*[1];

Aim/Introduction: CXCR4 is overexpressed on the majority of haematological and solid cancers and correlates with metastatic features. CXCR4 is a potential imaging target for the accuracy of diagnosis, staging and predictive treatment efficacy. [^{68}Ga]Ga-Pentixafor is the most advanced CXCR4 targeting PET tracer, nevertheless the sensitivity and specificity toward solid tumors is modest. A new CXCR4-targeting PET tracer, [^{68}Ga]Ga-R54 (PCT/EP2020/087792), specifically accumulated in CXCR4+ tumours in human xenograft models. Aims of the work are to extend the in vivo specificity and imaging efficacy of [^{68}Ga]Ga-R54 in lung cancer xenograft models and to proceed with a First in Man, Microdose trial to identify [^{68}Ga]Ga-R54 Pharmacokinetics/ Pharmacodynamic in metastatic/ advanced solid tumors. Toxicity and toxicokinetic study in rats demonstrated non-evident 2 and 14 days post-injection (p.i.) toxicity. A monocentric, nonrandomized, open label clinical trial with [^{68}Ga]Ga-R54 (R4-FOUR-PET EUCT:2024-513303-14-00) was recently approved. ***Materials and Methods:*** PET/CT imaging and biodistribution was conducted on athymic mice bearing subcutaneous H69 (SCLC, high CXCR4) and H460 (NSCLC, moderate CXCR4) tumors. R4-FOUR-PET will enrol 5-10 patients CXCR4+ advanced cancers (breast, colon, lung, pancreas and ovarian). Primary objective is to evaluate pharmacokinetics and pharmacodynamics of a single microdose (<100 µg) of [^{68}Ga]Ga-R54. Comparison with [18F]-FDG and correlation between SUVmax and CXCR4 IHC expression will be conducted. ***Results:*** Biodistribution studies in H69 and H460 xenograft models revealed high and specific tumour uptake in both tumors after 1 hour post injection (H69-tumor uptake: 12.2±1%ID/g; H460-tumor uptake: 2±0.4%ID/g) and rapid renal excretion. Competition with cold R54 reduced [^{68}Ga]Ga-R54 uptake by approximately 90% and 60% respectively showing CXCR4 specificity. Compared to [^{18}F]-FDG, [^{68}Ga]Ga-R54 showed significantly higher uptake in H69 tumors (12.2±1%ID/g vs 3.75±0.6%ID/g, p<0.001). Consistently, PET/CT scans clearly visualized tumors at 1 hour post tracer administration with significant reduction in accumulation due to cold R54. To date, 4 ovarian, 1 colon, 2 lung and 2 breast cancer patients were enrolled in the R4-FOUR-PET trial and the first patient (ovarian cancer CXCR4+) was injected with [^{68}Ga]Ga-R54. [^{68}Ga]Ga-R54 visualized metastatic lesion CXCR4+ with good image contrast at 1h p.i. and is not associated with any toxicity. ***Conclusion:*** [^{68}Ga]Ga-R54 can be used to image CXCR4 expressing SCLC/NSCLC xenografts. [^{68}Ga]Ga-R54 can be used to visualize CXCR4+ tumors in metastatic ovarian cancer patients.

EPS-056

Drug Kinetics and Therapeutic Efficacy of Non-targeted Astatine-labeled Gold Nanoparticles Administered Locally to Tongue Cancer

H. Kato[1], *H. Shimamoto*[2], *Y. Kadonaga*[1], *K. Ooe*[1], *S. Yamamoto*[3], *X. Huang*[4], *E. Hilmayanti*[5], *A. Shimoyama*[5], *K. Kabayama*[1], *A. Toyoshima*[6], *S. Murakami*[2], *K. Fukase*[6];
[1]*Institute for Radiation Sciences, The University of Osaka, Suita, Osaka, JAPAN,* [2]*School & Graduate School of Dentistry The University of Osaka, Suita, Osaka, JAPAN,* [3]*Waseda Research Institute for Science and Engineering, Tokyo, JAPAN,* [4]*Immunology Frontier Research Center (IFReC), Osaka University, Suita, Osaka, JAPAN,* [5]*Department of Chemistry, Osaka University Graduate School of Science, Toyonaka, Osaka, JAPAN,* [6]*Institute for Radiation Sciences, The University of Osaka, Toyonaka, Osaka, JAPAN.*

Aim/Introduction: Although surgery is the treatment of choice for early-stage tongue cancer, less invasive treatment is awaited because of the impact on quality of life, such as taste disorder and deterioration of speaking. We focused on locoregional administration of non-targeted RI labeled nanoparticles because of their versatility and fast drug excretion rate. In this study, we evaluated the efficacy and pharmacokinetics of [^{211}At]AuNP-S-mPEG (AuNP@PEG), a drug consisting of polyethylene glycol-modified gold nanoparticles labeled with the alpha-ray nuclide

astatine-211, administered locoregionally to tongue cancer patients. The AuNP@PEG was optimized with respect to particle size, particle morphology, PEG size, dosage, and administration method. ***Materials and Methods:*** We varied the administered AuNP size from 2 nm to 30 nm and the PEG chain length from 1kDa to 20 kDa. In addition, the drug AuNR@PEG was prepared by replacing AuNPs with gold nanorods (AuNR). The human pancreatic cancer cell line SAS was transplanted into the lateral abdomen of nude mice. One week after transplantation, the drug was administered slowly into the tumor and changes in tumor size and body weight were observed. In addition, we examined systemic and intratumor drug distribution after administration, respectively. ***Results:*** The locally administered drug effectively inhibited tumor growth of tongue cancer without serious side effects. No significant differences in efficacy were observed for AuNP and PEG sizes, but AuNR@PEG was less effective. The effect was enhanced in a dose-radioactivity-dependent manner, and divided dosing was more effective than single dosing. AuNP@PEG diffused slowly and uniformly into the tumor, while the distribution of AuNR@PEG within the tumor was heterogeneous. Smaller AuNPs showed faster systemic elimination. Intratumor administration of [^{198}Au]AuNP@PEG with a particle size of 5 nm and tracking of drug distribution up to 5 days after administration revealed that AuNPs persist in the liver, and spleen and in the tumor. ***Conclusion:*** Intratumoral administration of non-targeted astatine-labeled gold nanoparticles strongly inhibited tongue cancer growth in a radioactivity-dependent manner without apparent side effects. It was found that fractional dosing is more effective and that smaller gold nanoparticles are optimal for excretion.

EPS-057

Development of fluorinated D-peptide radiopharmaceutical with significantly high tumor uptake for potential combination immunotherapy

C. Liu[1], *S. Zhang*[1], *W. Liu*[1], *Q. Lu*[1], *F. Wang*[2], *R. Wang*[1], *K. Hu*[1]; [1]*Institute of Materia Medica, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.*

Aim/Introduction: [^{68}Ga]DPA exhibits diagnostic potential for non-invasive PD-L1 detection but suffers from suboptimal tumor uptake and transient retention time. The fluorine modification enhances both pharmacokinetic properties and tumor-targeting capacity. In this study, we developed DPA analogs via amino acid substitution with fluorinated optimization to improve tumor uptake and retention time. Furthermore, the optimized ^{177}Lu-labeled fluorinated DPA analog was evaluated for radionuclide therapeutic potential alone or in combination with immunotherapy in triple-negative breast cancer. ***Materials and Methods:*** Peptides were radiolabeled with ^{68}Ga for PET imaging in A375-PD-L1 tumor-bearing mice, with 3.7 MBq administered intravenously per mouse and PET/CT scans acquired at 0.5h/1h post-injection. For therapy, D3 and DPA-5F analogs were labeled with ^{177}Lu. BALB/c mice with bilateral 4T1 tumors were randomized into six groups. Primary tumors received 18.5 MBq ^{177}Lu-ligands intratumorally (monotherapy) or combined with 200 μg intraperitoneal anti-PD-1 every 3 days. Post-treatment, tumors were analyzed for DCs (anti-CD11c-APC/CD80-FITC/CD86-PE) and T cell subsets (anti-CD3-FITC/CD8-PE-Cy7/CD4-PE-Texas Red) via flow cytometry. ***Results:*** A two-stage screening strategy was conducted. In the first alanine scanning round, DPA analogs were assessed for binding affinity to human PD-L1 protein using BLI assay and evaluated for in vivo imaging performance using PET/CT scanning. The D3 analog demonstrated superior tumor uptake (5 %ID/g) compared to the parental DPA peptide (3.5 %ID/g). For subsequent optimization, we designed a series of fluorinated peptides based on D3. Second-stage PET evaluation identified DPA-5F as the lead compound, demonstrating peak tumor uptake (15.3 %ID/g) at 30 minutes, and prolonged retention time evidenced by the sustained tumor uptake through 4 h. To further investigate radionuclide therapeutic potential of [^{177}Lu]5F and combination therapy with anti-PD-1, 4T1 tumor-bearing mice were randomized into six groups: 1) control, 2) anti-PD-1, 3) [^{177}Lu]D3, 4) [^{177}Lu]5F, 5) [^{177}Lu]D3 + anti-PD-1, and 6) [^{177}Lu]5F + anti-PD-1. After 13-day treatment, group 6 exhibited significant antitumor efficacy. To understand this phenomenon, DC infiltration was first analyzed, revealing maximal DC accumulation in group 4. Flow cytometry analysis demonstrated increased percentages of CTLs and Th cells in group 4 (primary tumors) and group 6 (distant tumors). ***Conclusion:*** This investigation demonstrates that the fluorinated compound [^{68}Ga]DPA-5F achieves both increased tumor uptake and prolonged tumor retention. The combination therapy ([^{177}Lu]DPA-5F + anti-PD-1) effectively exerts potent antitumor effects, demonstrating the synergistic potential of radionuclide therapy and immunotherapy.

EPS-058

Preclinical Evaluation of a PSMA-targeting Theranostic Candidate with Reduced Gland Uptake

G. Chen, *X. Hu, Y. Cao, M. Hong, S. Xu, J. Wen; RadAlliance Therapeutics Inc, San Diego, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Although PSMA-617 has demonstrated superior commercial value, xerostomia caused by its undesired salivary gland uptake is still the issue to be solved. A novel PSMA agent REX003 has been investigated to address PSMA-617's unsolved challenges, particularly the undesired salivary gland uptake. ***Materials and Methods:*** Ga68, Cu64, Lu177, and Ac225 labeled REX003 were evaluated under in vitro, ex vivo and in vivo conditions, head to head to compare with PSMA-617. PSMA binding specificity and affinity were demonstrated. Biodistributions of Lu177-REX003 in xenograft mice with different PSMA expression level were used to assess its tumor-targeting specificity. A separated hot blood PK measurement was performed to evaluate blood exposure difference. PET imaging of Cu64-REX003 on the same NHP (n=2) was used to compare gland uptake. Both Lu177-REX003 and Ac225-REX003 were used to compare efficacy in xenograft model vs benchmark compound. ***Results:*** Preclinical evaluation of Lu-177-labeled REX003 has demonstrated its bigger therapeutic windows to PSMA-617 on salivary gland uptake of 8-fold+, on blood toxicity of 2-fold+ and on kidney 20-90%. Ac225-labeled REX003 could have more potential over PSMA-617 due to its PK profile and gland uptake selectivity. ***Conclusion:*** REX003, a PSMA-targeting agent with versatile radionuclides shows great potential in treatment and diagnosis of PSMA-positive prostate cancer.

EPS-059

Development and Preclinical Evaluation of Novel PSMA-Targeted Nanobody Radiopharmaceuticals for Prostate Cancer Treatment

B. Yang, *Y. Gai, Y. Liu, J. Hu, X. Zhang, M. Li, Y. Zhang, R. An, X. Lan; Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) exhibits specific high expression in prostate cancer (PCa) and low expression in normal tissues. Its expression level is highly correlated with tumor aggressiveness, making it a classical target for PCa. Currently, most proteins identified with sufficiently high affinity (in the nmol range) for the extracellular region of PSMA are monoclonal antibodies or antibody fragments. Nanobodies represent the smallest antibody units capable of stably binding

to antigens identified so far. Compared to traditional monoclonal antibody molecules, nanobodies, due to their smaller molecular weight, can directly penetrate dense tumor tissues. Structurally, they have a longer antigen-binding domain compared to traditional VH domains, resulting in stronger affinity for antigens. ***Materials and Methods:*** Three novel PSMA-specific antibodies, AP01, AP02 and AP03, were produced and labeled with ^{177}Lu to develop radiopharmaceuticals. The stability study and partition coefficient were determined. A series of cell assays was performed to identify the binding affinity and PSMA specificity in vitro. We performed SPECT/CT imaging and biodistribution studies with [^{177}Lu]Lu-AP01, [^{177}Lu]Lu-AP02 and [^{177}Lu]Lu-AP03 in subcutaneous LNCaP patient-derived xenograft models. ***Results:*** All radiopharmaceuticals were successfully prepared with high purity and stability. [^{177}Lu]Lu-AP01 was stable in saline for at least 120 h. They exhibit excellent stability in vitro with good water solubility. The [^{177}Lu]Lu-AP01, [^{177}Lu]Lu-AP02 and [^{177}Lu]Lu-AP03 exhibited high PSMA-binding affinity and specificity both in vitro and in vivo. Compared with the [^{177}Lu]Lu-AP02 and [^{177}Lu]Lu-AP03, [^{177}Lu]Lu-AP01 demonstrated remarkably enhanced tumor accumulation and tumor-to-nontumor ratios (28.58 ± 4.25 %ID/g for [^{177}Lu]Lu-AP01 vs. 16.10 ± 1.54 %ID/g for [^{177}Lu]Lu-AP02 and 15.45 ± 0.65 %ID/g for [^{177}Lu]Lu-AP02 at 48h post-injection). ***Conclusion:*** A series of novel PSMA-targeted nanobody radiopharmaceuticals have been developed and evaluated in vitro and in vivo. Significantly improved tumor uptake and retention were observed for [^{177}Lu]Lu-AP01. The favorable in vivo pharmacokinetics and excellent tumor accumulation, make it a promising radiopharmaceutical for prostate cancer treatment.

EPS-060

Development of [^{68}Ga]Ga-B6FA-01 as a Novel Radiotracer for Dual $\alpha_v\beta_6$and FAP-targeted Tumor PET Imaging

K. Xu[1], *Y. Wang*[1], *Y. Gai*[2], *P. Lei*[3], *Z. Xiao*[1], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, Wu Han, CHINA,* [2]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wu Han, CHINA,* [3]*Department of Immunology, School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wu Han, CHINA.*

Aim/Introduction: To overcome the limitation and imperfection on account of the tumor heterogeneity in single-targeting imaging, we developed a bi-specific tracer [^{68}Ga]Ga-B6FA-01, targeting two different chosen cell surface biomarkers, fibroblast activating protein (FAP) and integrin $\alpha_v\beta_6$. ***Materials and Methods:*** [^{68}Ga]Ga-B6FA-01 was designed and synthesized on the basis of quinoline-based FAP inhibitors (FAPI-04) and cyclic RGD peptide monomers1. In vitro formulation stability and metabolic stability were evaluated in PBS and serums (including mice, rats, NHPs, and human), respectively. Further preclinical evaluations of cell uptake and micro-PET/CT imaging were conducted with FAP-$\alpha_v\beta_6$ dual over-expressed HT1080 cells, and corresponding tumor xenograft models. ***Results:*** [^{68}Ga]Ga-B6FA-01 exhibited excellent formulation stability (>99% remained at 3h in PBS), and first-class metabolic stability in serums (>99% remained at 2h in mice, rats, NHPs, and human, respectively). Dual-target binding affinity was revealed significantly in the blocking cell uptake experiments with FAPI-04 ($P < 0.001$) and Trivehexin ($P < 0.001$) as the competitors. In PET/CT imaging, prolonged uptake values were observed (9.42±0.37, 2.62±1.15, and 4.02±1.04 %ID/g at 4h p.i. of [^{68}Ga]Ga-B6FA-01, [^{68}Ga]FAPI-04, and [^{68}Ga]Trivehexin, respectively), and optimized tumor/kidney ratio was revealed (4.68±0.82, and 0.18±0.02 of [^{68}Ga]Ga-B6FA-01, and [^{68}Ga]Trivehexin at 4h p.i.). Co-administration of unlabeled FAPI-04, Trivehexin, and both FAPI-04 and Trivehexin significantly lowered the tumor uptake (0.80±0.12, 1.57±0.16, and 0.60±0.09 compared with 1.37±1.38 %ID/g in baseline group at 1h p.i., respectively). ***Conclusion:*** This work demonstrated a FAP-$\alpha_v\beta_6$ dual-targeting tracer [^{68}Ga]Ga-B6FA-01, resulting in superior tumor uptake and retention time compared with mono-targeting tracers [^{68}Ga]Ga-FAPI-04 and [^{68}Ga]Ga-Trivehexin, and improved renal clearance over the trimer tracer [^{68}Ga]Ga-Trivehexin. Our findings strengthened the potential feasibility of heterodimeric tracers in clinical tumor PET imaging. ***References:*** 1.Neil Gerard Quigley et al, RSC Med. Chem. 2023, 14, 1564.

EPS-061

Preclinical Evaluation of [^{64}Cu]CuNODAGAPSMAI&T for Prostate Cancer Theranostics

Aim/Introduction: Prostate cancer (PCa) remains one of the most commonly diagnosed malignancies and a leading cause of cancerrelated mortality among men worldwide. Prostatespecific membrane antigen (PSMA) is a wellestablished biomarker overexpressed in PCa, making it an attractive target for both diagnostic imaging and targeted radionuclide therapy. Owing to its unique physical decay properties, copper64 has steadily gained traction in nuclear medicine. In this study, we evaluated the theranostic potential of [^{64}Cu]CuNODAGAPSMAI&T, a novel PSMAtargeting radioconjugate, in a preclinical model of PCa. We aimed to assess its in vivo imaging characteristics, ex vivo biodistribution, dosimetry, and therapeutic efficacy in tumourbearing mice. ***Materials and Methods:*** Copper64 was obtained inhouse by proton irradiation of enriched nickel64 liquid targets in a biomedical cyclotron, followed by postprocessing and NODAGAPSMAI&T radiolabelling. The radiochemical purity and stability of the radiolabelled compound was assessed by radioHPLC and iTLC. For in vivo PET/MR imaging and ex vivo biodistribution studies, Swiss nude mice were subcutaneously inoculated with PC3PIP (PSMApositive) or PC3Flu (PSMAnegative) cells. Dosimetric calculations were performed with OLINDA/EXM® software. The therapeutic efficacy of [^{64}Cu]CuNODAGAPSMAI&T was evaluated in PC3PIP tumourbearing mice. ***Results:*** [^{64}Cu]CuNODAGAPSMAI&T was consistently produced with high radiochemical yields (>85%) and suitable molar activities (20-30 GBq/µmol) for preclinical use. The radiochemical purity of the final product remained above 95% for at least 24 h after the end of synthesis. PET/MR imaging showed strong and selective uptake in PSMApositive tumours, but no uptake in PSMAnegative counterparts (~6% vs ~0.3% ID/g, respectively), confirming target specificity. There was no radiopharmaceutical accumulation in nontargeted organs or tissues besides the kidneys and the urinary bladder, indicative of its renal excretion. These findings were corroborated by the ex vivo biodistribution analysis. In PSMApositive tumourbearing mice, treatment with [^{64}Cu]CuNODAGAPSMAI&T significantly delayed tumour growth and extended survival compared to untreated controls. Dosimetric calculations expectedly identified the kidneys as the doselimiting organs, receiving an absorbed dose of 1.03e-01 mGy/MBq. The effective dose was estimated at 6.60e-03 mSv/MBq. ***Conclusion:*** [^{64}Cu]CuNODAGAPSMAI&T demonstrated excellent in vivo stability, high tumour uptake and specificity, and a favourable biodistribution profile, ultimately resulting in effective tumour growth control and improved survival in a preclinical PCa model. The dual capability of the radiopharmaceutical for both highcontrast PET imaging and targeted radionuclide therapy underscores its strong potential as a versatile theranostic agent. Altogether, these findings encourage further investigation

and support the progression of [^{64}Cu]CuNODAGAPSMAI&T toward clinical translation for the personalized management of PSMAexpressing PCa.

EPS-062

Discovery and preclinical characterization of ETN029, a novel radiotherapeutic agent for the treatment of DLL3-expressing cancers

A. Savinainen, *L. Wu, T. Bruton, A. Chonkar, J. Cupido, J. Dearling, C. Huang, K. Lee, Z. Ma, H. Mok, K. Nabi, A. Salih, A. Sutton, L. Tavera, M. Wan, Z. Weng, X. Xu, J. Xu, A. Zidell, A. Ricardo; Mariana Oncology a Novartis Company, Watertown, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Neuroendocrine neoplasms (NENs), including small cell lung cancer (SCLC) and neuroendocrine prostate cancer (NEPC), commonly exhibit upregulated surface expression of the atypical notch Delta-like ligand 3 (DLL3). ETN029 is a novel macrocyclic peptide binder to DLL3 designed to achieve high, rapid uptake and retention in tumor tissue and fast clearance of the unbound compound via the renal route. We have demonstrated that ETN029 has excellent binding kinetics and a favorable tumor:kidney (T/K) ratio and that a single dose of ^{225}Ac-ETN029 results in robust and sustained tumor regression and prolonged survival in a dose-dependent manner in subcutaneous cell-derived xenograft (CDX) SCLC models. Further, we have characterized the in vivo anti-tumor activity of ^{225}Ac-ETN029 in combination with different elements of standard-of-care for SCLC, including chemotherapy (cisplatin/etoposide) in CDX models and anti-programmed cell death ligand 1 (anti-PD-L1) checkpoint inhibitor therapy in a syngeneic model. ***Materials and Methods:*** Binding affinity and selectivity were characterized using surface plasmon resonance (SPR). Cell binding and internalization were determined in a cell-based assay in cell lines expressing DLL3. In vivo biodistribution and anti-tumor activity was assessed in mouse models expressing DLL3. ***Results:*** ETN029 binds rapidly and selectively to human DLL3 with picomolar affinity. ^{177}Lu-ETN029 exhibited high cell binding and internalization in DLL3 expressing cells. Biodistribution studies of ^{177}Lu-ETN029 in a mouse CDX model demonstrated rapid radionuclide tumor uptake, persistent tumor retention throughout the study, and a favorable T/K ratio. In vivo efficacy studies in CDX and syngeneic mouse models with tumors expressing human DLL3 demonstrated robust and sustained dose-dependent tumor regression and prolonged survival after a single dose of ^{225}Ac-ETN029 (0.25-1 µCi). While the highest dose of ^{225}Ac-ETN029 (1 µCi) resulted in complete tumor regression, therapy with either cisplatin/etoposide or anti-PDL-1 alone resulted in moderate tumor growth inhibition. When a low dose of ^{225}Ac-ETN029 (0.25 µCi) was combined either with chemotherapy in a CDX model or with anti-PD-L1 in a syngeneic model, the efficacy was improved over either treatment alone. ***Conclusion:*** Taken together, these studies support the use of ^{225}Ac-ETN029 either as single agent treatment or in combination with standard-of-care chemo- and/or immunotherapy in patients with SCLC and potentially other DLL3-expressing solid tumors.

EPS-063

High and Flow-Independent Extraction Fraction of ^{99m}Tc-4BOH in Langendorff Rat Hearts vs. Clinical SPECT Tracers

D. Ding[1], *Y. Gu*[1], *Y. Zhang*[2], *Z. Lv*[2], *L. Sun*[2], *J. Wang*[2], *F. Guo*[3], *W. Fang*[1], *T. Ma*[2], *L. Wang*[1];
[1]*Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences, Beijing, CHINA,* [2]*Tsinghua University, Beijing, CHINA,* [3]*Greater bay area national center of technology innovation, Guangdong, CHINA.*

Aim/Introduction: The novel SPECT myocardial perfusion tracer ^{99m}Tc-4BOH has shown preclinical advantages, including prolonged myocardial retention and high heart-liver contrast. This study evaluated the first-pass extraction fraction (EF) of ^{99m}Tc-4BOH in isolated rat hearts using the Langendorff perfusion method against ^{99m}Tc-Teboroxime and ^{99m}Tc-Sestamibi. ***Materials and Methods:*** Hearts from anesthetized male SD rats (275-325g, n=29) were aortic-cannulated and perfused non-recirculatingly with Krebs-Henseleit buffer at three controlled flow rates (5.0, 8.4, and 16.0 mL/min). ^{99m}Tc-Teboroxime, ^{99m}Tc-4BOH, and ^{99m}Tc-Sestamibi were separately tested by delivering a single bolus injection (1 mCi in 0.1 mL) to 3 to 4 isolated hearts at each specified flow rate. The time-activity curve in the heart was recorded over 10 min with Handheld Self-Collimation Gamma Camera. EF was quantified using the Raichle B/A ratio method. ***Results:*** ^{99m}Tc-4BOH exhibited a high overall EF of 93.98 ± 4.54% (n=10), which was comparable to that of ^{99m}Tc-Teboroxime (96.90 ± 1.95%, n=9; $p>0.05$), and significantly higher than ^{99m}Tc-Sestamibi (30.70 ± 7.31%, n=10; $p<0.01$). The EF measured at flow rates of 5.0, 8.4, and 16.0 mL/min were well-maintained for ^{99m}Tc-4BOH, with values of 93.37 ± 4.43%, 92.23 ± 6.92%, and 96.53 ± 0.67%, respectively ($p>0.05$). Similarly,^{99m}Tc-Teboroxime demonstrated stable EF values of 97.40 ± 0.57%, 98.10 ± 2.44%, and 95.18 ± 1.41% ($p>0.05$). In contrast, ^{99m}Tc-Sestamibi showed a significant decline in EF from 39.19 ± 4.93% to 30.88 ± 2.68% and 24.20 ± 3.25% ($p < 0.01$) at these flow rates. ***Conclusion:*** The high EF and the flow-independent characteristic of ^{99m}Tc-4BOH indicates its potential as a promising myocardial perfusion imaging agent, which may offer enhanced accuracy in blood flow quantification compared to conventional SPECT tracers.

Evaluation of Automatic Selective Body Part Reconstruction on a Long Axial Field of View PET/CT System

M. Olhaye, *H. Danielsen;*
Aarhus University Hospital, Aarhus, DENMARK.

Aim/Introduction: An inherent challenge on Long Axial Field of View (LAFOV) PET/CT scanner is handling very large data amounts due to their high sensitivity. Reconstruction times for full data set can be quite long, and, in some cases, only selective organ areas are of interest for the clinical reading. To mitigate this issue Siemens Healthineers introduced SMART Image Framer which selectively reconstructing up to four predefined areas - liver, brain, heart, and head/neck - in PET scans based on anatomical information acquired from the CT localizer radiograph. This study aims to evaluate the effectiveness and limitations of this application over a period of two months. ***Materials and Methods:*** One hundred patients, including five children aged 2-13 years, were scanned. Each patient's data was reconstructed using the SMART Image Framer for all four anatomic areas. The cohort included various scan protocols, bed positions, tracers, and patients of different ages and sizes. Data was assessed according to correct anatomy placement, misplaced anatomy, or failed reconstruction. Only single-bed examinations were included. ***Results:*** Of the 386 reconstructions, 40 were unusable, with 37 failed and three misplaced, yielding a success rate of 89.6%. The application bases reconstructions on the last acquired localizer in the protocol, leading to 7% of failures. In protocols where posterior-anterior localizer was scanned before lateral localizer, only the brain area

was reconstructed. Combined protocols with two localizers covering the torso and legs separately failed to reconstruct any anatomy of interest unless reconstructions were initiated before the second appended localizer was performed. 1.8% of failures were due to small or abnormal anatomy with lower success rates in children and for one patient with an enlarged liver. 1.3% failed for unknown reasons, including one case where only half the brain area was reconstructed. ***Conclusion:*** Overall, the study shows a promising tool with a high success rate. As long as the different limitations are known, the SMART image framer is easily applied and works well across a variety of protocols and patient groups. It significantly reduces data volume by selecting only relevant organ areas, enhancing daily clinical efficiency.

OP-884

Personnel dose in the [^{18}F]FDG workflow: LAFOV PET/CT versus SAFOV PET/CT

J. Effing, *T. Young-Mylvaganan, E. C. Streefkerk, J. Maarsen, E. A. Aalbersberg;*
The Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: The new highly sensitive LAFOV PET/CT (Siemens Biograph Vision Quadra) allows further reduction in administered activity and scan duration, which can lead to a significant reduction in dose exposure of PET/CT-related nuclear medicine personnel. The aim of this study is to determine the impact on the external radiation exposure of personnel on LAFOV PET/CT compared to SAFOV PET/CT. ***Materials and Methods:*** For dose analysis, data from all personnel (laboratory technologists, medical assistants and PET technologists) who worked on SAFOV PET/CT with full-dose (3.5 MBq/kg) were collected from July 2023 to December 2023, which was compared to data from July 2024 to December 2024 with low-dose (1.5 MBq/kg) on LAFOV PET/CT. During these periods, all personnel wore Thermo Luminescent Dosimeters (TLD) badges in the upper pocket of their uniform, for the preparation and administration of the radiopharmaceuticals, and patient positioning for the scan. During preparation, laboratory technologists wore extremity dosimeters on both hands, on the palmar side. ***Results:*** The average prepared dose of [^{18}F]FDG was 481 MBq (2278 injections) for SAFOV PET/CT and 271 MBq (2342 injections) for LAFOV PET/CT, resulting in a [18F]FDG dose reduction of 43.6%. With the introduction of LAFOV PET/CT, an average reduction of 52.4% was achieved for the external dose of laboratory technologists; from 17.11 µSv to 8.15 µSv. The extremity doses remained the same, 24.9 µSv compared to 23.6 µSv.The total amount of injected [^{18}F]FDG by the medical assistants was reduced from 562 GBq to 277 GBq, with a mean activity of 272 MBq reduced to 123 MBq per patient. This results in an average exposure dose from 17.29 µSv to 6.68 µSv per day, which is a 61.4% reduction. During the positioning of patients on the scanner, the personnel dose was also lowered from 2.71 µSv to 1.32 µSv per patient: a 51.3% reduction. ***Conclusion:*** By reducing the administered dose from 3.5 MBq/kilogram to 1.5 MBq/kilogram, the dose received by personnel has been drastically reduced. During all activities with [^{18}F]FDG, a clear decrease is seen.

OP-885

Optimising Zr-89-Trastuzumab PET/CT Imaging: Protocol Design for Short and Long Axial Field-of-View Systems

M. van der Vegt, *A. I. van Erp - Zeilstra, A. W. J. M. Glaudemans, W. Noordzij, R. H. J. A. Slart, E. H. J. G. Aarntzen, A. H. Brouwers, O. V. Ivashchenko;*
University Medical Centre Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Imaging with radiolabelled therapeutic monoclonal antibodies plays a growing role in tumour characterisation prior to treatment initiation, as well as in drug development to assess biodistribution and pharmacokinetics. However, the inherently low activity of Zr-89 necessitates lengthy PET/CT acquisition times. Long Axial Field-of-View (LAFOV) PET/CT systems offer increased sensitivity and improved image quality, making them well-suited for Zr-89 imaging. Yet, optimised protocols across different PET/CT platforms remain undefined, and the minimum image quality needed for reliable interpretation is unclear. This study aimed to determine the minimal image quality requirements for Zr-89-trastuzumab imaging on either digital Short Axial Field-of-View (SAFOV) and LAFOV PET/CT systems. ***Materials and Methods:*** Twenty breast cancer patients were analysed, scanned between April 2021 and September 2024, imaged with SAFOV or LAFOV PET/CT systems (10/system). The mean administered activity was 37.5±10% MBq and all scans were conducted on day 4 postinjection. Reconstructions were performed to simulate varying scan durations: 100%, 50%, and 33% of mean LAFOV count statistics, plus matched and 50% SAFOV count levels. SAFOV scans were reconstructed at 100%, 75%, 50%, and 25% of their typical duration. LAFOV data were reconstructed using high sensitivity (HS) and ultra-high sensitivity (UHS) mode. All images were reconstructed using clinical and Zr-89 EARL settings. Five nuclear medicine physicians rated image quality using a 5-point Likert-scale. Quantitative evaluation was based on signal-to-noise ratio (SNR) and tumour-to-background ratio (TBR) in lesions, spleen and blood pool. Liver was excluded as normal organ due to metastatic involvement in some patients. ***Results:*** Physicians required different SNR thresholds in the spleen for acceptable quality: SAFOV = 5.39, LAFOV-HS = 11.06, LAFOV-UHS = 10.83. At equal count statistics, LAFOV-HS and SAFOV scans showed no significant SNR difference (SNR-LAFOV-HS = 8,30, SNR-SAFOV = 7,39, p = 0.135). However, LAFOV-UHS scans showed significantly higher SNR (SNR-LAFOV-UHS = 10,34, SNR-SAFOV = 7,39, p = 0.005). Tumour SNR and TBR remained stable across scan times and systems. Scan time could be reduced by up to 67% with LAFOV and 50% with SAFOV without compromising diagnostic quality. SNR loss became significant only below 50% of standard SAFOV scan duration. ***Conclusion:*** Spleen SNR declines with shorter scans, but lesion visibility and TBR remain unaffected. LAFOV PET/CT enables shorter, high-quality Zr-89 scans. For 37 MBq injections with a skull-to-proximal femur scan on day 4 postinjection, we recommend 9.7-minute LAFOV-UHS and 1.1 mm/sec SAFOV acquisitions for optimal efficiency and image quality.

OP-886

Optimising Post-Yttrium-90 Radioembolization PET/CT Scan Times: A Comparative Evaluation of Standard and Long Axial Field-of-ViewDigital PET/CT in Clinical Practice

T. Stark, *N. Reitsma, W. Noordzij, O. V. Ivashchenko;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Post-treatment PET/CT imaging is essential for assessing the therapeutic efficacy of yttrium-90 (Y-90) radioembolisation. However, Y-90's extremely low positron emission yield (0.003%, compared to 98% for F-18) necessitates extended acquisition times, even with high administered activities (3-5 GBq). Building on prior phantom-based optimisation work, this study retrospectively evaluates and refines scan durations for both standard axial field-of-view (SAFOV) and long axial field-of-view (LAFOV) digital PET/CT systems in clinical practice. The aim is to minimise scan time without compromising quantitative accuracy or diagnostic image quality. ***Materials and Methods:*** Twenty patients who underwent post-radioembolization Y-90 PET/CT scans were included (10 SAFOV, 10 LAFOV). The mean administered activity was 2.5 GBq (range: 0.5-7.5 GBq), with an average imaging delay of 20.6 hours. To standardise image quality, the average total scan count from the SAFOV group (18,300,815 counts/scan) was used as a reference, reflecting administered activity, acquisition time, and scanner sensitivity. Simulated reconstructions were generated at 200%, 150%, 100%, 75%, and 50% of baseline counts.

All scans were reconstructed using consistent parameters (3D OSEM, 4 iterations, 5 subsets, 7 mm Gaussian filter, PSF modelling), with both full and partial sensitivity modes assessed for LAFOV systems. Although partial mode introduces a non-uniform image profile, it doubles the sensitivity at the centre of the field of view. Quantitative analysis included total activity (MBq), average activity concentration (Bq/ml), signal-to-noise ratio (SNR), tumour-to-background ratio (TBR), and contrast-to-noise ratio (CNR) in hepatic and tumour regions. ***Results:*** Tumour activity remained stable across all reconstructions (≤7% deviation). CNR and SNR improved with increasing scan duration. SNR rose from 2.54 ± 0.52 (50%) to 3.57 ± 1.06 (200%). CNR gains plateaued beyond 100%. For accurate quantification, 100% scan statistics were sufficient — equivalent to 8 minutes on SAFOV and 0.7-1.4 minutes on LAFOV for 2.5 GBq. For optimal SNR, 150% statistics were ideal (11 minutes SAFOV; 1-2 minutes LAFOV). Below 1 GBq, SAFOV required ≥30 minutes per bed for acceptable SNR, making LAFOV preferable. ***Conclusion:*** Quantification accuracy is maintained across a range of acquisition durations for both scanner types. However, tumour detectability, vital for post-therapy dosimetry, requires at least 11 minutes (SAFOV) or 1-2 minutes (LAFOV) for 2.5 GBq. For lower activities, LAFOV is recommended due to its higher sensitivity. To ensure consistent dosimetric accuracy, scan duration must be tailored to administered activity and system sensitivity. ***References:*** Croes, G., et al. (2023). OP-887

Optimization and harmonizaton of image reconstructions in [^{18}]F-FDG brain PET/CT for dementia

R. Klausen[1], *P. Braad*[2];
[1]*Department of Radiology, Hospital of Southern Denmark, Aabenraa, DENMARK,* [2]*Department of Clinical Imaging, Odense, DENMARK.*

Aim/Introduction: Time-of-flight (TOF) and block-sequential regularized expectation maximization (BSREM) reconstruction techniques, available on modern digital PET/CT systems, enhance quantitative accuracy and are recommended by the EANM procedure guidelines for [^{18}F]-FDG PET brain imaging. However, diagnostic tools such as 3D-SSP (Cortex-ID), which support dementia evaluation by comparing patient scans to a normal database, require that image reconstructions closely match those used to build the database. This study aimed to evaluate how BSREM reconstructions with and without TOF can be harmonized to comply with Cortex-ID. ***Materials and Methods:*** The Hoffmann 3D Brain Phantom (Data Spectrum) was filled with an aqueous homogeneous solution of [^{18}F]-FDG with a concentration of 36 kBq/ml and subsequently scanned on a Discovery MI 6R gen2 PET/CT system (GE Healthcare) using a standard 12.5 min static brain PET protocol. Phantom images were reconstructed in a field-of-view of 25 cm with a matrix size of 256 using the default ordered subset expectation maximization (OSEM) method (3 iterations/16 subsets) and compared to BSREM reconstructed images (w/wo TOF) with β parameters ranging from 100 to 2000. Images were segmented into grey and white matter regions and quantitation of each tissue type was calculated in 83 brain regions by registering the phantom to the Hammersmith brain atlas (n30r83). 5 patient scans were reconstructed using similar settings and the impact on Z-scores calculated by Cortex-ID was assessed. ***Results:*** TOF-BSREM underperformed compared to BSREM. Images reconstructed using BSREM with a β value of 1000 most closely matched the reference method in both visual quality and quantitative accuracy. On average, the deviations from the reference method were 1.8% in grey matter and -0.6% in white matter. Variations in individual brain regions ranged from -5% to 6% in grey matter and and -1% to 9% in white matter. In high-contrast areas, differences exceeding 10% were observed. Among patients, Z-scores derived from BSREM images were more consistent with the reference scores than those from TOF-BSREM. The mean absolute Z-score difference was 0.1 while differences up to 0.4 were measured in individual brain regions. ***Conclusion:*** Modern BSREM and TOF-based reconstruction techniques enhance image quality and uptake quantification. However, aligning these reconstructions with the normal database in 3D-SSP methods remains challenging, and care should be exercised when using BSREM for Z-score analysis in the evaluation of brain disorders.

OP-888

PET/CT imaging of Blood-Brain Barrier Integrity and inflammatory tracers during Alzheimer's Disease

B. Alenezi[1], *S. Paisey*[2], *T. Hughes*[3], *T. Webberley*[4], *D. Michael*[5], *S. Plummer*[6], *S. Plummer;*
[1]*Cardiff University, CF10 5NG, UNITED KINGDOM,* [2]*Wales Research and Diagnostic PET Imaging Centre, school of Medicine, Cardiff University Heath Park., Cardiff. CF14 4XN, UNITED KINGDOM,* [3]*Division of Infection and Immunity, Henry Wellcome Building, School of Medicine, Cardiff University Heath Park., Cardiff. CF14 4XN, UNITED KINGDOM,* [4]*Cultech Limited, Unit 2 Christchurch Road, Baglan Industrial Park, Port Talbot SA12 7BZ, UK., UNITED KINGDOM,* [5]*Cultech Limited, Unit 2 Christchurch Road, Baglan Industrial Park, Port Talbot SA12 7BZ, UK., UNITED KINGDOM,* [6]*Cultech Limited, Unit 2 Christchurch Road,, Baglan Industrial Park, Port Talbot SA12 7BZ, UK., UNITED KINGDOM.*

Aim/Introduction: Alzheimer's Disease (AD), the most common cause of dementia, is increasingly associated with immune system dysfunction, especially complement activation. Immuno-PET, which merges PET imaging's sensitivity with monoclonal antibody specificity, allows precise detection of disease-related targets. BB5.1, an antibody against murine complement protein C5, holds promise for imaging neuroinflammation. High-fat diets exacerbate inflammation, cognitive decline, and synaptic loss in 3xTg-AD mice—effects reduced by probiotic supplementation. We hypothesize that neurodegeneration and blood-brain barrier disruption in AD will allow radiolabeled BB5.1 to cross into the brain and visualize complement activity via immuno-PET. ***Materials and Methods:*** To investigate our hypothesis, in-vivo imaging was conducted on 3xTg-AD mice using ^{89}Zr-labeled BB5.1 to assess antibody biodistribution and brain penetration, and ^{18}F-FDG to evaluate brain metabolism. Imaging was performed at baseline (6 months) and endpoint (9 months), including PET/CT scans at 24h, 72h, and 144h post-injection of 2 MBq ^{89}Zr-BB5.1 or control antibody (^{89}Zr-D1.3), and 192h with 10 MBq ^{18}F-FDG. Mice were then assigned to one of four dietary groups (HFD±probiotics, chow±probiotics) for three months. Cognitive function was assessed by novel object recognition, inflammatory disease markers, and BBB integrity were evaluated by immunohistochemistry and qPCR. ***Results:*** In vitro hemolysis assays confirmed that ^{89}Zr-BB5.1 retained its ability to inhibit complement protein C5, indicating preserved biological activity. SDS-PAGE and RadioTLC analyses confirmed structural stability and successful radiolabeling with minimal impurities. PET/CT imaging showed reduced brain uptake of ^{89}Zr-BB5.1 in the high-fat diet control (HFDC) group compared to the chow control (ChowC) and high-fat diet probiotic (HFDP) groups. Behavioral analysis showed that HFDP group exhibited a slightly higher mean discrimination ratio compared to the HFDC group, indicating a trend toward improved performance potentially associated with probiotic supplementation. Immunohistochemistry analysis showed a significant increase in microglial expression and activation, evidenced by elevated levels of the proinflammatory marker CD11b, in the hippocampus and cortex of HFDC mice. ***Conclusion:*** The mAb ^{89}Zr-BB5.1 targeted against C5 complement protein was assessed as a BBB patency and complement activation PET tracer in mouse models of AD. Counter to expectation the percentage of injected dose found in the brain inversely correlated with AD progression, measured by microglial activation, suggesting a confounding influence of HFD on BBB penetration potential of

^{89}Zr-BB5.1. qPCR is underway to assess the C5 expression in the livers and brains of mice from the study. Increased peripheral C5 expression in the HFD groups would explain the unexpected PET results.

OP-889

Dynamic Dual-PET imaging for simultaneous metabolic and perfusion information for cardiac imaging

Â. Cardoso[1], *A. Lopez-Montes*[1], *H. Sari*[1,2], *K. Zeimpekis*[1], *N. Rathod*[1], *N. Encina*[3], *J. L. Herraiz*[3], *A. Rominger*[1], *K. Shi*[1], *F. Caobelli*[1];
[1]*Inselspital, University Hospital Bern, Department of Nuclear Medicine, Bern, SWITZERLAND,* [2]*Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, SWITZERLAND,* [3]*Universidad Complutense de Madrid, Madrid, SPAIN.*

Aim/Introduction: Assessment of both perfusion (e.g. using 82Rb-Cl) and metabolism (18F-FDG) is crucial in some applications of cardiac PET. Traditionally, separate scans are required due to indistinguishable annihilation photons from different tracers. Recently proposed multiplexed PET (mPET) based on triple coincidences from isotopes like 82Rb, enables separation of two PET signals from the same acquisition. However, low probability (~13%) of triple emission in 82Rb challenges mPET. This study explores an alternative: leveraging tracer half-life differences and biodistribution patterns to enable dual-tracer separation in standard dynamic PET. ***Materials and Methods:*** Differences in half-lives of 82Rb (76s) and 18F (109min) and in their dynamic distribution can be leveraged to achieve dynamic separation of both isotopes. We developed a method for separation of 18F and 82Rb signals in a long axial field-of-view scanner assuming 18F distribution to be constant in a single frame (20s frame). The baseline 18F component was initialized from late frames after 82Rb has decayed and iteratively refined for every time frame. The method was tested using a NEMA IQ phantom with a background activity of 3.3 kBq/ml of 18F and different concentrations of 18F and 82Rb in the spheres ranging from 0 to 4 times the activity concentration in the background. Moreover, we tested our method on a healthy volunteer injected with ^{18}F-FDG (60MBq) followed by 82Rb (185MBq). ***Results:*** In the phantom study, 18F activity after separation showed deviations of less than 6% from pre-82Rb values, even in regions with overlapping tracer distribution, where accuracy remained within 5%. In the clinical case, 82Rb images generated by our method closely matched those from a separate 82Rb-only scan. Compared to mPET, our method produced lower image noise and better tracer separation, especially near the injection site, where 82Rb activity was dominant and mPET failed to isolate 18F. Importantly, myocardial dynamics post-separation aligned well with prior 82Rb images. This approach enables accurate dual-tracer imaging for simultaneous perfusion and metabolism assessment in a single scan. ***Conclusion:*** This study demonstrates the feasibility of separating 18F and 82Rb signals by exploiting their distinct dynamic distributions. The method proved effective in both phantom experiments and a clinical case, paving the way for simultaneous assessment of perfusion and metabolism in a single PET scan. This approach could streamline cardiac imaging by enabling double-isotope studies without additional dose or scan time. Future work will explore combining this strategy with mPET to further enhance isotope separation.

OP-890

Defining the Optimal Timeframe For Left Ventricular Volume Measurements in Gated Reconstructions of ^{13}N[NH_3] PET/CT in Adenosine-stressed Patients

L. Does[1], *R. J. J. Knol*[1], *S. T. Martínez-Lucio*[2], *F. M. van der Zant*[1], *S. V. Lazarenko*[1];
[1]*Noordwest Ziekenhuis, Alkmaar, NETHERLANDS,* [2]*UMCG, Groningen, NETHERLANDS.*

Aim/Introduction: In proven ischemia, the left ventricle (LV) is known to temporarily dilate upon stress. The objective of the present study was to define the optimal timeframe to measure LV dilation in gated reconstructions of [^{13}N]NH_3 PET/CT scans while using adenosine as the stressor. ***Materials and Methods:*** [^{13}N]NH_3 PET/CT datasets of 10 patients referred to the Department of Nuclear Medicine between December 2020 and June 2023 were retrospectively included in this study. All patients had proven myocardial ischemia. In these patients, the end-diastolic LV volume was compared between rest (at 12-15 min after starting acquisition) and stress (at 1-3, 5-7, and 9-11 min after starting adenosine administration). Measurements were performed with two software packages, i.e. Cedars QGS and Corridor 4DM. Means ± SD were calculated. Data were checked for normal distribution, and differences were evaluated with paired T-tests. A two-tailed $p<0.05$ was considered significant. ***Results:*** Cedars: The mean LV end-diastolic volume at rest proved to be 125.4±28.9 ml. During adenosine stress, the LV volume was 130.1±34 ml when measured between 1-3 minutes after starting adenosine stress (not significantly different from rest, p=0.210). At 5-7 min, this was 141.6±37.4 ml (significantly different from rest, p=0.005), whereas at 9-11 min a LV volume of 136.7±33.9 ml was measured (significantly different from rest, p=0.006). 4DM: Rest LV end-diastolic volume was 136.4±35.5 ml. Between 1-3 min in stress, this was 140.3±40.9 ml (not significantly different, p=0.483). Between 5-7 min stress, the LV volume was measured as 158.2±42.3 ml (significant, p=0.004), and between 9-11 min, the LV volume was measured as 152.8±36.6 ml (significant, p=0.004). Also, the data suggest that the pattern of LV dilation is variable among patients. While dilation of the LV remains stable during stress in some patients, others show dilation initially, followed by normalization over time. ***Conclusion:*** The optimal timeframe for LV volume measurements in gated reconstructions is between 5-7 minutes after starting adenosine administration, independent of the software package used. Absolute LV volume measurements show variation between software packages.

Data-driven energy efficiency in a high-throughput PET/CT department: a model for sustainable nuclear medicine

M. De Summa[1], *S. Spinosa*[1], *S. Fusaro*[1], *S. Annunziata*[2], *M. Calcagni*[2];
[1]*MEDIPASS Ergèa Group, Rome, ITALY,* [2]*Nuclear Medicine Unit, Department of Diagnostic Imaging, Oncological Radiotherapy and Hematology, Fondazione Policlinico Universitario Agostino Gemelli, Rome, ITALY.*

Aim/Introduction: The healthcare sector is increasingly called to contribute to global sustainability goals. Nuclear medicine departments, due to their high technological intensity, are significant energy consumers. This project investigates a data-driven model to optimize energy use in a high-throughput PET/CT department, aiming to reduce environmental impact, operational costs, and energy waste without compromising diagnostic efficiency. The initiative aligns with broader green healthcare strategies and highlights the role of digital monitoring and clinical engineering in sustainable process governance. ***Materials and Methods:*** An advanced energy monitoring platform was integrated into a high-volume PET/CT department (approx. 50 exams/day). Real-time energy consumption data from imaging systems and facility environments were collected and visualized through a dedicated dashboard. Key inefficiencies were identified, including prolonged standby modes, suboptimal temperature/humidity settings, and peak-time overuse. Based on these insights, automated strategies were developed for: 1 smart shutdown of imaging systems during idle periods, 2 dynamic control of climate conditions based on room occupancy, and 3 rescheduling of energy-intensive tasks to off-peak hours. The model was simulated under various operational scenarios to estimate efficiency gains. ***Results:*** Preliminary simulation results indicate that implementing the proposed energy optimization strategies could lead to a 22%

reduction in overall energy consumption. Environmental efficiency, measured as energy usage per exam, improved by approximately 18%. Furthermore, the estimated economic savings reached 15% of the annual energy-related operational costs. Importantly, these outcomes were achieved without any measurable impact on patient throughput or diagnostic workflow, suggesting that sustainability can be enhanced without compromising service quality. ***Conclusion:*** This study demonstrates the potential of a data-driven approach to improve energy efficiency in Nuclear Medicine departments, particularly in high-throughput PET/CT settings. By leveraging real-time monitoring and automated adjustments, it is possible to reduce environmental impact and operational costs while maintaining clinical performance. The model presents a scalable, replicable framework that supports digital sustainability in healthcare and reinforces the strategic role of clinical engineering in process optimization. Future steps include real-world implementation and long-term impact assessment.

IL-13Rα2-Targeted Radiotheranostics for Sarcoma: Advancing Precision Antibody-Based Therapy
P. Jeanjean[1], *M. Kumpf*[1], *S. Lee*[1], *L. Carter*[1], *S. Lovibond*[1], *L. Gajecki*[1], *S. Krebs*[2], *D. Veach*[1];
[1]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [2]*MD Anderson Cancer Center, Huston, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Despite initial responses with standard-of-care treatment, soft-tissue sarcomas recur at a high rate (50-70%) and patients with an advanced-stage disease have few effective therapeutic options. Novel therapeutic strategies are urgently needed.(1) Interleukin-13 receptor alpha-2 (IL-13Rα2) is a high-affinity cell surface receptor for interleukin-13. IL-13Rα2 is classified as cancer/testis-like antigen due to its overexpression in several malignancies, including sarcomas, while being largely absent in normal tissues. Its overexpression also correlates with poor prognostic.(2) We developed KLG-3, an Fc-optimized IgG4 human monoclonal IL-13Rα2-targeted antibody to detect and treat IL-13Rα2 positive malignancies, like sarcomas.(3) This project evaluates KLG-3 as a theranostic radioimmunopharmaceutical in two models of leiomyosarcoma (LMS), the most common soft-tissue sarcoma. ***Materials and Methods:*** IL-13Rα2 expression in human LMS-derived cell lines, SK-UT-1 and RKN, was assessed by flow cytometry. Immuno-PET/CT imaging with 5µg of ^{89}Zr-labeled KLG-3 (0.9MBq) or control IgG was performed in mice bearing subcutaneous LMS tumors (N=4/group) to assess tumor uptake and biodistribution. For therapy, SK-UT-1 tumor-bearing mice received a single intravenous dose of ^{225}Ac-KLG-3 or ^{225}Ac-IgG (N=4/group). Therapeutic efficacy and systemic toxicity of 18.5, 9.25 or 3.7kBq per 5µg dose were evaluated by monitoring tumor growth, body weight, hematology and blood chemistry. ***Results:*** Immuno-PET imaging revealed high tumor uptake of ^{89}Zr-KLG-3 at 3d post-injection, with 43.1+10.8%ID/g (SK-UT-1) and 37.0+7.4%ID/g (RKN), followed by a plateau and gradual clearance over 14d. High tumor-to-background ratios (heart, kidney, muscle) were observed. Tumor uptake in ^{89}Zr-IgG group was similar to blood pool. Prospective PET imaging-derived dosimetry estimated maximum tolerated dose (MTD) on bone marrow of 18.5-37kBq for ^{225}Ac-KLG-3 and 18.5MBq for ^{177}Lu-KLG-3. The ongoing ^{225}Ac-KLG-3 pilot therapy study in a large tumor-burden model demonstrates tumor growth delay and increases in overall survival in the 18.5 kBq of ^{225}Ac-KLG-3 group only (32.5d; 2/4 deaths) compared to control (24.5d; 4/4 deaths). No evidence of acute toxicity has been observed in surviving animals at day 25; non-responders were euthanized at endpoint due to disease progression. ***Conclusion:*** These findings suggest that KLG-3 is a promising radioimmunotherapeutic agent for IL-13Rα2-positive sarcomas. ^{89}Zr-KLG-3 immuno-PET clearly delineated tumors in LMS xenografts and cleared well from off-target tissues. At 18.5kBq, ^{225}Ac-KLG-3 was well tolerated, resulted in significant therapeutic effect without evidence for acute toxicity. Ongoing dose-escalation studies will confirm the ^{225}Ac- and ^{177}Lu-KLG-3 MTD and compare therapeutic efficacy of α- versus β-emitting isotopes for KLG-3-based radioimmunotherapy. ***References:*** 1. OP-205

High Activity, Pain Relief, and Low Toxicity of ^{177}Lu-Labeled DOTA-IBA in the theranostics of Bone Metastases from Multiple Tumors: A Preliminary Clinical Trial

C. Qi[1,2], *C. Tian*[1,2], *F. Wu*[1,2], *J. Yang*[1,2], *W. Wang*[1,2], *X. Li*[3], *Y. Chen*[1,2];
[1]*Affiliated Hospital of Southwest Medical University, Luzhou, CHINA,* [2]*Nuclear Medicine and Molecular Imaging Key Laboratory of Sichuan Province*, *Southwest Medical University, Luzhou, CHINA,* [3]*Vienna General Hospital, Vienna, AUSTRIA.*

Aim/Introduction: ^{177}Lu-DOTA-IBA has been proven to be an excellent therapeutic radiopharmaceutical for bone metastases. This study aimed to explore its application value in bone metastases from various tumors. ***Materials and Methods:*** Advanced tumor patients with bone metastases and poor clinical outcomes were recruited for a study on ^{68}Ga/^{177}Lu-DOTA-IBA. Biochemical and hematological tests were performed before PET/CT examinations. Patients received ^{68}Ga-DOTA-IBA (0.05 mCi/kg) and ^{18}F-FDG (0.15 mCi/kg) intravenously on consecutive days, and PET/CT imaging was carried out 1.5-2 hours and 1 hour after administration, respectively. Nuclear medicine physicians evaluated patients' eligibility for ^{177}Lu-DOTA-IBA treatment based on their conditions and lesion imaging features. Eligible patients received 2 to 6 treatment cycles. After slowly intravenous infusion of 30 mCi of ^{177}Lu-DOTA-IBA, whole-body planar imaging (including anterior and posterior views) and single-photon emission computed tomography (SPECT)/CT imaging of the target area were performed at 4 hours, 24 hours, 48 hours, 72 hours, and 168 hours to assess biodistribution and dosimetry. The treatment efficacy and adverse events were evaluated by analyzing the changes in clinical symptoms, imaging comparisons, and biochemical indicators. ***Results:*** The research team has performed ^{68}Ga-DOTA-IBA imaging on more than 1,000 patients and administered ^{177}Lu-DOTA-IBA treatment to more than 300 patients. Groups A-F in the figure respectively display the maximum intensity projection (MIP) images of ^{68}Ga-DOTA-IBA PET/CT of patients with bone metastases from prostate cancer, lung cancer, breast cancer, pancreatic cancer, pheochromocytoma, and liver cancer before and after treatment. The ^{68}Ga/^{177}Lu-DOTA-IBA drug showed good tolerability, and no severe drug-related adverse events were observed in the studied cases. In a few cases, mild to moderate leukopenia occurred in treated patients. ^{68}Ga-DOTA-IBA is mainly excreted through the renal pathway and has minimal distribution in normal bone tissues. Similarly, ^{177}Lu-DOTA-IBA is also mainly excreted through the renal pathway and shows uptake and long-term retention in the areas detected as positive by ^{68}Ga-DOTA-IBA PET/CT. Bone pain relief was observed in 82.7% of the cases. From imaging results such as osteogenic reactions, it can be seen that this treatment showed significant therapeutic effects in some metastatic lesions. ***Conclusion:*** The current treatment cases illustrate the efficacy and safety of ^{68}Ga-DOTA-IBA PET/CT for disease imaging and ^{177}Lu-DOTA-IBA for treating bone metastases from various tumors. The integrated diagnostic and therapeutic approach of ^{68}Ga/^{177}Lu-DOTA-IBA is expected to make substantial contributions to the management of bone pain and bone metastases in cancer patients.

OP-206

Preclinical Evaluation of NYM096: A Novel ^{68}Ga/^{177}Lu-Labeled CAIX-Targeting Theranostic Pair for Clear Cell Renal Cell Carcinoma

W. Zhu[1], *S. Yang*[2], *W. Lv*[2], *W. Eng*[2], *P. Fang*[2], *L. Huo*[1];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*Norroy Bioscience Co., Ltd., Wuxi, CHINA.*

Aim/Introduction: Carbonic anhydrase IX(CAIX), markedly overexpressed in clear cell renal cell carcinoma (ccRCC) with restricted expression in healthy tissues, represents an ideal target for tumor-selective theranostics. This study investigated the diagnostic and therapeutic potential of NYM096, a novel ^{68}Ga/^{177}Lu-labeled small-molecule conjugate targeting CAIX, in ccRCC xenograft models. ***Materials and Methods:*** OS-RC-2 human ccRCC cancer cells were subcutaneously transplanted in BALB/c(nu/nu) mice (6 week-old). For PET imaging, ^{68}Ga-NYM096 (80±10uCi, n=4) was intravenously administered to tumor-bearing mice followed by scans at 0.5, 1, and 2 hours post-injection (p.i.). For biodistribution evaluation, ^{177}Lu-NYM096 (300± 20 uCi) was injected (n= 3 per time point), and mice were sacrificed for organ harvesting at 4 and 48 hours. Therapeutic experiments included three dose groups (0.22, 0.67, 2 mCi; n=6 /group) and a saline control (n=6), with blinded assessment of tumor volume and body weight monitored for 35 days. ***Results:*** PET imaging demonstrated rapid and specific delineation of OS-RC-2 xenografts using ^{68}Ga-NYM096, with progressive tracer accumulation peaking at 16.8 ± 3.2% ID/g by 2 hours p.i. and a tumor-to-muscle ratio of 12.8. The tracer was predominantly cleared via the renal pathway. Biodistribution studies revealed tumor-specific accumulation of

^{177}Lu-NYM096, achieving 16.0 ± 4.1% ID/g at 4 h and sustained retention of 6.3 ±2.6% ID/g at 48 h, significantly exceeding muscle tissue levels ($P < 0.05$). Therapeutic evaluation confirmed dose-dependent tumor growth inhibition ($P < 0.05$ for all doses vs control). In the high-dose (2 mCi) treatment group, tumors shrunk without regrowing up to 35 days after a single dose and the tumor growth inhibition rate was over 85%. Furthermore, histopathological analysis of major organs (heart, liver, kidneys, etc.) showed no significant differences in H&E staining scores between treatment and control groups. ***Conclusion:*** The CAIX-targeted theranostic pair ^{68}Ga/^{177}Lu-NYM096 demonstrates precise tumor visualization and potent therapeutic efficacy in ccRCC models, with preserved organ safety supporting clinical translation.

OP-207

Preclinical Evaluation of NYM097: A Novel ^{68}Ga/^{177}Lu-Labeled FAP-Targeting Theragnostic Pair for Pan-Cancer

F. Cui[1], *S. Yang*[2], *W. Lv*[2], *M. Ren*[2], *W. Eng*[2], *P. Fang*[2];
[1]*Department of Oncology, The People's Hospital of Ma Anshan, Ma Anshan, CHINA,* [2]*Norroy Bioscience Co., Ltd., Wuxi, CHINA.*

Aim/Introduction: Fibroblast activation protein alpha (FAP), markedly overexpressed in various solid tumor tissues with restricted expression in healthy tissues, represents an ideal target for tumor-selective theragnostic. This study investigated the diagnostic and therapeutic potential of NYM097, a novel ^{68}Ga/^{177}Lu-labeled small-molecule conjugate targeting FAP, in FAP humanized MC38 syngeneic mouse model. ***Materials and Methods:*** FAP humanized MC38 cells (B-hFAP MC38) were subcutaneously transplanted in C57BL/6 mice (6-8 weeks-old). For PET imaging, ^{68}Ga-NYM097 (80±16 μCi, n=5) was intravenously administered to the tumor-bearing mice followed by scans at 1, 2, and 4 hours post-injection (p.i.). For biodistribution evaluation, ^{177}Lu-NYM097 (300± 60 μCi) was injected (n=3 per time point), and mice were sacrificed for organ harvesting at 4 and 48 hours. Therapeutic experiments included a dose group (2 mCi; n=6) and a saline control (n=6), with blind assessment of tumor volume and body weight monitored for 19 days. ***Results:*** PET imaging demonstrated rapid and specific delineation of B-hFAP MC38 syngeneic models using ^{68}Ga-NYM097, with progressive tracer accumulation peaking at 3.6±2.0% ID/g by 1 hours p.i. and a tumor-to-muscle ratio of 13.1. The tracer was predominantly cleared via the renal pathway. Biodistribution studies revealed tumor-specific accumulation of ^{177}Lu-NYM097, achieving 9.6±0.2% ID/g at 4 h and sustained retention of 3.7±0.5% ID/g at 48 h, significantly exceeding muscle tissue levels. Therapeutic evaluation confirmed 2 mCi ^{177}Lu-NYM097 could significantly inhibit tumor growth (Tumor growth inhibition rate was 62.3%; $P<0.05$ for vs control), and animals have good tolerance to treatment during the experiment. ***Conclusion:*** The FAP-targeted theragnostic pair ^{68}Ga/^{177}Lu-NYM097 demonstrates precise tumor visualization and potent therapeutic efficacy in tumor models, with well safety supporting clinical translation.

OP-208

Identification and characterization of ^{64}Cu- and ^{225}Ac-PD-32766, a Carbonic Anhydrase IX targeting macrocyclic peptide radiotheranostic pair for clear cell renal cell carcinoma (ccRCC)

S. Tsuchida[1], *Y. Mizukoshi*[1], *S. Kato*[1], *H. Inaba*[1], *T. Kotake*[1], *T. Aoki*[1], *H. Shimizu*[1], *Y. Funase*[2], *N. Kanazawa*[2], *H. Yanagida*[1], *H. Kitamura*[1], *K. Matsuhara*[2], *K. Suzuki*[2], *S. Matsushima*[2], *M. Murakami*[1,2];
[1]*PeptiDream Inc., Kanagawa, JAPAN,* [2]*PDRadiopharma Inc., Chiba, JAPAN.*

Aim/Introduction: Carbonic Anhydrase IX (CA9) is a zinc metalloenzyme that contributes to the pH regulation of cells and tissues by catalyzing the conversion of carbon dioxide and water into bicarbonate and protons. CA9 expression is regulated by HIF1a and has been shown to be upregulated in hypoxic tumor microenvironments, including clear cell renal cell carcinoma (ccRCC), identifying CA9 as an attractive therapeutic target. Utilizing our proprietary Peptide Discovery Platform System (PDPS), PeptiDream has identified PD-32766, a novel macrocyclic peptide specifically targeting CA9 that can be labeled with radionuclides such as ^{64}Cu and ^{225}Ac enabling both PET imaging and targeted alpha therapy. Here we report the radiotherapeutic potential of PD-32766 for ccRCC. ***Materials and Methods:*** PD-32766 was identified from PDPS libraries containing trillions of macrocyclic peptides with non-canonical amino acids that were selected against CA9 using mRNA display and directed evolution. The binding affinity of PD-32766 was measured by SPR and the in vitro cellular internalization of PD-32766 was confirmed by confocal microscopy with fluorescent labelled PD-32766. ^{64}Cu- or ^{225}Ac-PD-32766 was dosed to VMRC-RCW (ccRCC cell line) xenograft mice and the percentage of injected dose (%ID/g) in tumors and major organs was quantified by cut and count method. For the PET imaging study, ^{64}Cu-PD-32766 was dosed to VMRC-RCW xenograft mice and scanning was performed at 1, 4, 24, 48 hrs. To measure efficacy, single dosing of ^{225}Ac-PD-32766 (30, 60, 120 kBq/mouse) was conducted in VMRC-RCW xenograft mice and the tumor volume was measured for up to 50 days after dosing. To estimate the dosimetry in adult human subjects, SD rats were injected with ^{225}Ac-PD-32766 and sacrificed at 0.083, 1, 4, 24, 48, 120, and 168 hours post injection to evaluate blood and tissue radioactivity concentration. ***Results:*** PD-32766 exhibited strong and specific binding to CA9 and fluorescence labeled PD-32766 was internalized in VMRC-RCW (CA9-expressing cell line), but not 786-O (CA9-negative cell line). Biodistribution studies with ^{64}Cu- and ^{225}Ac-PD-32766 showed significant and specific tumor accumulation in VMRC-RCW xenograft models, with enrichment of tumor accumulation over off target. PET imaging with ^{64}Cu-PD-32766 clearly detected tumors, consistent with the biodistribution data. In the efficacy study, ^{225}Ac-PD-32766 showed remarkable and dose dependent tumor volume reduction and prolonged overall survival, strongly suggesting robust anti-tumor effects with dosimetry experiments confirming fast renal clearance from blood. ***Conclusion:*** CA9 targeting PD-32766 is a promising radiotheranostic peptide for ccRCC.

OP-209

A Novel [^{11}C]/[^{211}At]-Labeled Radiopharmaceutical Pair Targeting mGluR1 for Melanoma Imaging and Therapy

L. Xie[1], *M. Hanyu*[1], *M. Fujinaga*[1], *Y. Zhang*[1], *T. Kokufuta*[1], *W. Mori*[1], *K. Minegishi*[1], *L. Zhang*[1,2], *R. Luo*[1,2], *H. Wakizaka*[1], *M. Zhang*[1];
[1]*National Institutes for Quantum Science and Technology, Chiba, JAPAN,* [2]*Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.*

Aim/Introduction: Metabotropic glutamate receptor 1 (mGluR1), an oncoprotein involved in glutamine metabolism and frequently overexpressed in a wide range of cancers, including melanoma, represents a promising target for pan-cancer management (1-2). Here, we developed a novel pair of mGluR1-targeted radiopharmaceuticals that combines positron emission tomography (PET) imaging and targeted alpha(α) therapy (TAT) for cancer diagnosis and therapy. ***Materials and Methods:*** Two small-molecule radiopharmaceuticals were synthesized by labeling the same small-molecule compound with either a diagnostic isotope ^{11}C or an α-emitting therapeutic isotope ^{211}At: 3-iodo-N-[4-[6-(methylamino)pyrimidin-4-yl]-1,3-thiazol-2-yl]-N-[^{11}C]methylbenzamide([^{11}C]IMTM) for PET imaging, and 3-[^{211}At]-astato-N-[4-[6-(methylamino)pyrimidin-4-yl]-1,3-thiazol-2-yl]-N-methylbenzamide ([^{211}At]AMTM) for TAT. Their diagnostic and therapeutic effects were assessed in vitro and in vivo using mGluR1-expressing B16F10 melanoma cells and corresponding tumor-bearing mouse models. ***Results:*** Both [^{11}C]IMTM and [^{211}At]

AMTM showed high binding affinity and specificity for mGluR1 in B16F10 cells in vitro. PET imaging with [^{11}C]IMTM clearly visualized subcutaneous and metastatic tumors in B16F10 melanoma models. [^{211}At]AMTM anchored to mGluR1, downregulated this oncoprotein expression, and was subsequently internalized to trigger cancer cell senescence via the p21/caveolin-1 pathway. In vivo, a single dose (2.96 MBq) of [^{211}At]AMTM significantly inhibited tumor growth and doubled survival in both subcutaneous and metastatic melanoma models. No significant body weight loss or adverse effects on liver or kidney function were observed in treated mice during the study period. ***Conclusion:*** The radiopharmaceutical pair [^{11}C]IMTM and [^{211}At]AMTM shows strong precise as mGluR1-targeted radiopharmaceuticals for radiotheranostics. They offer a precise and effective option for diagnosing and treating mGluR1-expressing cancers, such as melanoma, and hold considerable potential for clinical translation.

OP-210

Theranostic role of^{89}Zr and^{177}Lu labeled B7H3 probe in prostate cancer

L. Kang, *Y. Qiu, T. Wang, Q. Yang, L. Song, Y. Lei, X. Sun;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: B7-H3 is a cell surface immunomodulatory glycoprotein overexpressed in prostate cancers (PCs). Understanding its expression in PC lesions and exploring the integration of diagnosis and treatment are essential for the development of B7-H3 targeted therapy and patient selection. BH201 is an antibody-drug conjugate targeting B7H3 that has been shown to be effective against small cell lung cancer and nasopharyngeal carcinoma. Therefore, ^{89}Zr/^{177}Lu-labeled BH201 was investigated for its theranostic role in PCs. ***Materials and Methods:*** BH201 was radiolabeled with ^{89}Zr and ^{177}Lu. Flow cytometry was conducted to assess the binding affinity of BH201. Sequential positron emission tomography (PET) imaging was performed in PC tumor bearing mice following the administration of ^{89}Zr-labeled BH201. A treatment study was subsequently performed after the administration of ^{177}Lu-labeled BH201. Tumor volume was monitored, and single-photon emission computed tomography (SPECT) imaging along with biodistribution studies were executed. Safety evaluation was performed including body weight, blood cell measurement, and hematoxylin-eosin (H&E) staining of major organs. ***Results:*** FITC-labeled BH201 showed a strong binding affinity to B7H3 in PC 22RV1 cells by flow cytometry. Tumor uptake of ^{89}Zr-labeled BH201 peaked at 144 h (19.43 ± 3.24 %ID/g), which was significantly higher than that of blocking group (7.10 ± 0.96 %ID/g). After treatment with 7.4 MBq ^{177}Lu-labeled BH201, the tumor volume was significantly reduced, and the standardized tumor volume at day 20 was significantly less than that in the ^{177}Lu-labeled IgG group (71.11 ± 20.65% vs 272.50 ± 154.37%). Moreover, SPECT images confirmed high contrast between tumors and normal organs, indicating selective tumor uptake of ^{177}Lu-labeled BH201. No discernible abnormalities in blood cells, and no evident histopathological abnormality observed in liver, spleen, and kidney. ***Conclusion:*** The ^{89}Zr/^{177}Lu-labeled BH201 compound has the potential to serve as a specific marker for prostate cancers, offering diagnostic value and enhancing understanding of targeted therapeutic approaches for PCs treatment. Further clinical evaluation and translation of this compound could be highly significant for advancing PCs management.

Aim/Introduction: CD38 is a transmembrane glycoprotein overexpressed in haematologic malignancies, promoting tumour growth and immune evasion. Its overexpression in lymphoid malignancies renders CD38 an attractive theranostic target with antibodies such as isatuximab (ISA). The aim of our study was to design and develop an ISA-based radiotheranostic platform for both positron emission tomography (PET) imaging and targeted radionuclide therapy (TRT) in a CD38-positive lymphoma model. ***Materials and Methods:*** ISA was site-specifically conjugated to a bischelate scaffold (DFO-DOTAGA) and radiolabelled with either zirconium-89 ([^{89}Zr]Zr-DFO-DOTAGA-ISA) or lutetium-177 ([^{177}Lu]Lu-DFO-DOTAGA-ISA). In vitro binding assays were perfomed to confirm that conjugation and radiolabeling preserved CD38 affinity. Ramos Burkitt's lymphoma cells were implanted subcutaneously in Swiss nude mice (n = 12). Six mice received 50 µg of [^{89}Zr]Zr-DFO-DOTAGA-ISA (5 MBq) intravenously; PET scans were acquired at 6, 24, 48, 72 and 96h post-injection (p.i.), followed by ex vivo γ-counting at 96h. Specificity was confirmed by co-injection of a 100-fold excess of unlabelled ISA (blocking group, n = 3). For TRT, mice (n = 10 per group) received 25 µg of [^{177}Lu]Lu-DFO-DOTAGA-ISA at low (3 MBq), medium (7 MBq) or high (11 MBq) doses whereas control groups (n = 6) received either PBS or [^{177}Lu]Lu-DFO-DOTAGA-isotype (IgG1) at 3, 7 or 11 MBq. Single-photon emission computed tomography (SPECT) was performed at 48 h p.i., and mice were monitored for body weight loss, tumour volume, and complete blood count. ***Results:*** After radiolabeling and purification, the radiochemical purity of ISA exceeded 95% with a specific activity of 300 MBq/mg. In vitro experiments demonstrated good binding properties (Kd = 0.48 nM) close to the native antibody. PET imaging revealed progressive tumour uptake, peaking at 26.4 ± 1.5 %ID/g at 96h, while blocking reduced uptake by 3.5-fold (7.9 ± 1.5 %ID/g), as confirmed by ex vivo biodistribution. SPECT confirmed tumoral uptake in TRT groups. High-dose TRT induced significant tumour regression sustained for 10 days and improved survival compared with controls with no significant weight loss or haematological toxicity. ***Conclusion:*** Our study demonstrates that radiolabelled ISA may represent a promising radiotheranostic agent for CD38-positive lymphomas. The versatility of the DFO-DOTAGA bischelate enables TRT with 177Lu, supported by PET-derived dosimetry data. This strategy represents an initial step towards personalised treatment approaches, with the potential to enhance therapeutic efficacy while minimising adverse effects in various CD38 positive lymphoid malignancies.

A Novel CEA-Targeted Nanobody Conjugated with Radionuclides for the Theranostics of Colorectal Cancer

W. Wang, *C. Lu, M. Zhou, S. Hu;*
Xiangya Hospital of Central South University, Changsha City, CHINA.

Aim/Introduction: Colorectal cancer (CRC) is a highly lethal malignancy worldwide, with a 5-year survival rate of less than 20% in metastatic patients. There is an urgent need for novel targeted diagnostic and therapeutic strategies. Carcinoembryonic antigen

(CEA) is overexpressed in most CRCs and serves as a potential target for diagnosis and therapy. This study developed a novel CEA-targeted theranostic nanoprobe, [^{68}Ga/^{177}Lu]Ga-Nb-CEA-21, and evaluated its potential utility for non-invasive PET/CT imaging and radionuclide-targeted therapy (TRT) in colorectal cancer (CRC). ***Materials and Methods:*** CEA-specific nanobodies were selected using camel immunization and phage display technology. The affinity and stability of these nanobodies were confirmed by ELISA. High-affinity, stable nanobodies (e.g., CE-21, CE-88) were used to construct monovalent (CE-21), bivalent (CE-21-21), and trivalent (CE-21-21-21) structures, followed by molecular docking for target verification. Radiolabeling was performed with ^{68}Ga/^{177}Lu, and the radiochemical purity (>95%) and in vitro stability of the probes were measured using Radio-HPLC. Their targeting ability and biocompatibility were evaluated at the cellular level. PET/CT imaging of LS174T xenograft tumor models was performed using the [^{68}Ga] probe, and the [^{177}Lu] probe was tested in dose-dependent therapy experiments (7.4/18.5 MBq). Efficacy and safety were evaluated using HE staining, γH2A.X immunohistochemistry, and biochemical assays for liver and kidney function. ***Results:*** ELISA screening identified CE-21, CE-85, and CE-88 as high-affinity binders to CEA, with CE-21 and CE-88 demonstrating superior stability. The synthesized [^{68}Ga]Ga-Nb-CEA-21 probe remained stable in saline/serum for 4 hours, and PET/CT imaging showed tumor uptake of 3.67±0.05 %ID/g, with a T/M ratio of 15.98±3.18 at 1 hour post-injection, outperforming other variants. In therapy experiments, even the 7.4 MBq low-dose group significantly inhibited tumor growth (t-test, p=0.003). The 18.5 MBq group extended survival to twice that of the saline control group (Log-rank test, p<0.0001), with no significant liver or kidney toxicity. ***Conclusion:*** The [^{68}Ga]Ga-Nb-CEA-21 probe enabled precise PET/CT imaging of CEA-positive CRC, while the [^{177}Lu]Lu-Nb-CEA-21 probe demonstrated significant anti-tumor effects at low doses. This dual-modality probe provides an effective tool for integrated CRC diagnosis and treatment, showing significant clinical translation potential.

Can antigenicity counterbalance tumor low absorbed dose in targeted alpha therapy?

J. Pouget[1], *A. Parach*[1], *T. David*[1], *J. Karam*[1], *F. Bruchertseifer*[2], *A. Morgenstern*[2], *M. Jarlier*[3], *M. Bardiès*[1], *E. Deshayes*[1], *A. Gudin-De-Vallerin*[3], *F. Boissière-Michot*[3], *E. Crapez*[3], *J. Constanzo*[1]; [1]*INSERM, Montpellier, FRANCE,* [2]*European Commission, Joint Research Centre, Karlsruhe, GERMANY,* [3]*Institut régional du Cancer, Montpellier, FRANCE.*

Aim/Introduction: Preclinical and clinical studies increasingly show that the immune response plays a major role in radiotherapy. Here, we investigated the role of major histocompatibility complex class I (MHC-I) molecules recognized by cytotoxic CD8$^+$ T cells in the response to targeted alpha therapy (TAT). ***Materials and Methods:*** Two murine melanoma cell lines that express low or high MHC-I levels (B16F10 MHC-I^{low} and B16K1 MHC-I^{high}) were grafted in syngeneic or athymic/nude mice and the response to a single injection of [^{225}Ac]Ac-DOTA-TA99 monoclonal antibodies (9.25 or 18.5 kBq) was assessed and related to dosimetry. For clinical relevance, MHC-I expression was determined in samples from patients with well-differentiated, iodine-avid metastatic thyroid cancer and well-differentiated grade 2 midgut neuroendocrine tumors. ***Results:*** TAT efficacy was enhanced by T-cell presence and MHC-I expression. In mice harboring B16F10 and B16K1 melanoma tumors, TAT showed a stronger anti-tumor effect in C57BL/6J (immunocompetent) than in athymic/nude (immunodeficient) animals, suggesting a crucial role of T cell-mediated immune responses. Moreover, the response to irradiation was the same in B16K1 MHC-I^{high} tumors with low absorbed dose of TAT and in B16F10 MHC-I^{low} tumors with four times higher absorbed dose. These results indicate that CD8$^+$ T cells can counterbalance low tumor irradiation. Conversely, delivering high absorbed doses leads to side effects, and seems to prevent the immune system activation, thereby not taking advantage of these mechanisms. Our results also indicate that MHC-I can be used as a predictive biomarker of TAT response in lesions receiving low absorbed doses, and that TAT treatment regimens should be re-considered in function of the MHC-I expression level. ***Conclusion:*** This study shows that MHC-I expression can predict TAT immunostimulatory effects. This is relevant in metastatic disease where lesions in the same patient can receive very low or very high absorbed doses.

OP-214

Targeted Radionuclide Therapy as Immune Adjuvant for Cancer Treatment: Comparing Beta and Alpha Emitter Absorbed Doses to Stimulate Anti-Tumor Responses.

J. Pouget[1], *T. David*[1], *S. Atis*[1], *A. Pichard*[2,3], *S. Frost*[3,4], *J. Constanzo*[1]; [1]*INSERM, Montpellier, FRANCE,* [2]*Institut Roche, Boulogne-Billancourt, FRANCE,* [3]*Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, SWITZERLAND,* [4]*Roche Pharma Research and Early Development, Roche Innovation Center Welwyn, Welwyn Garden City, UNITED KINGDOM.*

Aim/Introduction: Targeted radionuclide therapy (TRT) has significantly advanced the treatment for neuroendocrine tumors and prostate cancer, but its curative potential remains limited. While external beam radiotherapy can induce immunogenic cell death and transform "cold" (immune-desert) tumors into "hot" (immune-inflamed) at specific doses, these parameters remain undefined for TRT. A recent study from our group demonstrates that alpha-TRT efficacy is enhanced by MHC-I expression and CD8+ T cell infiltration, even at low absorbed dose[1]. Here, we investigate in BALB/c mice orthotopically engrafted with the mouse mammary tumor cell line TUBO, the role of absorbed dose of radiopharmaceuticals modulating anti-tumor immune response, comparing a beta emitter (^{177}Lu) and an alpha emitter (^{212}Pb). ***Materials and Methods:*** In vivo biodistribution of ^{177}Lu- and ^{212}Pb-labeled anti-HER2 antibodies (^{177}Lu-TRT and ^{212}Pb-TRT) was determined to calculate tumor absorbed doses (Gy) using MIRD formalism. Next, the therapeutic efficacy (tumor growth and survival) of increasing ^{177}Lu-TRT activities (1-5-10 MBq, absorbed doses of 2-11-22 Gy) was assessed. Immunogenicity markers on tumor cells and immune cell populations in tumors post-treatment were analyzed by multi-color flow cytometry. ***Results:*** ^{177}Lu-TRT significantly improved tumor control and survival at absorbed doses above 2 Gy, with median survival increasing from 23 days (control) to 33 days (2 Gy), 78 days (11 Gy), and >110 days (22 Gy). Complete responses were observed in 30% (11 Gy) and 67% (22 Gy) of mice at day 74. Subsequent rechallenge of tumor-free mice with five-fold TUBO cells revealed enhanced protection in the 11 Gy group compared to the 22 Gy group, suggesting a potential in situ vaccine-like effect, inversely correlated with the tumor absorbed dose. Immunophenotyping revealed decreased immunosuppressive M2-like macrophages at both 11 Gy and 22 Gy, but significant CD8+ T cell infiltration occurred only at 11 Gy. In vitro studies demonstrated that ^{212}Pb-TRT induced higher expression of immunogenicity markers on tumor cells

compared to ^{177}Lu-TRT, potentially leading to better recognition by anti-tumor immune cells. ***Conclusion:*** Despite superior TUBO tumor control at higher absorbed doses, the intermediate ^{177}Lu-TRT dose resulted in enhanced long-term protective vaccine-like effects. In vitro, the stronger immunomodulatory profile of ^{212}Pb-TRT suggests that the alpha emitter may be more effective at activating immune responses. These findings indicate that an intermediate absorbed dose combined with immune checkpoint inhibitors may produce optimal therapeutic responses through enhanced immune system activation. ***References:*** MHC-I-Driven Antitumor Immunity Counterbalances Low Absorbed Doses of Radiopharmaceutical Therapy. Targeted Radionuclide Therapy Against Cancer-Associated Fibroblasts: A Promising Alternative or Complement to External Beam Radiotherapy

J. Pouget[1], *L. Ordas*[1], *S. Atis*[2], *S. Poty*[1], *A. Parach*[1], *T. Lahoutte*[2], *L. Navarro*[2], *M. D'Huyvetter*[2];
[1]*INSERM, Montpellier, FRANCE,* [2]*PRECIRIX, Brussels, BELGIUM.*

Aim/Introduction: The tumor microenvironment plays a crucial role in driving cancer progression. It is composed of the extracellular matrix and various non-cancerous cells, notably cancer-associated fibroblasts (CAFs). Conventional therapies, including chemotherapy and external beam X-ray radiotherapy (EBRT), often show limited success in improving patient survival. This limitation is largely attributed to pronounced desmoplasia, with CAFs identified as key contributors and potential therapeutic targets. Studies have shown that EBRT induces a senescence-associated secretory phenotype (SASP) in CAFs, which can enhance tumor cell invasion and growth. In this study, we investigate and compare the in vitro biological response of CAFs to EBRT and targeted radionuclide therapy (TRT). ***Materials and Methods:*** In vitro, immortalized human CAFs were exposed to TRT using single-domain antibodies radiolabeled with ^{177}Lu (^{177}Lu-sdAb; 0-8 MBq/mL), or to X-ray irradiation (0, 2, 4, 8 Gy). Clonogenic survival, proliferation, cell cycle progression, and senescence induction (assessed via β-galactosidase activity, persistent DNA damage, and lamin B1 expression) were evaluated. The CAF secretome following both treatments was analyzed using a multiplex cytokine array . In vivo, immunodeficient mice bearing subcutaneous patient-derived xenograft (PDX) ovarian tumors were treated with either various activities of ^{177}Lu-sdAb, different X-ray fractionation schemes, or a combination of TRT and EBRT. Tumor growth was monitored, and treatment-related toxicity was assessed. Dosimetry was performed at both the cellular and whole-body levels, and the biologically effective dose (BED) was used to compare the different radiotherapy modalities. ***Results:*** Clonogenic survival of CAFs decreased with increasing activity/dose following both EBRT and TRT. Specifically, CAF survival at 2 Gy or 2 MBq/mL (0.8 Gy) was approximately 50% and 55%, respectively. However, while clonogenic death was associated with cell proliferation arrest and senescence induction accompanied by SASP after EBRT, this was not observed following TRT. Interestingly, only the secretome of TRT-treated CAFs induced a cytotoxic bystander effect, reducing tumor cell clonogenic survival to 70%. In vivo, tumor growth was delayed after both TRT and X-ray irradiation, and BED was indicative of a long-term response. However, relapse was observed 140 days post-therapy with EBRT, while stable disease was maintained with TRT. ***Conclusion:*** Our findings suggest that CAF-targeted radionuclide therapy represents a promising strategy in cancer treatment. For an equivalent BED, continuous low dose rate irradiation of CAFs appears to be more advantageous than conventional EBRT. These results support the potential of TRT alone or in combination with EBRT as an effective therapeutic approach.

OP-216

Mechanistic insights into HSP90 inhibition as a sensitization strategy for PRRT

M. Sabatella*, P. Engbers, T. Reuvers, T. Heredia Genestar, J. Chang, N. Verkaik, J. Nonnekens;*
Erasmus Mc, Rotterdam, NETHERLANDS.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) employing [^{177}Lu]Lu-[DOTA-Tyr^3]octreotate (^{177}Lu-DOTA-TATE) has been established as treatment for patients with metastatic neuroendocrine tumors (NETs) overexpressing the somatostatin receptor (SSTR). While PRRT improves survival and quality of life, curative responses remain rare [1]. One way to enhance PRRT therapeutic efficacy is combining it with radiosensitizing agents such as heat shock protein 90 (HSP90) inhibitors. HSP90 is a highly conserved molecular chaperone essential for the maturation and stabilization of over 200 proteins, including proteins involved in the DNA damage response and oncogenic signaling [2]. HSP90-inhibition has been shown to potentiate PRRT [3], however the mechanism behind this radiosensitizing effect remains unknown. This study aimed to elucidate mechanisms involved in the radiosensitizing effect of HSP90 inhibition. ***Materials and Methods:*** We investigated the radiosensitizing potential of HSP90 inhibitor ganetespib in two NET cell lines: GOT1 and BON1-SSTR2. Cells were treated with X-ray as external beam radiotherapy (EBRT, 2 Gy) or PRRT (1 MBq/mL) alone or in combination with ganetespib and assessed cell viability (CellTiter-Glo assay) and cell death (flow cytometry). To investigate the influence of HSP90-inhibition on various DNA repair pathways, an end-joining assay was performed, as well as RAD51 (homologous recombination specific) and 53BP1 (double strand breaks in general) foci quantification. To investigate whether non-DNA damage response related mechanisms were involved in the radiosensitization potential of HSP90-inhibition, RNA sequencing was performed post-treatment, followed by differential expression and pathway enrichment analyses. ***Results:*** Ganetespib enhanced the cell killing efficacy of both PRRT and EBRT in GOT1 and BON1-SSTR2 cells. Although HSP90 inhibition reduced RAD51 foci numbers, its effect on non-homologous end joining and DNA damage persistence was limited. Transcriptomic analysis revealed enrichment of proteotoxic stress-related pathways - such as protein folding and stabilization - following combination treatment, which was consistent with effects observed in HSP90 inhibitor monotherapy. ***Conclusion:*** Since we do not find significant effects of HSP90-inhibition on direct DNA repair or transcriptomic responses, our findings suggest that HSP90 inhibition radiosensitizes NET cells by inducing a pleiotropic effect on multiple stress-related pathways rather than solely through disruption of DNA damage response mechanisms. This effect is likely driven by impaired proteostasis and induction of proteotoxic stress. ***References:*** [1] Strosberg, J.R., et al. (2021), Lancet Oncol. 22(12): p. 1752-1763. OP-217

Synthetically Lethal DNA Damage Response Inhibition Enhances [^{177}Lu]Lu-PSMA-617 Cure Rates in Advanced Prostate Cancer

M. Bio Idrissou*, E. Santos, H. Comas Rojas, A. Carston, O. Kwon, L. Wehner, N. Clemons, J. Munson, L. Batley, Y. Medina Guevara, I. Lambert, A. Pinchuk, B. Bednarz, G. Iyer, R. Hernandez;*
University of Wisconsin-Madison (UW-Madison), Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: [^{177}Lu]Lu-PSMA-617 has shown unprecedented therapeutic activity in metastatic castration-resistant prostate cancer (mCRPC). However, nearly half of the treated patients do not respond, and curative responses remain rare. We aim to expand [^{177}Lu]Lu-PSMA-617's efficacy by blunting the DNA

damage repair (DDR) response of mCRPC through a combination of poly(ADP-ribose) polymerase 1 (PARP1) and bromodomain and extra-terminal (BET) protein inhibition. ***Materials and Methods:*** A panel of prostate cancer (PCa) cells, including PC3-PIP, LNCaP, and 22Rv1, were treated with ^{177}Lu_(0.3-3 Gy), alone or combined with Talazoparib (PARP Inhibitor: TAZ), ABBV-075 (BET inhibitor), or both. Cell cycle profiling, RNA-sequencing, viability, clonogenic assays, and γ-H2AX staining were conducted. In vivo, PC3-PIP xenograft mice (N=5-10) received [^{177}Lu]Lu-PSMA-617_(37 MBq) with or without daily TAZ_(0.5 mg/kg), ABBV-075_(1 mg/kg), or both for 14 days. Controls received saline or monotherapy. Tumor progression, survival, and toxicity were monitored, with safety evaluated in naïve mice through hematology, biochemistry, and histopathology. ***Results:*** ABBV-075 treatment led to an increase in G1 arrest from 56.7 ±4.1 to 81.7 ±0.3% ($p < 0.04$) while TAZ and ^{177}Lu led to G2 arrest, from 17.9 ±4.1 to 85.1 ±0.2 and 81.3 ±0.1, respectively ($p < 0.02$) in AR-negative PC3-PIP cells. Importantly, ^{177}Lu+TAZ+ABBV-075 resulted in dual-phase (G1/G2) arrest, and the highest reduction in S-phase 9.6 ±1.2% versus 25.3 ±3.1% (control), 15.5 ±0.9% (^{177}Lu), 24.5 ±0.4% (^{177}Lu+TAZ), and 17.9 ±2.1% (^{177}Lu+ABBV-075). On the other hand, AR-positive LNCaP and 22Rv1 cells exhibited G1 arrest. RNA-sequencing data showed significant downregulation of key DDR-associated genes, including BRCA1/2, XRCC2, and RAD51 (Log_2FC: - 2 to - 4, $p < 0.001$) following ABBV-075 or ^{177}Lu+ABBV-075 treatments, across PCa cells. Viability and clonogenic assays corroborated enhanced cytotoxicity in all combination treatments, with the triple combination treatment (^{177}Lu+TAZ+ABBV-075, $p < 0.02$) consistently achieving the highest potency. Consequently, ^{177}Lu+TAZ+ABBV-075 displayed the highest number and persistent DNA breaks (γH2AX foci) compared with other treatments in PC3-PIP. In vivo, [^{177}Lu]Lu-PSMA-617+TAZ+ABBV-075 showed the highest efficacy (N= 8/8 complete response, $p < 0.05$) in the PC3-PIP xenograft model. No increase in toxicity was observed in combination treatments compared to [^{177}Lu]Lu-PSMA-617. ***Conclusion:*** Our result proved that pharmacologically induced G1/G2-phase arrest, S-phase suppression, and DDR downregulation are an effective radiosensitization strategy in mCRPC. This premise was demonstrated in vivo by the enhanced efficacy and curative rates achieved by the triple combination of TAZ+ABBV-075+[^{177}Lu]Lu-PSMA-617. Importantly, this enhanced treatment potency did not come with a safety tradeoff, thus suggesting an improvement in the overall therapeutic window.

OP-218

Transcriptional Silencing of DNA Repair Improves Targeted Alpha Therapy in Advanced Prostate Cancer

M. Bio Idrissou, *E. Santos, H. Comas Rojas, A. Carston, O. Kwon, L. Wehner, N. Clemons, J. Munson, L. Batley, Y. Medina Guevara, L. Lambert, A. Pinchuk, B. Bednarz, G. Iyer, R. Hernandez;*
University of Wisconsin-Madison (UW-Madison), Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Approximately 40% of metastatic castration-resistant prostate cancer (mCRPC) patients treated with [^{225}Ac]Ac-PSMA fail to respond, and cure rates remain at single-digit percentages. Unfortunately, xerostomia prohibits further dose escalation. Our approach to improve treatment responses in mCRPC involves Bromodomain and Extraterminal protein (BET) inhibition to suppress double-strand DNA repair genes and enhance the radiobiological efficacy of [^{225}Ac]Ac-PSMA. ***Materials and Methods:*** In vitro, PC3-PIP, LNCaP, and 22Rv1 cells were treated with ^{225}Ac (0.03-1 Gy) ± ABBV-075 (500 nM), a BET inhibitor (BETi). Assays included cell cycle analysis, RNA-sequencing, viability, clonogenic survival, and γH2AX (DNA breaks) staining. In vivo, nude mice bearing PC3-PIP xenografts (N=4-8) received ABBV-075 (1 mg/kg, 14 days) starting 3-days before, 3-days after, or with [^{225}Ac]Ac-PSMA (37 kBq, IV). Tumor growth and survival were monitored thrice weekly. Safety was assessed in naïve mice through biochemistry, complete blood count, and histopathology at days 7, 28, or 120. ***Results:*** In AR-negative PC3-PIP cells, ABBV-075 treatment significantly increased the G1 cell population from 56.7 ±4.1 to 81.7 ±0.3% ($p < 0.04$). On the other hand, ^{225}Ac primarily induced G2 arrest, from 17.9 ± 0.2 (control) to 78.9 ±0.2% ($p = 0.0037$). Combination of ABBV-075 with ^{225}Ac led to dual-phase (G1/G2) arrest and significantly reduced the S-phase population from 25.3 ±3.1% (control) to 10.53 ±3.2% ($p < 0.05$). AR-positive LNCaP and 22Rv1 cells mostly exhibit a G1-phase arrest. As expected, RNA-sequencing data revealed that ABBV-075 treatment was associated with downregulation of key DNA damage repair (DDR) genes, including BRCA1/2, XRCC2, and RAD51 (Log_2FC -2 to -6, $p < 0.001$), thereby sensitizing PCa cells to ^{225}Ac radiation. Viability and clonogenic assays revealed significantly enhanced cytotoxicity with ABBV-075 + ^{225}Ac ($p < 0.02$) across cell lines, resulting in a consistent 6 to 10-fold increase in relative biological effectiveness (RBE) compared to ^{225}Ac alone. Furthermore, ABBV-075 + ^{225}Ac induced sustained γH2AX foci, reflecting the diminished repair capacity in ABBV-075-treated cells. In vivo, all three tested combination treatments significantly enhanced tumor growth delay and extended overall survival compared to [^{225}Ac]Ac-PSMA alone ($p < 0.02$), with no noticeable toxicity. ***Conclusion:*** Our data provides a robust mechanistic and efficacy foundation warranting further exploration of BETi in combination with [^{225}Ac]Ac-PSMA in mCRPC. The observed dual-phase cell cycle arrest, downregulation of key DNA repair genes, and sustained DNA breaks in PCa cells demonstrate strong radiosensitization by ABBV-075, enhancing efficacy. Future efforts will focus on clinical translation and potential expansion to other RPT indications.

OP-219

Dissecting the Transcriptional and Cell Cycle effects of Alpha and Beta emitting Radionuclides on Prostate Cancer Cells

M. Bio Idrissou, *E. Santos, O. Kwon, B. Bednarz, G. Iyer, R. Hernandez;*
University of Wisconsin-Madison (UW-Madison), Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Radiopharmaceutical therapies (RPT) such as [^{177}Lu]Lu-PSMA-617 and [^{225}Ac]Ac-PSMA-617 have shown clinical benefit in patients with advanced prostate cancer (PCa), but only in half of the patients treated. To understand the mechanisms behind treatment failures, we performed comprehensive transcriptional and phenotypic profiling across a panel of PCa cell lines treated with ^{177}Lu or ^{225}Ac. ***Materials and Methods:*** PC3-PIP, LNCaP, and 22Rv1 were treated (24h) in vitro with ^{177}Lu (0.3-3 Gy) or ^{225}Ac (0.03-1 Gy). A comprehensive battery of in vitro assays, including flow cytometry, RNA-sequencing, γH2AX immunofluorescence, and clonogenic, was performed to assess treatment effects on cell cycle, gene expression, DNA repair dynamics, and radiosensitivity. ***Results:*** ^{177}Lu and ^{225}Ac treatments resulted in dose-dependent G2-phase arrest, increasing from 17.9 ±0.2 (control) to 83.8 ±0.9% and 78.9 ±0.2% ($p = 0.0037$) at 1 Gy in PC3-PIP_(PSMA+/AR-) cells. AR-positive LNCaP and 22Rv1 cells showed a trend towards G1-phase increases ($p > 0.05$). RNA-sequencing revealed broader changes in gene regulation for ^{177}Lu (3,257 DEGs: Differentially Expressed Genes) than for ^{225}Ac (1,451 DEGs) in PC3-PIP. Both treatments upregulated CCNG2 and BBC3 genes, involved in cell-cycle arrest and apoptosis, while ^{225}Ac uniquely downregulated DNA repair genes such as LIG1, and RAD54L (Log_2FC: -1.5 to -1.66; padj <0.005). In LNCaP cells, ^{225}Ac elicited stronger p53 pathway activation, with upregulation of TP53I3, and CDKN1A (Log_2FC: 3.27-6.41; padj <1E-3), and downregulated multiple homologous recombination (HR) genes, including BRCA1/2 (Log_2FC: -1.18 to -6.09; padj <1E-10), while ^{177}Lu induced less pronounced pro-apoptotic responses.

In 22Rv1, ^{225}Ac induced fewer DEGs (538 vs. 2,588 with ^{177}Lu) but robustly upregulated CDKN1A and BBC3 (Log_2FC: 2.35 to 2.99; padj <1E-40) and suppressed DNA repair genes. Several senescence markers (≥80) were significantly upregulated (Log_2FC >3; padj <0.0001) alongside cell cycle arrest across PCa cell lines. Notably, DNA repair genes were not upregulated, suggesting early responses prioritize arrest over repair. Immunofluorescence showed more persistent clustered DNA breaks with ^{225}Ac than ^{177}Lu. Clonogenic survival assay confirmed higher cytotoxicity of ^{225}Ac, with relative biological effectiveness (RBE) ranging from 6.2 to 10.1 across cell lines. ***Conclusion:*** Our data identified cell cycle arrest and senescence rather than enhanced DNA repair as key early responses and potential contributors to radioresistance in PCa cells. ^{225}Ac demonstrates superior cytotoxicity compared to ^{177}Lu, despite eliciting a more limited transcriptional response. We will continue mining our RNA-sequencing data and identifying potential PCa vulnerabilities that can be tackled pharmacologically to augment the depth and durability of RPT therapeutic responses.

Aim/Introduction: Radioimmunotherapy (RIT) combines the specificity of monoclonal antibodies with the cytotoxic radionuclides. Terbium-161 (Tb-161) offers an advantage over the clinically established lutetium-177 (Lu-177) by emitting both β^- particles and ultra-short-range conversion and Auger electrons (CE/AE), enhancing its potential to eradicate single cancer cells and metastases. This study investigates and compares molecular responses to Tb-161- and Lu-177-based RIT in two distinct cancer models: L1 cell adhesion molecule (L1CAM) overexpressing high-grade serous ovarian cancer (HGSOC) and CD30-positive T-cell lymphoma. ***Materials and Methods:*** Anti-L1CAM monoclonal chCE7 antibodies were radiolabeled to produce [^{161}Tb]Tb-DOTA-chCE7 and [^{177}Lu]Lu-DOTA-chCE7 radioimmunoconjugates (RICs) for the treatment of ovarian cancer OVCAR8 cells, whereas in the lymphoma model, CD30-targeted RICs ([^{161}Tb]Tb-cAC10 and [^{177}Lu]Lu-cAC10) were assessed for RIT of Karpas 299-tumor bearing nude mice. Tandem mass tagging (TMT)-based integrated phosphoproteomics and proteomics was employed for MS-based peptide identification and quantification. Comparative bioinformatics analyzed signaling network alterations in response to RIT with Tb-161 and Lu-177. ***Results:*** In ovarian cancer cells, phosphoproteomics combined with matching proteomics quantified 22101 phosphopeptides and 7484 proteins, whereas in the lymphoma model, 12548 phosphopeptides and 7763 proteins were quantified. Both [^{177}Lu]Lu-DOTA-chCE7 and [^{161}Tb]Tb-DOTA-chCE7 treatments induced pathways involved in DNA damage response (DDR) and repair, signal transduction (including EGFR, VEGFR, and mTOR signaling), mRNA processing, cell cycle and cytoskeleton regulation, translation, apoptosis, and glycogen metabolism. Similarly, in lymphoma in vivo model both [^{177}Lu]Lu-cAC10 and [^{161}Tb]Tb-cAC10 induced alterations in DDR and replication stress response (RSR), cell cycle arrest, and protein metabolism regulation. To further investigate the potential differences between both radionuclides, we directly compared the phosphopeptide abundance after Tb-161 and Lu-177 RITs. While most alterations were common to both treatments, the phosphorylation of a few proteins associated with chromatin methylation, GTPase activation, and chromosome structure was either uniquely induced or significantly more pronounced with Tb-161 as compared to Lu-177 RIT. We are currently conducting further bioinformatics analyses and validation study. ***Conclusion:*** This dual-model study underscores the potential of Tb-161 and Lu-177 to activate signaling networks in both solid and hematologic malignancies. Through in-depth proteomic and phosphoproteomics profiling, the study provides comprehensive insights into the molecular responses triggered by β^- and CE/AE radiation. ***References:*** E. Live-cell imaging of [^{177}Lu]Lu-DOTA-TATE: towards linking intracellular distribution and DNA damage kinetics for improved dosimetry

J. Nonnekens*, P. Engbers, T. de Wolf, G. Tamborino, J. Zink, D. Chapeau, Y. Seimbille, M. Sabatella;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) using [^{177}Lu]Lu-[DOTA-Tyr^3]octreotate ([^{177}Lu]Lu-DOTA-TATE) is effective in treating metastatic neuroendocrine tumors, yet curative responses remain rare due to therapeutic limitations and toxicity. Compared to external beam radiotherapy (EBRT), little is known about the radiobiological effects of PRRT. Given their distinct irradiation kinetics, PRRT likely has a different dose-effect relationship than EBRT. Determining these relationships requires precise knowledge on the absorbed cellular doses, which are influenced by intracellular radiopharmaceutical localization. Due to its limited spatial resolution, nuclear imaging cannot resolve subcellular radiopharmaceutical distribution. Therefore, we employed confocal microscopy, which offers sub-micrometer resolution, to accurately map intracellular localization. This study aimed to correlate the subcellular distribution of [^{177}Lu]Lu-DOTA-TATE with DNA damage kinetics using live-cell microscopy, as a basis for improving microdosimetric modeling. ***Materials and Methods:*** To evaluate DNA damage kinetics induced by [^{177}Lu]Lu-DOTA-TATE and compare it to EBRT, we used CRISPR/Cas9 genome editing to create a functional 53BP1-mClover knock-in (53BP1 is a marker for DNA double strand breaks (DSBs)) in the human osteosarcoma cell line U2OS which overexpress the somatostatin receptor 2 (SSTR2). Cells were treated with equitoxic doses of EBRT (2 Gy) or [^{177}Lu]Lu-DOTA-TATE (1 MBq/mL) and 53BP1 foci formation and resolution were tracked for 24h by live cell imaging. DNA damage kinetics were quantified using an artificial intelligence-driven pipeline which includes fully automatic cell nucleus detection, reduction of noise, and detection and tracking of DNA repair foci. To visualize radiopharmaceutical distribution, we created a fluorescently labelled [^{177}Lu]Lu-DOTA-TATE (Cy5-[^{177}Lu]Lu-DOTA-TATE). U2OS-SSTR2 53BP1 mClover cells were incubated with Cy5-[^{177}Lu]Lu-DOTA-TATE for 2 hours, and radiopharmaceutical internalization and 53BP1 foci dynamics were co-imaged during and after the incubation period. ***Results:*** Competition binding assays showed limited influence of Cy5 on the binding affinity of [^{177}Lu]Lu-DOTA-TATE . Live-cell imaging revealed dynamic internalization of Cy5-[^{177}Lu]Lu-DOTA-TATE and localization close to the nucleus, consistent with localization to the Golgi apparatus. Quantification of 53BP1 foci numbers revealed

differential kinetics upon EBRT and PRRT, while 53BP1 foci track durations showed the same distributions. ***Conclusion:*** Differences in 53BP1 foci formation illustrate the distinct therapeutic window between EBRT and PRRT, while the similar foci track duration, reflecting DSB persistence, suggests comparable DSB complexity. Ongoing analyses aim to directly link Cy5-[^{177}Lu]Lu-DOTA-TATE localization with DNA damage induction. These insights will support more accurate dosimetric modeling and help refine the dose-effect relationship of PRRT relative to EBRT, ultimately improving its therapeutic efficacy.

Dual time point lymphoma [^{18}F]FDG Total-Body PET/CT - a prospective single center AI-aided study to assess therapy response prediction

*C. Mingels[1], **F. Sen**[2], H. Nalbant[2], K. Chung[2], N. S. Esteghamat[3], M. Rokni[2], J. M. Tuscano[3], A. Rominger[1], Y. Abdelhafez[2], R. D. Badawi[2], B. Spencer[2], L. Nardo[2];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [3]Department of Bone Marrow Transplant, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To evaluate dual time point (DTP) [^{18}F]FDG total-body (TB) PET/CT with regard to therapy response evaluation. We hypothesized that DTP TB imaging might be able to provide new biomarkers for therapy response assessment in lymphoma patients. ***Materials and Methods:*** A total of 75 lymphoma patients received DTP [^{18}F]FDG TB PET/CT imaging 60- and 120-minutes post injection for staging and restaging. PET images were segmented using an artificial intelligence (AI)-driven algorism. Segmentation was scrutinized and edited by a nuclear medicine physician. Lesion uptake was characterized by standardized uptake values (SUV), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) on a lesion--basis and by total metabolic tumor volume (TMTV) and TLG on a per-patient basis. $SUV_{mean/max/peak}$ was used to calculate the tumor-to-background ratio (TBR) and contrast-to-noise ratio (CNR). Follow up data (12±2 month) were used to assess overall (OS) and progression free survival (PFS). ***Results:*** A total of 977 lesions were identified and analyzed. DTP imaging showed no significant difference regarding the tumor uptake between the two analyzed time points (SUV_{max} 60min: 3.89±3.43 vs. 120min: 3.65±3.37, p=0.09). MTV and TLG were also not significantly different between the two timepoints (MTV p=0.72; TLG p=0.56). However, TBR and CNR were significantly higher in late TB PET images (TBR 60min: 3.32±4.54 and 120min 6.40±6.28, p<0.01; CNR 60min: 13.56±23.07 vs. 120 min: 30.44±41.19, p<0.01). Patients with high lesion uptake (SUV_{max}>11.0) showed significantly shorter OS than patients with low [^{18}F]FDG uptake in both time points (p<0.05). PFS was not different in patients with high and low lesion uptake. TMTV over 20ml was prognostic for shorter PFS (median 18 month) in both time points. However, OS was not different in patients with high and low TMTV. ***Conclusion:*** DTP [^{18}F]FDG TB PET/CT is a useful tool to assess new biomarkers in lymphoma patients to evaluate patients' outcome prediction. With its long--axial field-of-view (> 100cm) it enables to scan the entire patient in a single bed position. SUV_{max} was prognostic for OS and TMTV for PFS in our small study cohort. Larger studies are necessary to confirm our results and apply TB PET's new prognostic biomarker on different lymphoma subtypes.

Quantitative Dual-Tracer PET Biomarkers for Optimizing Patient Selection in CXCR4-Targeted Radioligand Therapy for Multiple Myeloma

***N. Dreher**[1], S. Xue[2], S. Kraus[3], J. S. Enke[1], K. Michalski[4], M. Hacker[2], H. Einsele[3], A. K. Buck[4], X. Li[2], C. Lapa[1];*
[1]Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY, [2]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA, [3]Department of Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY, [4]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: CXCR4-directed radioligand therapy (CXCR4-RLT) is an emerging treatment modality for patients with relapsed or refractory (r/r) multiple myeloma (MM). However, heterogeneous treatment responses underscore the limitations of current patient selection approaches, which to a certain extent rely on qualitative assessments of CXCR4/FDG-PET concordance. This study evaluates whether quantitative imaging biomarkers derived from dual-tracer PET/CT can enhance patient stratification and predict therapeutic response and survival outcomes. ***Materials and Methods:*** We retrospectively analyzed 28 patients with r/r MM who underwent CXCR4-directed [^{68}Ga]Ga-PentixaFor and [^{18}F]FDG PET/CT imaging prior to CXCR4-RLT. Lesions and organs were segmented using a deep learning-based pipeline, followed by dual-tracer image fusion. Quantitative imaging features—including SUVmean, SUVmax, molecular tumor volume (MTV), total lesion glycolysis (TLG), and total lesion CXCR4 uptake (TLC)—were extracted from both concordant and discordant lesions. Treatment response was assessed based on International Myeloma Working Group (IMWG) criteria. Decision tree analysis was used to identify imaging biomarkers associated with treatment response and 6-month survival. Furthermore, a survival tree was constructed to identify imaging-based risk stratification rules using time-to-event data. Imaging features selected by the survival tree were further evaluated using Kaplan-Meier survival analysis, with statistical significance assessed by log-rank tests. ***Results:*** Decision tree analyses identified complementary imaging biomarkers predictive of treatment response and 6-month survival following CXCR4-RLT in MM. For treatment response, CXCR4-MTV ≤ 450 cm^3 was the primary stratification feature, with all such patients responding to therapy. In patients with higher tumor burden, non-response was linked to CXCR4-SUVmax > 23.7 and FDG-SUVmax > 9.0, while lower CXCR4-SUVmean within $CXCR4^+$/FDG^+ overlap regions (≤ 3.12) was associated with improved response. For 6-month survival, FDG-SUVmean with a threshold of ≤ 6.61 within $CXCR4^+$/FDG^+ overlap regions was associated with significantly improved survival. Survival tree analysis further identified FDG-TLG as the strongest survival predictor, with values > 2276 significantly associated with reduced survival (p < 0.01, HR = 4.1). ***Conclusion:*** Quantitative imaging features from dual-tracer PET/CT are strong indicators of both treatment response and short-term survival following CXCR4-RLT in MM. Both CXCR4 tumor burden and metabolic activity in $CXCR4^+$/FDG^+ concordant lesions are key predictors of response and short-term survival following CXCR4-RLT. FDG-TLG was identified as the strongest predictor of overall survival, with high values linked to significantly reduced survival. These findings underscore the prognostic value of integrating lesion-level dual-tracer imaging biomarkers to guide patient selection and risk assessment.

Seragnoli" IRCSS Azienda Ospedaliero-Universitaria Policlinico-S.Orsola Malpighi, Bologna, ITALY,* [5]*Dipartimento di Scienze Mediche e Chirurgiche, Università di Bologna, Bologna, ITALY.*

Aim/Introduction: Long-axial-field-of-view PET (LAFOV-PET) provides superior sensitivity and spatial resolution compared to conventional short-axial-field-of-view PET (SAFOV-PET). As the Deauville Score (DS) was established using SAFOV-PET, it is essential to evaluate the concordance between these two modalities in lymphoma assessment. This study aims to compare LAFOV-PET and SAFOV-PET in lymphoma staging and treatment response evaluation. ***Materials and Methods:*** Patients with a confirmed diagnosis of lymphoma underwent [18F]FDG-PET/CT imaging 60 minutes post-injection, first using SAFOV-PET, immediately followed by LAFOV-PET (Protocol number: 598/2024/Oss/AOUBo). Depending on the clinical indication, some patients underwent multiple paired scans. The two acquisitions were compared based on positivity/negativity concordance, number of detected lesions, SUVmax-SUVmean in the reference lesion and reference regions (liver-lv, bloodpool-bp, bone marrow-bm), metabolic-tumour-volume (MTV), total-lesion-glycolysis (TLG) and DS classification. ***Results:*** Seventeen patients underwent paired PET/CT imaging, contributing a total of 34 scan pairs for analysis. Overall agreement for lesion positivity/negativity between SAFOV-PET and LAFOV-PET was 94.1% (32/34 scans; Cohen's kappa-κ = 0.88), with lesion count agreement at 76.5% (26/34; weighted κ = 0.80). LAFOV-PET showed higher median SUVmax in reference lesions: 7.1 (IQR 2.6-14.4) vs 5.7 (IQR 2.4-12.3) in SAFOV-PET. Conversely, reference tissues showed lower median SUVmax on LAFOV-PET vs SAFOV-PET: lv 2.4 vs 3.6, bp 1.7 vs 2.6, bm 2.4 vs 3.0 respectively, reflecting enhanced image contrast. MTV (mean 242.3 cm^3 vs 228.6 cm^3) and TLG (mean 1012.4 vs 927.5) were also higher on LAFOV-PET vs SAFOV-PET. DS classification agreement was 91.2% (31/34 scans; weighted κ = 0.93), with phase-specific agreement of 85.7% pre-therapy (12/14 scans; κ = 0.76), 100% interim (8/8 scans; κ = 1.0) and 91.7% post-therapy (11/12 scans; κ = 0.93). ***Conclusion:*** The higher sensitivity of LAFOV-PET allows the detection of additional lesions, particularly at baseline, and yields higher SUVmax values at target lesions along with slightly lower background uptake in reference tissues. This results in improved lesion-to-background contrast compared to SAFOV-PET, likely reflecting superior image quality and signal-to-noise characteristics. Despite these technical differences, the high concordance in DS classification, especially during interim and post-therapy phases, confirms that response assessment remains consistent. These findings support the continued applicability of established DS-based criteria to LAFOV-PET in clinical lymphoma evaluation.

Aim/Introduction: Multiple myeloma (MM) is a heterogeneous hematologic malignancy whose outcome in some patients is difficult to predict using conventional factors. This study evaluates the interest of total metabolic tumor volume of the bone marrow (TMTV-BM), derived from 2-[^{18}F]fluoro-2-deoxy-D-glucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) at baseline, in predicting survival outcomes in a multicenter cohort of newly diagnosed MM patients. ***Materials and Methods:*** Patients were enrolled in the CASSIOPET protocol, an ancillary study of the CASSIOPEIA protocol sponsored by the IFM group. The total population underwent whole-body ^{18}F-FDG PET/CT imaging before treatment. The population treated with Daratumumab after the first and/or second randomization was termed the DARA population. Skeleton, liver, and skull were automatically segmented from the CT images using the pre-trained MOOSE algorithm, with manual corrections applied as needed. CT-based skeletal and liver segmentations were then resampled and applied to standardized uptake value PET images. To reduce the influence of intense brain ^{18}F-FDG uptake, the skull was excluded from analysis. TMTV-BM was defined as the number of voxels with uptake greater than the median liver uptake. The potential of TMTV-BM, in combination with clinical and conventional PET-derived features, for progression-free survival (PFS) and overall survival (OS) was evaluated. In the total population, three additional treatment arm features were also considered according to the CASSIOPEIA study design. Four machine learning algorithms were trained using uncorrelated features from consensus-based hierarchical clustering and feature selection, with hyperparameter optimization performed using three outer/inner fold nested cross-validation. Final predicted risk scores for the outer test samples were calculated by averaging the predictions of the four optimized models in each outer fold. Feature importance was assessed using Shapley additive explanation values. ***Results:*** The total population comprised 239 patients, of which 172 were classified as the DARA population. In the total population, the final model achieved a concordance index (C-index) of 0.642±0.007 for PFS and 0.577±0.020 for OS. In the DARA population, C-indices of 0.619±0.032 and 0.642±0.069 were observed for PFS and OS, respectively. TMTV-BM was the most informative feature for predicting OS in the total population and PFS in the DARA population. It ranked third for PFS in the total population, following two treatment arm combinations, and third for OS in DARA, after R-ISS and IMPeTUs criteria. ***Conclusion:*** Our results highlight the considerable potential of TMTV-BM, which may play a critical role in identifying high-risk MM patients at baseline in future clinical practice.

OP-226

Baseline [^{18}F]FDG PET Biomarkers of Host and Tumor Predict Efficacy and CRS in Multiple Myeloma Patients Treated with CAR T Cells

S. Xue[1], *Y. Jia*[1], *J. Chen*[2], *G. Hu*[3], *M. Hacker*[1], *X. Li*[1], *Z. Cai*[2];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Marrow Transplantation Center, Department of Hematology, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, CHINA,* [3]*Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.*

Aim/Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy has transformed the management of relapsed/refractory multiple myeloma (r/r MM), yet therapeutic response and toxicity—particularly cytokine release syndrome (CRS)—remain highly variable. Although tumor burden is often quantified on [^{18}F]FDG PET/CT, the metabolic activity of immune-related organs may reflect host immune status and influence CAR-T outcomes. ***Materials and Methods:*** We retrospectively evaluated baseline [^{18}F]FDG PET/CT scans from 120 patients with r/r MM treated with BCMA-directed CAR-T therapy. Quantitative metrics were extracted from both tumor lesions and immune-related organs, including the spleen, liver, and bone marrow. Treatment response was defined by IMWG criteria, and CRS was graded per ASTCT guidelines. A transformer-based machine learning model was trained to integrate PET-derived and clinical features for predicting both therapeutic response and CRS severity. ***Results:*** Patients with lower spleen SUVmean at baseline were significantly more likely to achieve a deep treatment response (≥VGPR) (OR 3.8, 95% CI: 1.7-8.3; P < 0.001). Conversely, elevated metabolic activity in extramedullary lesions—especially high SUVmax and metabolic tumor volume (MTV)—was associated with poor response (OR 0.4, 95% CI: 0.2-0.8; P = 0.007). For toxicity, increased liver and spleen total lesion glycolysis (TLG) independently predicted grade ≥2 CRS (OR 3.2, 95% CI: 1.5-6.9; P < 0.001). The integrated model combining imaging and clinical data achieved an AUC of 0.83 for predicting treatment response and 0.79 for CRS severity. ***Conclusion:*** Baseline [^{18}F]FDG PET/CT features—particularly spleen SUVmean and liver/spleen TLG—are associated with both therapeutic efficacy and immune-mediated toxicity in CAR-T-treated multiple myeloma. These imaging biomarkers may reflect host immune readiness and systemic inflammation, offering a noninvasive tool for pre-infusion risk stratification. Prospective studies are warranted to validate these findings, including correlation with peripheral and tumor-associated immune profiles assessed via flow cytometry and tissue sampling.

Aim/Introduction: Patients with relapsed or refractory Follicular Lymphoma (R/R-FL) often experience brief progression-free survival (PFS) after two or more therapies. CAR-T-cell-therapy was recently approved for these patients, demonstrating high complete response rates and extended PFS in phase II studies. Predicting outcomes after CAR-T-cell-therapy could guide further treatment in FL patients at high risk of relapse. We aim to evaluate early relapse predictors using machine learning (ML) models after CAR-T-therapy in R/R-FL patients. ***Materials and Methods:*** Patients with R/R-FL from the DESCAR-T-registry (NCT04328298), treated with tisagenlecleucel (tisa-cel) or axicabtagene-ciloleucel (axi-cel), and with FDG-PET/CT before lymphodepletion (Pre-LD) and 1,3,6, and 12 months (M) after infusion, available for central review, were included. Total Metabolic Tumor Volume (TMTV) and SUVmax were measured and Deauville score (DS) was registered. PFS is the time between CAR-T-cell infusion and progression or death during follow-up. Four models (random forest,logistic regression,decision tree,XGBoost) were trained (80% dataset) and tested (20%) to predict progression at M3. Model performance was assessed using AUC, sensitivity, specificity, and predictive values, including clinical (age,sex,Ann-Arbor stage,ECOG,prior treatment), biological (LDH,ferritin,CRP at infusion), and imaging parameters (pre-LD SUVmax and TMTV). The best predictive factors from the best ML model were then computed in a multivariate Cox model to establish a score based on Hazard Ratios values. Cutoff values for quantitative variables prior to the Cox model were estimated to maximize the log-rank statistics. ***Results:*** FDG-PET/CT were available for 94 R/R-FL patients (77 treated with tisa-cel,17 with axi-cel), predominantly male (71.3%),mean age of 62 years, mostly in advanced-stage disease (69.9% Ann-Arbor stage III-IV). Median follow-up since infusion was 7.1 months with 21 patients experiencing progression/relapse before M3. Death rate was 5.3% (5patients), preventing OS analysis. At M1, 75 patients (79.8%) had a complete response (CR,DS1-3) and 56 (77.7%) maintained CR at M3. One patient with DS4 at M1 showed a CR at M3.Random Forest was the best-performing model (AUC:1.0) outperforming other models (Logistic Regression:0.89;XGBoost:0.75;Decision Tree:0.73). A prognostic score (FAST) ranging 0-8 points (pts) was developed including retained predictors from Random Forest (elevated ferritin:1pt, Age<71years:3pts, pre-LD SUVmax>8.4:3pts, pre-LD TMTV>448 ml:1 pt) and distinguished 3 risk groups: 1)0-3:low risk (n=23,100% PFS at 12 months), 2)4-6:intermediate risk (n=39,69%) and 3)7-8pts:high risk (n=32,51%). ***Conclusion:*** We introduce a novel prognostic score FAST (elevated ferritin and age at infusion, SUVmax and TMTV pre-LD) allowing improved accuracy of early risk stratification that could drive post-CAR-T monitoring and therapeutic strategies.

Prognostic significance of image-based biomarkers in baseline FDG PET/CTs of patients with DLBCL from the CALGB50303 study - Comparison of manual and AI-based segmentation

D. Hellwig[1,2], *J. Mikolajczak*[2], *V. Langguth*[2], *A. Hellwig*[2], *D. Schmidt*[2];
[1]*University Regensburg, Regensburg, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital Regensburg, Regensburg, GERMANY.*

Aim/Introduction: Image-based biomarkers (IBBs) gain importance as their prognostic relevance is recognized for several tumor entities, e.g. aggressive non-Hodgkin's lymphoma (aNHL). For clinical stratification of patients, cut-off values for parameters like metabolic tumor volume (MTV) or total lesion glycolysis (TLG) must be established by rigorous methodology and prospectively confirmed in trials. Here we intend to derive thresholds for MTV and TLG from FDG PET/CT images from a prospective trial to be used as risk stratificator in the analysis of further prospective

trials in aNHL. ***Materials and Methods:*** PET/CT image data of the randomized CALGB50303 trial (testing standard versus experimental chemoimmunotherapy in aNHL) [1] acquired in the imaging substudy CALGB580603 [2] were obtained from The Cancer Imaging Archive (TCIA) [3]. Baseline FDG PET/CTs were used to measure total MTV and TLG by delineating lymphoma manifestations using 41% of the lesional SUV maximum (SUVmax), restricted to lesions volume above 1 mL, using a CE-certified analysis tool (MTV_syngo, TLG_syngo) or a self-trained convolutional neural network (MTV_unet, TLG_unet) based on the nnU-Net framework [4] trained with a subset of lymphoma patients (n=131) from the AutoPET data set [5] without further supervision. Results were analysed for prognostic relevance compared to clinical parameters by log-rank tests and Cox-regression using follow-up data from TCIA. ***Results:*** Baseline PET/CT was available for 150 of 155 patients in the imaging substudy. MTV_syngo and MTV_unet as well as TLG_syngo and TLG_unet were highly correlated (r>0.95, p<0.001). Larger deviations between manual and AI-based segmentation were classified as related to false-positive and false-negative results of AI. Optimal cut-offs were 150 mL for both MTV_syngo and MTV_unet for progression-free survival and 650 mL for overall survival (OS). p-values for IBBs from manual segmentation were lower (and thus Hazard ratios higher) than from AI-based IBBs. No differences in demographics, IBBs, response rate, or survival were observed between treatment arms or age groups ≤60 and >60 years (p>0.10). ***Conclusion:*** TCIA is a valuable source to establish IBBs from reused imaging data of prospective trials. As neither treatment arms nor age affected outcome, IBBs derived here can be used in further prospective trials as already planned for the currently finished OPTIMAL>60 trial (NCT01478542). ***References:*** 1. Aim/Introduction: CAR T-cell therapy has become a standard treatment for relapsed/refractory aggressive B-cell lymphoma (r/r ABCL) [1,2]. However, predicting the long-term outcome remains challenging. The primary aim of this study was to identify reliable morphological molecular imaging biomarkers predicting the long-term therapeutic outcomes of CAR T-cell therapy in relapsed/refractory aggressive B-cell lymphoma (r/r ABCL). ***Materials and Methods:*** Multicenter study of 63 r/r ABCL patients from four institutions treated with CAR T-cells. Data included detailed clinical records, longitudinal CAR T-cell expansion (via PCR or flow cytometry), and baseline PET scans. Median SUVmax was 18.63; median lesions per patient:4; MTV: 127.1 cm^3; TLG: 804.9 g. Known prognostic factors (e.g., ECOG performance status, pre-apheresis LDH) were analyzed [3]. PET scans were segmented with MIM Encore and processed for morphological, metabolic, and radiomic features using MATLAB's radiomic functions (R2024a). Survival analyses (Cox regression, Kaplan-Meier estimates, log-rank tests) assessed links between imaging, CAR T-cell dynamics, and progression free survival (PFS). A compartmental mechanistic model explored tumor growth, immune suppression, and treatment effects on PFS. ***Results:*** Median patient age was 61 years (range 32-79), with a median of 2 prior therapy lines. A multivariate Cox model identified SUVmax of the most irregular lesion (SUVmaxMinSpher) as the only significant predictor of shorter PFS (p = 0.029) [4,5]. Univariate analysis confirmed this (p = 0.001), with Kaplan-Meier survival differences above/below the median (log-rank p = 0.0044). The effect remained significant across the two CAR T-cell products tested (likelihood ratio p = 0.09). Simulations suggest larger contact surfaces in irregular lesions promote immune suppression, reducing CAR T-cell efficacy [6,7]. High SUVmaxMinSpher patients had slower expansion (peak at 21 vs. 7 days) but stronger response (p = 0.05) [8]. ***Conclusion:*** Prognosis was worse for r/r ABCL patients post-CAR T-cell therapy with highly metabolically active, irregular lesions. Thus this biomarker may help to identify patients at elevated risk of disease progression following CAR T-cell treatment for B-cell lymphoma. ***References:*** 1. Risk Prediction of ^{68}Ga-FAPI-46 PET/CT-Derived Parameters in Lymphoma Patients

X. Chen[1], *T. Yuan*[2], *X. Wang*[3];
[1]*Beijing Tsinghua Changgung Hospital, School of Clinical Medicine , Tsinghua University, Beijing, CHINA,* [2]*Peking University First Hospital, Beijing, CHINA,* [3]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

Aim/Introduction: we aimed to evaluate and compare in vivo tumor metabolism and cancer-associated fibroblast activation using ^{68}Ga-FAPI PET/CT for prediction of survival in lymphoma patients. ***Materials and Methods:*** Participants with different lymphoma subtypes, who were prospectively recruited from May 2020 to December 2021, underwent ^{68}Ga-FAPI and ^{18}F-FDG PET/CT. The tracer uptake was determined as maximum tumor standardized uptake value (SUV_{max}), FAPI-avid tumor volume (FTV), total lesion FAP expression (TLF) and target-to-liver ratios (TLR). Paired parameters were compared using the paired t test or the Wilcoxon matched-pairs signed-rank test. Kaplan-Meier curves were generated to calculate progression-free survival (PFS) and overall survival (OS) rates, and Cox regression analysis was performed to determine which PET/CT parameters were prognostic factors for PFS and/or OS. ***Results:*** In total, 201 participants (median age: 52 years [interquartile range: 18-79 years]; 99 women) were included. The median follow-up of 30.0 months (range, 3.6—101.1). Receiver-operating-characteristic curve analysis identified SUV_{max}, FTV, TLF, and TLR were not significant predictors for 2-year PFS and OS of total lymphomas and Aggressive B-cell lymphomas, that all the p values were greater than 0.05. TLR was significantly associated with OS of Aggressive T-cell lymphomas in the univariate analysis. Furthermore, in patients with Diffuse large B-cell lymphoma (DLBCL), SUV_{max} and

TLR were significantly associated with PFS and OS in the univariate analysis, and TLR was an independent risk factor for both PFS (HR, 0.155; 95% CI, 0.047-0.511; P = 0.002) and OS (HR, 0.154; 95% CI, 0.036-0.657; P = 0.011) in the multivariate analysis. ***Conclusion:*** This pilot study revealed that it appears unlikely that ^{68}Ga-FAPI-46 PET/CT-derived markers will generally replace ^{18}F-FDG PET/CT for prognostic stratification, yet it may have prognostic value for patients with DLBCL treated with standard chemotherapy, with TLR particularly promising.

Wavelet Diffusion Modeling Enables Individualized FDG-PET Synthesis for Early Diagnosis of Neurodegenerative Diseases

S. Xue[1], *J. Ding*[2], *M. Hacker*[1], *J. Zhao*[2], *X. Li*[1];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Nuclear Medicine, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: Neurodegenerative diseases such as Alzheimer's disease (AD) and Parkinson's disease (PD) are irreversible, but early intervention during the presymptomatic stage can slow disease progression. FDG-PET enables the detection of glucose metabolism changes in the brain, offering potential for early diagnosis. However, individual variability in FDG metabolism poses challenges for quantitative assessment. This study aims to develop a deep learning model capable of generating individualized healthy FDG-PET templates to facilitate voxel-wise comparison and precise identification of metabolic changes. ***Materials and Methods:*** A Wavelet Diffusion Model (WaveDM) was employed to synthesize FDG-PET images from T2-weighted MRI. This generative framework combines wavelet decomposition and diffusion modeling for high-resolution 3D image-to-image translation. A dataset of 1,060 paired PET/MRI scans was used for training and validation (9:1 split), with an additional 158 AD cohort scans (Normal Control (NC), Mild Cognitive Impairment (MCI), and AD) for testing. Model performance was compared to a 3D U-Net baseline using normalized root mean square error (NRMSE), peak signal-to-noise ratio (PSNR), and structural similarity index measure (SSIM). Qualitative assessments are ongoing, with physicians reviewing the synthesized PET images and evaluating diagnostic accuracy in differentiating AD, MCI, and NC using voxel-wise difference maps from the individualized healthy templates. ***Results:*** The WaveDM model demonstrated superior performance compared to the baseline U-Net model on the validation dataset, achieving a 12.3% increase in PSNR, a 6.6% improvement in SSIM, and a 20.5% reduction in NRMSE. Testing on the AD cohort demonstrated the model's ability to differentiate between NC, MCI, and AD through voxel-wise difference map analysis. ***Conclusion:*** The WaveDM framework provides a robust and versatile approach for generating individualized FDG-PET templates from MRI data. By enabling precise voxel-wise metabolic assessment, it shows great promise in enhancing the early diagnosis and management of neurodegenerative diseases. Moreover, this technique is adaptable to various neurological conditions, including the early detection of brain tumors or other disorders with detectable metabolic changes on neuro-PET imaging, broadening its potential clinical applications.

Fronto-striatal disconnection contributes to striatal degeneration in behavioural variant frontotemporal dementia: preliminary results

S. Xie[1,2], *Y. Mayr*[1,2], *T. Grimmer*[3], *I. Yakushev*[1,2];
[1]*Department of Nuclear Medicine, School of Medicine, Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY,* [2]*Graduate School of Systemic Neurosciences, Ludwig Maximilian University of Munich, Munich, GERMANY,* [3]*Department of Psychiatry and Psychotherapy, School of Medicine, Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: Behavioral variant frontotemporal dementia (bvFTD) is traditionally characterized by frontal and temporal cortical degeneration, yet mounting evidence identifies striatal degeneration as a critical component of disease pathophysiology with significant implications for patient prognosis. While pathological aggregation of tau and TDP-43 proteins is considered a primary driver of striatal degeneration, fronto-striatal disconnection may represent an important secondary mechanism. This study investigated the relationship between striatal degeneration and fronto-striatal disconnectivity in bvFTD. ***Materials and Methods:*** A group of 19 individuals with mild bvFTD and 19 matched healthy controls (HC) underwent FDG-PET and diffusion weighted imaging (DWI). Standardized uptake value ratios (SUVr) in the frontal and striatal regions were quantified with reference to the cerebellar grey matter after correction for partial volume effects. White matter tracts of the frontal and striatal regions were reconstructed using probabilistic tractography. We specifically isolated white matter tracts a) within the frontal lobe and b) those between the frontal lobe and striatum. Node strength was used as index of anatomical connectivity (AC). ***Results:*** Frontal and striatal SUVr was lower in bvFTD patients relative to HC by 25% and 23% (both $p<0.001$), respectively. Frontal and fronto-striatal AC was lower in bvFTD patients relative to HC by 21% and 15% (both $p<0.001$), respectively. Notably, a robust correlation ($r=0.99$, $p<0.001$) was observed between fronto-striatal AC and SUVr across four key striatal regions (bilateral putamen and caudate nuclei). ***Conclusion:*** While further analyses are ongoing, we found a pronounced striatal hypometabolism and fronto-striatal disconnection in patients with bvFTD. These patterns were strongly related at the level of key striatal regions. Even though preliminary, this study provides the first direct evidence that deafferentation from frontal cortex contributes to striatal degeneration in bvFTD. Beyond improving understanding of disease pathophysiology, these results may guide future therapeutic approaches targeting secondary neurodegeneration to slow disease progression in bvFTD.

Multimodal Characterisation of Cerebral Amyloid Angiopathy in Mild Cognitive Impairment Using Amyloid PET/MRI and FDG-PET

M. Pudis, *L. Rodríguez-Bel, M. Suarez-Piñera, B. Hervás-Sanz, J. Diaz-Moreno, M. Zamorano-Rivas, A. Bagan-Trejo, A. Dacosta-Escobar, C. Martínez-Ramos, M. Cortés-Romera;*
Nuclear Medicine - PET (IDI), Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: This study aimed to describe amyloid PET findings in patients with mild cognitive impairment (MCI) who met the Boston Criteria 2.0 for cerebral amyloid angiopathy (CAA). We hypothesised that a multimodal imaging approach combining PET and MRI could reveal distinctive patterns of amyloid deposition and metabolic alterations, indicative of underlying mixed pathology. ***Materials and Methods:*** We retrospectively

included consecutive patients referred for [^{18}F]flutemetamol PET/MR in our centre between 2023 and April 2025. From a cohort of 412 subjects with cognitive complaints, we selected those meeting Boston 2.0 criteria for possible or probable CAA based on MRI findings, including lobar haemorrhages, cortical superficial siderosis, and cerebral microbleeds. Sixteen patients fulfilled inclusion criteria (12 men, 4 women; mean age 75 years [68-80]). Amyloid PET was analysed visually and semi-quantitatively, with SUVr and Centiloid conversion (whole cerebellum as reference). Occipital-to-frontal and occipital-to-global SUVr ratios were also calculated. FDG PET (n = 7) was assessed visually and using voxel-wise comparison to a normative database. Blood biomarkers (pTau and beta-amyloid 42/40) were available in five patients. Neuropsychological assessments complemented imaging data. ***Results:*** Amyloid PET was visually positive in 14/16 patients (88%). Mean SUVr was 0.75 (range 0.47-0.97); mean Centiloid value was 89.4 (range 38.6-205). One patient had discordant findings, with a small focus in the left frontal and insular cortices (SUVr 0.47; Centiloid 38.6). Of the 10 patients classified as probable CAA, 9 were PET positive; of the 6 possible CAA cases, 5 were PET positive. Occipital-to-frontal SUVr ratio >1 in 7 patients; occipital-to-global >1 in 6. No clear pattern differences were seen among PET-positive cases (5 posterior-predominant, 9 anterior-predominant). MRI revealed >10 lobar microbleeds in 9 patients, mainly frontoparietal and occipital; cortical superficial siderosis in 8; lobar haemorrhage in 6. FDG PET showed AD-like hypometabolism in 5 cases (matching blood biomarkers) and frontotemporal pattern in 2, including the only amyloid-negative case. ***Conclusion:*** Only 16 out of 412 patients (~4%) met imaging-based Boston Criteria 2.0 for CAA in our memory clinic cohort. Most patients demonstrated a high amyloid burden, although PET-negative cases and atypical regional patterns were observed. The integration of amyloid PET/MRI and FDG PET enhances the diagnostic characterisation of CAA and reveals overlap with Alzheimer's and other pathologies. These findings support the clinical relevance of multimodal imaging approach in evaluating complex dementia cases.

OP-234

Robustness of the Centiloid Scale to Data Decimation using Florbetaben PET

J. Perucho, *B. Spottiswoode, R. Fahmi;*
Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Amyloid-β (Aβ) positron emission tomography (PET) imaging is an essential diagnostic tool for Alzheimer's Disease (AD). Florbetaben (FBB), one of three clinically approved amyloid-PET radiotracers, typically requires 20-minute-long acquisitions. Quantification of these radiotracers can be standardized with the Centiloid (CL) method. Previous studies demonstrated the feasibility of reducing scan time without compromising AD diagnosis. This study aims to assess the robustness of CL values to the shortening of PET scans on a digital ultrafast time-of-flight (TOF) system. ***Materials and Methods:*** Co-registered dynamic (four 5-min frames) FBB-PET images from 50 subjects acquired on SiPM PET-CT scanner with 214ps TOF resolution were obtained from the ADNI database. For each scan, 5-, 10-, 15-, and 20-min summed frames were generated. Each frame was used to calculate CL values with a commercial package using a PET-only processing pipeline with tracer-specific target regions, and either the whole-cerebellum (WCB) or the cerebellar-gray-matter (CGM) as the reference region (RR). CL values corresponding to shorter scans were compared to those calculated using the 20-min summed image. Subjects were then dichotomized into positive and negative Aβ status using a threshold of 30 CL[1] to investigate bias in CL levels. ***Results:*** Using ANOVA tests, no group differences were found between CL values across all summed frames using WCB as the RR (p=0.259), whereas a significant difference was found when CGM was used as the RR (p=0.019). There was no significant difference between 5-min and 20-min CL values when using the WCB as the RR (p=0.376), but there was a significant difference when using the CGM as the RR (p=0.019) as determined by paired t-tests. Bland-Altman analysis resulted in a bias of -0.91 (Limits of Agreement (LoA): -15, 13) CL and -4.04 (LoA: -27, 19) CL for WCB and CGM as RR, respectively. This pattern was consistent when considering Aβ+ and Aβ- groups separately with p=0.451 and p=0.658 when comparing 5-min vs. 20-min CL, respectively, using WCB as the RR versus p=0.030 and p=0.396, respectively when using CGM as the RR. ***Conclusion:*** Decimated (5-min) FBB scans from an ultrafast-TOF PET scanner produced CL measurements that are not significantly different from CL measures from standard 20-min scans when the WCB was used as the RR. The error introduced by data-decimation falls within CL test-retest variability. Decimations to lower frame lengths and with other tracers will be investigated. ***References:*** 1. L. E. Collijet al., Alz. & Dement. 20(12), 9037-9048 (2024). DOI: 10.1002/alz.14336.

OP-235

Impact of Deep Learning-Based Noise Reduction on Centiloid Quantification in Reduced-Dose Amyloid PET Imaging

A. Tahmazov[1], *M. Doyen*[2,1], *S. Heyer*[1], *L. Imbert*[1,2], *A. Verger*[1,2];
[1]*Department of Nuclear Medicine and Nancyclotep Imaging Platform, University of Lorraine, Nancy Regional Hospital Centre, Nancy, FRANCE,* [2]*University of Lorraine, IADI, INSERM U1254, Nancy, FRANCE.*

Aim/Introduction: Quantitative analysis of amyloid PET imaging plays a critical role in selecting and monitoring patients undergoing anti-amyloid therapy. This study evaluates the impact of a deep learning-based noise reduction algorithm on centiloid (CL) quantification when simulating reduced injected doses of [^{18}F]flutemetamol. ***Materials and Methods:*** Patients with objective cognitive impairment who underwent list-mode [^{18}F]flutemetamol PET scans (185 MBq, acquired 90-110 minutes post-injection) were included. Standard images were visually assessed as amyloid-positive or -negative by expert nuclear medicine physicians. Simulated reduced-dose images (50%, 25%, 12.5%, and 5% of the original dose) were generated, and a deep learning noise reduction algorithm (DLNRA) was applied, resulting in ten reconstructions per patient. CL values were calculated using a validated in-house MATLAB pipeline, using the whole cerebellum as the reference region and converted to [^{18}F]flutemetamol-equivalent centiloid values. Differences in CL values between the full-dose reference and the reduced-dose images (with and without DLNRA) were analyzed. ***Results:*** A total of 310 PET reconstructions from 31 patients (mean age 71.6 years; 12 women; 17 visually positive scans; median CL: 8.1 [range -2.7 to 49.1]) were analyzed. Among the 17 visually positive cases, 4 were classified as CL-negative (CL < 24). CL values increased both at the 50% dose level and with DLNRA application (respectively +3% and +7% in medians, $p < 0.01$). Across the cohort, the full-dose DLNRA images showed a median CL deviation of less than 10% from the reference (6%), with only two amyloid-negative patients exceeding a 10% difference. In patients eligible for anti-amyloid therapy follow-up (CL > 24), all reconstructions, especially full-dose DLNRA and 50% dose images (with or without DLNRA) with no individual case exceeding a CL 10% deviation, showed a median CL deviation of less than 10% from the reference. ***Conclusion:*** While reduced-dose imaging can impact CL quantification, applying DLNRA to full-dose images maintains robust quantitative accuracy. In longitudinal anti-amyloid treatment monitoring, reducing the dose by up to 50%—with or without DLNRA—is feasible, although the impact on visual interpretation warrants further investigation. ***References:***

Synthetic [18F]AV45 PET Image Generation from [18F] FDG PET and MRI Using Multimodal Deep Learning: A High-Accuracy Alternative for Amyloid-β Assessment

Y. Zhang[1], *X. Fu*[2], *H. Shao*[1], *Y. Jin*[2], *N. Zhang*[2], *Z. Hu*[2], *Y. Wang*[1], *G. Huang*[1], *J. Liu*[1];
[1]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*Research Center for Medical AI, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences Key Laboratory of Biomedical Imaging Science and System, Chinese Academy of Sciences, State Key Laboratory of Biomedical Imaging Science and System, Shenzhen, CHINA.*

Aim/Introduction: Alzheimer's disease (AD) is characterized by amyloid-β (Aβ) pathology, the accurate detection of which is critical for early diagnosis and intervention. While [^{18}F]Florbetapir (AV45) PET imaging serves as a gold standard for quantifying Aβ deposition, its clinical utility is limited by high costs and limited accessibility. To address this challenge, we developed a novel deep learning approach to synthesize AV45 PET images from more widely available [^{18}F]FDG PET and T1-weighted MRI (T1WI) data acquired on an integrated PET/MR scanner. ***Materials and Methods:*** This study utilized a dataset of 249 patients with paired [^{18}F]FDG PET, T1WI, and [^{18}F]AV45 PET scans. We developed a multimodal deep learning framework based on ControlNet and Stable Diffusion to synthesize AV45 PET images from [^{18}F] FDG PET and T1WI inputs, training the model to capture Aβ deposition patterns through cross-modal feature fusion. To evaluate synthetic image accuracy, we quantified Aβ load using Centiloid (CL) values for both synthetic and real [^{18}F]AV45 PET scans, then classified the images into three clinical categories based on CL thresholds: negative (CL ≤ 12), weakly positive (12 < CL < 30), and positive (CL ≥ 30). Statistical agreement was assessed through Pearson correlation (for CL values) and Cohen's Kappa (for classification consistency). ***Results:*** The synthetic [^{18}F]AV45 PET images demonstrated high fidelity to real scans, with an MAE of 6.55, an MSE of 76.58, an excellent Pearson correlation of 0.97 ($P < 0.001$) , and a regression slope of 1.02 (intercept = 0.06, $R^2 = 0.95$) in Aβ quantification. Classification analysis revealed 95.8% overall consistency between synthetic and real images, achieving perfect agreement for negative and positive categories, while 3 of 10 weakly positive cases were misclassified as negative. For classification consistency, a strong Cohen's kappa coefficient of 0.93 was reflected. These results indicate the model's high accuracy in replicating definitive amyloid status while suggesting the need for improved sensitivity in borderline cases. ***Conclusion:*** This study demonstrates that synthetic [^{18}F]AV45 PET images generated from [^{18}F]FDG PET and MRI T1WI using a multimodal deep learning model achieve high accuracy in amyloid-β assessment, offering a cost-effective alternative where amyloid imaging is unavailable. Further optimization is needed for weakly positive cases.

Aim/Introduction: A growing body of research highlights neuroinflammation as a key factor in neurodegenerative diseases like Alzheimer's (AD), characterized by cognitive decline, functional impairment and currently limited treatment options. This study investigates the spatiotemporal dynamics of reactive astrogliosis, captured by the MAO-B specific radiotracer [^{18}F] Fluorodeprenyl-D2 ([^{18}F]F-DED), across all clinical AD stages, and in relation to beta-amyloid and tau pathology. ***Materials and Methods:*** Our multimodal study included 25 AD patients and 11 age-matched controls who underwent dynamic (0-60 min p.i.) [^{18}F]F-DED PET, along with native T1-weighted cMRI for spatial normalization. The data were processed using the PMOD software and volumes of distribution (VT) were calculated using a One-Tissue-Compartment model (1TC2k) with carotid image-derived input function. AD patients were classified into three subgroups: subjective memory complaints (SMC), mild cognitive impairment (MCI), and dementia (mild, moderate, severe DEM). MMSE scores, CSF Amyloid-beta 42/40 ratios and phosphorylated Tau-181 were recorded together with amyloid and tau load measurement via [^{18}F]Flutemetamol and [^{18}F]PI-2620 PET imaging. Using statistical parametric mapping (SPM), VT images of AD patients were compared voxel-wise to controls and also correlated with centiloid scores and metatemporal tau levels. In addition, intergroup comparisons and tracer correlations were subsequently cross-validated with VOI-based astrocyte PET quantification. ***Results:*** AD patients exhibited significantly higher [^{18}F]F-DED binding than controls, with highest differences in the white matter of the temporal and frontal lobe ($p(FWE) < 0.05$). VT increases were already strong at SMC stage and did not differ significantly from MCI and DEM stages across all brain regions. The explorative SPM analysis of all AD patients revealed a positive correlation between [^{18}F]F-DED VT and centiloid-amyloid, primarily in the ACC, parietal and temporal regions, as well as a negative correlation with metatemporal-tau, especially in the temporal, frontal and occipital white matter ($p < 0.05$, uncorrected). ***Conclusion:*** Our results suggest that [^{18}F]F-DED tracer binding is noticeably elevated in patients across the AD continuum and closely associated with underlying AD pathophysiology, potentially establishing it a promising biomarker for assessing reactive astrogliosis in early-stage AD.

Aim/Introduction: Metabotropic glutamate receptor subtype 5 (mGluR5) has been implicated in the pathogenesis of Alzheimer's disease (AD), and various plasma biomarkers have been shown to play a role in AD. However, the relationship between mGluR5 availability, measured with ^{18}F-PSS232 PET, and these plasma

biomarkers has not been thoroughly investigated. This study aims to assess the relationship between mGluR5 availability and plasma biomarkers. ***Materials and Methods:*** This cross-sectional study included 71 participants, consisting of 17 cognitively unimpaired (CU) individuals, 10 with early-onset cognitive impairment (EOCI), and 44 with late-onset cognitive impairment (LOCI). The Aβ pathology was quantified using the ^{18}F-Florbetapir PET, whereas mGluR5 availability was assessed using ^{18}F-PSS232 PET. Partial correlation analyses were applied to explore the correlation between mGluR5 availability and various plasma biomarkers, including plasma glial fibrillar acidic protein (GFAP), neurofilament light chain (NfL), and tau phosphorylated at T181 (p-tau181). Mediation analysis was performed to determine whether plasma GFAP mediated the association between age and entorhinal mGluR5 availability. A series of interaction analyses was conducted to explore the potential confounding effects of extraneous variables on the correlation between mGluR5 and GFAP. ***Results:*** The mGluR5 availability was associated with increased plasma GFAP levels, but not plasma NfL and ptau-181 in individuals over 65 years old and within the LOCI group. Plasma GFAP partially mediated the correlation of age and entorhinal mGluR5 availability (indirect effects = 0.007, SE = 0.014, 95% CI [0.001, 0.014]; direct effects = 0.019, SE = 0.034, 95% CI [0.003, 0.034]). The positive relationship of mGluR5 with plasma GFAP in the LOCI group only survived in the Aβ positive subgroup (r = 0.475, p = 0.011), as well as in groups with lower plasma Aβ42/Aβ40 ratios (r = 0.513, p = 0.025) and higher plasma NfL levels (r = 0.593, p = 0.007). ***Conclusion:*** This study indicated that age played a key role in the investigations of mGluR5 and plasma GFAP in AD. Increased mGluR5 availability is significantly associated with elevated plasma GFAP levels dependent on age.

Aim/Introduction: Alzheimer's disease (AD) and Cardiac amyloidosis (CA) are both associated with amyloid deposits but of different chemical composition. We used combined cerebral and cardiac amyloid PET/MRI in a "one-stop-shop" approach to investigate co-occurrence and potential correlation between cerebral amyloid deposits (indicating AD) and cardiac amyloid deposits (indicating CA). ***Materials and Methods:*** We included persons with clinically diagnosed mild cognitive impairment (MCI) or mild dementia suspected of AD who were referred for cerebral amyloid PET in this prospective study. Exclusion criteria included pre-existing cardiac conditions and contraindication for MRI. Dynamic cardiac PET/MRI data were acquired for 60 min directly after injection of 298 MBq ± 30 MBq [^{18}F]F-Florbetaben (mean ± SD). Approximately 65 minutes after tracer injection, a static brain PET/MRI was performed for 15 minutes. All patients underwent CA-specific laboratory tests and echocardiography. Primary study endpoint was the frequency of cardiac amyloid deposits in patients with cerebral amyloid deposition. For detection of cardiac amyloid, visual evaluation of static PET images (reconstructed from minutes 40-60 p.i.) and analysis of the established myocardial tracer retention (MTR) from left ventricular uptake curves were performed. The Centiloid scale was used to evaluate the extent of cerebral amyloid deposition. ***Results:*** We screened N=64 patients with MCI and mild dementia who were referred for amyloid PET imaging. Of these, N=15 patients (10 female, 5 male, mean ± SD age 69 ± 7 years) were included (main exclusion criteria: inability for MRI due to neuropsychologic reasons). Amyloid-related brain alterations consistent with AD were detected in N=12/15 patients (80%), one patient presented with cerebral amyloid angiopathy. Median ± IQR Centiloid score was 102.7 ± 43. No signs of cardiac amyloid deposits were detected by visual evaluation or evaluation of the MTR (median ± IQR MTR: 29.8 ± 2.6). Cardiac MRI did not reveal any patients with suspected CA (median ± IQR T1 relaxation time: 1254 ms ± IQR 47.5 ms, no detection of transmural late gadolinium enhancement, only one patient with left ventricular hypertrophy that was asymmetric and probably post-ischemic). ***Conclusion:*** No co-occurrence of cerebral and cardiac amyloid deposits was found in our primary analysis of PET and MRI data. Analysis of secondary endpoints (including laboratory values and echocardiographic findings) is ongoing. Currently, the study data does not support routine combined amyloid imaging in order to simultaneously detect cardiac amyloid deposition in patients with MCI or suspected AD.

OP-241

Evaluation of F-18 FDG PET/CT and Ga-68 DOTATOC PET/CT scans in Assessing Patients with Differentiated Thyroid Carcinoma Exhibiting Elevated Serum Thyroglobulin Levels and Negative Whole-Body Scans with I-131 (TENIS Syndrome)

A. Aghaee*, M. Esmatinia, K. Aryana;*
Nuclear Medicine Research Center,Mashhad University Of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This study aims to critically assess the effectiveness of ^{18}F-FDG PET/CT and 68Ga-DOTATOC PET/CT in detecting recurrent or metastatic differentiated thyroid cancer (DTC) in patients with elevated serum thyroglobulin(Tg) levels and negative I-131 whole-body scans. The study investigates the potential of these diagnostic tools to enhance the identification of residual or recurrent disease, thereby refining treatment strategies for DTC patients. ***Materials and Methods:*** This retrospective study examined 20 patients with DTC at the thyroid clinic of the Ghaem Hospital's nuclear medicine ward in Mashhad. The study

focused on patients who exhibited recent negative whole-body I-131 scans and serum Tg levels exceeding 10 ng/mL following thyroid-stimulating hormone (TSH) stimulation via levothyroxine withdrawal, Each patient underwent an initial ^{18}F-FDG PET/CT scan, followed by a Ga-68 DOTATOC PET/CT scan within one week. ***Results:*** A total of 20 patients with TENIS syndrome were evaluated;19 had papillary thyroid cancer (PTC), and 1 had follicular thyroid cancer (FTC). Both imaging modalities identified 23 out of 27 lesions. The 68Ga-DOTATOC and ^{18}F-FDG scans were positive in 65% and 70% of patients, respectively. Most patients were classified as stage IV according to the seventh edition of the AJCC staging system, while 10 patients were classified as stage I according to the eighth edition. Among the patients with positive 68Ga-DOTATOC results, 13 were candidates for therapy: six received Lu-177-DOTATATE, five underwent surgery, one had surgery combined with radiotherapy, and one received both Lu-177-DOTATATE and radiation therapy. Of the 14 patients with positive ^{18}F-FDG scans, six underwent surgery, and one received a combination of [KA(3] radiation and surgery. No statistically significant relationship was observed between the positive and negative results of both PET tracers (P=1), [KA(5] nor between the 68Ga-DOTATOC and ^{18}F-FDG scan results and patient Tg levels (P=0.67). However, a significant association was noted between Tg levels and ^{18}F-FDG scan results, particularly under non-TSH stimulation conditions (P=0.015), but not in the TSH stimulation state (P=0.262). No[KA(6] association was found between Tg levels and tumor subtypes (P=0.602). ***Conclusion:*** : 68Ga[KA(1] -DOTATOC PET/CT demonstrates somatostatin receptor expression in patients with negative whole-body iodine scans and elevated Tg levels, indicating its potential as a viable alternative diagnostic modality for restaging and metastatic evaluation. The positive results from both imaging techniques showed no significant differences. The study suggests that 68Ga-DOTATOC PET/CT may assist in guiding therapy with Lu-177-DOTATATE for patients exhibiting positive FDG PET/CT results who require systemic treatment.

OP-242

Evaluating the Detection Rate of DTC Metastatic Lesions Using Technetium-99m FAPI Scan in Patients with Elevated Thyroglobulin and Negative Iodine Scan

A. Aghaee[1], *S. Soltani*[2], *K. Aryana*[1], *A. Vasei*[1], *S. Zakavi*[1], *F. Karamian*[1];
[1]*Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Kidney Transplantation Research Center, Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Conventional imaging methods like WBIS often fail to detect these metastases in TENIS (thyroglobulin elevated and negative iodine scan) patients due to the inability of certain cancer cells to capture iodine. Fibroblast Activation Protein (FAP), has emerged as a significant biomarker in oncology. FAP-targeted imaging techniques, such as Fibroblast Activation Protein Inhibitor (FAPI) SPECT imaging, offer enhanced tumor visualization with high sensitivity and specificity. This Study aims to evaluate the detection rate of metastatic lesions using technetium-99m FAPI scans in TENIS patients. ***Materials and Methods:*** This prospective study included eight eligible patients referred to Ghaem Hospital's clinic in 2024. Eligible patients had a confirmed diagnosis of DTC, elevated serum thyroglobulin levels (> 10 ng/mL, excluding those with a doubling time of more than five years), and negative iodine scan results within the past six months. All patients had recently undergone neck ultrasonography and thoracic HRCT or FDG PET/CT, which identified the locations of metastases. Our aim was to assess the FAPI avidity of these metastatic lesions. ***Results:*** A total of eight patients with PTC (median age 49 years; range 25-64 years; 3 [37.5%] men and 5 [62.5%] women) underwent [99mTc] FAPI SPECT/CT. The tumor subtypes included: classic (n=3), follicular variant (n=2), classic with follicular areas (n=1), and not reported (n=1). Seven patients had positive FAPI scans, while one patient had a negative scan. In recent lung and mediastinal HRCT and/or FDG PET/CT scans of the seven positive patients, a total of 20 metastatic lesions were detected. All metastatic lesions in four patients showed FAPI avidity, 90% in one patient showed FAPI avidity, and 50% in two patients showed FAPI avidity. Our study found an overall FAPI avidity of approximately 73%. No drug-related side effects occurred during or after [99mTc] FAPI injection, and SPECT/CT imaging was well tolerated by all patients. No new symptoms were reported during the observation period. ***Conclusion:*** In conclusion, the study's findings suggest that technetium-99m FAPI scans are promising in enhancing the detection of metastatic lesions in TENIS patients. These results have significant implications for clinical practice, supporting further exploration and eventual integration of this imaging technique into standard care protocols for TENIS patients. We believe this new imaging modality has the potential to transform the evaluation and management of TENIS patients.

OP-243

Identification of Rare and Unusual Sites of Metastatic Localizations in Differentiated Thyroid Carcinoma by Means of I-124 PET-CT. A National Cancer Institute of Malaysia Review.

M. Abdul Onny[1,2], *N. Mokhtar*[1], *N. Sulaiman*[1], *A. Kindu*[1], *N. Ali*[1];
[1]*National Cancer Institute Malaysia, Putrajaya, MALAYSIA,*
[2]*University Medical Center Groningen, Groningen, NETHERLANDS.*

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is the 7th most common cancer in Malaysia, predominantly in female with age incident rate of 3.2. A local or regional disease has an excellent 5-year survival of >98% but drop drastically with distant metastasis (50%). The common sites of metastases are lung and bone. However, presence of rare metastatic sites such as brain, kidney, adrenal and pituitary carry poorer prognosis hence, identification of these unusual sites is paramount in allowing prompt initiation of therapies. Thyroidectomy followed by radioiodine therapy (RAI) are the standard-of-care but other form of therapies such as targeted radiotherapy or systemic therapy are useful in advance cases. The advancement of radiopharmaceutical and imaging technique has led to the utilization of I-124 PET-CT which has revolutionized the management of DTC particularly in detecting previously unseen lesions and utilized for personalized RAI treatment through dosimetry. ***Materials and Methods:*** We conduct a retrospective review of the DTC cases which had undergone I-124 PET-CT scans for dosimetry from year 2015-2023. A total of 83 patients had undergone a total of 117 imaging procedures. Each case was reviewed and sites of metastases were identified. Cases with uncommon metastasis were specifically identified. ***Results:*** 15 cases (11-female and 4-male) with mean age of 47.2-year-old, (range 22-78) were identified. Patients had total thyroidectomy followed by varying courses of RAI (range 1-6 courses) via empirical or dosimetry-guided dosing with mean total cumulative dose of (847.3mCi, range 300-2000). The metastatic sites were renal(3), skeletal muscles(4), brain(2), adrenal(1), breast(1), pituitary(1), heart(2), and sphenoid sinus(1) in addition to the usual lung and bone metastases. ***Conclusion:*** The significantly higher resolution of I-124 PET-CT which translate to better sensitivity has resulted in detection of more sites of metastasis. In addition, it led to escalation of treatment including metastatic targeted or systemic therapies. Furthermore, it is invaluable for personalised RAI through its dosimetry capabilities. ***References:*** 1. Azizah,A.M., et al,(2019) 'Malaysia National Cancer Registry Report 2012-2016'. 2. OP-244

Diagnostic performance of [^{68}Ga]OncoFAP-PET compared with [^{18}F]DOPA-PET in patients with recurrent medullary thyroid carcinoma

W. Roll, *D. Ventura, M. Schäfers, B. Noto, P. Backhaus, K. Rahbar, B. Riemann, P. Schindler;*
University Hospital Münster, Münster, GERMANY.

Aim/Introduction: Molecular imaging of advanced or recurrent medullary thyroid cancer (MTC) remains a clinical challenge. Currently, [^{18}F]DOPA-positron emission tomography (PET) has demonstrated the highest sensitivity, though this has only been shown to reach 70%. Fibroblast activation protein (FAP) inhibitor (FAPI) PET-based imaging has emerged as a valuable imaging modality in the context of several malignancies, exhibiting favorable uptake and sensitivity. The aim of this study is to evaluate the detection rate of FAPI-PET with [^{68}Ga]OncoFAP in comparison with [^{18}F]DOPA-PET, given the high level of fibroblast activation of MTCs. ***Materials and Methods:*** Eight patients were analyzed who had histologically proven MTC and suspicion of recurrence with elevated tumor marker level calcitonin. The patients underwent both [^{18}F]DOPA and [^{68}Ga]OncoFAP-PET. The comparative analysis included both a patient-based and a lesion-based approach. Our quantitative analysis compared maximum and mean standardized uptake values (SUV_{max}/SUV_{mean}), metabolic tumor volume (MTV), and maximum tumor-to-background ratios (TBR_{max}). ***Results:*** The median time between the two PET acquisitions was 30.4 d (range: 7-56 d). A total of 35 tracer-avid lesions were detected in both imaging modalities. [^{68}Ga]OncoFAP-PET detected significantly more lesions than [^{18}F]DOPA-PET (34 [97%] vs. 16 [46%], $P < 0.001$). A total of 15 (43%) lesions presented with elevated uptake in [^{68}Ga]OncoFAP and [^{18}F]DOPA-PET, while 19 (54%) were only [^{68}Ga]OncoFAP-positive and 1 (2.9%) was only [^{18}F]DOPA-positive. Quantitative analysis with TBR_{max} revealed significantly higher tracer affinity for [^{68}Ga]OncoFAP, e. g., blood pool TBR_{max} with 6.3 vs. 3.5 ($P < 0.001$). ***Conclusion:*** In this limited patient cohort, the lesional detection rate of [^{68}Ga]OncoFAP-PET was superior to that of [^{18}F]DOPA-PET. Further prospective multicentric investigations with larger patient numbers are warranted.

OP-245

Comparison of ^{68}Ga-FAPI and ^{18}F-DOPA PET/CT in patients with medullary thyroid cancer

D. Hescheler[1], *D. Atiyat*[1], *A. Heinzel*[2], *K. Lorenz*[3], *P. Reschke*[4], *E. Epphard*[1], *J. Wuestemann*[1], *M. C. Kreissl*[1];
[1]*Division of Nuclear Medicine, Department of Radiology and Nuclear Medicine, University Hospital Magdeburg, Magdeburg, Germany, Magdeburg, GERMANY,* [2]*Department of Nuclear Medicine, University Medicine Halle, Halle, Germany,, Halle, GERMANY,* [3]*Department of Visceral, Vascular and Endocrine Surgery, University Medicine Halle, Halle, Germany, Halle, GERMANY,* [4]*University Hospital Frankfurt, Frankfurt, GERMANY.*

Aim/Introduction: Accurate staging is critical for the management of medullary thyroid cancer (MTC). The abundant stroma in most thyroid cancers, including MTC, opens new opportunities to target cancer-associated fibroblasts (CAFs) for novel molecular imaging and therapeutic targets. Fibroblast activation protein inhibitor (FAPi) molecules labeled with [^{68}Ga] Ga have enabled alternative molecular diagnostics of thyroid cancer. The aim of this study was to compare PET/CT using ^{68}Ga-RTX-1363R (^{68}Ga-FAPI) and PET/CT using ^{18}F-DOPA PET/CT for the staging of MTC. ***Materials and Methods:*** In this retrospective study, ^{18}F-DOPA- and ^{68}Ga-FAPI-PET/CT imaging was compared using per-patient analysis and per-lesion analysis in patients with MTC. The results of the two scans were correlated with morphological findings (CT/MRI/sonography) or histology. Quantitative assessment included a comparison of standardized uptake values and tumor background ratio (TBR). ***Results:*** 9 patients with a mean age of 55 years (34 - 80 years) and 62 lesions were included in the study. In the group of patients with lymph node metastases (n=4), more patients were detected with ^{68}Ga-FAPI than with ^{18}F-DOPA (100% (4/4) patients vs. 50% (2/4) patients). Accordingly, the analysis per lesion showed a higher detection rate with higher TBR values for lymph node metastases with ^{68}Ga-FAPI than with ^{18}F-DOPA (true-positive [TP] 100% [8 of 8] vs. 50% [4/8]), mean TBR 10.9 vs. 6.9). In the group of patients with liver metastases (n=3), all patients were detected with both ^{68}Ga-FAPI and ^{18}F-DOPA. The analysis per lesion also showed a higher detection rate with higher TBR values for liver metastases (TP 100 % [22/22] vs. 22.7 % [5/22], mean TBR 24.1 vs. 2.7). In the group of patients with lung metastases (n=3), more patients were detected with ^{68}Ga-FAPI than with ^{18}F-DOPA (100 % (3/3) patients vs. 67 % (2/3) patients). Per lesion analysis showed a higher detection rate with higher TBR values for lung metastases (TP 86% [12/14] vs. 43% [6/14], TBR 6.1 vs. 3.6). ***Conclusion:*** ^{68}Ga-FAPI PET shows a higher detection rate with higher TBR values in metastases of MTC. ^{68}Ga-FAPI PET/CT could improve the diagnosis of MTC.

Aim/Introduction: Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumour accounting for 1-2% of all thyroid cancers. 18F-DOPA PET/CT is an established imaging tool for MTC staging, although the optimal acquisition timing remains controversial. Aim of the study was to retrospectively compare both visually and semiquantitatively early and delayed images in patients with histologically confirmed MTC. ***Materials and Methods:*** Among 18F-DOPA PET/CT scans performed between 2022 and 2025 in confirmed MTC pts, only those studied for staging were included. According to EANM guidelines, 60minutes standard acquisition was preceeded by an early acquisition centered on the thyroid [1]. Primary tumours' SUVmax and contrast-to-noise ratio (CNR) were measured on early and delayed images [2]. ***Results:*** Overall, 16 patients (33% male; mean age 52 years) were included. 18F-DOPA PET/CT was positive in all primary lesions at the early acquisition while in 6 cases visual lesion detection was not possible in the delayed scans. SUVmax values were higher on early acquisitions in all patients. CNR values decreased between early and delayed scans in the entire study population, with a mean reduction of 62% (range 15-100%). In 6/16 patients, while the delayed- CNR fell below 5 (a critical threshold for reliable lesion detection) [2], the early -CNR always remained above 6. In 3/6 with delayed-CNR below 1, visual lesion detection was not possible. In 10/16 cases, a detailed pathologic report including differentiation grade was available: low-grade MTC was observed in 4/10 (all presenting delayed- CNR <5) while high-grade MTC was detected

in the remaining 6/10 (with delayed-CNR>6). ***Conclusion:*** Our preliminary data show that 18F-DOPA PET/CT early acquisition detected the primary tumour in all cases. Although limited by the small cohort of retrospective patients included in the study, performing delayed imaging alone would have resulted in a higher rate of false-negative findings. ***References:*** [1] Giovanella L, Treglia G, Iakovou I, Mihailovic J, Verburg FA, Luster M. OP-247

Feasibility of ^{68}Ga-SSO-120 PET/CT Imaging in Medullary Thyroid Carcinoma: A Retrospective Analysis

I. Ciuciulkaite, *T. Brandenburg, W. Jentzen, W. Fendler, P. Fragoso Costa, M. Nader, S. Himmen, H. Lahner, L. Umutlu, D. Führer-Sakel, K. Herrmann, H. Hautzel, D. Kersting;*
Essen University Hospital, Essen, GERMANY.

Aim/Introduction: Most patients with medullary thyroid carcinoma (MTC) present with advanced, metastatic disease. Somatostatin receptor (SSTR) expression in MTC offers diagnostic and therapeutic potential. However, SSTR agonist-based PET/CT imaging has shown suboptimal detection rates in MTC. Newer SSTR antagonists provide improved sensitivity, lesion detection, and image contrast in imaging, as well as higher tumour uptake, longer tumour residence time, and better tumour-to-kidney dose ratios in therapeutic settings. This study aimed to investigate the feasibility of PET/CT with ^{68}Ga-SSO-120, an SSTR antagonist, in patients with MTC. ***Materials and Methods:*** Patients with newly diagnosed MTC or elevated calcitonin levels who underwent whole-body ^{68}Ga-SSO-120-PET/CT were retrospectively included. The mean administered activity was 134.7 MBq, with a mean uptake time of 63 minutes. Lesions with uptake above background were evaluated across five anatomical regions (thyroid bed, regional lymph nodes, liver, bone, and other metastases), according to the 8th edition TNM classification. SUVmax, SUVmean, SUVpeak, and peak tumour-to-liver ratio (TLRpeak) were measured for each lesion, with TLRpeak calculated by dividing lesion SUVpeak by liver SUVmean. For theranostic evaluation, whole-body (WB) SUVmean and TLRmean were assessed per patient. WB SUVmean was the mean SUV in all PET-positive lesions per patient, and WB TLRmean was calculated by dividing WB SUVmean by liver SUVmean. Continuous variables were reported as medians and ranges; categorical variables as counts and percentages. ***Results:*** Thirty-five patients were included. 68Ga-SSO-120-positive tumours were detected in 24 patients (68.6%) and in 41 of 175 evaluated regions (23.4%). Patient-based median SUVmax, SUVpeak, and TLRpeak values were 5.7 (1.6-20.9), 4.0 (1.4-14.9), and 1.0 (0.4-4.8), respectively. Region-based median SUVmax values were 3.9 (2.2-12.3) for the thyroid bed, 5.1 (1.6-20.9) for lymph node, 7.6 (4.2-12.0) for liver, 4.6 (2.0-10.0) for bone, and 3.7 (2.0-8.9) for other metastases. Lesion-based analysis identified 10 lesions in the thyroid bed, 43 lymph node, and 58 distant metastases, with median SUVmax values of 3.6 (2.1-12.5), 4.8 (1.0-21.5), and 4.6 (1.4-19.6), respectively. Median WB SUVmean and TLRmean were 2.8 (range 0.9-11.5) and 0.9 (range 0.1-3.8), respectively. WB TLRmean was <1 in 62.5% of patients, between 1-3 in 33.3%, and >3 in 4.2%. ***Conclusion:*** ^{68}Ga-SSO-120-PET/CT demonstrated potential for imaging in patients with MTC. Further investigation is warranted to identify predictive parameters for high tumour uptake and select patients who might benefit from SSTR antagonist PRRT.

Aim/Introduction: 6-[^{18}F]fluoro-L-DOPA(18F-DOPA)-PET/CT is the gold standard imaging for staging/restaging medullary thyroid carcinoma (MTC), a rare neuroendocrine tumour. Dynamic PET/CT acquisitions allow analysis of tracer kinetics, potentially improving the detection and characterization of T (primary tumour), lymphnode involvement (N) and distant metastases (M). Aim: to evaluate 18F-DOPA pharmacokinetics in dynamic-uExplorer LAFOV-PET in MTC patients. ***Materials and Methods:*** Among patients who underwent 18F-DOPA-PET/CT for suspected/known MTC, only those with pathological confirmation were retrospectively included. Dynamic-LAFOV- 18F-DOPA-PET/CT images were acquired over 25minutes (intravenous injected activity:3MBq/kg) completed by standard static 60-minutes acquisition (STD). Volumes of interest were manually drawn over lesions sites and reference healthy tissue(contralateral thyroid lobe) by experienced nuclear medicine physicians. 18F-DOPA uptake and pharmacokinetics were evaluated using standardized uptake value (SUV), graphical analysis (Patlak and RE-plots) and two-tissue compartment models, including both the reversible (2TC) and irreversible (2TiC) approaches. Mean absolute scaled error (MASE) and Akaike Information Criterion (AIC) were used to assess the best fitting model for each VOI. ***Results:*** Ten MTC-confirmed patients (males:females=2:8;mean age:66.2years) were included. PET/CT was positive in 8/10 patients (at≥1 site: T in 4/8; N in 4/8; M in 3/8, all positive at bone level, 1 also at liver level) and true negative in 2/10. 18F-DOPA demonstrated rapid blood clearance and early accumulation in both pathological lesions and background tissues, typically within 1-2minutes post-injection. All VOIs were better fitted by reversible kinetic models (RE-plots and 2-tissue compartment reversible model-2TC), which provided significantly higher mean distribution volume (DV) values in all lesions (DV_T=3.8±2.1,DV_N=2.0±1.3,DV_M=3.9±2.8) compared to reference healthy thyroid tissue (DV_thyroid=0.7). The rate constant k4 was markedly decreased in pathological VOIs (k4_T= 0.1±0.02,k4_N=0.1±0.08,k4_M=0.1±0.1) compared to normal thyroid tissue (k4_thyroid=0.5±0.06), reflecting increased tumour tracer retention. Time-activity-curves showed a trend towards uptake reduction over the dynamic-acquisition time-frame, especially at primary and nodal level. STD confirmed reduction of the uptake, except for some bone lesions that either became apparent only in STD or increased uptake. ***Conclusion:*** MTC lesions demonstrate intense 18F-DOPA uptake and retention, as reflected by elevated DV and reduced k4 value compared to background healthy tissues. A relatively rapid wash-out was observed in several lesions, particularly at primary and nodal level, suggesting heterogeneity in tracer handling and lesions' metabolic activity supporting the potential added value of early dynamic acquisitions to define the best time-frame-window for image acquisition.Further studies are needed to elucidate the metabolic behaviour mechanisms at the basis of lesions' differential tracer retention/clearance.

Dynamic ^{18}F-FDG PET/CT Imaging Combined with Machine Learning Models for Improved Classification of Solitary Pulmonary Lesions: A Series of Studies

Y. Luo, *L. Huang, W. Ma, J. Liu;*
The Second Hospital of Lanzhou University (Second Clinical Medical College), lanzhou, CHINA.

Aim/Introduction: Accurate differentiation of solitary pulmonary lesions (SPLs) has long been a clinical challenge. This study aimed to integrate dynamic ^{18}F-fluorodeoxyglucose (FDG) PET/CT imaging with machine learning (ML) to improve the diagnostic accuracy of SPL classification in terms of benign/malignant nature and histopathological subtypes. ***Materials and Methods:*** Retrospective analysis of dynamic PET/CT imaging data from 150 SPL patients enrolled between 2017 and 2025 (scanned at 1, 2, 3, and 4h after ^{18}F-FDG injection) was conducted. Metabolic parameters (SUVmax, SUVmean, standardized SUV [stdSUV], metabolic homogeneity) were extracted and to assess their diagnostic efficacy, and dynamic metabolic curves(DMCs) were fitted for observation. Six ML models were constructed, and their performance was evaluated through ROC-AUC analysis, 10-fold cross-validation, and external validation. ***Results:*** In the discrimination of benign and malignant SPLs, thresholds based on 4-h average stdSUV (stdSUVavg4h: 2.7 for benign vs. malignant, 4.76 for squamous cell carcinoma vs. tuberculosis, 4.12 for squamous cell carcinoma vs. inflammatory lesions, 2.36 for adenocarcinoma vs. inflammatory lesions) and stdSUVmax4h(7.43 for squamous cell carcinoma vs. adenocarcinoma, 6.20 for tuberculosis vs. inflammatory lesions) demonstrated good classification accuracy (AUC: 0.82-0.97); the ability to discriminate adenocarcinoma from tuberculosis was limited. DMCs showed that the DMCs of malignant SPLs were generally higher than those of benign lesions (squamous cell carcinoma > adenocarcinoma > tuberculosis > inflammatory lesions); over time, the DMCs of lung cancer and tuberculosis continued to rise (with tuberculosis showing a smaller increase than lung cancer), while the DMCs of inflammatory lesions decreased to varying degrees. DMCs also showed good efficacy in differentiating adenocarcinoma from tuberculosis. ML models further enhanced the classification capability of PET/CT for SPLs, with the random forest (RF) model achieving the best performance (AUC: 0.97, sensitivity: 93%, specificity: 89%); additionally, ML models using dual-time-point (1,4h) and four-time-point (1, 2, 3, and 4 hours) imaging exhibited comparable efficiency, reducing radiation exposure by 40%. ***Conclusion:*** Multi-phase ^{18}F-FDG PET/CT imaging combined with DMC analysis and ML models can effectively distinguish the benign/malignant nature and subtypes of SPLs. Dual-time-point (1, 4h) imaging reduces the number of scans while maintaining diagnostic accuracy, supporting its clinical adoption. ***References:*** Luo Y. Differential diagnosis of lung cancer and tuberculosis based on 18F-fluorodeoxyglucose PET/CT multi-time points imaging. Nucl Med Commun. 2023; 44(8): 732-740.

EPS-074

Effect of data-driven motion correction for respiratory movement on lesion detectability in PET-CT: a phantom study

M. de Winter[1], *R. Gevers*[1], *J. Lavalaye*[1], *J. Habraken*[1], *M. Maspero*[2]; *[1]Sint Antonius Hospital, Nieuwegein, NETHERLANDS, [2]University Medical Center Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: While DDMC techniques have proven to enhance the visibility of lesions affected by motion, their impact on overall detectability remains unclear. This study investigates whether data-driven motion correction (DDMC) improves lesion detectability in PET-CT. ***Materials and Methods:*** A moving platform simulated respiratory motion in a NEMA-IEC body phantom with varying amplitudes (0, 7, 20, 30 mm) and target-to-background ratios (2, 5, 10.5). Scans were reconstructed with and without DDMC, and the spherical targets' maximal and mean recovery coefficient (RC) and contrast-to-noise ratio (CNR) were measured. ***Results:*** DDMC results in higher RC values in the target spheres. CNR values increase for small, high-motion affected targets but decrease for larger spheres with smaller amplitudes. A sub-analysis shows that DDMC increases the contrast of the sphere and the background noise by 17%. ***Conclusion:*** While DDMC significantly enhances contrast (RC), its impact on detectability (CNR) is less profound due to increased background noise. CNR improves for small targets with high motion amplitude, potentially enhancing the detectability of low-uptake lesions. Given that the increased background noise may reduce detectability for targets unaffected by motion, we suggest that DDMC reconstructions are used best in addition to non-DDMC reconstructions.

EPS-075

Linearity and Dynamic Range of Digital PET Systems for Myocardial Blood Flow Quantification

R. DeKemp[1], *J. Huettges*[2], *J. Abele*[3], *R. Hung*[3], *M. Iwanochko*[4], *M. Alwan*[5], *M. Al Mallah*[5], *S. Chih*[1]; *[1]University of Ottawa Heart Institute, Ottawa, ON, CANADA, [2]Cardiac Imaging Inc, Houston, TX, UNITED STATES OF AMERICA, [3]University of Alberta Hospital, Edmonton, AB, CANADA, [4]University Health Network, Toronto, ON, CANADA, [5]Houston Methodist Hospital, Houston, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: Digital PET-CT scanners have generally improved performance over PMT-based systems, however their accuracy for quantification of myocardial blood flow (MBF) has not been evaluated systematically. Rb-82 is the most commonly used tracer for MBF imaging but may exceed the count-rate limits for linearity and accuracy at the guideline-recommended dose of 10 MBq/kg. This study aimed to characterize the dynamic range of four current digital PET-CT scanners based on established methodologies (Renaud et al. JNM 2017). ***Materials and Methods:*** Rubidium-82 (2000-3000 MBq) was injected directly into the heart wall of a cardiac insert within large and small torso phantoms (Spectrum Dynamics) to simulate different patient sizes. List-mode scans (6 min) were started at the end-of-injection when the heart wall activity was well-mixed and homogeneous. Dynamic images were reconstructed with all corrections enabled, and volumes of interest were drawn around the entire cardiac insert to measure the total (decay-corrected) activity vs time. Three different metrics were used to evaluate scanner dynamic range defined at the measured heart wall activity with <10% bias relative to the end-of-scan value used as the accuracy standard: 1. True activity in the LV heart wall, 2. Prompt coincidence count-rate, 3. Coincidence dead-time correction factor. ***Results:*** For all systems, the prompt count-rates and dead-time factors increased monotonically with total activity in the LV heart wall. At the 10% bias limit, true heart wall activity was systematically higher in the large vs small phantom due to higher attenuation losses. Conversely, the

prompt count-rates were systematically lower in the large vs small phantoms at the 10% bias limit, due to changes in patient scatter and dead-time corrections. Dead-time factors were higher in the large vs small phantom due to increased incidence of scattered events. ***Conclusion:*** The dynamic range available for accurate measurement of cardiac activity varies greatly among current digital PET-CT scanners. The prompt count-rate and total activity limits (at 10% bias) will vary between patients based on the discrepant results in the small and large torso phantoms. Cardiac-specific performance standards may be required to characterize the high-count-rate accuracy for quantification of myocardial blood flow using rubidium-82 PET imaging. ***References:*** 1. EPS-076

^{82}Rb Myocardial perfusion imaging - how high can you go?

C. López Martínez[1], *H. McMeekin*[1,2], *M. Burniston*[1], *B. Sanghera*[1]; [1]*Barts Health NHS Trust, London, UNITED KINGDOM,* [2]*Hermes Medical Solutions, London, UNITED KINGDOM.*

Aim/Introduction: Cardiac positron emission tomography/computed tomography (PET/CT) with rubidium-82 (^{82}Rb) is a powerful tool in the diagnosis of coronary arterial disease and microvascular disease. Myocardial blood flow rates (MBFs) are determined from the first-phase dynamic data. Due to the short half-life of ^{82}Rb (75 seconds), the first-pass phase can have extremely high count-rates which may saturate the detectors, making deadtime correction factors (DTCFs) insufficient and resulting in reduced MBF quantitative accuracy. This work characterises the count-rate performance of the scanner, aiming to find an upper limit to the weight-based dosing for accurate activity quantitation in the dynamic image. ***Materials and Methods:*** The method by (Renaud, et al.) was reproduced: 2220 MBq of ^{82}Rb were injected into the myocardium insert of a cardiac anthropomorphic phantom and dynamic images were acquired. The activity in the myocardium was measured and DTCF information was collected at each time frame. 10% difference between the measured and known myocardial activity was chosen as the maximum allowable error; the DTCFs at these count rates were recorded to establish the dynamic range. Similar acquisitions and analyses were repeated with two larger phantom sizes and with an ^{18}F-FDG source outside the FOV. The known activities corresponding to the dynamic range limits were converted into activity-per- weight to establish limits for quantitatively accurate scanning. ***Results:*** The scanner underestimates activity in the myocardium at high count-rates. Dynamic range limits were measured as DTCFs of 1.45, 1.80, 1.83 and 1.68 for the acquisitions with the standard phantom size, two larger phantom sizes, and activity outside the FOV, respectively. The maximum activity per weight for quantitative accuracy was calculated as 14.50 MBq/kg. ***Conclusion:*** The count-rate limitations of a PET/CT scanner depend on patient size; the scanner can process higher DTCFs for larger patients due to the increased attenuation. Having a source of activity outside the FOV increases the DTCF limit, as expected, as the total counts received by the detectors are greater. If a large proportion of these counts originate from outside the FOV then the maximum myocardial activity for quantitative accuracy will be reduced. The activity-per-weight currently administered to patients of 10 MBq/kg is below the limit for quantitative accuracy found in this work, inferring the weight-based dosing is optimised for MBF accuracy. ***References:*** Renaud, J. M., et al., Characterization of 3-Dimensional PET Systems for Accurate Quantification of Myocardial Blood Flow, J Nucl Med, 58, 103-109 (2017)

EPS-077

Potential of Lean Body Mass-Adjusted FDG PET/CT Parameters to Predict Pathologic Findings in Overweight Endometrium Cancer Cases

F. Avci[1], *A. Tunc*[1], *B. K. Erkek*[2], *A. A. Ozsaran*[3], *G. Serin*[4], *O. Zekioglu*[4], *Z. Burak*[1]; [1]*Ege University, Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Agri Training and Research Hospital, Nuclear Medicine, Izmir, TÜRKIYE,* [3]*Ege University, Obstetrics and Gynecology, Izmir, TÜRKIYE,* [4]*Ege University, Pathology, Izmir, TÜRKIYE.*

Aim/Introduction: This study aims to evaluate the potential of metabolic and volumetric F-18 FDG PET/CT parameters, adjusted for lean body mass (LBM), in predicting pathological findings in overweight patients diagnosed with endometrial cancer who underwent preoperative PET/CT imaging. ***Materials and Methods:*** Between 2021 and 2024, a total of 80 endometrial cancer patients with a body mass index (BMI) ≥25 kg/m^2, who had not received neoadjuvant therapy prior to undergoing total abdominal hysterectomy and bilateral salpingo-oophorectomy (TAH-BSO), were included. Demographic and postoperative pathological data were obtained from the hospital's electronic records. PET/CT images were evaluated both visually and semi-quantitatively to calculate tumor-associated parameters, including SULmax, SULmean, SULpeak, metabolic tumor volume (MTV), and total lesion glycolysis adjusted for lean body mass (TLG-LBM). Histopathological and immunohistochemical features of tumors were analyzed. Results were retrospectively analysed using SPSS v25. ***Results:*** The mean age at diagnosis was 60.34 years (44-84), and the mean BMI was 34.48 kg/m^2 (25.01-55.10). PET parameters are presented in Table 1. Among the cases, 69 were endometrioid, 5 mucinous, 3 serous, and 3 carcinosarcoma. The average tumor size was 3.96 cm (1-9 cm), and staging revealed 10 cases at Stage I, 56 at Stage II, and 14 at Stage III. Lymphovascular invasion was detected in 22 cases, and cervical involvement in 9 cases. Lymph node dissection was performed in 60 patients, 6 of whom had micrometastases. SULmean showed weak but statistically significant correlations with age (r=0.25), tumor size (r=0.34), Ki-67 index (r=0.25), and estrogen receptor percentage (r=-0.25) ($p<0.05$). SULmax also showed a weak but significant correlation with the Ki-67 index (r=0.26). Estrogen receptor expression, a known favorable prognostic factor, was inversely correlated with PET parameters, excluding MTV. No significant relationships were found between PET parameters and progesterone receptor levels or p53 expression. Histologic grade correlated significantly with SULmax ($p=0.008$), SULmean, and SULpeak. Interestingly, SULmean values were significantly higher in patients with lymphovascular invasion ($p=0.008$) and lymph node metastasis ($p=0.011$). However, no significant associations were found between PET parameters and histologic subtype, myometrial invasion, or cervical involvement. ***Conclusion:*** Our findings suggest that in overweight patients with endometrial cancer, SUL parameters play a more effective role than SUV parameters in assessing clinical and pathological characteristics. Specifically, SULmean demonstrated significant correlations with prognostically critical variables. These results indicate that SULmean may serve as a potential tool in the diagnostic stratification and treatment planning of endometrial cancer.

EPS-078

Optimization of Whole-Body Dynamic ^{68}Ga PET Acquisition Protocols Using a 32 cm Axial Field of View: A Phantom Study

Q. Maronnier, *S. Brillouet, C. Lamesa, F. Courbon, O. Caselles;*
Oncopole Claudius Regaud, Toulouse, FRANCE.

Aim/Introduction: Dynamic PET imaging provides additional clinical insights over static imaging, potentially enhancing patient selection for targeted therapies. However, traditional PET systems are limited by narrow axial fields of view (FOV), restricting whole-body (WB) radiotracer kinetic assessment. WB dynamic imaging can be performed using image-derived input function (IDIF) from a blood pool and sequential WB passes [1]. This study aims to produce optimized protocols for WB dynamic acquisitions with ^{68}Ga-labeled radiotracers, ensuring reliable semi-quantitative metrics while increasing the number of WB passes for improved kinetic analysis. ***Materials and Methods:*** Phantom experiments were conducted on a 32cm axial FOV PET/CT system using ^{68}Ga, with two components: simulating the IDIF and multiple WB passes. These included evaluating bolus measurement accuracy and assessing image quality and quantification. A Jaszczak phantom, with a 10cc syringe (25mm cross-section) containing ^{68}Ga, was used for bolus measurement accuracy. 6 minutes scan time was rebinned into 12×5s, 6×10s, and 8×30s frames. Derived from the EARL image quality procedure, a body phantom containing spheres of 10 to 37mm in diameter with a contrast ratio of 10.15 was scanned over one hour. The data were then rebinned with various framing (1, 1.5, 2, and 2.5 min/FOV) and reconstruction parameters (β of 750, 1000, and 1250). Mean and maximum recovery coefficients (RC) were calculated and compared to the reference clinical protocol used for static imaging (2.5 min/FOV, β = 750). ***Results:*** Two dynamic acquisition protocols were designed, one with 4 bed positions (vertex-thighs) and the other with 8 bed positions (total-body), both incorporating IDIF and WB passes. In the IDIF experiment, less than 5% variation in RCmean and RCmax was observed. In the WB experiment, the coefficient of variation over frames from the phantom background was 10.1% for the optimized series and 10.2% for the reference series. The standard deviation of RCmean and RCmax in spheres over frames was generally lower and more consistent for the optimized series. A slight decrease in RC metrics was noted, with the largest difference observed in the smallest target (12% for RCmax and 9% for RCmean). ***Conclusion:*** We produced dynamic ^{68}Ga PET acquisition protocols that provide reliable semi-quantitative metrics with minimal variation across frames while allowing for an increased number of WB passes within the same acquisition time. ***References:*** 1. Dias AH, Jochumsen MR, Zacho HD, Munk OL, Gormsen LC. Multiparametric dynamic whole-body PSMA PET/CT using [68Ga]Ga-PSMA-11 and [18F]PSMA-1007. EJNMMI Res. 2023 Apr 15;13(1):31.

EPS-079

Optimisation of [^{18}F]FDG dosage for quantitative whole-body PET: ensuring image quality anthropometric independency and EARL harmonisation

I. Baltabaev, *A. Khalimon, A. Nikiforuk, B. Shvets, M. Khodzhibekova, G. Khamadeeva, D. Khodakova, T. Lazutina, I. Pylova, A. Leontev;*
P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Consistent image quality independent of patient-specific anthropometric variability in whole-body PET imaging remains a challenge when using standardised [^{18}F]FDG dosing protocols. This study aimed to develop and validate an optimised anthropometry-based dosing regimen for [^{18}F]FDG administration, with a focus on EARL2-harmonisation and reduction of signal-to-noise ratio (SNR) dependency on anthropometric parameters. ***Materials and Methods:*** A total of 250 patients were included in a prospective study: 90 to determine a new dosage protocol and 160 for its validation. The local [^{18}F]FDG dosing regimen, clinical PET/CT acquisition protocol (3min/bed) and two EARL2-harmonised reconstructions (BSREM with β=400 and 3D-OSEM+PSF with 11 iterations, 6 subsets, 5 mm Gaussian filter) were utilised. Liver SNR was measured and normalised to administered activity for both reconstructions. Acceptable SNR (SNR_{acc}) was determined by physicians based on visual assessment. The dependence of normalised SNR on various patient-specific parameters was analysed using multiple regression models. The anthropometric parameter and regression model with the highest R^2, along with the predefined SNR_{acc}, were used to determine the new dosing regimen, which was prospectively validated using only BSREM reconstruction method. Additionally, minimum acceptable EARL2-compliant activity was derived from NEMA IEC Body Phantom NU2-2018 acquisition conducted in accordance with the EARL ^{18}F-standards accreditation manual. ***Results:*** The best regression model between patient-specific anthropometric parameters and normalized SNR was observed for body surface area (Haycock formula) and body weight. SNR_{acc} was defined as 17 for BSREM and 10.5 for 3D-OSEM+PSF. Due to its practical simplicity, body weight was selected as the patient-specific parameter for the new dosing regimen. The power-law model demonstrated the best fit, yielding R^2=0.67 for BSREM and R^2=0.59 for 3D-OSEM+PSF ($p<0.001$). Consequently, administered activity was defined as $A=4.31\times m^{1.04}$ for BSREM and $A=1.2\times m^{1.34}$ for 3D-OSEM+PSF. After the validation with BSREM reconstruction, the new regimen demonstrated no correlation between SNR and body weight (r=-0.05 and p=0.53) and reduction in SNR's coefficient of variation to 8.8% compared to 14.3% observed with the local dosing regimen, with a mean value of SNR 16.9. The minimum acquisition time per bed ensuring EARL2-harmonisation was derived from the phantom study and accounted for 75 seconds for BSREM. Using reference activity and weight values of the phantom (300MBq and 75kg), minimum acceptable activity was set as $A_{min}=1.4\times m^{1.04}$ for clinical 3min/bed acquisition protocol with BSREM algorithm. ***Conclusion:*** The proposed patient-specific anthropometry-based optimisation of [^{18}F]FDG dosing regimen improves image quality stability and satisfies EARL2-harmonisation standards in quantitative whole-body PET imaging.

EPS-080

A Systematic Exploratory Study on SUV Harmonization for Long Axial PET/CT

Y. Li, *X. Lu, H. Pang;*
Department of Nuclear Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: European Association of Nuclear Medicine (EANM) have launched EANM Forschungs GmbH (EARL) to achieve harmonization of standard uptake value (SUV), which aimed to align SUV obtained from different scanners and algorithms. EARL developed the standard protocol of SUV harmonization for short-axis PET (SaPET). However, Long-axis PET (LaPET) demonstrated completely different scan mode and SUV harmonization logic when compared to SaPET, and there were no relative studies specifically focused on the SUV harmonization of LaPET. Our purposes were to perform systematical researches on SUV harmonization of LaPET, establish the standardized protocol and conduct clinical validation to verify its efficacy. ***Materials and Methods:*** Firstly, we compared the SUVs of NEMA IEC phantoms obtained from different scanners (SaPET and LaPET) and algorithms. Secondly, to explore the SUV harmonization protocol for LaPET, a specific scan mode was proposed. The long-axial detector was divided into five parts according to the patient position, within which most patient's head and neck, chest,

abdomen, pelvis and leg could be correspondingly placed. After 5 times of scanning (one-bed, phantom placed at the middle of each part), SUV harmonization for each scan was performed. Post-filters (F-brain, F-chest, F-abdomen, F-pelvis and F-leg, namely filter of corresponding position) were then determined, and recovery coefficients (RC) were calculated. The the root mean square error (RMSE) of adjusted RC to RCexpected was then calculated to describe the success of harmonization. Finally, we applied the SUV harmonization to the DICOMs of the same patient obtained from LaPET and SaPET. ***Results:*** The phantom SUVs varied between SaPET and LaPET, as well as among different algorithms, confirming the necessity of SUV harmonization. The RMSE of adjusted RC to RCexpected were 0.048, 0.045, 0.053, 0.061 and 0.045 for head and neck, chest, abdomen, pelvis and leg positions under our clinically reconstruction algorithms (3i20s, Gaussian post-filtering 2mm), respectively. Meanwhile, SUVs from the same patient significantly differed from LaPET to SaPET, and SUV harmonization explained a lot for the abnormal SUV observed in clinic. ***Conclusion:*** SUV harmonization showed great significance between SaPET and LaPET, and special harmonization protocol showed be established for LaPET, by which each body part showed be harmonized separately according to its position in detector.

EPS-081

Validation of image-derived SUV estimates for ultra-low ^{18}F-FDG PET imaging using a large axial field-of-view PET/CT system

C. Smith, *G. J. C. Zwezerijnen, J. Heijmen, M. E. den Hollander, J. M. Zijlstra, C. Menke-van der Houven van Oordt, I. Bahce, M. Yaqub, R. Boellaard;*
Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: Large-axial field of view (LAFOV) PET/CT systems enable image-derived quality control of standardised uptake values (SUV) by extracting ^{18}F-FDG activity and body weight from the total and half-body scans [1]. Additionally, these systems offer ultrahigh sensitivity and signal-to-noise ratios, allowing lower tracer doses and shorter acquisition times. This study examined whether previously published QC methods remain valid when using significantly lower ^{18}F-FDG activities with LAFOV PET/CT. ***Materials and Methods:*** Ten patients with cancerous tumours underwent two ^{18}F-FDG PET/CT scans: one with standard activity (3.0 MBq/kg) and, within 7 days, one with ultra-low activity (0.3 MBq/kg). List-mode data of both scans were resampled to simulate activities of 0.3 and 0.03 MBq/kg. We applied linear regressions from Smith et al. [1] to the test, retest, and simulated activities to assess their applicability at lower activities. ***Results:*** Image-derived body weight significantly predicted reported body weight across test, retest, and simulated 0.3 and 0.03 MBq/kg scans for both total (r= 0.964; r= 0.982; r= 0.964; r= 0.918) and half body (r= 0.988; r= 0.988; r= 0.988; r= 0.976) data, respectively. A small underestimation at simulated 0.03 MBq/kg was found but could be corrected with additional Gaussian filtering. Image based estimated ^{18}F-FDG activity showed biases of more than 15% in case of half body retest scans (when using low injected activities) which improved to within 5% after adding an interaction term between image based activity and patient length in the original independent training fits. Image based estimated ^{18}F-FDG activity accurately (within 5%) predicted reported injected activity across test, retest, and simulated 0.3 and 0.03 MBq/kg scans for both total (r= 0.964; r= 0.964; r= 0.973; r= 0.964) and half body (r= 0.964 r= 0.976; r= 0.973; r= 0.988) data, respectively. ***Conclusion:*** Body weight and injected activity can be accurately derived from total and half-body scans, even at significantly reduced doses (0.3 MBq/kg). This supports continuing to use image-derived QC for SUV calculation for high and low-activity protocols. Standardisation of low-dose protocols for LAFOV PET/CT systems aligns with ALARA/ALAPA principles, which is particularly relevant for radiation-sensitive patients such as children and pregnant women. ***References:*** Smith, C. L., Zwezerijnen, G. J., den Hollander, M. E., Weijland, J., Yaqub, M., & Boellaard, R. (2024). Mitigating SUV uncertainties using total body PET imaging. Redefining Ultra-low Dose: Full-sensitivity LAFOV PET/CT for Paediatric Imaging

G. C. van den Oever, *J. H. van Snick, K. P. Koopmans, E. H. J. G. Aarntzen, R. H. J. A. Slart, W. Noordzij, A. H. Brouwers, G. N. Stormezand, T. Velleman, A. W. J. M. Glaudemans, O. V. Ivashchenko;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Long axial field-of-view (LAFOV) PET/CT systems, with scans over 1 metre, offer superior sensitivity. This enables faster scanning and reduced radiopharmaceutical doses, benefitting paediatric imaging due to children's higher radiosensitivity. However, no international guidelines for paediatric LAFOV PET/CT dosing exist. While early studies suggest substantial dose reduction potential, recent advances including full-acceptance angle acquisition have doubled sensitivity. This mode can cause non-uniform image quality unless scanning is performed in multiple bed positions, which is often unnecessary in children, as most major organs fall within 1 metre. Bed movement may also increase stress or necessitate sedation. This study investigates optimal use of full-sensitivity LAFOV PET/CT in paediatrics, balancing dose reduction and diagnostic quality. ***Materials and Methods:*** This retrospective study included 56 [^{18}F]FDG-PET/CT scans from patients aged 0.2-17.5 years (mean 9.9 ± 5.2), performed for oncological (n=25) or infectious/inflammatory (n=31) indications. Reference image quality (RIQ) was defined from average count statistics per bodyweight from scans conducted at our centre between October 2021 and December 2024. Full-sensitivity reconstructions were created at 0.39%, 1.56%, 6.25%, 12.5%, and 25% of RIQ, following evidence of a 50% dose reduction with partial system sensitivity. Three nuclear medicine specialists rated image quality on a 5-point Likert scale, with 3 considered clinically acceptable, and re-evaluated images after reviewing clinical indications. Signal-to-noise ratio (SNR) in the liver, tumour-to-background ratio (TBR), and lesion SUVs were analysed. SNR liver was normalised for administered activity and scan duration. Optimal dose-modelling parameters (weight, height, BMI, bodyweight-per-height (BWH), and body surface area) were determined using goodness-of-fit metrics and F-tests. ***Results:*** An SNR of 12.3 correlated with clinically acceptable quality. Primary oncological scans with previously unacceptable Likert scores were upon re-evaluation more frequently rated as clinically acceptable than follow-up scans ($p = 0.03$). TBR showed no significant change across reconstruction percentages. Weight and BWH showed the best fit ($R^2 = 0.88$ and 0.89), with no significant difference between models ($F = 2.13$, $p = 0.15$). Weight was selected due to ease of clinical use. The resulting model indicated a 97% (96-98) dose reduction compared to current EANM guidelines. ***Conclusion:*** Full-sensitivity LAFOV PET/CT achieves a 97% dose reduction in paediatric imaging while maintaining clinically acceptable quality. Weight and BWH are optimal for dose modelling, highlighting LAFOV PET/CT's potential in paediatrics and the need for further protocol optimisation. ***References:*** 1) van der Kaap, et al. DOI:10.1007/s00259-024-06838-z. 2) EANM Dosage Card 2016. 3) de Groot, et al. DOI:10.1186/2191-219X-3-63

EPS-083

The effect of Dead Time Correction on the accuracy of brain PET imaging quantification

A. Issa[1], *J. Scheins*[1], *L. Tellmann*[1], *C. Brambilla*[1], *P. Lohmann*[1], *H. Herzog*[1], *N. Shah*[1,2,3], *C. Lerche*[1];
[1]*Institute of Neuroscience and Medicine 4, INM-4, Forschungszentrum Jülich GmbH, Jülich, GERMANY,*
[2]*Institute of Neuroscience and Medicine 11, INM-11, JARA, Forschungszentrum Jülich, Germany, Jülich, GERMANY,*
[3]*Department of Neurology, RWTH Aachen University, Aachen, Germany, Aachen, GERMANY.*

Aim/Introduction: One of the most important corrections to allow accurate image quantification is the dead time correction (DTC). In our institute, we run a dedicated Siemens 3T MR BrainPET insert which utilizes a global DTC. This method is based on an average DTC factor estimated for all detector blocks. However, it fails to account for count rate variations of the individual blocks, which can depend on their positions. Additionally, MR compatibility limits the placement of radiation shields, making it difficult to reduce these variations. To address this, we have implemented a block-pairwise method for DTC at the level of individual scintillation block detector pairs. ***Materials and Methods:*** The new DTC method utilizes delayed random coincidence count rates to estimate the dead time function (D*f*) for individual block pairs. This method was evaluated through decay experiments using phantom measurements with both homogeneous and inhomogeneous activity distributions. We compared the two DTC methods and evaluated the differences in the quantification of images using three tracers. We analyzed the impact on the time-activity curves (TACs) of [^{11}C]ABP688, as well as derived quantities such as the non-displaceable binding potential (BP_{ND}) and the total distribution volume (V_T). Additionally, we assessed [^{18}F]-FET TACs, including the tumor-to-background ratios (TBR_{max} and TBR_{mean}). Finally, applying kinetic modeling, we evaluated the effects on [^{15}O]H_2O TACs, obtained the regional cerebral blood flow (rCBF), the rate constant k_2, and the V_T. ***Results:*** The validation of the phantom measurements indicated that the global DTC introduced significant biases, particularly in areas with high activity concentrations. In contrast, the block-pairwise method resulted in less bias in these regions, even though the noise levels were comparable for both methods. The evaluation of patient and volunteer measurements revealed a notable difference between the two DTC methods. For the [^{11}C]ABP688 measurements, the global method exhibited a significant bias in V_T across all relevant brain regions. For [^{18}F]-FET, we found a difference of up to 10% in the TBR_{max} between the two methods. The evaluation of [^{15}O]H_2O measurements revealed that the global method showed a significant bias in rCBF, k_2, and V_T in both gray matter and white matter regions. ***Conclusion:*** The developed block-pairwise method corrected DT losses more accurately when applied to acquisitions with the 3T MR-BrainPET insert, consistently increasing the quantitation accuracy for different tracers and quantities.

EPS-084

Optimization of the imaging protocols for a SAFOV digital PET/CT

C. Steenhout, *C. Bernard, D. Palmeri, L. Seidel, C. Lachapelle, S. Marchiori, A. Jadoul, C. Derwael, P. Lovinfosse, N. Withofs, R. Hustinx;*
CHU Liège, Liège, BELGIUM.

Aim/Introduction: Digital Positron Emission Tomography/Computed Tomography (PET/CT) has improved image quality and lesion detection compared to analog PET. This study aims at optimizing the counting statistics, i.e. scanning time/injected activity in clinical protocols with the digital PET/CT Siemens Biograph Vision 600 system. ***Materials and Methods:*** One-hundred-and-fifty patients who underwent [^{18}F]FDG (n=100, 2.5 MBq/kg), [^{68}Ga]Ga-PSMA-11 (n=30, 1 MBq/kg) and [^{68}Ga]Ga-DOTANOC (n=20, 1 MBq/kg) PET/CT scans were retrospectively evaluated. According to our clinical protocol, a typical 170-cm subject underwent a whole-body (WB) study in 400 seconds and a total-body (TB) study in 596 seconds. The list-mode PET data were reconstructed using the clinical reconstruction protocol (hereafter referred to as "100%"), and using 80, 60, 40 and 20% of the acquired counts. Each dataset was evaluated by at least 2 nuclear medicine physicians regarding the image quality, using a 5-point Likert-scale. Three categories were considered for statistical purposes: Likert 1-2 as "clinically insufficient", Likert 3 as "fair" and Likert 4-5 as "clinically good". Lesion detection capability was assessed by reporting visible lesions (from "no" to "more than 10" lesions). Agreement between the observers was assessed by Cohen's Kappa coefficient (κ) and by Intraclass Correlation Coefficient (ICC). Youden indexes were calculated establishing the maximal weight keeping a good image quality while reducing the acquired counts. In addition, reconstructed images were quantitatively assessed for comparison of standardized uptake values (SUVs) and noise. ***Results:*** There is a significant agreement between observers regarding both the overall image quality (considering Likert 1-2-3 versus 4-5: $0.36 \leq \kappa \leq 0.82$) and the number of detected lesions ($0.82 \leq ICC \leq 0.99$).The 60% counts datasets were considered as "clinically good" in 62% of the [^{18}F]FDG, 53.3% of the [^{68}Ga]Ga-PSMA-11 and 80% of the [^{68}Ga]Ga-DOTANOC scans, respectively. Regarding "clinically good" image quality, Youden indexes are 76kg, 78kg and 70kg for [^{18}F]FDG and [^{68}Ga]Ga-PSMA-11 and [^{68}Ga]Ga-DOTANOC, respectively. Below these thresholds, the proportion increases to 72.4%; 78.6% and 100%, respectively. For each radiotracer, no significant difference ($p > 0.05$) was found between lesion SUVs comparing 100% and other reconstructions, but an increase in noise was observed. ***Conclusion:*** Compared to the default protocol (i.e. 2,5 MBq/kg [^{18}F]FDG and 400 seconds for a 170-cm individual), the scanning time and/or injected activity could be reduced by 40% for patients weighting less that 76 kg and 20% for those weighting more, without significant loss of quality. Results are comparable with [^{68}Ga] labeled compounds.

EPS-085

Evaluation of deep learning-based reconstruction models on non-TOF BGO PET/CT: Impact of acquisition times and BSREM penalization factors

S. Kvernby[1,2], *A. Stenvall*[1], *E. Trägårdh*[2,3], *D. Minarik*[1,2];
[1]*Radiation Physics, Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Sweden, Lund, SWEDEN,* [2]*Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN,*
[3]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Malmö, SWEDEN.*

Aim/Introduction: A new generation PET scanners based on BGO detectors, without time of flight (TOF) capability, are now available. They incorporate deep learning-based (DLb) models to compensate for the lack of TOF. These DLb-TOF models have not been evaluated with block-sequential regularized expectation maximization (BSREM) reconstruction methods for different acquisition times. This study aims to evaluate the impact of different acquisition times combined with different BSREM penalization factors (β) on image quality and lesion detectability for FDG whole-body images using DLb-TOF models. ***Materials and Methods:*** Fourteen patients referred for a clinical FDG PET scan were included. Each patient was injected with 3.5 MBq/kg of [^{18}F]-FDG and underwent a whole-body PET acquisition (120 s/bed) on a digital BGO PET/CT (32 cm FOV) 60 minutes post-injection. Data were reconstructed into images (384x384 matrix) representing different acquisition times (120s, 90s, 60s, 45s, 30s and 15s) using BSREM with various penalization factors (β50, β100, β300, β500, β700, β900 and β1100) and with three DLb-TOF

models (Low, Medium and High). Volumes of interest were placed in the liver and in two avid lesions for each patient. SNR were calculated as $SUVmean_{liver}/SD_{liver}$ and detectability were calculated as $SUVpeak_{tumor}/SUVpeak_{liver}$. ***Results:*** SNR increased with longer acquisition times and higher β-factors (range: 0.7 (β50/15s) - 24.3 (β1100/120s)). Applying DLb-TOF models increased SNR for all acquisition times and β-factors, with the Low DLb-TOF model producing the largest increase (66%). Lesion detectability depended on the acquisition time and β-value. For the longest acquisition times (120s and 90s), the highest detectability were observed at β100, while shorter acquisition times (60s-15s), required a higher β-value (β300) for optimal detectability. For the DLb-TOF models, the High DLb-TOF model provided the highest detectability, but varying with acquisition time and β-value. The Low DLb-TOF model achieved the highest detectability at lower β-values compared to the High DLb-TOF model. ***Conclusion:*** SNR increased with higher β-values, longer acquisition times, and the application of DLb-TOF models. Lesion detectability depended on the β-value, acquisition time, and the DLb-TOF model used. The Low DLb-TOF model had the best SNR but at the expense of detectability. The optimal parameters for the evaluated BGO PET/CT system, balancing SNR and lesion detectability within a clinical reasonable acquisition time, were 60-90 s with β-values of 500-300, in combination with the Medium DLb-TOF model.

EPS-086

Performance Evaluation of Advanced PET Reconstruction Algorithms Using Phantom and Patient Datasets

P. Goorhoo*, M. Qebetu, K. Banda, K. Legodi, C. Davis, L. Smith, S. Sibiya, A. Mdlophane, S. Mdanda, K. Mokoala, M. Sathekge, K. Ramonaheng;*
Nuclear Medicine Research Infrastructure (NuMeRI), Pretoria, SOUTH AFRICA.

Aim/Introduction: Quantitative accuracy and spatial resolution in PET imaging are limited by partial volume effects (PVEs). Advances in digital PET/CT systems, such as LYSO crystals, SiPMs, and deep learning-based reconstruction algorithms, have improved image quality and reduced PVEs. This study assesses the quantitative and qualitative performance of the 3D-Ordered Subset Expectation-Maximization (OSEM), Hyper Iterative, and Hyper DPR (Deep Progressive Reconstruction) algorithms by evaluating recovery coefficients (RCs), overall system performance using the Jaszczak phantom, and SUVmean analysis from three patient datasets. ***Materials and Methods:*** PET/CT imaging was performed using the uMI 550 digital system (United Imaging Healthcare). The NEMA IEC Body Phantom and Jaszczak phantom, both filled with Fluorine-18, were used to simulate clinical imaging scenarios. Clinical data from three patients were also acquired using standard acquisition parameters. PET data was acquired in list mode with a single 15-minute bed position. Reconstruction was performed using 3D-OSEM (2-10 iterations, 20 subsets), Hyper Iterative (strengths 0.2-1.0), and Hyper DPR (strengths 1-5), across acquisition durations ranging from 10 to 90 seconds. Image analysis was carried out using AMIDE and ImageJ to evaluate RCs, image contrast, spatial resolution, uniformity, and SUVmean from the clinical datasets. Optimized reconstruction settings were identified based on the phantom analysis and subsequently applied to the patient data; semi-quantitative analysis for the patient data was performed. ***Results:*** Hyper DPR showed RCs, with values increasing from 0.613 ± 0.041 (10 mm) to 0.824± 0.005 (37 mm) at strength 5 with 90 seconds. Optimal hot (0.849 ± 0.003) and cold contrast (0.723 ± 0.003) were observed. Spatial resolution allowed visualization of all rods ≥6.4 mm. Hyper Iterative achieved stable RCs across strengths and durations, peaking at 0.820 ± 0.002 (37 mm), with consistent contrast and uniformity values (1.277% differential; 1.825% integral). 3D-OSEM exhibited minimal variation across iterations, reaching an RC of 0.830 ± 0.002 (37 mm). OSEM with PSF-on and TOF-off yielded the highest hot/cold contrast and spatial resolution, with 27 of 32 rods (6.4 mm) resolved. Clinical Data: Analysis of three patient datasets confirmed consistent SUVmean values for OSEM and Hyper Iterative reconstructions. Hyper DPR yielded the highest SUVmean at strength 5. ***Conclusion:*** Overall, the selection of reconstruction algorithm and optimization of parameters play a critical role in enhancing PET image quality and semi-quantitative analysis, with Hyper DPR demonstrating the potential for minimizing PVEs and improving quantification accuracy in digital PET/CT imaging.

EPS-087

Clinical Protocol Simulations and Phantom Validations for a dual-collimator 3D CZT Camera

R. Zananiri*, Y. Odes, O. Ziv, A. Shtangel, N. Didi, B. Yuzefovich, J. Sachs, A. Efrati, H. Kosovezer, G. Rabin, A. Devir-Wolfman, J. Bouhnik;*
GE HeathCare, Haifa, ISRAEL.

Aim/Introduction: With the emergence of 3D-CZT SPECT cameras over the last years, many clinical protocols have been developed, showing their potential in clinical practice. In this report, we introduce a GE Healthcare StarGuide™-based system design equipped with smaller pixels and two collimators, noted the dual-collimator StarGuide (DCS). The high sensitivity (HS) collimator is designed to enable swift acquisition durations with increased sensitivity (~1.9x) without compromising the physical resolution of StarGuide™. Beyond the physical detector design, DCS is equipped with deep learning (DL) reconstructions for image enhancement and/or scan time reduction. Here, we report the simulation and phantom validations for whole body bone (WBB), cardiac, DaTScan, and Lu177 protocols in comparison to StarGuide™ and dual-head NaI-based camera. ***Materials and Methods:*** WBB: Simset-XCat male95 and female50 with 8:1 features to background (F:B) ratio were scanned and DL-reconstructed, in StarGuide™ and DCS-HS. DCS-HS WBB scans were optimized for (1.5′, 3′ and 1.5′ for head, torso and legs, respectively) as opposed to 4′, 8′ and 4′ for the same body parts in StarGuide™. Additionally, a 5.4mCi, 8:1 IEC NEMA body phantom was acquired for physical validation. Phantoms were assessed for image quality (IQ) using Contrast, CNR and Background Variability, following NEMA. Cardiac: Simset-XCat gated cardiac phantom was scanned and DL-reconstructed, in StarGuide™ and DCS-HS. Additionally, a static anthropomorphic torso phantom was acquired on DCS and StarGuide. Data was assessed visually and quantitatively for Image quality using Xeleris-Myovation app. DaTScan: Simset-XCat Striatal patient was scanned and reconstructed in StarGuide™ and DCS-HS. Additionally, a striatal phantom was filled with a left 8:1 and right 10:1 F:B ratio and scanned on DCS-HS, StarGuide and 870DR-LEHRS for comparison. Xeleris DaT-Quant app was used to assess the result quantitatively. Lu177: 54 mCi IEC Phantom acquisitions with F:B 8:1 was scanned on StarGuide™, DCS-HS, DCS-LP. Data was assessed for IQ using Contrast, CNR and Background Variability, following NEMA NU-1-2023. ***Results:*** WBB: Comparable IQ at 15′ WBB scan versus StarGuide in 40′. Cardiac: Improved gated IQ for 4′/6′stress/rest versus StarGuide at same acquisition durations DatScan: Comparable IQ at 7.5′ versus StarGuide 15′. Lu177***:*** Comparable IQ for DCS-HS at 9′ eye-to-thigh on IQ (4 FOVs) scan versus 12′ for StarGuide™. ***Conclusion:*** Here, we show the potential of the double sensitivity of DCS (versus StarGuide™) enabling faster clinical scans. Patient scans are needed to verify the protocols developed and further optimizations are needed to show the potential of this system design.

EPS-088

Characterisation of Tungsten-Collimator Penetration in Cadmium Zinc Telluride-based Detectors for ^{123}I: A Monte Carlo Simulation Study

I. Ceric Andelius[1,2], *P. Kalaitzidis*[1], *J. Oddstig*[1,2], *D. Roth*[3], *M. Ljungberg*[3];
[1]*Radiation Physics, Department of Haematology, Oncology, and Radiation Physics, Skåne University Hospital, Lund, SWEDEN,* [2]*Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN,* [3]*Medical Radiation Physics Lund, Lund University, Lund, Sweden, Lund, SWEDEN.*

Aim/Introduction: Although ^{123}I primarily emits photons at 159 keV, additional emissions of higher energy photons (248-784 keV) contribute to image degradation due to scatter and collimator penetration, potentially affecting quantitative imaging. Previous research has demonstrated that tungsten collimators enhance image quality for NaI(Tl)-based SPECT cameras [1]. The integration of tungsten collimators with Cadmium Zinc Telluride (CZT) detectors may further improve image quality and quantitative accuracy, leveraging the inherent properties of CZT detectors. This simulated study compares the ^{123}I spectra for a dual-headed CZT-SPECT system equipped with either tungsten or lead collimators. ***Materials and Methods:*** The energy spectrum for the ^{123}I NEMA body phantom was simulated for a full-sized system with a parallel hole collimator using the SIMIND Monte Carlo code, which includes a model for CZT charge induction [2]. Spectra and planar images were generated for a point source in air and inside an 11 cm water phantom, and line-spread functions (LSFs) were calculated. Additionally, SPECT images of a NEMA phantom with spheres of various activity concentrations and radii were simulated for both hot and cold cases. The phantom was placed 15 cm from the detector. In both studies, the fractions of detections originating from geometrically collimated (gc), septal penetrated (pc), and collimator scattered (sc) photons within the main energy window (143-167 keV) were calculated. ***Results:*** The point source simulations indicate that tungsten collimators exhibit lower penetration compared to lead collimators. Specifically, the percentage gc/pc/sc fractions of tungsten [69.1/15.4/15.5] were more favourable when compared to lead [58.3/26.2/15.5]. Therefore, the tails of the LSFs are significantly reduced, resulting in enhanced spatial resolution and improved contrast in reconstructed images. The sensitivities for the point source simulation were 28.83 and 34.4 cps/MBq for tungsten and lead, respectively. No significant difference in phantom scatter-to-total fractions between tungsten and lead was observed. ***Conclusion:*** The use of tungsten collimators will reduce collimator penetration significantly and result in improved spatial resolution and contrast in reconstructed images. ***References:*** 1. EPS-089

The effect of SPECT pulmonary ventilation/perfusion scintigraphy on the efficacy of pulmonary endarterectomy in treating chronic thromboembolic pulmonary hypertension

P. Han, *R. Ma, W. Xie, H. Li, Q. Huang, Z. Zhai, L. Fu;*
China Japan Friendship Hospital, Beijing, CHINA.

Aim/Introduction: Surgery is the definitive treatment for chronic thromboembolic pulmonary hypertension (CTEPH). Pulmonary endarterectomy (PEA) can effectively restore pulmonary blood perfusion, reduce pulmonary arterial pressure, and yield excellent outcomes. Evaluating PEA's effectiveness is crucial for enhancing patient management, boosting treatment success rates, and improving prognosis. This study explored the utility of quantitative analysis of pulmonary Ventilation/Perfusion (V/Q) scintigraphy in assessing PEA efficacy in CTEPH patients. ***Materials and Methods:*** This retrospective study included patients with CTEPH who underwent PEA at our hospital between April 2018 and December 2024. Enrolled patients underwent SPECT pulmonary V/Q scintigraphy within 2 weeks preoperatively and follow-up right heart catheterization (RHC) and V/Q scans 3-6 months postoperatively. We analyzed pre- and postoperative clinical data and parameters from RHC and SPECT V/Q scans. ***Results:*** Sixty patients were enrolled, including 43 (71.7%) male, with an average age of 49 ± 14 years. Post-PEA, significant improvements were observed in SPECT V/Q scan parameters, including total segmental perfusion defects (TSPDs), Begic's score, volume percentage of mismatched defects (VPMD) calculated by software, NYHA classification, six-minute walk distance (6MWD), NT-proBNP levels, and RHC-associated parameters [systolic pulmonary arterial pressure (sPAP), mean pulmonary arterial pressure (mPAP) and pulmonary vascular resistance(PVR)] (Table 1, P all < 0.001). The parameters of V/Q scans and clinical information presented a positive correlation with mPAP, sPAP, and PVR, with correlation coefficients (r) ranging from 0.44 to 0.51 and P all < 0.05. In 23 patients who underwent V/Q imaging 1-2 years postoperatively, TSPDs, Begic's score, and VPMD showed no significant changes compared to earlier postoperative assessments (P value: 0.33, 0.19, 0.14, respectively). ***Conclusion:*** PEA surgery leads to significant improvements in pulmonary perfusion, which presented positive correlations with hemodynamic parameters. Pulmonary blood flow perfusion tends to stabilize around six months post-surgery. Our findings underscore the value of quantitative V/Q scintigraphy analysis in evaluating postoperative outcomes in CTEPH patients.

EPS-090

Comparison of Three Diagnostic Strategies for Suspicion of Pulmonary Embolism: Planar Ventilation-Perfusion Scan (V/Q), Computed Tomography Pulmonary Angiography (CTPA), and Single Photon Emission Computed Tomography Ventilation-Perfusion Scan (SPECT V/Q): a multicenter, non-inferiority randomized controlled trial

R. Le Pennec[1], *P. Le Roux*[1], *P. Robin*[1], *F. Couturaud*[1], *M. Righini*[2], *A. Trinh-Duc*[3], *P. Roy*[4], *E. Leung*[5], *A. Helias*[6], *L. Bertoletti*[7], *C. Revel*[8], *O. Sanchez*[9], *J. Schmidt*[10], *C. Moreau-Triby*[11], *D. Goetghebeur*[1], *H. Robert-Ebadi*[12], *M. Blondon*[12], *D. Momboisse*[3], *P. Guillo*[1], *G. Le Gal*[5], *P. Salaün*[1];
[1]*Brest University Hospital, Brest, FRANCE,* [2]*HUG, Génève, SWITZERLAND,* [3]*Agen Hospital, Agen, FRANCE,* [4]*Angers University Hospital, Angers, FRANCE,* [5]*Ottawa Hospital, Ottawa, ON, CANADA,* [6]*Toulon Hospital, Toulon, FRANCE,* [7]*Saint Etienne University Hospital, Saint Etienne, FRANCE,* [8]*Saint Denis La Reunion Hospital, Saint Denis La Reunion, FRANCE,* [9]*APHP, Paris, FRANCE,* [10]*Clermont Ferrand University Hospital, Clermont Ferrand, FRANCE,* [11]*Lyon University Hospital, Lyon, FRANCE,* [12]*HUG, Genève, SWITZERLAND.*

Aim/Introduction: Nuclear medicine physician community has widely adopted single-photon emission computed tomography (SPECT) V/Q instead of planar ventilation/perfusion (V/Q) scan for pulmonary embolism (PE) diagnosis. However, to date, no management outcome study or randomized trial has evaluated an algorithm based on SPECT V/Q for PE diagnosis. Due to this lack of supporting evidence, ESC/ERS recommendations state: "SPECT may be considered for PE diagnosis with class of recommendation IIb (efficacy is less well established by evidence)". To fill this knowledge gap, and address the discrepancy between clinical and nuclear medicine physician' point of view, we conducted a randomized controlled trial comparing SPECT V/Q, CTPA, and

planar V/Q scan-based strategies in patients with suspected PE. NCT 02983760 ***Materials and Methods:*** In a multicenter, non-inferiority trial, we randomized patients with clinical suspected PE and either non-high pre-test probability but positive d-dimer, or high pre-test probability , into three arms using a diagnostic algorithm based on either SPECT V/Q, CTPA, or planar V/Q scan, with an unbalanced allocation (2:1:1). The primary outcome was the 3-month risk of venous thromboembolism (VTE) in patients left untreated after a negative diagnostic work-up, comparing SPECT V/Q patients to the combined group of CTPA and planar V/Q patients with a non-inferiority margin of 1%. Secondary outcomes included PE diagnosis rates. The trial was prematurely discontinued in October 2024 due to slow patient recruitment and funding expiry. ***Results:*** Between July 2017 and October 2024, we randomized 603 patients with either a positive d-dimer or high pre-test probability. PE was diagnosed in 61/303 (20.3%), 31/150 (20.7%) and 24/150 (16.1%) in the SPECT V/Q, CTPA and planar V/Q scan arms, respectively. The 3-month VTE risk among negative, untreated patients was 1/221 (0.5% ; 95%CI 0.0% to 2.5%), 0/107 (0.0% ; 95%CI 0.0% to 3.4%) and 1/118 (0.8% ; 95%CI 0.0% to 4.6%), respectively. The difference in the 3-month outcome rate between the SPECT V/Q and the combined CTPA and planar V/Q arm was 0% (95%CI -1.2% to 1.3%), p for non-inferiority 0.75. ***Conclusion:*** Although we could not demonstrate the non-inferiority of SPECT V/Q as compared with CTPA and planar V/Q based strategies, the 3-month risk of VTE in patients left untreated after a negative SPECT V/Q was in range with accepted standards, supporting the safety of ruling out PE based on a negative SPECT-based algorithm. PE diagnosis rate was in line with that observed when using previously validated imaging modalities.

Optimizing Quantitative ^{177}Lu SPECT-CT: Effects of OSEM Parameters and Deadtime

R. Albergueiro[1,2], *A. Carvalho*[1], *J. Santos*[2];
[1]*Unidade Local de Saúde do São João, Porto, PORTUGAL,* [2]*IPO Porto Research Center, Porto, PORTUGAL.*

Aim/Introduction: Quantitative SPECT-CT imaging plays a crucial role in dosimetry after ^{177}Lu radiopharmaceutical therapy. This study aims to optimize quantification by: (1) evaluating the influence of OSEM reconstruction parameters; (2) assessing gamma camera performance via deadtime (DT) analysis in post-therapy acquisitions to define optimal imaging timing; and (3) investigating the stability of the calibration factor (CF) using consistent acquisition and reconstruction conditions. ***Materials and Methods:*** A NEMA IEC phantom containing six spherical inserts was filled with 7.9GBq of ^{177}Lu, using a sphere-to-background ratio of approximately 10:1. Ten SPECT-CT time point acquisitions were performed on a Symbia Intevo 6 system at decreasing activity levels, using a 208keV±10% energy window. Images were reconstructed using OSEM with Hybrid Recon™, varying the number of iterations from 8 to 32 while fixing the number of subsets at 4. Quantitative and qualitative metrics were assessed, including contrast recovery coefficients (CRCs), coefficients of variation (CV), contrast-to-noise ratio (CNR), CF, and activity recovery coefficients (ARCs). Following reconstruction parameter optimization, the system's count rate performance was analyzed by plotting measured count rate versus true activity and fitting the data to a paralyzable detector model to estimate DT. CF was evaluated across all time points to confirm consistency over a broad activity range. ***Results:*** The optimal balance between contrast, noise, and activity quantification was achieved with OSEM reconstruction using 24 iterations and 4 subsets. This configuration yielded the highest CRCs and ARCs across all spheres, while maintaining a CV around 5%. All spheres were detectable according to the Rose criterion, indicating adequate CNR. The CF remained stable at (18.3 ± 0.3)cps/MBq, regardless of the iteration number. Count rate analysis showed a linear relationship with activity, with a slope of (17.97 ± 0.02)cps/MBq and an R^2 of 0.9988. Fitting to a paralyzable model was not applicable due to the absence of detector saturation, indicating that SPECT/CT acquisitions can be performed on the day of therapy without significant DT effects. CF values were consistent across all time points, averaging (18.0 ± 0.5)cps/MBq and ranging from 17.3 to 18.7cps/MBq, further supporting the minimal impact of DT. ***Conclusion:*** OSEM reconstruction with 24 iterations and 4 subsets provided optimal image quality and quantification. The linear detector response and consistent calibration factors confirm negligible DT effects, even at activities up to 8 GBq, due to the low γ yield and minimal bremsstrahlung of ^{177}Lu. These findings support reliable quantitative SPECT-CT for post-therapy dosimetry, protocol standardization, and inter-patient dose comparison.

Acquisition and Reconstruction Parameters for ^{32}P Imaging in a CZT Gamma Camera

P. Guardiola-Zaragoza[1], *D. Sánchez-Artuñedo*[1], *I. Navales-Mateu*[2], *M. López-Arribas*[2], *D. Borrás-Sánchez*[2], *C. Gamez-Cenzano*[2], *M. Beltran-Vilagrasa*[1];
[1]*Servei de Física i Protecció Radiològica. Hospital Universitari Vall d'Hebron, Barcelona, SPAIN,* [2]*Servei de Medicina Nuclear. Hospital Universitari Vall d'Hebron, Barcelona, SPAIN.*

Aim/Introduction: Phosphorus-32 (^{32}P), a pure beta emitter, is implanted intratumoral for the treatment of locally advanced pancreatic cancer. After treatment, a bremsstrahlung SPECT/CT image is acquired to verify the correct administration. Post-treatment imaging is challenging due to the low administered activities and the bremsstrahlung spectra. New CZT gamma cameras as StarGuide (GE Healthcare) have higher sensitivity, therefore could enhance ^{32}P SPECT imaging. This works aims to assess the minimum ^{32}P activity visually detectable in a StarGuide, and the acquisition and reconstruction parameters that improve image quality. ***Materials and Methods:*** Syringes with different punctual activities of ^{32}P: 0.4, 0.8, 2.9, 4.5, 10.3 and 14.7 MBq were prepared. Each syringe was placed in a water-filled Jaszczack phantom. SPECT/CT images were acquired with acquisition parameters: •Time: 30 min. •Emission Window: 75 keV (±25%). Reconstruction parameters were: •Algorithm: Q.Clear (20 iterations, 10 subsets). •Regularisation method: RDP, γ=1, β=0.2. • Attenuation correction and resolution recovery correction. The camera sensitivity was calculated for each image. To assess the visual detectability of the syringes, reconstructions were created varying the acquisition time: 10 and 20 min. We determined the minimum activity visually detectable and its corresponding contrast-to-noise ratio (CNR) threshold value. We fitted a power curve of the CNR versus the product activity×time. Setting the CNR value to $CNR_{threshold}$, we established the formula relating the minimum acquisition time (t_{min}) and the administered activity. To assess the impact of the reconstruction parameters in the image quality, additional reconstructions were created varying iterations and subsets, regularisation method (MRP), and the γ and β values. For each SPECT we calculated the contrast, the CNR and the tomographic spatial resolution with the FWHM, the MTF50% and the MTF10%. ***Results:*** The mean camera sensitivity value was 15.7 cps/MBq. The minimum activity visually detectable was 0.8 MBq with a $CNR_{threshold}$ of 13.2. The fitted relation was $CNR = 0.8\times(activity\times time)^{0.5}-10.6$ (R^2=0.96). The t_{min} value regarding the administered activity can be calculated from: $activity \times t_{min} = 922.2$ MBq s. Using the MRP regularisation method, the mean FWHM in all directions was reduced by 0.9 mm, and the MTF50% and MTF10% increased by 0.002 mm^{-1}. Default reconstruction parameters optimized the CNR values. ***Conclusion:*** The minimum ^{32}P activity detectable in a StarGuide with a 30 min acquisition time is 0.8 MBq. Based on the administered activity, acquisition time can be tailored with the obtained formula. The MRP regularisation method improves tomographic spatial resolution.

EPS-093

Phantom-based characterisation of an ultra-fast and ultra-low-dose tomographic molecular breast imaging system

A. Cherlin[1], *K. Erlandsson*[2], *N. Atkins*[1], *M. Exley*[1], *I. Baistow*[1], *K. Thielemans*[2], *B. Hutton*[2];
[1]*Kromek Ltd, Sedgefield, UNITED KINGDOM,* [2]*Institute of Nuclear Medicine, University College London, London, UNITED KINGDOM.*

Aim/Introduction: Molecular Breast Imaging (MBI) demonstrates high sensitivity for the detection of breast cancer, particularly in dense breast tissue. Despite its diagnostic advantages, the clinical adoption of MBI has been limited by ~40 minutes acquisition time and higher radiation dose (~2.4 mSv) compared to mammography (~0.5 mSv). In alignment with the 2018 ACR recommendations, implementation of MBI for screening requires a reduction in radiation dose to ≤1 mSv. Also, a substantial decrease in scan time is required to improve patient throughput. In response to these requirements, a novel MBI prototype has been developed and evaluated. ***Materials and Methods:*** The prototype is comprised of two heads, each having a 4x6 array of 3D position-sensitive 5 mm thick CZT detectors covering the FOV of 132 mm x 88 mm, and a densely packed multi-pinhole 3D-printed tungsten collimator with 294 pinholes. The detectors have an 11x11 array of 2 mm pixels. The acquired images include significant multiplexing due to overlap of pinhole data, resulting in adverse artefacts which are mitigated by de-multiplexing algorithms that benefit from 3D position of interaction information. The detector data is analysed using a machine-learning model providing significant improvement in sub-pixel position resolution. The performance is characterised using Tc99m-filled phantoms comprised of 5 to 10 mm spherical lesions with uniform background. Non-Local Means noise filtering is applied to the reconstructed images. ***Results:*** Initial prototype evaluation using 2D projection images demonstrated a significant advancement in detector resolution, achieving 5×5 sub-pixelisation, or the position resolution of 450 µm and average depth resolution of ~700 µm. This improvement in the image resolution surpasses the performance of existing SPECT and MBI systems utilizing CZT detectors. The results have been validated through simulated and experimental image reconstructions, showing enhancement in image quality and improved de-multiplexing algorithm performance. Dose/time reduction factors were estimated based on published count density data for a standard administered 300 MBq clinical activity. Preliminary results show the reduction factor of 8 for ≥6 mm lesions. ***Conclusion:*** The novel detector, collimator and image reconstruction technology implemented in the prototype enhance the performance of tomographic image reconstruction and allow significant reduction of scan time while maintaining the radiation dose below 1 mSv. Current results show the potential to shorten the scan time from 40 to 10 min for ≥6 mm lesions. Further work on improving the results and comparison with an existing commercial MBI scanner is ongoing and will be reported.

Impact of Interim ^{18}F-FDG PET/CT Metabolic Parameters and Deauville Score on Outcomes of Pediatric Hodgkin Lymphoma

O. Kodaz[1], *A. Pala*[1], *G. Kaya*[2], *B. Volkan Salanci*[1], *P. Ozgen Kiratli*[1];
[1]*Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Yozgat City Hospital Department of Nuclear Medicine, Yozgat, TÜRKIYE.*

Aim/Introduction: Assessing interim 18F-FDG-PET/CT (iPET) scans in pediatric Hodgkin lymphoma (HL) patients present significant challenges. In addition to the established Deauville-Score (DS), metabolic parameters derived from PET/CT imaging, such as total lesion glycolysis (TLG), metabolic tumor volume (MTV), and quantitative PET (qPET), are also critical. This study aims to investigate the prognostic value of iPET in pediatric-HL patients by comparing visual analysis with semiquantitative analysis. ***Materials and Methods:*** iPET images of pediatric FDG-avid HL patients were evaluated retrospectively. Tumor-segmentation was defined using the threshold SUVmax of 2.5, and the MTV&TLG values were obtained. DS were also recorded for each patient. qPET was calculated by dividing the SUVpeak of residual tumors by the average liver uptake, which is measured using standardized volumes of interest. MTV&TLG values greater than 0 and DS values of 4 or higher were considered residual disease. Survival analysis and diagnostic parameters of each patient were examined. Death and disease progression were accepted as an event. Kaplan-

Meier curves and the log-rank test were used to compare survival experiences between metabolic PET parameters at cut-off values (ROC-curve and Youden Index). ***Results:*** A total of 50 pediatric-HL patients (F/M: 18/32; mean age: 12.4 year, SD: 3.92) who were diagnosed between 2014 and 2024 were included. Nodular sclerosing (54%) and mixed cellularity (20%) were the most common subtypes. On iPET scans, median MTV was 0 cm3 (range: 0-30.7), TLG was 0 (range: 0-109.81), DS was 2 (range: 1-5), and qPET was 0.465 (range: 0-3.43). On MTV&TLG analysis, 10 patients were positive for the minimal residual disease, while 17 were positive in the DS group. None of the patients was classified negative on DS but positive on MTV&TLG. Patients accepted positive with MTV&TLG and DS differed significantly from each other (p<0.001). Mean time to event was shorter in patients who were positive for both MTV&TLG and DS compared to those positive for only DS (52.4 vs 101.7; p=0.29). Cox analysis showed that the proportional hazard ratio was 5.3 for MTV&TLG positivity (lower 0.6 and upper 47.9, CI 95%; p=0.134). Positive-predictive value of MTV&TLG positivity was %70. The optimal cut-off value for qPET was found to be 1.53; qPET positivity was significantly associated with EFS (42.3 vs 106.7; p<0.001). ***Conclusion:*** MTV&TLG and DS assessments, although it didn't reach statistical significance, differ in pediatric HL patients. MTV&TLG appear superior to DS in these patients. Additionally, qPET values are predictive for EFS.

OP-255

The value of PET/MR in prognostic evaluation of nephroblastoma in children

Y. Xu*;*
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To assess the prognostic value of ^{18}F-FDG PET/MR-derived metabolic parameters and clinicopathological features in pretreatment nephroblastom. ***Materials and Methods:*** A retrospective cohort of 92 children with newly diagnosed nephroblastom undergoing ^{18}F-FDG PET/MR was analyzed. Clinicopathological variables (e.g., histology subtype, lymph node involvement, serum lactate dehydrogenase [LDH]) and metabolic indices, including maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG), were evaluated using univariate and multivariate Cox regression models to predict event-free survival (EFS) and overall survival (OS). ***Results:*** During a median follow-up of 42 months, disease progression or relapse occurred in 32 patients (34.78%). Univariate analysis revealed that, unfavorable histology (P=0.007), lymph node metastasis (P=0.004), elevated LDH (P=0.018), MTV (P=0.005), and TLG (P=0.008) were significantly associated with reduced EFS and OS. Multivariate analysis identified TLG (EFS: P=0.013; OS: P=0.017) and lymph node metastasis (EFS: P=0.025; OS: P=0.031) as independent prognostic factors for both endpoints. Additionally, MTV remained predictive of OS (P=0.029). ***Conclusion:*** Pretreatment ^{18}F-FDG PET/MR offers critical prognostic insights in pediatric nephroblastom. Higher TLG, lymph node metastasis, and increased MTV correlate with adverse outcomes, underscoring their potential for refining risk-adapted treatment strategies and improving clinical decision-making.

OP-256

Early TreatmentResponse Assessment with 68GaDOTANOC PET/CT: Superior Concordance with Clinical Outcome

N. Kundu*, D. Khan, S. Sagar, A. Mahalik, A. Roy, A. K. Pandey, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Recent advancements in histopathological assessment and functional imaging modalities have significantly enhanced the diagnostic accuracy and restaging processes in pediatric neuroblastoma. These developments have facilitated more accurate quantification of tumor burden and improved evaluation of therapeutic response, thereby supporting more individualized and effective treatment stratification strategies.Although the International Neuroblastoma Response Criteria endorse the use of metaiodobenzylguanidine (mIBG) scintigraphy or [F-18]2-fluoro-2-deoxyglucose (FDG) PET/CT for disease evaluation, the present study aims to assess and compare the efficacy of 68Ga-DOTANOC PET/CT and mIBG scintigraphy in classifying early treatment response following induction chemotherapy in patients with high-risk neuroblastoma. ***Materials and Methods:*** 19 pediatric patients with known neuroblastoma underwent baseline and posttherapy 68GaDOTANOC PET/CT and 131ImIBG planar +/-SPECT/CT imaging after initial chemotherapy. Both the pre and post chemotherapy 68Ga-DOTANOC PET MIP and 131I-mIBG planar were compared to look for response assessment. Responses were defined by reduction/disappearance of DOTANOC or mIBG avid lesions and SIOPEN score decrease ≥50 % (partial) or 100 % (complete). Imaging findings were crosschecked with clinical/marrow status at 6 months. ***Results:*** Median follow-up period was 4 months, ranging from 2 to 11 months. Of these 19 patients, 12 underwent both 68Ga-DOTANOC and 131I-mIBG at baseline and follow-up. 18 out of 19 patients received chemotherapy, while one patient received mIBG therapy. Patients received an average of 5 chemotherapy cycles, with minimum of 3 cycles, and maximum of 8 cycles. Due to technical issues and unavailability of radiotracer, 7 patients underwent only 131I-mIBG on follow-up. DOTANOC and mIBG were concordant in 10/12 paired followups. All six complete/partial responses confirmed clinically were DOTANOCpositive; mIBG missed two partial responses owing to baseline underrepresentation of marrow disease. Two discordant cases (DOTANOCPR vs mIBGSD) involved extensive baseline DOTANOC+/mIBG- marrow spread that regressed on PET but remained occult on planar scans. Among 14 patients with available marrow histology, positivity at diagnosis predicted nonresponse (P = 0.03). Male sex also associated with poorer imaging outcome (P = 0.02). ***Conclusion:*** DOTANOC PET/CT demonstrates superior sensitivity to early therapeutic change, especially in initially mIBGoccult marrow metastases, and aligns more faithfully with shortterm clinical remission. Baseline marrow infiltration and male sex emerged as adverse predictors, suggesting intensified or alternative approaches for these subsets. Thus, DOTANOCbased response criteria may merit incorporation into future responseadapted protocols.

OP-257

Comparative Analysis of Diagnostic Efficacy:[^{68}Ga] DOTATATE PET/CT Versus[^{123}I]MIBG Scintigraphy in Paediatric Neuroblastoma Detection

N. Gülaldi*, A. Karacan;*
University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: [^{123}I]MIBG scintigraphy is used routinely for staging and treatment response evaluation of pediatric neuroblastoma patients. [^{68}Ga]DOTATATE PET/CT imaging has also gained popularity in recent years. We aimed to reveal the diagnostic performance of the Somatostatin PET/CT results to find if it is logical to add this modality for the clinical evaluation of the patients. ***Materials and Methods:*** Fourteen children diagnosed with neuroblastoma between March 2019 and July 2024 were included in the study (age-10 months-7 years). [^{68}Ga]DOTATATE PET/CT study was performed within 1 month in addition to the [^{123}I]MIBG scan with SPECT/CT study for the lesion area when the treatment administration was not started or was equal. Soft tissue and bone involvement groups were noted and because of their non-homogeneous distribution pattern, they were evaluated by the Wilcoxon-signed rank test. ***Results:*** 6 of 14 patients had

only soft tissue lesions detected by both imaging modalities. In 1 patient, soft tissue lesions were visualized with [^{68}Ga]DOTATATE in a larger area. In 3 patients, bone lesions were present and although detected by both imaging modalities, more bone lesions were recorded by [^{68}Ga]DOTATATE in 2 patients. In 1 patient, both imaging modalities were negative despite the presence of anatomical lesions. In 2 patients, bone marrow metastases were detected only with [^{68}Ga]DOTATATE PET/CT. 2 patients showed soft tissue uptake on [^{123}I]MIBG only. No statistically significant superiority was found between the two imaging modalities (p>0,05). Only borderline values were obtained with a hypothesis that [^{68}Ga]DOTATATE PET/CT was superior to [^{123}I]MIBG scan (p=0,07). ***Conclusion:*** According to our study, [^{68}Ga]DOTATATE PET/CT scan can be used as a complementary imaging modality in pediatric neuroblastoma patients. We believe that because of the superior image quality of PET/CT compared to SPECT/CT images, somatostatin imaging can detect a higher number of lesions, especially in bone and bone marrow if done in larger series. [^{123}I]MIBG scan looks like better delineates soft tissue involvement. We also believe that scoring should be performed by evaluating both modalities together especially if the treatment algorithm will change according to the presence of active metastatic bone lesions or soft tissue lesions.

OP-258

The value of ^{18}F-FDG PET/MR radiomic features in predicting WT1 and CTNNB1 mutations in nephroblastoma in children

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: This study aims to evaluate the predictive capability of ^{18}F-FDG PET/MR radiomics features for identifying WT1 and CTNNB1 mutations in nephroblastoma in children, critical molecular alterations associated with tumor progression and therapeutic resistance. ***Materials and Methods:*** A retrospective analysis was performed on 115 nephroblastoma patients (median age 3.2 years, range 0.6-14.1 years). Clinical parameters, including tumor stage, histological subtype, and serum lactate dehydrogenase (LDH) levels, were incorporated into a clinical model (C_model). Radiomic features were extracted from pre-treatment PET/MR images using the PyRadiomics platform. The Least Absolute Shrinkage and Selection Operator (LASSO) regression was applied to select significant radiomic features and construct a radiomics model (R_model). Predictive performance of C_model, R_model, and a combined model (CR_model) was assessed via receiver operating characteristic (ROC) analysis. A nomogram integrating radiomics scores (rad-score) and clinical variables was developed. ***Results:*** Patients were stratified into a training cohort (n=80) and a validation cohort (n=35). LASSO identified 7 radiomic features for WT1 mutations and 6 features for CTNNB1 mutations. The R_model achieved AUCs of 0.91 (training) and 0.88 (validation) for WT1, and 0.89 (training) and 0.86 (validation) for CTNNB1. The C_model showed lower performance (AUCs: 0.74-0.78). The CR_model demonstrated superior predictive ability, with AUCs of 0.96 (WT1) and 0.94 (CTNNB1) in training, and 0.92 (WT1) and 0.90 (CTNNB1) in validation ($P < 0.05$). ***Conclusion:*** Pre-therapeutic ^{18}F-FDG PET/MR radiomics features effectively predict WT1 and CTNNB1 mutations in nephroblastoma, providing a non-invasive method to enhance molecular subtyping, risk stratification, and personalized treatment planning. This approach may reduce reliance on invasive biopsies and optimize clinical management.

OP-259

Incidental Detection of Non-Ossifying Fibroma in Pediatric Oncology: FDG PET/CT Features and Diagnostic Pitfalls

B. Arca[1], *E. G. Isik*[1], *Z. Bayramoglu*[2], *K. Aslaner*[1], *Z. G. Ozkan*[1], *S. Kuyumcu*[1];
[1]*Istanbul University, Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE,* [2]*Istanbul University, Istanbul Faculty of Medicine, Radiology Department, Istanbul, TÜRKIYE.*

Aim/Introduction: Non-ossifying fibromas (NOFs) are common benign bone lesions frequently encountered in radiological practice. Typically arising during childhood, they are often (~75%) detected incidentally in the second decade of life. NOFs are usually located in the metaphyseal-diaphyseal regions of the femur or tibia and may show increased FDG uptake on PET/CT, mimicking bone metastases. This study aims to evaluate the visual and quantitative features of incidentally detected NOFs in pediatric patients undergoing F-18 FDG PET/CT. ***Materials and Methods:*** F-18 FDG PET/CT scans performed in pediatric patients (≤18 years old) at our clinic between 2015 and 2024 were retrospectively analyzed. Patients were categorized based on clinical indications. Lesion localization and size were recorded. Mean and maximum standardized uptake values (SUVmax and SUVmean) were calculated and compared with the mediastinal blood pool, the liver (right lobe), and, if present, the primary tumor. ***Results:*** Among 1,500 pediatric FDG PET/CT scans, 40 lesions from 32 patients (mean age: 15 years (6-18); 62% male) were retrospectively evaluated. Clinical details are summarized in Table 1. Regarding the localization of the NOF lesions: 24 were located in the distal femur, 2 in the femoral head region, 11 in the proximal tibia, 1 in the distal tibia, and single cases in the humerus and iliac bone. The mean craniocaudal length of the lesions was 14.2 mm (8-70 mm). The average SUVmax and SUVmean were 2.9 (0.5-19.9) and 1.1 (0.2-4.0) respectively. Reference average SUVmax values were 2.1 (0.6-3.4) for the liver and 1.5 (0.4-3.4) for the mediastinal blood pool. Among 24 patients with malignancy, 6 had undergone surgery. In the remaining 18, the average SUVmax of the primary malignant lesions was 11,9 (3,3-24,5). SUVmax exceeded liver and mediastinal reference values in 48% (n:19) and 60% (n:24) of NOF lesions, respectively. In two patients, the NOF lesions demonstrated higher SUVmax values than the primary tumor (4.7 vs. 3.3 and 19.9 vs. 6.7). In this subgroup, the average NOF SUVmax was calculated as 4.4. ***Conclusion:*** Non-ossifying fibromas (NOFs) are common benign bone lesions typically asymptomatic in nature. However, their variable metabolic activity on FDG PET/CT can lead to misinterpretation as a malignant lesion, potentially impacting disease staging and clinical management. Therefore, the morphological clues from the CT component of PET/CT and, lesion localization are essential for accurate diagnosis and to avoid diagnostic pitfalls due to FDG uptake.

OP-260

Gallium-68 labelled satoreotide trizoxetan in pediatric patient with neuroblastoma: biodistribution and radiation dosimetry results

L. Teles[1], *R. van Rooij*[1,2], *M. van Noesel*[1,3], *A. Poot*[1,2], *N. Tolboom*[1,2], *A. Braat*[1,2,4];
[1]*Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS,* [2]*University Medical Center Utrecht / Wilhelmina Children's Hospital, Utrecht, NETHERLANDS,* [3]*Division Imaging and Cancer, University Medical Center Utrecht, Utrecht, NETHERLANDS,* [4]*Netherlands Cancer Institute, Utrecht, NETHERLANDS.*

Aim/Introduction: The current clinical standard for neuroblastoma (NBL) imaging is based on metaiodobenzylguanidine (mIBG), which has multiple known limitations. These limitations can be overcome by somatostatin receptor (SSTR) targeted positron

emission tomography (PET/CT) imaging. Experience with SSTR2 agonists already exists, but a subsequent improvement will be SSTR2 antagonist imaging with [^{68}Ga]Ga-satoreotide trizoxetan ([^{68}Ga]Ga-SSO120 or [^{68}Ga]Ga-SATO).[1,2] This antagonist targets both active and inactive receptors, instead of active ones alone, potentially improving lesion detection. Here we present the biodistribution and radiation exposure results of [^{68}Ga]Ga-SATO PET/CT imaging in paediatric patients with NBL. ***Materials and Methods:*** After administering 2 MBq/kg of [^{68}Ga]Ga-SATO, a 60-min dynamic and a static PET/CT (2h post-injection) were acquired. Standardized uptake values (SUV_{max}, SUV_{mean}, SUV_{peak}) were measured in suspected tumour lesions and various tissue compartments. Tumour-to-liver ratios (TLR) were calculated. Organs were automatically segmented with TotalSegmentator, followed by manual adjustment in MIM Software. Radiation dose to various organs and the total-body effective dose were computed via OLINDA/EXM software V1.0 (based on a 5-year-old phantom model). ***Results:*** Five patients underwent dynamic [^{68}Ga]Ga-SATO PET/CT scanning with, in total, 17 suspected NBL lesions. Median administered activity was 2.5 MBq/kg (range 2.1-2.8 MBq/kg). At 60 min post-injection, mean tumour SUV_{max} and SUV_{peak} were 5.41 (1.89 - 18.27) and 3.72 (1.23 - 14.93), and TLR was 2.43. The highest exposure was in the bladder (22.3 ± 4.3 µSv/MBq) due to renal excretion of [^{68}Ga]Ga-SATO, like most radiopharmaceuticals. The effective dose was 0.0875 ± 0.0135 mSv/MBq. Quantitative analysis of imaging showed clear improvement over mIBG imaging. ***Conclusion:*** These results show that [^{68}Ga]Ga-SATO PET/CT is safe and feasible in NBL patients with a low effective radiation dose in individual organs, and that it is capable of detecting NBL lesions with a good target-to-noise ratio. Future work will directly compare the lesion detection ability of [^{68}Ga]Ga-SATO PET/CT against standard mIBG imaging. ***References:*** 1. Virgolini I, Bahri S, Kjaer A, et al. Stable clinical metrics of metabolic activity in synthetic CT based pediatric PET during and following treatment from a LAFOV scanner

S. Honoré d'Este[1], *M. E. Montgomery*[1], *F. L. Andersen*[1,2], *C. Schulze*[1], *E. S. Saxtoft*[1], *C. N. Ladefoged*[1], *K. F. Andersen*[1];
[1]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Copenhagen, DENMARK,*
[2]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: In a previous study, we demonstrated the potential of an Artificial Intelligence (AI) based synthetic Computed Tomography (sCT) generated from non-attenuation correction (NAC) Positron Emission Tomography (PET) data for use in attenuation correction in a pediatric population. The model allows for elimination of the additional and conventionally utilized AC-CT, reducing overall radiation exposure while limiting motion artefacts and inconsistencies due to hyperdense CT structures. The improved image quality ensures more definitive tumor margins and ultimately leads to superior tumor delineation. This study aims to quantify clinical metrics to evaluate diagnostic performance of the AI based sCT for PET attenuation correction both during initial staging and treatment response assessment in the same pediatric cohort. ***Materials and Methods:*** 14 oncologic pediatric patients (1y-17y) with [18F]FDG avid lesions were included. Four patients had multiple scans performed during the inclusion period, leading to an included total of 20 scans from the initial test cohort[1]. Imaging was performed on 106cm Long-Axial-Field-Of-View (LAFOV) PET/CT. An ultra-low-dose CT (ULDCT) was acquired for conventional attenuation correction. A standard protocol of 1.5MBq/kg [18F]FDG administered 60min prior to 5min scanning was applied. The sCT was generated from the NAC-PET data, through a 3D parameter transferred conditional generative adversarial network (cGAN), previously described in detail[2]. Attenuation correction was performed two ways: from the sCT (sPET) and from the conventional ULDCT (cPET). Blinded lesion delineation and corresponding background liver volume-of-interests (VOI), diameter of 3cm (1cm in two cases), were drawn for comparative and quantitative analysis. ***Results:*** A total of 55 lesions (n_{lung}=3, n_{bone}=7, $n_{soft\ tissue}$=45) were identified and analyzed. We measured no significant difference in image noise depicted as mean Coefficient Of Variance (COV) ± standard deviation (SD) (COV_{sPET}=0.07 ±0.03, COV_{cPET}=0.07 ±0.02, p=0.55), in maximal Standardized Uptake Value (SUV_{max}) (p=0.06-0.83) or in SUV_{peak} (p=0.09-1.00) in either tissue subgroup. In soft tissue lesions the sPET reached higher clinical metrics than cPET when comparing Metabolic Tumor Volume with threshold of 40%SUV_{max} (MTV) and Tumor Lesion Glycolysis (TLG) with a borderline significant difference observed (P_{MTV}=0.04, P_{TLG}=0.04). We found that these results remained constant during and following scheduled treatment in the four repeat patients. ***Conclusion:*** The sPET images demonstrate image noise equal to that of cPET. Further clinical metrics of metabolic activity in lung, bone and soft tissue lesions remained stable both during initial staging and following treatment indicating useability in response assessment criteria such as Deauville and PERCIST. ***References:*** [1] doi:10.3390/diagnostics14242788 [2] doi:10.3390/diagnostics13243661

Potential for Shortening Acquisition Time or Administered Activity in Paediatric Bone Scans with a 360-Degree Digital SPECT/CT Camera

Z. Bar-Sever[1], *S. Caduri*[1], *A. P. Steinmetz*[2];
[1]*Schneider Children's Medical Center of Israel, Petach Tikva, ISRAEL,* [2]*Rabin Medical Center, Petach Tikva, ISRAEL.*

Aim/Introduction: To determine if the superior sensitivity and spatial resolution of 360-degree CZT Digital SPECT/CT cameras over conventional SPECT/CT allows shortening of acquisition time or dose reduction in pediatric bone scans ***Materials and Methods:*** 22 successive bone scans of children (ages 3-17, mean 10.2 years) were retrospectively analyzed. Injected activity was based on the EANM dosage calculator. Vendor-recommended acquisition included a blood pool (BP) SPECT covering the trunk, pelvis, and lower extremities (50 seconds per bed position), and whole-body skeletal SPECT (trunk and pelvis, 5 minutes per bed, head and feet, 3 minutes). Original study counts (100%) were truncated by 30% and 50% to simulate acquisition time or dose reduction. The 100%, and the resulting 70%, and the 50% count groups were reconstructed using similar OSEM parameters without CT-based attenuation correction or image enhancement. All reconstructions were presented in random order to an experienced reader blinded to the clinical and truncation data. Each reconstruction was evaluated for the following parameters: Overall blood pool and skeletal image quality (Likert scale 1-5). Uptake in 4 skeletal landmarks (1st metatarsal growth center, metacarpophalangeal joints, occipital protuberance, and anterior ribs) was graded 0-2 and summed. Abnormal tracer uptake was recorded. Differences between count groups were analyzed with the Mann-Whitney U test. ***Results:*** Mean Likert scores for the 100%, 70%, and 50% groups were 4.45, 4.09, and 3.81 for the whole-body skeletal SPECT, and 4.09, 3.53, and 3.27 for the BP SPECT, respectively. No significant differences were noted between the 100% and 70% skeletal SPECT groups. Differences were significant between the 100% and 50% skeletal SPECT and between the 100%, 70%, and 50% BP SPECT groups. The visibility of kidneys, ureters, and arteries was not significantly different between the groups. The mean cumulative skeletal landmark score was 6.5, 6.27, and 5.95 for the 100%, 70%, and 50% count groups, with no statistically significant differences.

Abnormal uptake was present in 7 studies and interpreted as spondylolysis, osteomyelitis (2 cases), fibrous dysplasia, condylar hyperplasia, and osteoid osteoma (2 cases). These findings were all seen on the BP and skeletal phase SPECT following 30 and 50% count truncations (except for condylar hyperplasia on the 50% truncation). ***Conclusion:*** Reducing vendor-recommended acquisition time or the EANM-recommended injected activity by 30% does not compromise the diagnostic quality of pediatric bone scans when performed with a 360-degree digital CZT SPECT/CT camera. These preliminary observations should be substantiated in larger cohorts.

Engineered Helper Lipid Extracellular Vesicles for Pulmonary siRNA Delivery: PET Imaging-Guided Therapy of Lung Metastasis
R. Guo, *X. Lan, R. An, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College,Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Pulmonary diseases, including malignancies and chronic airway diseases, pose substantial global health challenges requiring advanced therapies. While extracellular vesicles (EVs) show promises as natural delivery vectors, their clinical application is limited by hepatic tropism. To date, no rational design for selectively lung-targeted EVs has been developed. We modulated tumor-derived microvesicles (TMVs) with cationic DOTAP lipids to alter their internal charge and tissue tropism. We accurately tracked the biodistribution of TMVs-DOTAP in vivo via high-sensitivity positron emission tomography (PET) imaging, indicating their enhanced lung-targeting specificity. Furthermore, we developed an innovative siRNA delivery system, TMVs-DOTAP/siPD-L1, which specifically and effectively targets PD-L1 and enhances tumor immune responses. Mechanistic studies revealed the role of the protein corona in determining tissue tropism. ***Materials and Methods:*** To prepare TMVs-DOTAP, the DOTAP solution dissolved in anhydrous ethanol (50 mg/mL) was mixed with TMVs in a 1:10 volume ratio. PET/CT imaging was conducted to observe the distribution of ^{68}Ga-TMVs and ^{68}Ga-

TMVs-DOTAP in healthy mice, using a micro-PET/CT scanner. To assess the knockdown efficiency of PD-L1 protein, TMVs-DOTAP/siNC and TMVs-DOTAP/siPD-L1 were incubated with B16F10 cells for 48 h. Subsequently, intrapulmonary delivery and in vivo anti-tumor efficacy of TMVs-DOTAP/siPD-L1 were validated. Moreover, we systematically evaluated the compositional and quantitative alterations in the protein corona on TMVs-DOTAP/siNC. ***Results:*** The TMVs and TMVs-DOTAP were dispersed in PBS, with hydrodynamic diameters of 211.03 ± 17.94 and 241.81 ± 39.36 nm respectively. PET/CT imaging revealed that TMVs-DOTAP selectively accumulated in the lung (10.45 ± 0.32%ID/g at 0.5 h p.i.), while the signal in the liver significantly reduced to 2.15 ± 1.58%ID/g at 0.5 h p.i.. The results suggest that DOTAP modification enables tissue-specific retargeting of TMVs from the liver to the lung. Encouraged by the strong lung-targeting ability of engineered nanovesicles TMVs-DOTAP in vivo, we designed TMVs-DOTAP/siPD-L1 as a potential therapeutic strategy for lung metastasis. The TMVs-DOTAP/siNC group exhibited elevated levels of key pulmonary delivery-associated proteins, including fibrinogen, vitronectin, apolipoprotein A-I, and prothrombin, compared to the TMVs group. Our findings highlight the complex relationship between protein corona composition and organ-targeting outcomes of EVs. ***Conclusion:*** We developed a lung-targeted EVs platform, TMVs-DOTAP, and tested its feasibility using TMVs-DOTAP/siPD-L1 for the treatment of lung metastasis. This platform circumvents liver-specific delivery mechanisms, enabling effective access to lung tissue and enhancing therapeutic efficacy in the lung metastasis model. ***References:*** Selective organ targeting (SORT) nanoparticles for tissue-specific mRNA delivery and CRISPR-Cas gene editing. OP-275

Preclinical Comparison of [^{161}Tb]Tb-NM600 and [^{177}Lu]Lu-NM600 in a Murine Triple Negative Breast Cancer Model

Y. Medina Guevara, *H. Comas Rojas, O. Bio Idrissou, L. Lambert, A. Pinchuk, L. E. Wehner, A. Carston, N. Clemons, J. Weichert, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Triple-negative breast cancer (TNBC) is characterized by aggressive behavior, a high propensity for metastatic spread, and poor survival. These outcomes are largely attributable to the frequent presence of micrometastatic disease at diagnosis and the lack of effective molecularly targeted therapies. To improve the clinical efficacy of radiopharmaceutical therapy (RPT) in TNBC, we evaluated NM600, an alkylphosphocholine analog that demonstrates enhanced tumor uptake and retention. NM600 was used to deliver Terbium-161, whose Auger/Conversion electron emissions are optimally suited for treating disseminated and occult disease. ***Materials and Methods:*** We radiolabeled NM600 with ^{161}Tb and ^{177}Lu under similar reaction conditions and molar activity. The radiochemical stability of the compounds was assessed in saline and human serum using iTLC. For in vitro cytotoxicity studies, 4T1 cells (metastatic murine TNBC) were incubated with increasing activities of free ^{177}Lu or ^{161}Tb (0-2 MBq/mL), or with their respective NM600-labeled forms, and cell viability was measured. In vivo, therapy studies were conducted in 8-week-old female Balb/c mice (***n*** = 5 per group) bearing 4T1 tumors. Mice were intravenously injected with [^{161}Tb]Tb-NM600 (250 or 500 µCi), [^{177}Lu]Lu-NM600 (250 µCi), or vehicle. Tumor growth, animal survival, and overall well-being were monitored thrice weekly. Treated mice also underwent serial SPECT/CT scans from 2 to 168 hours post-injection (p.i.) to evaluate radioligand biodistribution and estimate radiation dosimetry. Toxicological studies conducted in 8-week-old female Balb/c mice are currently underway to assess the safety profile of [^{161}Tb]Tb-NM600. ***Results:*** [^{161}Tb]Tb-NM600 achieved >95% radiolabeling yield and radiochemical purity, remaining stable in human serum for up to 168 hours (~98 %). Treatment with free ^{161}Tb and ^{177}Lu showed non-statistically differences, but [^{161}Tb]Tb-NM600 resulted in statistically significant increased cytotoxicity at 2 MBq/mL (p=0.03), compared to [^{177}Lu]Lu-NM600, highlighting the dosimetric advantage of ^{161}Tb's low-energy Auger electrons. SPECT/CT imaging revealed higher tumor uptake of [^{161}Tb]Tb-NM600 compared to [^{177}Lu]Lu-NM600, with mean committed tumor doses of 50 Gy and 30 Gy, respectively. In therapeutic studies, mice treated with [^{161}Tb]Tb-NM600 exhibited tumor regression and prolonged survival compared to control or those receiving the [^{177}Lu]Lu-NM600. Overall survivals of 11, 21, and 29 days were recorded for vehicles, [^{177}Lu]Lu-NM600 and [^{161}Tb]Tb-NM600, respectively. No overt radiotoxicity was observed with either treatment. ***Conclusion:*** Our findings demonstrate the enhanced pharmacologic profile of [^{161}Tb]Tb-NM600, resulting in superior dose deposition and therapeutic efficacy compared to [^{177}Lu]Lu-NM600. These results reinforce the promise [^{161}Tb]Tb-NM600 as a compelling RPT agent, particularly for the treatment of residual or micrometastatic disease.

OP-276

Radium-223-Loaded Radioactive Metal-Organic Framework Induces Alpha-Particle-Driven PANoptosis to Halt Cancer Progression

F. Yu[1], *J. Zhang*[1], *K. Kabayama*[2], *K. Fukase*[2], *T. Watabe*[2], *Y. Feng*[3], *K. Shi*[4];
[1]*Department of Nuclear Medicine, Shanghai Tenth People's Hospital and Institute of Nuclear Medicine, School of Medicine, Tongji University, Shanghai, CHINA,* [2]*Institute for Radiation Sciences, Osaka University, Osaka, JAPAN,* [3]*Department of Radiology, Duke University Medical Center, Durham, NC, UNITED STATES OF AMERICA,* [4]*Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Radium-223 (^{223}Ra) is a potent alpha-particle-emitting radionuclide that effectively induces double-strand DNA breaks in tumor cells, which makes it a promising candidate for cancer therapy. However, the precise mechanisms of action of ^{223}Ra, beyond its DNA damage capabilities, remain poorly understood. This study aims to explore the effects of ^{223}Ra on gene expression related to PANoptosis, a cell death mechanism that integrates pyroptosis, apoptosis, and necroptosis, in Lewis lung carcinoma (LLC) cells. The study also investigates the potential of ^{223}Ra-MOF-74(Fe) nanoplatforms in enhancing therapeutic efficacy and overcoming apoptosis resistance in cancer therapy. ***Materials and Methods:*** In this study, a ^{223}Ra-MOF-74(Fe) nanoplatform was developed to deliver radium-223 to the target cells. RNA sequencing was employed to analyze gene expression changes in LLC cells treated with the nanoplatform, with a focus on pathways related to PANoptosis. In vitro experiments were conducted to measure the production of reactive oxygen species (ROS) and assess mitochondrial dysfunction. Tumor growth inhibition was evaluated in vivo, and off-target toxicity was assessed to determine the safety profile of the treatment. ***Results:*** The RNA sequencing analysis revealed that treatment with ^{223}Ra-MOF-74(Fe) significantly alters gene expression patterns associated with PANoptosis, resulting in the activation of pyroptosis, apoptosis, and necroptosis pathways. In vitro experiments showed that ^{223}Ra-MOF-74(Fe) markedly increased ROS production and caused mitochondrial dysfunction in LLC cells. These cellular effects were associated with the activation of PANoptosis pathways. In vivo, ^{223}Ra-MOF-74(Fe) demonstrated strong tumor growth inhibition in LLC tumor-bearing mice, with minimal off-target toxicity, suggesting its potential as an effective cancer treatment with a favorable safety profile. ***Conclusion:*** This study provides new insights into the novel mechanism by which ^{223}Ra-MOF-74(Fe) induces PANoptosis in tumor cells. By enhancing ROS production and mitochondrial dysfunction, ^{223}Ra-MOF-74(Fe) activates the PANoptosis pathways, offering a promising strategy to overcome apoptosis resistance in cancer therapy. The results demonstrate the therapeutic potential of this nanoplatform in inhibiting tumor growth while minimizing toxicity, providing a new avenue for effective cancer treatment.

OP-277

Conjugation and Radiolabelling of anti-EphA3 Antibody [^{225}Ac]Ac-macropa-tzPEG$_3$Sq-chIIIA4 and Preclinical Evaluation in a Murine Glioblastoma Model

C. Wichmann[1], *K. Morgan*[2], *L. Osellame*[1], *Z. Cao*[1], *N. Guo*[1], *H. Gan*[1], *I. Burvenich*[1], *P. Donnelly*[2], *A. Scott*[1];
[1]*Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*University of Melbourne, Parkville, AUSTRALIA.*

Aim/Introduction: Alpha-particle based radioimmunotherapy has shown success in clinical malignancies. ^{225}Ac-Labelled antibodies or peptides demonstrated effective treatment in patients with myeloid leukemia or mCRPC. Macropa is a promising chelator capable of forming stable complexes with Ac-225. Here we explore radioimmunotherapy with ^{225}Ac-labelled H$_2$macropa-chIIIA4 which binds EphA3 receptor on tumour cells as well as in the tumour microenvironment. ***Materials and Methods:*** Conjugation of chIIIA4 to H$_2$macropa-tzPEG$_3$SqOEt and radiolabelling with Ac-225 was optimized. Affinity of immunoconjugates was confirmed using FACS. Radioimmunoconjugates were characterised by TLC, HPLC, and immunoreactive fraction, and stability evaluated in human serum. In-vitro efficacy of [^{225}Ac]Ac-macropa-tzPEG$_3$-chIIIA4 (^{225}Ac-chIIIA4) in U251 glioma cells was evaluated against ^{225}Ac-IgG1, ^{225}Ac-only, and chIIIA4 controls using MTS cytotoxicity assays. Biodistribution of ^{225}Ac-chIIIA4 and ^{225}Ac-IgG1 control was determined in a murine U251 xenograft model. In-vivo therapy studies with ^{225}Ac-chIIIA4 were performed in the same model and evaluated against ^{225}Ac-labelled and unlabelled controls. ***Results:*** Labelling of H$_2$macropa-tzPEG$_3$Sq-chIIIA4 with Ac-225 showed quantitative conversion after 15 and 5 minutes for 10^{-7} M and higher concentrations of chelator, respectively. At EOS, typical apparent specific activity was 37 MBq/mg and radiochemical purity was always >99%. SE-HPLC of unlabelled and ^{225}Ac-labelled immunoconjugates showed negligible levels of protein aggregation and immunoreactivity in U251 cells was >98%. Stability in human serum was excellent with radiochemical purity and immunoreactivity >95% and 60% after 7 days, respectively. In-vitro efficacy of ^{225}Ac-chIIIA4 in U251 cells was evident in cytotoxicity assays, although low grade bystander effects were observed with ^{225}Ac-containing controls. Biodistribution of ^{225}Ac-chIIIA4 in U251 murine xenograft models showed maximum tumour uptake of 20 %ID/g on day 2 post-injection. General organ uptake was low (<9 %ID/g) apart from high uptake in spleen and liver which naturally express EphA3 receptor. Single-dose treatment with ^{225}Ac-chIIIA4 (18.5 kBq) was well tolerated and demonstrated significant, sustained tumour growth inhibition, with all mice achieving at least partial response at study termination (day 53 post-treatment). Mice in the chIIIA4 treated cohort reached ethical endpoint on day 13 due to progressive disease. Mean tumour volume in the ^{225}Ac-chIIIA4 cohort was significantly lower compared to the ^{225}Ac-IgG1 treated cohort (7.4±4.5 mm3 vs 226±70 mm3, p=0.0022) with all mice in the latter cohort showing progressive disease. ***Conclusion:*** Radiosynthesis of ^{225}Ac-chIIIA4 was achieved in quantitative radiochemical yield and passing quality control criteria typical for clinically applied radiopharmaceuticals. In-vivo therapy studies showed prolonged survival and eradication of tumours in the ^{225}Ac-chIIIA4 treated cohort compared to controls.

OP-278

Preclinical Assessment of ^{177}Lu- and ^{161}Tb-Labeled DZ-HX3 Cyanine Probes for Theranostic Targeting of Solid Tumors

W. Wang[1], *M. Huang*[1], *Y. Wang*[2], *R. Wang*[1], *Y. Zhang*[3], *R. Tian*[1];
[1]*Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA,* [2]*Department of Nuclear Medicine and Clinical Nuclear Medicine Research Lab, West China Hospital, Sichuan University, Chengdu, CHINA,* [3]*Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Radionuclide-based agents with broad-spectrum antitumor activity and theranostic potential represent a promising approach to address tumor heterogeneity and therapeutic resistance. DZ-1, a heptamethine carbocyanine dye, demonstrates broad tumor selectivity through preferential uptake and mitochondrial/lysosomal localization in diverse cancer types. Previous studies showed that conjugating DZ-1 with chemotherapeutics facilitates efficient intracellular delivery and tumor suppression. This study developed and systematically evaluated the preclinical targeting, efficacy, and safety of ^{177}Lu- and ^{161}Tb-labeled DZ-HX derivatives. ***Materials and Methods:*** A modified DZ-HX3 platform was synthesized with enhanced molecular stability and metabolic properties. Cellular uptake was assessed in H1975, HeLa, and MIA PaCa-2 cell lines. In vitro validation included cell binding assays and dose-dependent cytotoxicity evaluations (0-3.7 MBq). Pharmacokinetic profiles were assessed via serum clearance studies and Micro-SPECT imaging. Biodistribution was analyzed across time points (4-168 h), comparing tumor and normal organ uptake. Therapeutic efficacy was evaluated in subcutaneous and orthotopic tumor models using single and multiple-dose regimens (18.5, 7.4, 3.7 MBq), combined with serial SPECT/CT imaging and tumor volume measurements. All studies included blood work and histopathology of major organs for safety assessment. ***Results:*** High uptake was observed in tumor cells, peaking at 5.45 ± 0.57% (HeLa) and 7.38 ± 0.21% (H1975). Cytotoxicity assays revealed dose-dependent reductions in viability, with 3.7 MBq exposure lowering cell viability to < 35% ($P < 0.0001$ vs. free radionuclides). Micro-SPECT/CT imaging showed rapid tumor localization within 24 h, peaking at 48 h (^{177}Lu-DZ-HX3: 13.85 ± 1.31 %ID/g; ^{161}Tb-DZ-HX3: 19.56 ± 0.99 %ID/g in HeLa). This differential uptake persisted in MIA PaCa-2 models (^{177}Lu-DZ-HX3: 11.39 ± 2.90 %ID/g; ^{161}Tb-DZ-HX3: 21.24 ± 6.84 %ID/g at peak), with both probes maintaining >7 %ID/g tumor retention at 96 h. The tumor-to-muscle ratio reached 24.62 ± 8.96, highlighting strong tumor specificity.Therapeutic outcomes reflected these pharmacokinetic advantages. High-dose ^{177}Lu-DZ-HX3 treatment achieved tumor inhibition rates of 87.20% (H1975), 93.90% (HeLa), and 90.61% (MIA PaCa-2), while ^{161}Tb-DZ-HX3 at 18.5 MBq showed 97.14% (HeLa) and 97.96% (MIA PaCa-2) inhibition. Fractionated low-dose ^{177}Lu-DZ-HX3 (11.1 MBq) induced complete remission in 43% of orthotopic lung cancer models, with no recurrence observed during 60-day monitoring. Treatment was generally well tolerated, with no significant histopathological findings or weight loss. ***Conclusion:*** ^{177}Lu- and ^{161}Tb-labeled DZ-HX3 demonstrated strong tumor targeting and therapeutic efficacy. While ^{161}Tb-DZ-HX3 showed slightly greater tumor uptake and inhibition, both agents effectively suppressed tumor growth, with ^{177}Lu-DZ-HX3 inducing complete remission in orthotopic models. These results support further development for targeted radionuclide therapy.

OP-279

Simultaneous Alpha- and Beta-Particle Digital Autoradiography for Evaluating Co-Therapy and Theranostic Differential Activity Uptake Distributions: Initial Results in Pre-Clinical Studies of Co-Injected Ac-225 with Lu-177 and with Diagnostic PET Tracers

B. W. Miller[1,2], *S. S. Rinne*[3], *N. Aguirre*[4], *B. Vaughn*[5], *A. Wacker*[6], *A. Le Roux*[4], *J. Kelly*[6], *S. M. Cheal*[6];
[1]*The University of Arizona, Tucson, AZ, UNITED STATES OF AMERICA,* [2]*QScint Imaging Solutions, LLC, Tucson, AZ, UNITED STATES OF AMERICA,* [3]*Uppsala University, Uppsala, SWEDEN,* [4]*Memorial Sloan Cancer Center, New York, NY, UNITED STATES OF AMERICA,* [5]*Convergent Therapeutics, Cambridge, MA, UNITED STATES OF AMERICA,* [6]*Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: The development of a quantitative digital autoradiography system, called iQID (ionizing-radiation Quantum

Imaging Detector), represents a significant advancement in the field of molecular imaging. This system is capable of simultaneously imaging alpha- and beta-particle emissions (co-therapy electrons or positrons), providing enhanced resolution, quantification capabilities, and specificity in pre-clinical digital autoradiography studies. ***Materials and Methods:*** The iQID system leverages a novel particle discrimination method where alpha and beta particles are distinguished from one another based on event area and summed signal within the event cluster. We utilized the iQID device to simultaneously image alpha-emitting Ac-225 and beta-emitting tracers (labeled with Lu-177, Zr-89, or Ce-134) in pre-clinical organ samples. Organs samples were prepared by co-injection of 225Ac-labeled radioligands with their either Lu-177 (therapeutic electron), Zr-89 (diagnostic positron) or Ce-134 (diagnostic positron) labeled analogues. Monoisotope injections were included as control. Tissue was collected 24h after administration of the radioligand, flash frozen in OCT, and sectioned (7µm) on to Gadox (Gd2O2S) scintillation paper, which is sensitive to both alphas and beta emitters. Tumors and normal organs were imaged. Listmode data for each detected particle and energy cuts to discriminate between particles were used to construct digital autoradiographs (pixel values in units of counts detected) of total-counts images, alpha-only images, and beta-only images. ***Results:*** Distinct uptake patterns were observed between the alpha and beta emitters, exhibiting different uptakes at both cellular and sub-organ levels. The differences in signal acquisition between the particles suggest variability in tracer localization and retention, underscoring the importance of evaluating diagnostic and therapeutic strategies at resolutions higher than those achievable with PET or SPECT imaging. ***Conclusion:*** Our findings highlight the need in radiopharmaceutical development for precise analysis of radionuclide distributions at near-cellular levels. This study demonstrates the potential of the iQID system to facilitate the concurrent imaging of multiple particle types, offering a novel approach for evaluating complex radiopharmaceuticals and their therapeutic potential, particularly for co-therapies (e.g., Ac-225 and Lu-177) and positron radionuclide imaging pairs. ***References:*** Miller, Brian W., et al. "Quantitative single-particle digital autoradiography with α-particle emitters for targeted radionuclide therapy using the iQID camera." Medical physics 42.7 (2015): 4094-4105.

Targeted Alpha Therapy (TAT) in AML: CD38 as a Promising Alternative to CD33

M. Sorin[1], *S. Gouard*[1], *S. Marionneau-Lambot*[1,2], *C. Maingueneau*[1], *A. Morgenstern*[3], *F. Bruchertseifer*[3], *M. Chérel*[1,4], *F. Haddad*[5,6], *M. Allard*[1], *J. Gaschet*[1];
[1]Nantes Université, Inserm, CNRS, Université d'Angers, CRCI2NA, Nantes, FRANCE, [2]Nantes University Hospital, Nantes, FRANCE, [3]European Commission, Joint Research Centre, Directorate for Nuclear Safety and Security, Karlsruhe, GERMANY, [4]ICO-René Gauducheau Cancer Center, Saint-Herblain, FRANCE, [5]GIP ARRONAX, Saint-Herblain, FRANCE, [6]Nantes Université, IMT Atlantique, CNRS-IN2P3, SUBATECH, Nantes, FRANCE.

Aim/Introduction: Acute Myeloid Leukemia (AML) is the most common leukemia in adults, characterized by a poor prognosis and a 5-year survival rate below 30%, largely due to chemoresistance. Targeted alpha-therapy (TAT) has emerged as a promising approach for treating disseminated tumors such as AML. Clinical trials using a [^{225}Ac]Ac-anti-CD33 monoclonal antibody (mAb) have demonstrated encouraging responses, as CD33 is expressed in 85-90% of AML cases. However, this approach is frequently associated with prolonged myelosuppression, primarily due to CD33 expression on normal hematopoietic cells. To broaden therapeutic options while minimizing off-target toxicity, we explored CD38 as an alternative and innovative target. CD38 is a well-established therapeutic antigen in multiple myeloma, where daratumumab, an anti-CD38 mAb, has shown remarkable efficacy. Although CD38 expression in AML is heterogeneous, daratumumab has demonstrated only modest anti-tumor activity in this context. We hypothesize that using [^{225}Ac]Ac-anti-CD38 mAb for TAT could overcome these limitations and provide a novel therapeutic strategy for AML, particularly in patients with higher CD38 expression than CD33. ***Materials and Methods:*** The human AML cell lines, MOLM-14 and THP-1 were characterized for their expression of CD33 and CD38 and use to establish disseminated preclinical AML models in NSG mice. Anti-CD33 and anti-CD38 mAbs underwent comprehensive characterization and their radiolabelling with [^{225}Ac] was optimized. The maximum tolerated activity (MTA) was determined in naïve animals. Efficacy studies were performed 6 days post-engraftment, assessing the impact of TAT on median survival (MS) of mice bearing either MOLM-14 or THP-1 disseminated AML models. ***Results:*** Both MOLM-14 and THP-1 cell lines expressed CD33 and CD38. MOLM-14 cells had a higher density of CD33 binding, while THP-1 cells showed greater CD38 expression. The MTA for [^{225}Ac]Ac-anti-CD33 mAb in naïve NSG mice was established at 0.5 kBq/g. Treatment with either [^{225}Ac]Ac-anti-CD33 or [^{225}Ac]Ac-anti-CD38 mAb at 0.5 kBq/g significantly prolonged MS in both disseminated MOLM-14 and THP-1 AML models compared to non-radiolabeled counterparts or a [^{225}Ac]Ac-isotype control mAb. Consistent with antigen expression, [^{225}Ac]Ac-anti-CD33 mAb was more effective in the MOLM-14 AML model compared to [^{225}Ac]Ac-anti-CD38 mAb. Conversely, in the THP-1 AML model, [^{225}Ac]Ac-anti-CD38 mAb demonstrated superior efficacy over [^{225}Ac]Ac-anti-CD33 mAb. Toxicity analyses are ongoing. ***Conclusion:*** This study demonstrates that CD38-targeted TAT could offer a promising alternative to CD33 in AML, potentially reducing off-target toxicity. In particular, for AML cases with higher CD38 expression than CD33, CD38-directed TAT could provide enhanced therapeutic efficacy, offering a novel therapeutic avenue for treating AML.

The dose-response effects of ^{225}Ac-Labeled MOF regulates endoplasmic reticulum stress to induce antitumor immunity

F. Yu[1], *X. Luan*[1], *T. Watabe*[2], *Y. Feng*[3], *K. Shi*[4], *K. Kabayama*[2], *K. Fukase*[2];
[1]Department of Nuclear Medicine, Shanghai Tenth People's Hospital and Institute of Nuclear Medicine, School of Medicine, Tongji University, Shanghai, CHINA, [2]Institute for Radiation Sciences, Osaka University, Osaka, JAPAN, [3]Department of Radiology, Duke University Medical Center, Durham, NC, UNITED STATES OF AMERICA, [4]Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Radionuclide therapy has emerged as a critical modality for cancer treatment, with growing interest in its potential to activate immune responses. Alpha radionuclides are particularly notable for their unique characteristics of high energy and short range, allowing them to induce cell death with exceptional efficiency. Among alpha radionuclides, ^{225}Ac has gained significant attention for its clinical applications. This study investigates the mechanisms by which low-dose ^{225}Ac-labeled metal-organic frameworks (^{225}Ac/MOF) induce endoplasmic reticulum stress (ERS) and immune activation. ***Materials and Methods:*** ^{225}Ac/MOF was developed to deliver Actinium-225 to the target cells, the materials are characterized first to clarify their basic properties. Subsequently, cell experiments with different nuclide concentrations were conducted, including cytotoxicity tests, ROS generation determination, cell cycle experiments, apoptosis experiments. At the same time, the safety of ^{225}Ac/MOF material was also verified. The experiment conducted RNA sequencing for both high and low dose groups to verify the effects of different nuclide doses on cells. The relationship between endoplasmic reticulum stress and the activation of anti-tumor immunity at different doses was verified at the animal experiment level. ***Results:*** The results demonstrated that, compared to high-

dose treatment (11.10 kBq), low-dose radionuclide therapy (3.70 kBq) more effectively induces endoplasmic reticulum stress, significantly upregulating CHOP expression ($p < 0.01$). The increased CHOP level further promotes the translocation of HMGB1 from the intracellular to the extracellular space, ultimately eliciting a more pronounced antitumor immune response. Animal experiments also proved this point. Mice in the low-dose group (3.70 kBq) were superior to those in the high-dose group (11.10 kBq) in terms of tumor size and survival time. As for ERS and tumor immune activation markers, the low-dose group is also better than the high-dose treatment. ***Conclusion:*** In conclusion, our study reveals the mechanisms by which ^{225}Ac/MOF regulate ER stress to enhance antitumor immunity. The activation of the CHOP and HMGB1 pathways represents a key axis in this process. These findings provide new insights into optimizing radionuclide therapy strategies and provide a theoretical basis for incorporating ER stress-induced immune regulation into comprehensive cancer treatment regimens. Moreover, ^{225}Ac/MOF treatment exhibited a distinct dose-dependent effect, highlighting the importance of optimizing the dose to achieve a balance between therapeutic efficacy and minimizing adverse effects.

OP-282

^{191}Pt-labeled agents targeting tumor DNA in vivo: compound design and biological evaluation for targeted Auger electron therapy

H. Obata[1], *A. B. Tsuji*[1], *Y. Feng*[2], *M. R. Zalutsky*[2], *M. R. Zhang*[1]; *[1]National Institutes for Quantum and Radiological Science and Technology, Chiba, JAPAN, [2]Duke University Medical Center, Durham, NC, UNITED STATES OF AMERICA.*

Aim/Introduction: Pt-191-labeled agents are promising candidates for DNA-targeted Auger electron cancer therapy, but there has yet to be an established drug design that enables targeting tumor DNA efficiently in vivo. Herein, we explored linker structures for ^{191}Pt-labeled complexes targeting both tumor antigen and genomic DNA, and demonstrated DNA binding of novel ^{191}Pt-labeled complexes in targeted tumors in vivo. ***Materials and Methods:*** We synthesized six different conjugates composed of a trithiol ligand for ^{191}Pt labeling, Hoechst for DNA binding, and a glutamic acid-urea-lysine moiety for targeting prostate-specific membrane antigen (PSMA) (Trithiol-Hoechst-PSMA: THP1, 2-4, 2-8, 3-4, 3-8, 4). They contain different structures and lengths of linkers between either side of the trithiol ligand and Hoechst/the PSMA-targeted moiety. After ^{191}Pt labeling, the DNA binding ability and PSMA targeting specificity of the [^{191}Pt]Pt-THP complexes were evaluated in cell experiments, and their biodistribution was investigated in mice bearing tumors with/without PSMA expression. Finally, tumor DNA binding of [^{191}Pt]Pt-THP3-4 and 3-8 was evaluated in vivo. ***Results:*** All six [^{191}Pt]Pt-THP complexes were obtained with radiochemical yields of 60-80%, and ^{191}Pt-labeled products were successfully separated from their precursors. [^{191}Pt]Pt-THP3-4 and 3-8, in which Hoechst is on one side of the trithiol ligand across a linear PEG linker and the PSMA-targeted moiety on another side across a C4 linker, maintained PSMA targeting specificity and DNA binding ability in cultured cells than the other complexes. In vivo experiments for [^{191}Pt]Pt-THP3-4 and 3-8 showed rapid drug clearance from normal organs and long retention in the kidneys and tumors expressing PSMA. Notably, the two complexes exhibited almost the same DNA binding ratio in PSMA-positive tumors in vivo as in the cultured cells. ***Conclusion:*** This study demonstrated that two novel ^{191}Pt-labeled agents efficiently bind the genomic DNA of PSMA-positive tumors in vivo. Comparison of six different [^{191}Pt]Pt-THP complexes suggests that two linkers (1) a PEG linker between the trithiol ligand and the Hoechst compound and (2) a C4 linker between the trithiol ligand and the PSMA ligand were crucial for delivering ^{191}Pt-labeled complexes to tumor DNA. These findings would facilitate drug development using Pt radionuclide for radiopharmaceutical therapy, especially DNA-targeted Auger electron cancer therapy.

Evaluation of MRgTOF-BSREM PET Reconstruction for Accurate T Classification in Oral Cancer

M. Nogami[1,2], *J. Inoue Inukai*[3], *F. Zeng*[3], *N. Sugiyama*[3], *M. G. Spangler-Bickell*[4], *T. Kurimoto*[5], *K. Kubo*[1], *Y. Kiyono*[2], *T. Murakami*[3,1]; *[1]Department of Radiology, Kobe University Hospital, Kobe, JAPAN, [2]Biomedical Imaging Research Center, University of Fukui, Fukui, JAPAN, [3]Department of Radiology, Kobe University Graduate School of Medicine, Kobe, JAPAN, [4]GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA, [5]GE HealthCare, Hino, JAPAN.*

Aim/Introduction: For pretreatment staging of oral cancer, PET/MRI is known to outperform PET/CT in assessing local tumor extension due to its superior soft tissue contrast and simultaneous acquisition capabilities. However, PET inherently suffers from partial volume effects, leading to underestimation of tracer uptake. The newly proposed PET image reconstruction method—MR-guided Time-of-Flight Block Sequential Regularized Expectation Maximization (MRgTOF-BSREM)—leverages anatomical information from simultaneously acquired MRI to guide noise control in BSREM reconstruction, thereby allowing PET reconstruction with enhanced spatial resolution. The aim of this study was to evaluate the diagnostic performance of MRgTOF-BSREM for assessing local tumor invasion in oral cancer patients and to compare its semiquantitative metrics (SUV) with those of conventional reconstruction, in order to assess its clinical utility. ***Materials and Methods:*** A retrospective analysis was performed on 54 consecutive patients who underwent FDG PET/MRI for pretreatment staging of oral cancer. Head and neck PET list-mode data were reconstructed using MRgTOF-BSREM and the conventional TOF-Ordered Subset Expectation Maximization (TOF-OSEM) method. MRgTOF-BSREM reconstruction incorporated simultaneously acquired 3D T2-weighted sagittal MRI as a prior in BSREM, with both PET and MRI data corrected for motion using PET list-mode live reconstruction. Two readers independently interpreted fused PET/MRI images of the head and neck. Pathological findings after surgery were used as the reference standard. Agreement in T classification (TNM system) was assessed using the kappa statistic, and diagnostic confidence (rated on a 5-point scale) was compared using the Wilcoxon test. SUVmax of the primary tumor was measured and compared between methods using intraclass correlation coefficient (ICC) and Bland-Altman analysis. ***Results:*** Agreement with pathological T classification was higher with MRgTOF-BSREM (reader 1: $\kappa = 0.787$; reader 2: $\kappa = 0.749$) than with TOF-OSEM (reader 1: $\kappa = 0.738$; reader 2: $\kappa = 0.721$). Diagnostic confidence was significantly higher with MRgTOF-BSREM than with TOF-OSEM for both readers ($p = 0.038$ and 0.034, respectively). SUVmax of the primary tumor showed excellent correlation between MRgTOF-BSREM and TOF-OSEM (ICC = 0.975), with a minimal mean difference of 0.004 (upper and lower limits of agreements: 4.334 and -4.342, respectively). ***Conclusion:*** MRgTOF-BSREM PET reconstruction in PET/MRI improves diagnostic performance in assessing local tumor extension in oral cancer patients, while maintaining excellent quantitative agreement with conventional methods.

Aim/Introduction: Simultaneous MR/PET imaging offers a huge potential for neuroscience, especially for correlating processes of neuronal activity during cognitive or pharmacological challenges with the binding characteristics of neurotransmitters. We recently developed and built an ultra-high field MRI-compatible PET insert for neuroscientific imaging in humans with high sensitivity and high homogeneous spatial resolution. The design and the imaging performance of this system will be presented. ***Materials and Methods:*** The PET insert was built for a human 7T MRI scanner and comprises a total of 8 ultra-high field compatible PET modules in a carbon fibre housing. Each module has 3 × 5 pixelated scintillation detector blocks with three staggered layers of LSO scintillator coupled to arrays of digital SiPMs. The three staggered layers are used for depth of interaction detection. The BrainPET-7T insert is equipped with liquid cooling for optimal temperature stabilization, a low noise power supply unit, and a mostly (approx. 92% transmission) gamma-ray transparent 8-channel prototype transceiver array. In a baseline performance evaluation without MR system, we determined system sensitivity, noise-equivalent count rates (NECR), and spatial resolution (determined with mini-Derenzo phantom). In a second evaluation, we determined the PET inserts´ RF noise detectable with the MR system. We also measured prompt and true coincidence count rates with MP2RAGE, TSE, FLAIR, and EPI MR imaging sequences at different typical activities between 20 and 160 MBq and acquired simultaneous MR/PET images of different phantoms including fruits and an anthropomorphic head phantom. ***Results:*** The transversal spatial resolution was determined to be ≈ 1.6 mm at the isocentre and at 10 cm off-centre. No difference in spatial resolution was observed when comparing the spatial resolution from the baseline performance evaluation and from the performance evaluation with running MR. The peak NECR was measured to be 414 kcps at 12 kBq/ml and the system sensitivity with a shielded RF coil array was 57.2 kcps/MBq (energy window: 420-650 keV, coincidence window: 2.5 ns). During repetition of the NECR measurement with running MR sequences, no influence on coincidence resolving time, energy resolution, and count rates by MR sequences was observed for the tested sequences. No visible image artefacts were observed in MR or PET images when simultaneously acquiring data. ***Conclusion:*** The new BrainPET-7T system provides simultaneous high-quality PET and MR images. No mutual interference or incompatibility have been observed in the reconstructed images when acquiring MR and PET data simultaneously.

OP-285

Impact of MR-Guided TOF-BSREM Reconstruction on Visual Interpretation in [^{18}F]Flutemetamol PET/MR

J. Inoue Inukai[1], *M. Nogami*[2,3], *F. Zeng*[2], *K. Kubo*[2], *T. Kurimoto*[4], *F. Kotasidis*[5,6], *M. Spangler-Bickell*[6], *M. W. Huellner*[5], *T. Murakami*[1,2]; [1]*Department of Radiology, Kobe University Graduate School of Medicine, Kobe, JAPAN,* [2]*Department of Radiology, Kobe University Hospital, Kobe, JAPAN,* [3]*Division of Medical Imaging, Biomedical Imaging Research Center, University of Fukui, Fukui, JAPAN,* [4]*GE Healthcare, Hino, JAPAN,* [5]*Department of Nuclear Medicine, University Hospital Zurich and University of Zurich, Zurich, SWITZERLAND,* [6]*GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: [^{18}F]Flutemetamol PET is a type of amyloid PET that enables visualization of fibrillar β-amyloid plaques, aiding in the diagnosis of mild cognitive impairment due to Alzheimer's disease. Visual interpretation as positive or negative is required. However, in some cases, uptake in the cortical margins remains ambiguous owing to partial-volume effects. Time-of-flight (TOF) block-sequential regularized expectation maximization (BSREM) allows for highly converged PET image reconstruction while maintaining quantifiability and image quality. Furthermore, MR-guided BSREM, which incorporates voxel-level MR anatomical priors into the PET regularization process, is expected to improve the noise control and spatial accuracy. This study aimed to evaluate whether MR-guided TOF-BSREM improves reader confidence in the binary classification of amyloid PET findings compared with conventional TOF-ordered subset expectation maximization (OSEM) reconstruction. ***Materials and Methods:*** This study analyzed a total of 41 cases who underwent Flutemetamol PET/MR imaging—using the same PET/MRI scanner, 11 cases were conducted at Institution 1 and 30 cases at Institution 2. For each subject, PET images were reconstructed using both conventional TOF-OSEM and MR-guided TOF-BSREM methods. Centiloid scales were calculated using both reconstruction methods and assessed for correlations. Visual interpretation was conducted according to the standardized Flutemetamol PET reading methodology, in which each brain region was assessed individually. Two experienced readers independently evaluated both conventional and MR-guided TOF-BSREM reconstructed images, assigning a 5-point score for each region as well as for the overall classification of amyloid positivity or negativity. The diagnostic performance was compared using receiver operating characteristic analysis and the DeLong test. Confidence score distributions were assessed using the Wilcoxon signed-rank test and visualized using histograms. The reference standard for amyloid positivity or negativity was determined by consensus among the two readers and a third independent expert. ***Results:*** The centiloid scales between the two reconstruction methods showed a strong positive correlation ($r = 0.997$). In visual interpretation, both readers showed higher area under the curves for MR-guided TOF-BSREM than for conventional TOF-OSEM (Reader 1: 0.997 > 0.974; Reader 2: 0.993 > 0.971). Although the difference in confidence score distribution was not statistically significant ($p = 0.068$), the histograms suggested a greater proportion of extreme confidence scores with MR-guided TOF-BSREM, indicating more definitive interpretations. ***Conclusion:*** MR-guided TOF-BSREM reconstruction for Flutemetamol PET/MR may enhance reader confidence in binary visual interpretation, potentially leading

to more reliable assessments of amyloid positivity or negativity compared to conventional reconstruction. ***References:*** 1) JAMA Neurol. 2015;72:287-294. 2) J Nucl Med. 2007;48:932-945.

OP-286

New Discoveries in Systemic Amyloidosis: A Network of Brain and Organ Relationships Based on ^{11}C-PiB PET/MRI

S. Wei, *W. Ruan, Z. Zhou, D. Zheng, Y. Lv, Z. Dai, Y. Gai, X. Lan, C. Qin;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, CHINA.

Aim/Introduction: Primary systemic amyloidosis is a disorder characterized by abnormal extracellular amyloid protein deposition, resulting in multi-organ dysfunction. ^{11}C-PiB PET is widely used to diagnose Alzheimer's disease and has shown potential in assessing systemic amyloidosis. However, the correlation between brain ^{11}C-PiB uptake and other organs, as well as between different organ uptake, remains unclear. This study explores the correlation between amyloid protein deposition in the brain and various organs. ***Materials and Methods:*** A retrospective analysis was conducted on patients who underwent whole-body ^{11}C-PiB PET/MRI for suspected or confirmed systemic amyloidosis. Brain PET images were segmented into 70 regions in MATLAB with SPM12, and SUV values were extracted for each region. ROIs were delineated in multiple organs to acquire UVmax. Pearson correlation coefficients (r) and p-values were calculated between various brain regions and multiple organs, as well as across different organs, using Python programming to assess the correlation of amyloid deposition among different organs. ***Results:*** Fifty patients with systemic amyloidosis (case group), 9 with other plasma cell diseases, and 4 controls were included. In the control group, 57, 22, and 24 brain regions exhibited extremely strong correlations with spleen, renal parenchyma, and bone marrow, respectively (with the strongest correlation being r = 0.981-0.997, all P < 0.05). In the other plasma cell disease group, 60, 23, 6, and 31 brain regions had strong correlations with myocardium, spleen, renal parenchyma, and bone marrow, respectively (r = 0.742-0.814, all P<0.05). All brain regions showed a poor or no correlation with lung, liver, gastric wall, and pancreas in the aforementioned two groups. Conversely, in the case group, merely 22 and 4 brain regions weakly correlated with pancreas and bone marrow (r = 0.345, 0.340, all P<0.05), while all showed poor or no correlation with lung, myocardium, liver, spleen, gastric wall, and renal parenchyma. Meanwhile, clear organ correlations were exhibited in the non-amyloidosis groups (the control group and other plasma cell disease groups), including myocardium-bone marrow, myocardium-spleen, myocardium-gastric wall, lung-liver, spleen-gastric wall, spleen-bone marrow, and gastric wall-bone marrow (r = 0.678-0.857; all P <0.05). However, these organ correlations significantly decreased or even vanished in the case group. ***Conclusion:*** We preliminarily constructed a network of relationships between PiB uptake in the brain and multiple organs, as well as between organs. Primary systemic amyloidosis significantly disrupts the correlation of PiB uptake between the brain and various organs, as well as between organs.

OP-287

Posterior Putamen Vulnerability in Parkinson's Disease: Multimodal ^{18}F-FPCIT PET/MRI Reveals Iron-Mediated Nigrostriatal Degeneration and Microstructural Decoupling

H. Lin[1], *Y. Wei*[2], *Y. Zhu*[1], *Z. Lin*[2], *Y. Yang*[3], *C. Zuo*[1];
[1]Deparment of Nuclear Medicine / PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [2]United Imaging Healthcare Co., Ltd., Shanghai, CHINA, [3]Beijing United Imaging Healthcare Co., Ltd., Beijing, CHINA.

Aim/Introduction: Parkinson's disease (PD) is characterized by posterior-to-anterior striatal dopaminergic denervation, most pronounced in the posterior putamen (pPut). However, the microstructural mechanisms driving this spatial gradient remain unclear. This study investigates nigrostriatal pathway alterations by correlating substantia nigra pars compacta (SNc) iron deposition/diffusion metrics with striatal dopamine transporter availability (DaT-SBR) to elucidate why pPut is preferentially affected. ***Materials and Methods:*** We performed ^{18}F-FPCIT PET/MRI in 53 PD patients and 10 controls. Striatal DaT-SBR (caudate, anterior/middle/posterior putamen [aPut/mPut/pPut]) and SNc microstructural metrics (iron deposition via quantitative susceptibility mapping; diffusion tensor imaging [DTI: axial/mean/radial diffusivity (AD/MD/RD), fractional anisotropy [FA]) were analyzed. Group differences and SNc-striatal correlations were assessed using general linear models adjusted for age, disease duration. ***Results:*** PD patients exhibited marked DaT-SBR reductions in bilateral caudate and putamen (p<0.0001 vs. controls), with maximal loss in the right pPut. A posterior-to-anterior DaT-SBR gradient was confirmed (aPut>mPut>pPut, all p<0.0001). SNc iron deposition inversely correlated with DaT-SBR in the clinically affected hemisphere's right caudate (R=−0.548, P=0.001) and pPut (R=−0.422, P=0.016), and contralaterally in the left caudate (R=−0.486, P=0.005). No associations were observed in aPut/mPut or left putamen (P>0.05). Adjusted for covariates, SNc DTI metrics demonstrated distinct spatial patterns: SNc AD/MD/RD positively correlated with putaminal diffusivity (MD/AD/RD: R=0.421-0.518, P≤0.009), strongest in aPut and weakening in pPut. Conversely, SNc FA negatively correlated with caudate diffusivity (R=−0.418-−0.430, P≤0.003). Notably, SNc AD/MD showed inverse correlations with pPut FA (R=−0.295-−0.306, P≤0.044), suggesting microstructural decoupling in posterior regions. ***Conclusion:*** This multimodal study reveals two key mechanisms underlying pPut vulnerability in PD: (1) Stronger nigrostriatal associations in anterior regions (SNc diffusivity-aPut diffusivity) may reflect compensatory axonal plasticity, while weaker posterior correlations (SNc-pPut) indicate disrupted connectivity. (2) Inverse SNc iron-DaT-SBR links in pPut and caudate suggest iron-mediated dopaminergic toxicity, particularly in the clinically affected hemisphere. The posterior-anterior DaT-SBR gradient mirrors diminishing SNc-striatal microstructural coherence, supporting a model where posterior striatal regions are more susceptible due to both reduced compensatory capacity and iron-related neurodegeneration. These findings provide novel insights into the microstructural basis of PD's spatial progression, emphasizing SNc iron homeostasis and axonal integrity as potential therapeutic targets.

OP-288

Impact of Continuous Bed Motion on Image Quality and Quantification with a LAFOV PET/CT: A Comparative Study

F. Schmidt[1,2], *W. Lan*[1], *P. M. Linder*[1], *E. Calderón*[1], *C. la Fougère*[1,3];
[1]Nuclear Medicine and Clinical Molecular Imaging, University Hospital Tuebingen, Tuebingen, GERMANY, [2]Werner Siemens Imaging Center, Dep Preclinical Imaging and Radiopharmacy, University of Tuebingen, Tuebingen, GERMANY, [3]Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tuebingen, Tuebingen, GERMANY.

Aim/Introduction: To extend the axial coverage of 106 cm of a long axial field of view (LAFOV) PET/CT scanner, continuous bed motion (CBM) has been introduced. In this study, we evaluated the impact of CBM compared to standard step-and-shoot (SS) acquisition on image uniformity, noise characteristics, and potential discrepancies in quantification. ***Materials and Methods:*** Ten oncological patients underwent sequential [18F]-FDG or [18F]-PSMA PET/CT scans (2 MBq/kg, 60 min p.i.) scans using a standard protocol at your institute (SS, 300 s, 4 iterations/5

subsets OP-OSEM with PSF+TOF, ultra-high-sensitivity (UHS) mode) and additional CBM (bed speed 2.8 mm/s, 106 cm, 380 s, UHS). SUVmean, SUVmax and coefficient of variation (CV) were determined for lesions and liver to assess quantification and noise. A uniform cylindrical phantom (diameter: 5.5 cm, length: 140 cm) filled with 2 kBq/ml F-18 was scanned with CBM at various speeds (2.8 mm/s to 50 mm/s) and compared to SS protocols (300 s and 380 s). Image uniformity (percentage standard deviation of mean activity concentration) and noise (CV) were evaluated over the central 80 cm axial FOV. Additionally, a NEMA NU-2 2018 IEC phantom (sphere-to-background ratio 4:1, 2 kBq/ml F-18) was used to compare contrast recovery coefficients (CRC) for different sphere sizes at axial positions of 0, 45, and 50.5 cm for CBM vs. SS. ***Results:*** For patient data, strong correlations were observed between SS and CBM across all quantitative parameters ($R^2 > 0.98$). Mean lesion SUVmean was 9.1 ± 8.1 (SS) vs. 8.3 ± 7.3 (CBM), SUVmax 14.7 ± 14.2 (SS) vs. 13.7 ± 13.0 (CBM), and lesion CV 20.5 ± 3.9% (SS) vs. 20.3 ± 4.2% (CBM). Liver SUVmean remained stable 8.9 ± 4.3 (SS) vs. 9.0 ± 4.4 (CBM), with comparable noise levels of 7.1 ± 1.1% (SS) vs. 6.6 ± 1.2% (CBM). Phantom studies confirmed a high uniformity of 0.9% (CBM, 2.8mm/s) comparable to 0.7% (SS, 380 s), with degradation at higher speeds to 3.6% (50 mm/s). CV was slightly increased with CBM (5.9 ± 1.0%) compared to 4.7±0.7% (SS, same 380 s), but comparable to 300 s SS with 5.4±0.8%. CRC values were preserved with CBM, e.g., with 0.46 (10 mm sphere) and 0.75 (28 mm) at center FOV, comparable to SS (0.46 / 0.76). Even at off-center positions, CBM maintained quantification for slow speeds, but showed degradation at high speeds, e.g., 50.5 cm, 8.4 mm/s CRC 0.38 (10 mm) / 0.69 (28 mm). ***Conclusion:*** CBM acquisition on LAFOV PET/CT systems enables extended axial imaging without introducing inhomogeneities or great deviations in quantification compared to conventional SS protocols. Slight increases in image noise under CBM can be compensated by modest extensions of scan duration.

OP-289

Less Is More: Tailored Low-Dose [^{18}F]FDG PET/CT Imaging in Pregnant Patients Using LAFOV Technology

I. S. Deurloo[1,2], *M. M. Steemers-de Boer*[3], *J. H. van Snick*[2], *K. P. Koopmans*[2], *R. H. J. A. Slart*[2], *W. Noordzij*[2], *A. H. Brouwers*[2], *G. N. Stormezand*[2], *T. Velleman*[2], *E. Aim/Introduction: PET/CT is essential for diagnosing and monitoring cancer in pregnant patients. The recent introduction of long axial field-of-view (LAFOV) PET/CT scanners—offering up to 10× higher sensitivity than conventional PET—presents a unique opportunity to reduce radiopharmaceutical dose, especially important due to foetal radiosensitivity and the need for repeated imaging of pregnant oncological patients. However, standard adult imaging protocols are still commonly used during pregnancy. In clinical practice, PET dose and scan time are guided by desired image quality, often including a buffer to account for variability in preferences of physicians. For pregnant patients, minimizing this buffer to reduce foetal exposure is essential. Additionally, altered maternal body composition may render conventional adult dose models suboptimal. This study evaluates the image quality-dose trade-off in pregnant patients scanned with LAFOV PET/CT and identifies the most predictive body composition metric for image quality to support development of a tailored dose model. ***Materials and Methods:*** PET/CT scans from 11 pregnant patients, acquired using a LAFOV PET/CT system and ultra-low-dose CT (tin filter), were retrospectively analysed. [^{18}F]FDG was administered using either a quadratic (0.26 MBq/kg^2) or linear (0.3 MBq/kg) regimen, with 15-20 minute acquisitions—approximately 7-fold lower than standard adult dosing. A reference image quality (RIQ), based on average counts per kg, was defined. Images were reconstructed at 100-12.5% RIQ with clinical and EARL2 settings, and assessed by 11 physicians using a 1-5 Likert scale (≥3 = acceptable). Liver signal-to-noise ratio (SNR) served as an objective image quality metric. The minimum required scan statistics was modelled based on the SNR threshold for acceptable image quality and patient body composition. Foetal dose was estimated using uterine segmentation, PET conversion factors[1], and SSDE-adjusted CTDIvol. ***Results:*** SNR correlated well with Likert scores (R^2 = 0.80), with an SNR of 10.72 corresponding to acceptable image quality. Body surface area (BSA) was the best predictor for required image quality (R^2 = 0.85), outperforming weight, weight/height, and body-mass-index. The proposed model (A[MBq] × t[min] = 25.21 × BSA^1.8) yields a PET dose of 5.2 MBq for a 75 kg/170 cm patient, reducing dose by 74-97% compared to current protocols. Estimated foetal doses are expected to be 0.0049 mGy (PET) and 0.31 mGy (CT) after introduction of the proposed protocol. ***Conclusion:*** LAFOV PET/CT enables substantial [^{18}F]FDG dose reduction in pregnant patients. A BSA-based dose model provides optimal prediction of image quality while ensuring minimal foetal exposure. ***References:*** [1]Zanotti-Fregonara et al., J Nucl Med. 2016;57(11):1760-1763.

^{212}Pb PSMA imaging by pair production PET confirms localisation of alpha emissions within tumour lesions

M. Griffiths[1], *L. Campbell*[1], *M. Latter*[1], *D. Wyld*[1], *E. OMahoney*[2], *I. Holmes*[2], *L. Katchel*[2], *S. Baker*[2], *A. Hansen*[2], *M. Baronet*[3], *S. Rose*[3], *A. Karmann*[3], *D. Pattison*[1];
[1]*Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA,* [2]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [3]*AdvanCell, Sydney, AUSTRALIA.*

Aim/Introduction: ^{212}Pb PSMA SPECT/CT imaging has been shown to confirm the localisation of the in vivo alpha generator ^{212}Pb in PSMA-avid tumour lesions. ^{212}Pb decays into ^{212}Bi (60 min half-life) which either emits an alpha particle or decays into ^{212}Po (3 µs half-life) which emits an alpha particle; neither ^{212}Bi nor ^{212}Po produce imageable emissions. The alpha emitting ^{212}Bi atoms decay into ^{208}Tl (3 min half-life) which emit a 2.6MeV gamma. 2.6 MeV gamma interactions with atomic nuclei can cause pair production allowing imaging with a PET camera. The number of positrons per voxel is dependent on the number of gamma rays in the voxel and the density of the material. As photon density decreases with 1/distance^2 the highest photon density is associated with the highest concentration of ^{209}Tl / ^{212}Bi. We have investigated PET imaging of the ^{212}Pb decay chain in phantoms and in patients receiving ^{212}Pb-ADVC001 in the TheraPb trial (NCT05720130). ***Materials and Methods:*** ^{212}Pb point sources in glass capillary tubes in water filled phantoms were imaged to determine the FHWM. An IEC phantom was imaged with activities matching patient concentrations of 160 MBq administration of ^{212}Pb-ADCV001. Patient imaging following administration of 160 and 200 MBq of ^{212}Pb-ADVC001 were performed at two clinical sites using Siemens Vision PET cameras. ***Results:*** The FWHM of ^{212}Pb on the Vison was 4.9 mm. An IEC phantom with a concentration simulating a 160 MBq administration of ^{212}Pb-ADVC001, with zero background, allowed visualisation of the 13 mm sphere. There was increased background between the two largest spheres indicating pair production around the ^{212}Pb sources. The recorded counts were linear with radioactivity. Clinical imaging of ^{212}Pb PET pair production is feasible. Conventional scatter correction is not suitable due to the high proportion of down scattered gamma rays in the PET energy window compared to the number of pair production positrons. Blood pool activity in early time point images and out of field activity contribute to image background. Transaxial slices show diffuse localisation however MIP images provide a clearer indication of localisation of positrons hence ^{208}Tl and ^{212}Bi in lesions concordant with diagnostic PSMA PET imaging. ***Conclusion:*** Clinical ^{212}Pb PSMA PET imaging of ^{208}Tl gamma pair production confirms the localisation of ^{208}Tl, ^{212}Bi and hence alpha emissions from ^{212}Pb-ADVC001within PSMA-avid tumour lesions. Investigation of post processing of pair production PET images is needed to enhance image quality.

OP-291

A PET/CT Phantom Study on the Potential Overcorrection of Lesion Activity in Cortical Bone like Structures and a Potential Solution

J. Ni, *A. Haslauer, S. Nekolla;*
Department of Nuclear Medicine, TUM Klinikum Rechts der Isar, Technical University Munich, School of Medicine & Health, Munich, GERMANY.

Aim/Introduction: In PET/CT systems, an attenuation map (μ-map) is generated by extrapolating the CT Hounsfield units to 511 keV PET linear attenuation coefficients (LAC). However, due to the higher photoelectric effect at lower CT energies, high-density tissues like cortical bone may cause overcorrection of lesion activity. ***Materials and Methods:*** A 3D printed phantom (500 HU) using stone-like PLA based filament was used to simulate cortical bone. Different sized holes in the phantom wall allowed the lesions to simulate cortex intrusion. PCR tubes of different diameters (7mm, 10mm, 15mm) containing solidified mixture of ^{18}F-FDG and dental gypsum were fixed in dedicated cavities to simulate bone lesions, and the phantom was placed in a water bucket simulating a body. Identical tubes filled only with ^{18}F-FDG solution were fixed in the water bucket to simulate soft tissue lesions as reference. Additionally, two 28mm-diameter tubes containing ^{18}F-FDG solids and solution, respectively, were fixed in the cavity of the phantom to minimize partial volume effects. Scans were performed in a clinical digital PET/CT. To evaluate potential overcorrection, we used a cardiac-metal-artifact-reduction (cMAR) option, which is originally developed to reduce metal induced attenuation artifacts. This technique clips the LAC greater than 0.1 cm^{-1} in the μ-map to 0.1 cm^{-1}, and was used to evaluate the effect of the absence of cortical bone tissue in the attenuation correction. PET data were reconstructed using six different methods (FBP-TOF, OP-TOF, OP-TO PSF-TOF, and their corresponding cMAR versions) ***Results:*** For lesions with diameters of 7mm, 10mm, and 15mm, in reconstructions without cMAR, the mean and maximum tracer uptake concentrations in simulated bone lesions were significantly higher than those in soft tissue lesions, with the difference increasing with lesion size. FBP-TOF as most analytical reconstruction approach showed the most significant overestimation in the maximum value (up to 17.5% at 15 mm). cMAR significantly reduces the overestimation across all reconstruction methods, especially in PSF-TOF cMAR, where the differences dropped below 4% for all sized lesions. For the 28mm-diameter lesions, cMAR reduced the overestimation of the maximum tracer uptake concentration from more than 10% to approximately 0% in all reconstruction methods. ***Conclusion:*** In PET/CT scans, the tracer uptake concentration is potentially overestimated in bone cortical invasion lesions. This can be attributed to an overcorrection in high-density tissue due to technical limits of the CT to 511keV extrapolation. Clipping cortical bone LAC in attenuation correction could be a potential solution.

OP-292

The MELATEP study: Diagnostic performance of [18F]FDG-PET/CT follow-up for patients on adjuvant immunotherapy for melanoma in real-life setting

A. Bauduer, *V. Sibaud, C. Pages, F. Courbon, M. Terroir;*
Oncopole, Toulouse, FRANCE.

Aim/Introduction: There is no international consensus on the optimal follow-up for patients treated with adjuvant immunotherapy after melanoma resection. Although [18F]FDG-PET/CT is frequently used, its relevance remain debated. The objective was to evaluate the diagnostic accuracy of FDG-PET/CT in real-life setting. ***Materials and Methods:*** This was a single-center retrospective study enrolling 278 patients with resected stage IIB to IV melanoma treated with adjuvant immunotherapy : 151 patients were monitored by CT and 127 patients by FDG-PET/CT. Recurrence was confirmed by biopsy, other imaging or clinical follow-up. Incidence of recurrence, sensitivity, specificity, median time to detect recurrence and mean lesion size were outcome measures. ***Results:*** Median follow-up was 31 months. 42% recurrences were observed : 39% by CT (59/151) and 45% by FDG-PET/CT (57/127). Sensitivity and specificity were respectively 89% and 91% for FDG-PET/CT and 73% and 99% for CT. The median time to detect recurrence was 9 months for FDG-PET/CT and 12 months for CT. The main site of recurrence was lymph nodes in both groups. The mean lesion size detected was 21 mm by CT and 16 mm by FDG-PET/CT. 18% of total recurrences were missed by cross-sectional imaging. The false negative rates were 25% in the CT group (15/59) and 11% in the FDG-PET/CT group (6/57). The skin represented by far the main site of recurrence (81%), of which 76% occurring on limbs. These lesions were discovered by clinical follow-up or ultrasound. 69% of patients received adjuvant immunotherapy for a minimal 12 month-duration. The main cause of premature discontinuation was toxicity occurring in 18% of patients. Gastrointestinal and hepatic toxicities were the most frequent (47% of all toxicities). ***Conclusion:*** [18F]FDG-PET/CT is an effective tool for monitoring patients treated with adjuvant immunotherapy for melanoma. In comparison with CT, it detects smaller recurrences at an earlier stage. It seems particularly relevant for cutaneous recurrence especially on limbs. Its lower specificity should encourage early reassessment in case of doubtful imaging. ***References:*** Andersen, J.A.S., Spatzek, A.D., Vilstrup, M.H. et al. The diagnostic accuracy and clinical impact of FDG-PET/CT follow-up for patients on adjuvant immunotherapy for high-risk malignant melanoma. Eur J Nucl Med Mol Imaging 49, 2342-2351 (2022)

DYNAMO: Dynamic Total Body FDG PET/CT and Kinetic Modeling for Early Lesion-Level Response Assessment in Metastatic Melanoma Undergoing Immunotherapy - Preliminary Results from a Prospective Study

A. Di Giorgio[1], *D. Dall'Olio*[2], *I. Brusa*[3], *P. Marchese*[4], *G. Siepe*[5], *M. Assenza*[6], *A. Zappacosta*[3], *C. Nanni*[3], *B. Melotti*[4], *G. Castellani*[2,7], *S. Fanti*[1,3], *A. Farolfi*[3];*
[1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY, [3]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Medical Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]Radiation Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [6]Professional Development and Implementation of Research in Health Professions Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [7]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Malignant melanoma, characterized by its aggressive nature with rising incidence and frequent metastasis, remains a challenge for timely treatment response assessment despite advancements like immunotherapy and stereotactic radiotherapy. Long-axial field-of-view(LAFOV)-PET/CT, a recent technology enabling sensitive, single-bed dynamic whole-body imaging, may improve early detection of therapeutic response and disease progression. Preliminary data suggest LAFOV-PET/CT offers superior lesion detection and earlier identification of therapy-induced metabolic changes over conventional PET/CT. This prospective study(DYNAMO) investigates whether dynamic LAFOV FDG PET/CT with kinetic modeling can identify early metabolic changes in melanoma lesions predictive of treatment response ***Materials and Methods:*** Prospective single-center study consecutively enrolling treatment-naïve metastatic melanoma

patients initiating first-line systemic immunotherapy(CE AVEC:447/2024/Oss/AOUBo). Patients underwent a 60-minutes total-body dynamic [18F]-FDG PET/CT scan using the uExplorer system. Images were evaluated qualitatively and quantitatively for metabolic and dynamic parameters. [18F]-FDG uptake and pharmacokinetics were assessed by SUV by two–tissue compartment models(reversible 2TC, irreversible 2TiC). Model selection used mean absolute scaled error(MASE) and the Akaike Information Criterion(AIC). A post-treatment [18F]-FDG-PET/CT was performed on a digital tomograph for response assessment. Lesions were defined as responding if they demonstrated complete metabolic resolution or a reduction in SUVmax on follow-up imaging. Kinetic parameters(K_1, k_2, k_3, K_i, DV) were compared between responding and non-responding lesions and with healthy reference tissues. Lesions treated with concurrent stereotactic body radiation therapy(SBRT) were excluded. ***Results:*** Fourteen patients(median age 65 years, IQR 63-71; 50% female) underwent dynamic PET/CT. Four patients completed follow-up with post-treatment scans. Overall, 12(85%) patients had positive baseline scanfor metastatic disease (median lesion SUVmax 6.1, IQR 4.0-8.8, SUVmean 4.0, IQR 3.2-5.7), while 2(15%) were negative. Among the 14 patients, a total of 34 FDG-positive lesions were identified: 14(41%) pulmonary and 20(58%) lymphatic/subcutaneous metastases. Kinetic parameters K_1, k_2, k_3, K_i, and DV) significantly differed between lesions and healthy reference tissues such as liver(p=0.0019), lung parenchyma(p=0.0006), and muscle(p=0.006). In a region-based analysis, among 12 lesions with paired pre- /post-scans, responding lesions demonstrated statistically significant differences in K_1(p=0.0136), k_3(p=0.0087) , and K_i(p=0.0055) compared to non-responding lesions. Baseline SUVmax and SUVmean did not significantly differ between responding and non-responding lesions(p=0.1047 and p=0.0896, respectively). ***Conclusion:*** Dynamic LAFOV-FDG PET enables extraction of Kinetic parameters that may outperform conventional SUV in early discrimination of treatment response in metastatic melanoma. K_1, k_3, and K_i appear particularly promising for lesion-level response assessment. These preliminary data support the potential role of dynamic LAFOV-[18F] FDG-PET/CT as a biomarker for guiding immunotherapy in melanoma.

OP-294

Artificial intelligence-assisted assessment of metabolic response to tebentafusp in metastatic uveal melanoma: a long axial field-of-view [^{18}F]FDG PET/CT study

C. Sachpekidis[1], *D. Machiraju*[2], *C. Ziener*[1], *L. Edenbrandt*[3], *J. C. Hassel*[4], *A. Dimitrakopoulou-Strauss*[1];
[1]*German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [2]*National Center for Tumor Diseases (NCT), Heidelberg, GERMANY,* [3]*Sahlgrenska University Hospital, Gothenburg, Gothenburg, SWEDEN,* [4]*National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: Tebentafusp, a T-cell receptor-bispecific molecule targeting glycoprotein 100 and CD3, is the first systemic therapy to significantly improve survival in treatment-naïve HLA-A*02:01+ adult patients with unresectable or metastatic uveal melanoma (mUM). To identify potential surrogate markers of response, we investigate the prognostic value of [^{18}F]FDG PET/CT in monitoring treatment response in mUM patients receiving tebentafusp. ***Materials and Methods:*** Fifteen patients with mUM undergoing tebentafusp therapy were evaluated with [^{18}F]FDG PET/CT at baseline and at 3 months, using a long axial field of view (LAFOV) PET/CT system (Biograph Vision Quadra, Siemens Healthcare). Tumor response was assessed according to PET-based metabolic criteria: EORTC, PERCIST, and immunotherapy-modified PERCIMT. Metabolic responses were classified into complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), or progressive metabolic disease (PMD), and dichotomized into disease control (DC = CMR + PMR + SMD) vs. PMD. Whole-body metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were quantified using a 3D AI-based tool (RECOMIA), with occasional manual refinements for optimal delineation. Liver tissue MTV and TLG were also calculated. Overall survival (OS) was assessed for all patients. ***Results:*** Median follow up [95% CI] was 14.1 months [12.9 months - NA]. PET-based response assessments yielded the following disease control rates and corresponding median OS:• EORTC: 4 DC (OS: 24.5 months, 95% CI: NA-NA); 11 PMD (OS: 14.6 months, 95% CI: 14.3-NA)• PERCIST: 6 DC (OS: 24.5 months, 95% CI: NA-NA); 9 PMD (OS: 14.6 months, 95% CI: 14.3-NA)• PERCIMT: 9 DC (OS: 24.5 months, 95% CI: 14.6-NA); 6 PMD (OS: 14.3 months, 95% CI: 3.3-NA)Across all criteria, patients achieving DC showed a trend toward improved OS, most notably with PERCIST (p=0.08). AI-derived metrics revealed that high whole-body baseline MTV and TLG (above median) of tumor lesions were associated with significantly shorter OS (MTV: 16.9 vs. 27.2 months; TLG: 16.9 vs. 27.2 months; p<0.05). Similarly, elevated MTV and TLG at 3 months were predictive of poorer survival (MTV: 14.3 vs. 24.5 months; TLG: 14.3 vs. 24.5 months; p<0.05). Additionally, increased liver MTV and TLG at 3 months were associated with shorter survival (p < 0.05). ***Conclusion:*** Automated volumetric assessment of [^{18}F]FDG PET/CT using whole-body and liver MTV and TLG provides robust prognostic insights in tebentafusp-treated mUM patients. These AI-derived metrics outperform conventional PET response criteria and offer a promising tool for response monitoring and risk stratification.

OP-295

Pseudoprogression Rates in the Dutch Melanoma Population suggest Opportunities for Cost-Effective Use of [^{18}F]FDG PET/CT during Therapy with Immune Checkpoint Inhibitors

S. van Mossel[1,2], *D. Vriens*[3], *D. Kersbergen*[1], *M. Bloem*[4], *E. Kapiteijn*[1], *H. Koffijberg*[2], *S. Saing*[2], *L. De Geus-Oei*[1,2,5];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*Radboud University Medical Center, Nijmegen, NETHERLANDS,* [4]*Dutch Institute for Clinical Auditing, Leiden, NETHERLANDS,* [5]*Delft University of Technology, Delft, NETHERLANDS.*

Aim/Introduction: Unconventional modes of responses, beyond RECIST criteria (v1.1), are frequently observed in patients treated with immune checkpoint inhibitors, showing delayed apparent therapy efficacy. Therefore, healthcare professionals in melanoma care should reconsider the conventional ways of interpreting radiological tumour responses. The joint EANM/SNMMI/ANZSNM practice guidelines on recommended use of [^{18}F]FDG PET/CT during immunomodulatory treatments in patients with solid tumours provide procedure standards for a more accurate interpretation of tumour responses in the rapidly evolving immunotherapeutic landscape. [^{18}F]FDG PET/CT is especially recommended early after therapy initiation, commonly after 8-12 weeks (3-4 cycles), to complement contrast-enhanced CT and resolve discordant findings related to pseudoprogression and mixed or dissociated responses. This study builds on the joint EANM/SNMMI/ANZSNM practice guidelines. It indicates pseudoprogression rates in the Dutch Melanoma Treatment Registry (DMTR) and relates decreasing pseudoprogression rates, when using [^{18}F]FDG PET/CT, to potential cost savings and clinical benefits for melanoma patients. ***Materials and Methods:*** This study consisted of a care pathway analysis to map the specific clinical decisions for melanoma patients in the Netherlands and a review of a Dutch response-based survival model [1]. In 514 patients from the Dutch response-based survival model with known response status at 3 and 6 months after therapy initiation, changes in response status were analysed. Pseudoprogression and mixed responses were related to the costs of ineffective therapy in the event of true

tumour progression, and missing an early opportunity to shift to alternative treatment options. ***Results:*** Pseudoprogression was suggestive for at least 23 patients. Ineffective therapy in the event of true tumour progression was suggestive for 262 patients, resulting in premature death within 6 months after therapy initiation in 147 patients. A subgroup of at least 39 patients was suggestive of missing an early opportunity to start an alternative (likely effective) treatment. Immunotherapy-related costs were estimated at €10,000 per month per patient, where medication costs contribute to at least 80% of these costs. High therapy costs contrast sharply with the cost of [^{18}F]FDG PET/CT estimated at €1,000 per scanning procedure, suggesting an opportunity for cost-effective use of [^{18}F]FDG PET/CT compared to usual care. ***Conclusion:*** We suggest a clear opportunity for potential cost-effective use of [^{18}F]FDG PET/CT during immunomodulatory treatments. However, full health economic evaluations are lacking (but needed). ***References:*** [1] van Breeschoten J et al. Population mortality in advanced melanoma patients with and without response and progression; data from the Dutch Melanoma Treatment Registry. Eur J Cancer. 2023 Mar;182:132-143

OP-296

Comparison of melanin-targeted [^{18}F]DMPY2 and [^{18}F] FDG PET/CT in Advanced Melanoma Patients

Y. Yang, *M. Zhou, J. Su, X. Chen, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Our previous research demonstrated that a melanin-targeted PET probe [^{18}F]DMPY2 outperformed [^{18}F]FDG in detecting primary lesions and sentinel lymph nodes in operable melanoma patients [1]. This study aims to compare the diagnostic efficacy of [^{18}F]DMPY2 PET/CT and [^{18}F]FDG PET/CT in advanced melanoma patients, with a focus on detecting small-sized (<1 cm) metastases in the brain and liver, where [^{18}F]FDG typically shows limited sensitivity. ***Materials and Methods:*** Twenty-six patients (14 men, 12 women; mean age: 54 ± 18 years; mean weight: 60.54 ± 2.14 kg) with histologically confirmed melanoma underwent both [^{18}F]DMPY2 PET/CT and [^{18}F]FDG scans within one week. The mean injected activities were 6.56 ± 0.22 mCi for [^{18}F]DMPY2 and 6.64 ± 0.26 mCi for [^{18}F]FDG. Lesion positivity rates and standardized SUVmax (calculated as SUVmax divided by the aortic arch SUVmean) were compared between the two tracers in both patient- and lesion-based analyses. ***Results:*** The cohort comprised eleven melanoma patients undergoing initial staging and fifteen under restaging, including nine with stage III and seventeen with stage IV disease. Both [^{18}F]DMPY2 and [^{18}F]FDG detected all eleven primary lesions, with comparable SUVmax values (14.24 vs. 6.04, $p = 0.016$). Moreover, [^{18}F]DMPY2 PET/CT demonstrated significantly higher SUVmax values in brain (14.28 vs. 0.68, $p < 0.0001$), liver (10.65 vs. 4.76, $p = 0.0005$), lung (8.80 vs. 4.84, $p = 0.028$), bone (14.71 vs. 5.71, $p = 0.009$), lymph node (11.82 vs. 7.28, $p < 0.0001$), and other metastatic lesions (20.02 vs. 6.71, $p = 0.0002$) compared to [^{18}F]FDG. In terms of sensitivity, [^{18}F]DMPY2 PET/CT was superior to [^{18}F]FDG PET/CT across brain metastases (100% [4/4] vs. 25% [1/4]) and liver (100% [6/6] vs. 83% [5/6]). It was comparable to [^{18}F]FDG PET/CT in primary tumors, lung, bone, lymph nodes, and other metastases. Lesion-based analysis showed that [^{18}F]DMPY2 identified 45 more metastatic foci than [^{18}F]FDG in brain (13 vs. 1), liver (41 vs. 35), lungs (144 vs. 133), bone (209 vs. 202), lymph nodes (299 vs. 290), and other metastases (90 vs. 89). ***Conclusion:*** [^{18}F] DMPY2 PET/CT demonstrates superior diagnostic performance compared to [^{18}F]FDG PET/CT in advanced melanoma, particularly in detecting small-sized metastases in the brain and liver. [^{18}F] DMPY2 may serve as a promising imaging agent for accurate staging and comprehensive assessment of metastatic burden in melanoma patients. ***References:*** [1] Yang, Y., Ming Z., Shuang, Z., et al. (2025). First-in-human PET imaging and evaluation of melanin-targeted [^{18}F]DMPY2 in malignant melanoma patients. Theranostics. Doi:10.7150/thno.109243

[^{68}Ga]Ga-DPI-4452 PET/CT for Staging of Patients with Clear Cell Renal Cell Carcinoma (ccRCC)

A. Küper[1], *D. Kersting*[1], *K. Pabst*[1], *M. Nader*[1], *C. Darr*[2], *L. Umutlu*[3], *U. Krafft*[2], *V. Grünwald*[2], *B. Hadaschik*[2], *K. Herrmann*[1], *W. Fendler*[1];
[1]*Department of Nuclear Medicine, University Hospital Essen, GERMANY,* [2]*Department of Urology, University Hospital Essen, GERMANY,* [3]*Department of Radiology, University Hospital Essen, GERMANY.*

Aim/Introduction: The aim of this study was to evaluate the diagnostic accuracy of [^{68}Ga]Ga-DPI-4452 PET/CT in comparison to conventional imaging (+/- [^{18}F]FDG PET/CT), as well as its safety and theranostic potential in ccRCC. ***Materials and Methods:*** From July 2024 to March 2025, 20 patients (62y, IQR 14y) with histologically confirmed ccRCC (T1, n=5; T2, n=3; T3, n=6; T4, n=0; unknown, n=6) were examined. 15 patients also underwent [^{18}F] FDG PET/CT (≤ 2 weeks). Each scan was assessed for the presence of primary tumor or recurrence, as well as for the detection of metastases in local and distant lymph nodes, liver, bones, and other regions. The analysis included SUVmax/SUVmean tumor-to-liver ratios (TLR), and tumor volume (presented as mean ± SD). ***Results:*** The average injected activity was 84 MBq for [^{68}Ga]Ga-DPI-4452 and 260 MBq for [^{18}F]FDG, with an average uptake time of 46 to 76 minutes. No acute or long-term side effects were observed. Two out of 20 patients (10 %) showed no viable tumor in the current examinations; both were receiving targeted therapy. One of them had residual pulmonary metastases and presumably reactive hilar lymph nodes on CT, without DPI or FDG uptake uptake. A total of 36 [^{68}Ga]Ga-DPI-4452-positive regions were detected in 18 (90 %) patients. In patients who received dual PET/CT imaging, 25 [^{68}Ga] Ga-DPI-4452-positive regions were identified, 9 of them were also detected by [^{18}F]FDG PET/CT (36 %) and one confirmed by biopsy (4 %). No [^{18}F]FDG-positive [^{68}Ga]Ga-DPI-4452-negative regions were detected. The average SUVmax of all [^{68}Ga]Ga-DPI-4452-positive regions was 54.5 ± 65.1. The highest regional uptake was measured in bone metastases (average SUVmax 139.2 ± 146.6), and the highest physiological uptake in the stomach (average SUVmax: 77.0 ± 53.9). Tumor segmentation revealed 131 [^{68}Ga]Ga-DPI-4452-positive lesions (total volume 380.6 cm^3). The average SUVmean for all [^{68}Ga]Ga-DPI-4452-positive lesions was 27.4 ± 31.4. [^{68}Ga]Ga-DPI-4452 showed a high TLR with a global average TLR (SUVmean / liver SUVmean) of 10.3 ± 8.0 ***Conclusion:*** [^{68}Ga] Ga-DPI-4452 PET/CT is a promising imaging tool for ccRCC with superior detection when compared to [^{18}F]FDG PET/CT. High SUV values indicate potential for a theranostic application.

OP-298

First-in-Human Phase I Study of [^{68}Ga]Ga-OncoCAIX: Preliminary Results on Safety, Dosimetry, Pharmacokinetics, and Diagnostic Performance

F. Gelardi[1], *M. Sollini*[2,1], *C. Pini*[2,1], *L. Antunovic*[1], *A. Maielli*[1], *R. Petrelli*[1], *G. Bonfitto*[1], *A. Tudda*[1], *M. Minotti*[1], *J. Mock*[3], *S. Cazzamalli*[3], *S. Oehler*[3], *M. Müller*[3], *D. Neri*[3], *A. Alessi*[4], *P. Erba*[5,6], *A. Chiti*[2,1];
[1]*IRCCS Ospedale San Raffaele, Milan, ITALY,* [2]*Università Vita-Salute San Raffaele, Milan, ITALY,* [3]*Philochem AG, Otelfingen, SWITZERLAND,* [4]*Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY,* [5]*Università degli Studi di Milano-Bicocca, Milan, ITALY,* [6]*ASST Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, ITALY.*

Aim/Introduction: Conventional imaging techniques remain limited in accurately characterising and staging clear cell renal cell carcinoma (ccRCC). Carbonic anhydrase IX (CAIX), a transmembrane protein overexpressed in ccRCC, has emerged as a promising molecular target for imaging. [^{68}Ga]Ga-OncoCAIX is a novel radiopharmaceutical with high in vitro selectivity for CAIX and a favourable biodistribution in preclinical models, showing high tumour-specific uptake and minimal background in healthy tissues, including the kidney. We report the preliminary first-in-

human data from an ongoing multicentre, prospective, phase I clinical trial evaluating the safety, dosimetry, pharmacokinetics, and diagnostic performance of [^{68}Ga]Ga-OncoCAIX in patients with suspected ccRCC. ***Materials and Methods:*** The present study is planned to include up to 20 patients with renal masses suspected of ccRCC. Enrolled patients are divided into two cohorts: cohort A includes six patients with suspected primary tumour only, while cohort B can also include patients with metastatic disease. All patients receive a single intravenous administration of 250 MBq of [^{68}Ga]Ga-OncoCAIX, followed by serial PET/CT imaging at 0 - 30 min, 60 min, and 120 min post-injection. Blood and urine samples are collected at predefined time points to assess pharmacokinetics and excretion. Adverse events (AEs) are reported and graded according to Common Terminology Criteria for Adverse Events (CTCAE) v.5.0. Where available, [^{68}Ga]Ga-OncoCAIX PET imaging results are correlated with histopathological findings from biopsy or surgical specimens. ***Results:*** As of 2 May, three patients have been enrolled and undergone [^{68}Ga]Ga-OncoCAIX PET imaging. All patients presented with an incidental renal mass on contrast enhanced CT suspicious for ccRCC and were scheduled for surgical resection. No adverse events were reported during the study. [^{68}Ga]Ga-OncoCAIX showed favourable biodistribution with renal excretion, low activity in healthy kidney parenchyma and physiological uptake in the gastrointestinal tract, particularly in the stomach. In two patients, moderate radiopharmaceutical uptake was observed in the suspected renal mass early at the post-injection acquisition, with increasing intensity at 60- and 120-minutes scans (SUVmax 25.5 and 60.8 at 60 minutes, respectively). One patient showed no significant uptake in the suspected renal lesion. ***Conclusion:*** Preliminary first-in-human data showed that [^{68}Ga]Ga-OncoCAIX is safe and well tolerated, with favourable biodistribution and low background activity in healthy kidney tissue. Early imaging results suggested promising tumour-to-background contrast in suspected ccRCC lesions. Histopathological confirmation will determine the diagnostic accuracy for ccRCC discrimination and potential clinical utility.

OP-299

The impact of ^{68}Ga-Pentixafor PET/CT imaging with solid tumours, a comparison with ^{18}F-FDG: a prospective cross-sectional study

B. Hadebe-Chonco[1], *L. Harry*[1], *N. Ndlovu*[1], *M. Patel*[1], *L. Gabela*[1], *S. Masikane*[1], *V. Pillay*[1], *T. Nxasana*[1], *T. Mkhize*[1], *M. Msimang*[2], *M. Sathekge*[3], *M. Vorster*[1];
[1]*University of KwaZulu Natal, Nuclear Medicine Department, Durban, SOUTH AFRICA,* [2]*University of KwaZulu Natal, Anatomical Pathology Department, Durban, SOUTH AFRICA,* [3]*Department of Nuclear Medicine, University of Pretoria, Pretoria, SOUTH AFRICA.*

Aim/Introduction: ^{68}Ga-Pentixafor, offers a novel, non-invasive imaging tool for CXCR4 expression. Although it has shown promising utility in hematological malignancies, evidence in solid tumours remains limited. This study aimed to evaluate the impact of ^{68}Ga-Pentixafor PET/CT in patients with solid tumours, comparing uptake patterns with ^{18}F-FDG PET/CT and CXCR4 immunohistochemistry (IHC) to determine whether CXCR-4 targeted imaging may be a surrogate for IHC staining. ***Materials and Methods:*** One hundred and nineteen patients with histologically proven cancers of the breast (n=53), head and neck (n=23), gynecological (34), male genitourinary tract (n=2), gastrointestinal tract (n=6), lung (n=1) and pancreas (n=1) underwent ^{68}Ga-Pentixafor PET/CT imaging. ^{18}F-FDG PET/CT images were available in 92/119 cases (77%). Semi-quantitative parameters including maximum standardized uptake values (SUVmax), total lesion uptake (TLU), metabolic tumour volume (MTV) and tumour-to-background ratios (TBR) of primay lesions were measured and correlated with HIV status, tumour grade and CXCR4 immunohistochemistry staining (n=69) using the t-test or Wilcoxon test as appropriate. Pearson correlation coefficients were used to assess the correlation between ^{68}Ga-Pentixafor uptake and overall survival. ***Results:*** Seventy-nine percent (94/119) were female, the median age (Q1-Q3) was 53.0(47.0-68.0). Forty five percent (55/119) of patients (46%) were HIV positive. ^{68}Ga-Pentixafor uptake was visually detectable in 105/119 (88%) of the primary tumours and was generally lower and more heterogeneous than ^{18}F-FDG. However, high uptake was observed in aggressive tumour subtypes, including triple-negative breast cancer (TNBC), high-grade tumours and HIV-positive patients. HIV-positive patients were significantly younger median age (IQR) 48.0(42.5-58.0) compared to HIV-negative 53.0(47.0-68.0) p=0.012. Triple-negative breast cancer, vulva, ovarian and nasopharyngeal carcinomas demonstrated higher ^{68}Ga-Pentixafor avidity than the other solid tumours. A significant positive correlation was found between ^{68}Ga-Pentixafor uptake and CXCR4 IHC expression in head and neck cancer r= 0,5 p=0,02. Notably, ^{68}Ga-Pentixafor detected additional metastatic lesions in the brain and skull, while ^{18}F-FDG remained superior in identifying skeletal metastases. A weak negative correlation was also noted between ^{18}F-FDG SUVmean and overall survival r=-0,1983 (p=0.057). ***Conclusion:*** ^{68}Ga-Pentixafor uptake was high in triple-negative breast cancer, vulva, ovarian and nasopharyngeal carcinomas. ^{68}Ga-Pentixafor PET/CT may complement ^{18}F-FDG, adding value particularly in the detection of brain lesions and in HIV-infected individuals with breast cancer. Future studies should explore its value in prognostication and guiding CXCR4-targeted therapies. The high uptake of ^{68}Ga-Pentixafor in HIV-infected patients with solid malignancies emphasizes the importance of exploring the potential synergistic effect of CXCR4 targeted therapies in these patients.

OP-300

Prospective Head-to-Head Comparison of ^{18}F-FDG PET/CT and ^{18}F-FAPI-42 PET/CT for Assessing Inguinal Lymph Node Metastases in Penile Squamous Cell Carcinoma

X. Tong[1], *W. Ouyang*[1], *W. Hou*[1], *C. Zhou*[1], *H. Fu*[1], *J. Liu*[1], *Q. Wang*[1], *Z. Liu*[2], *K. Cao*[1], *K. Yao*[1], *X. Li*[3], *L. Wang*[1], *M. Zhao*[1];
[1]*Third Xiangya Hospital of Central South University, Changsha, Hunan, CHINA,* [2]*The Affiliated Cancer Hospital of Xiangya School of Medical, Changsha, Hunan, CHINA,* [3]*Medical University of Vienna, Vienna, Austria, AUSTRIA.*

Aim/Introduction: This study aimed to compare the diagnostic performance of ^{18}F-FAPI-42 PET/CT and ^{18}F-FDG PET/CT in detecting inguinal lymph node (ILN) metastases in penile squamous cell carcinoma (PSCC) and to explore the correlation between tracer uptake and fibroblast activation protein (FAP) and glucose transporter 1 (GLUT1) expression. ***Materials and Methods:*** This prospective study included 21 patients with clinically node-positive (cN+) PSCC, who underwent both ^{18}F-FDG PET/CT and ^{18}F-FAPI-42 PET/CT within one week prior to surgical resection. Visual PET/CT interpretations were compared with histopathological findings, and quantitative PET parameters (SUVmax, SUVmean, TBR) were analyzed. McNemar's test was used to compare diagnostic performance metrics, and Spearman's correlation assessed the relationship between tracer uptake and immunohistochemical FAP/GLUT1 expression ***Results:*** A total of 359 lymph nodes were dissected. ^{18}F-FAPI-42 PET/CT exhibited superior diagnostic performance compared to ^{18}F-FDG PET/CT, with higher staging accuracy (99.72% vs. 91.92%), sensitivity (95.65% vs. 86.96%), and specificity (100% vs. 92.26%). ^{18}F-FAPI-42 identified 22 of 23 metastatic LNs, whereas ^{18}F-FDG PET/CT identified 19. Additionally, ^{18}F-FDG PET/CT produced 26 false positives, while ^{18}F-FAPI-42 PET/CT had none, highlighting its superior specificity in differentiating metastatic from inflammatory lymphadenopathy. In patient-based analyses, ^{18}F-FDG PET/CT demonstrated diagnostic performance with 9 true-positive, 1 false-negative, 8 true-negative, and 3 false-positive cases, yielding an overall accuracy of 80.95%. In comparison, ^{18}F-FAPI PET/CT exhibited superior diagnostic capability, achieving 100% accuracy in detecting LNs metastases among PSCC, with no false-positive or false-negative results observed. Immunohistochemical analysis revealed a strong correlation between FAP expression and ^{18}F-FAPI-42 SUVmax ($r = 0.78$, $P < 0.001$), while GLUT1 expression correlated with ^{18}F-FDG SUVmax ($r = 0.81$, $P < 0.001$) ***Conclusion:*** ^{18}F-FAPI-42 PET/CT outperformed ^{18}F-FDG PET/CT in ILN staging, demonstrating higher accuracy and specificity with fewer false positives. These findings suggest that ^{18}F-FAPI-42 PET/CT could

refine nodal staging, reduce unnecessary inguinal lymph node dissection (ILND), and enhance clinical decision-making in PSCC management.

First-in-human study of a ^{18}F-labeled PET tracer for glutamate AMPA receptors, [^{18}F]K-40

S. Ichijo[1], *Y. Kimura*[2], *T. Arisawa*[1], *M. Hatano*[1], *W. Nakajima*[1], *T. Miyazaki*[1], *T. Eiro*[1], *Y. Takada*[1], *R. Iai*[1], *A. Sano*[1], *M. Sonoda*[1], *Y. Takayama*[1], *T. Takahashi*[1];
[1]*Yokohama City University, Yokohama, JAPAN,* [2]*Kindai University, Osaka, JAPAN.*

Aim/Introduction: Although alteration of glutamate α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid receptor (AMPAR) distribution has been believed to underlie physiological and pathological neuronal function, there has been no modality to evaluate AMPA receptors in the living human. [11C]K-2, the PET tracer we previously developed, is the first and only technology to visualize AMPAR densities in the living human brain. Despite its favorable kinetics as a PET tracer, the short half-life of the 11C limits availability of [11C]K-2. We recently developed an 18F-labeled PET tracer, [18F]K-40, which demonstrated AMPAR-specific binding properties and brain distribution similar to that of [11C]K-2 in preclinical studies. The purpose of this first-in-human study is to evaluate the properties of [18F]K-40 in the human and to compare the kinetics and PET images of [18F]K-40 with those of [11C]K-2. ***Materials and Methods:*** Five healthy volunteers were enrolled and underwent dynamic PET scanning using [18F]K-40 and [11C]K-2. Non-displaceable binding potential (BPND) with white matter as reference was calculated by Logan graphical analysis using tissue time-activity curves (tTACs), and VT of [18F]K-40 was calculated using plasma time-activity curves (pTACs). The intraindividual correlation between the BPND values obtained for [18F]K-40 and [11C]K-2 was examined. To optimize the time window for PET scanning, BPND and standardized uptake value ratio (SUVR) were evaluated. ***Results:*** The tTACs of [18F]K-40 showed similar curves to those of [11C]K-2. Logan graphical analysis using pTACs revealed reversible binding of [18F]K-40. BPND obtained with [18F]K-40 and [11C]K-2 significantly correlated in each corresponding region and showed very good correlation, which indicated that K-40, as observed with K-2, can provide PET images that reflect the amount of AMPA receptors. A good linear relationship was observed between BPND and the summation image of SUVR between 40 and 50 minutes after radiotracer injection. ***Conclusion:*** [18F]K-40, as [11C]K-2, has favorable binding properties as an AMPA-PET tracer. Thus, [18F]K-40 could characterize AMPAR distribution in pathophysiological conditions of the brain and facilitate the development of novel diagnostics of neuropsychiatric disorders.

Quantitative Detection of Limbic-predominant Age-related TDP-43 Encephalopathy (LATE) Using Brain FDG PET: An IAEA Multinational Neuroimaging Consortium

T. Thientunyakit[1], *J. Arbizu*[2], *M. Garcia-Granero*[3], *D. Cross*[4], *A. Damián*[5], *J. Warwick*[6], *J. Jamsek*[7], *J. Reimand*[8], *M. Tripathi*[9], *M. Trošt*[7], *N. Sultana*[10], *O. Pellet*[11], *D. Paez*[11], *S. Minoshima*[4];
[1]*Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, THAILAND,* [2]*Clinica Universidad de Navarra, Pamplona, SPAIN,* [3]*Consultoria Estadistica Marta Garcia-Granero, Pamplona, SPAIN,* [4]*The University of Utah, Salt Lake City, UT, UNITED STATES OF AMERICA,* [5]*Centro Uruguayo de Imagenología Molecular (CUDIM), Montevideo, URUGUAY,* [6]*Stellenbosch University, Stellenbosch, SOUTH AFRICA,* [7]*University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [8]*North Estonia Medical Centre, Tallinn, ESTONIA,* [9]*All India Institute of Medical Sciences, New Delhi, INDIA,* [10]*NINMAS, Bangladesh Atomic Energy Commission (BAEC), Dhaka, BANGLADESH,* [11]*The International Atomic Energy Agency, Vienna, AUSTRIA.*

Aim/Introduction: Limbic-predominant age-related TDP-43 encephalopathy (LATE) is increasingly recognized among dementia patients. Brain FDG PET has revealed unique metabolic signatures associated with LATE. This study investigated a quantitative method for detecting LATE-related changes in brain FDG PET based on autopsy-confirmed LATE and Alzheimer's disease (AD) cases. The method was applied to mild cognitive impairment or mild AD patients with possible comorbidities recruited through the International Atomic Energy Agency (IAEA) Multinational Neuroimaging Consortium. ***Materials and Methods:*** Brain FDG PET scans from 4 groups were analyzed with NEUROSTAT/3D-SSP: 133 IAEA cohort cases from 6 countries (mean age 67.8±9.1 years, MMSE 24.7±3.5, CDR 0.6±0.4); 6 autopsy-confirmed LATE cases (ADNI); 32 autopsy-confirmed AD cases (University of Utah); and 20 healthy controls with negative amyloid PET. Group Z-score maps for autopsy-confirmed LATE and AD were generated using the healthy controls for reference. Individual Z-score maps of the IAEA cohort cases were generated using the same controls. To quantify individual's disease patterns, Z-score products were calculated by multiplying each individual's Z-score map with the disease template (LATE or AD) on a pixel-by-pixel basis, averaging across the brain. Z-score product thresholds of 16 (Z=4x4) and 9 (Z=3x3) were used to identify probable LATE and AD, respectively. ***Results:*** The autopsy-proven LATE template demonstrated unique hypometabolism in the medial temporal lobe, anterior temporal lobe, and inferior frontal lobe, contrasting with the relatively mild medial temporal hypometabolism in AD. Among the IAEA cohort, 8 patients (6%) were identified as probable LATE (mean age 67.3±8.1, MMSE 23.9±3.1, CDR 0.79±0.3) and 15 (11%) showed features of both LATE and AD (mean age 71.1±8.8, MMSE 21.1±2.2, CDR 0.80±0.3), indicating a total 17% prevalence of LATE pathology. Visual inspection confirmed typical LATE patterns in these patients, and 17 additional cases (13%) showed subthreshold LATE features. Among probable LATE cases, 77% had positive amyloid biomarkers (amyloid PET or CSF analysis). ***Conclusion:*** Brain FDG PET combined with Z-score product analysis based on autopsy-confirmed LATE and AD cases reveled probable LATE pathology in patients with MCI or mild AD. While LATE findings can exist independently, a larger proportion of cases demonstrated co-existing LATE and AD pathologies, further supported by positive amyloid biomarkers. The notable presence of LATE pathology in this population underscores the need for further investigation into the epidemiology of LATE and its potential synergistic relationship with AD.

OP-303

Variations in Glucose Metabolism Covariance Pattern Linked to Aβ Status in Subjective Cognitive Decline

Aim/Introduction: Subjective Cognitive Decline (SCD) lies between cognitively normal individuals and those with Mild Cognitive Impairment (MCI) on the Alzheimer's Disease (AD) clinical continuum. While not all SCD individuals progress into MCI or AD dementia, concomitant Amyloid-beta (Aβ) positivity significantly increases the risk[1]. Investigating differences in glucose metabolism between Aβ-positive and Aβ-negative SCD patients offers a unique opportunity to help illuminate early metabolic changes associated with amyloid pathology, providing insights into the mechanisms driving clinical progression. ***Materials and Methods:*** FDG-PET and MPRAGE data of SCD participants were obtained from the DELCODE[2] study. Using established analysis pipelines for FBB-PET (PMID: 37070734), Aβ status was determined using centiloid (CL) scores from corresponding FBB-PET data, classifying Aβ-negative (CL≤12), Aβ-positive (CL>30), and Intermediate (12<CL≤30). Glucose metabolism of 24 Aβ-positive participants (73.4±5.2 years; 13 male) were compared with 24 demographically matched Aβ-negative participants (71.5±5.1 years; 13 male) using Scaled Sub-Profile Modeling (SSM) PCA[3]. Preprocessed (motion-corrected, co-registered, smoothened, spatially normalized, and intensity-normalized[4]) FDG-PET data were analyzed in ScanVP[5]. The glucose metabolism covariance pattern that best separated the two groups was identified based on combinations of Group-Invariant Subprofiles (GIS) whose resulting scores separated the two groups with the minimum Akaike Information Criterion value. The pattern was verified using Leave-One-Out-Cross-Validation (LOOCV), and further validated against similarly preprocessed FDG-PET data from 19 Intermediates. ***Results:*** A glucose metabolism covariance pattern was identified that significantly separated Aβ-positive from Aβ-negative participants: p=0.00011 (two-tailed Student's t-test, unequal variance), AUC=0.80, Sensitivity=0.71, Specificity=0.79 and Accuracy=0.75. Key regions showing hypermetabolism included cingulate/paracingulate gyri, thalamus, insula, putamen and left cerebellum, while hypometabolism predominated in the occipital/temporal/parietal/frontal lobes, caudate, and hippocampal regions. Subject scores of LOOCV-generated patterns correlated highly with the original pattern (r=0.96±0.03). Additionally, the scores of the Intermediate participants (z=0.66±0.94) lay between those of the Aβ-negative (z=0.00±0.82) and Aβ-positive groups (z=1.05±0.89) and were significantly different from Aβ-negative scores (p=0.019). ***Conclusion:*** This study successfully identified a glucose metabolism covariance pattern that distinguishes Aβ-positive from Aβ-negative SCD participants, highlighting early metabolic changes associated with amyloid pathology. The Intermediate group's scores suggest a continuum of metabolic alterations across the SCD spectrum, underscoring the value of FDG-PET in identifying early biomarkers for AD progression. ***References:*** [1] Elman et al., Biol. Psych., 2021; [2] Jessen et al., Alzheimer's Research & Therapy, 2018; [3] Moeller et al., JCBFM, 1987; [4] López-González et al., NeuroImage, 2020; [5] Spetsieris et al., JoVE., 2013.

OP-304

The interaction among Amyloid, tau and FDG metabolism in Alzheimer's disease using PET-based Braak staging

G. Huang[1], *Y. Zhou*[1], *H. Shao*[1], *J. Hao*[2], *L. Qi*[2], *J. Liu*[1], *C. Zhang*[1]; *[1]Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: Alzheimer's disease (AD) is characterized by the accumulation of amyloid-β (Aβ) plaques and tau neurofibrillary tangles, followed by neurodegeneration and progressive cognitive decline. The ATN framework, a biomarker-based diagnostic system for AD, categorizes amyloid-β (A), tau (T), and neurodegeneration (N) biomarkers as core diagnostic components. This study applies the Braak neurofibrillary tangle staging system to PET imaging data in AD patients. Within the ATN framework, we investigate the dynamic interplay between FDG metabolism, Aβ, and tau across different AD stages, as well as their associations with cognitive performance. ***Materials and Methods:*** All participants (n = 84; mean age 68.58 ± 7.51 years; age range 56-81; 64.3% female; MMSE score 15.73 ± 7.08; MoCA score 11.30 ± 6.29) underwent standardized clinical evaluations, including comprehensive history collection, neurological examinations, caregiver interviews, and multimodal neuroimaging: brain [^{18}F]FDG PET/MR, [^{18}F]Florbetapir PET/CT (Aβ-PET), and [^{18}F]PI2620 PET/CT (tau-PET). Cognitive assessments included the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). Consensus diagnoses were provided by a multidisciplinary team. Image preprocessing involved partial volume effect correction and segmentation using the AAL brain atlas via uWS-MI/MR software. Reference regions were defined as cerebellar grey matter for Aβ-PET and tau-PET, and the entire cerebellum for FDG-PET. Braak stage-specific regions of interest (ROIs) were analyzed to calculate standardized uptake value ratios (SUVRs). Mediation analysis evaluated causal pathways among biomarkers, while Pearson correlations assessed associations between biomarker SUVRs and cognitive scores. ***Results:*** AD exhibited Braak stage-dependent biomarker dynamics: Aβ directly drove early FDG hypometabolism (Braak I/II: $\beta = 0.32$, $p = 0.003$; Braak III: $\beta = 0.29$, $p = 0.006$), whereas tau mediated late-stage metabolic decline (Braak V: $\beta = -0.51$, $p < 0.001$). Braak IV demonstrated synergistic Aβ-tau effects (combined $\beta = -0.62$, $p < 0.001$). FDG-PET SUVRs strongly correlated with MMSE/MoCA scores across Braak stages (Braak I-V: $R > 0.3$, $p < 0.05$), while tau-PET SUVRs showed inverse correlations (Braak I-V: $R < -0.3$, $p < 0.05$). Aβ-PET exhibited no significant cross-biomarker associations. ***Conclusion:*** Multimodal PET biomarker analysis enhances diagnostic accuracy by capturing complementary pathological and metabolic signatures in AD. Braak staging elucidates stage-specific contributions of Aβ and tau to neurodegeneration, with PET-Braak stages correlating with biomarker progression and cognitive decline. These findings underscore the potential of in vivo PET staging to refine AD diagnosis and monitor disease trajectory.

OP-305

Glymphatic system dysfunction is strongly linked to neurodegeneration and serves as a bridge between ATN biomarkers and cognitive decline in sex-dependent in Alzheimer's disease

J. Wang;
Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, China, Shanghai, CHINA.

Aim/Introduction: To elucidate how glymphatic function disruption affects AD pathology and explore its relationships with ATN biomarkers, with a focus on the effects of sex and amyloid

status on these relationships. ***Materials and Methods:*** We recruited 1,135 individuals from the Chinese Preclinical Alzheimer's Disease Study (CPAS), including 247 AD patients, 283 individuals with mild cognitive impairment (MCI), and 605 cognitively unimpaired (CU) participants. All participants underwent Aβ-PET, diffusion magnetic resonance imaging (MRI), and neuropsychological assessments; additionally, 695 participants underwent FDG-PET, 394 underwent tau-PET, and 615 provided blood samples to measure plasma ATN biomarkers. Glymphatic function was evaluated using the diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) index. A one-way analysis of variance was conducted to examine the differences among DTI-ALPS, imaging, and blood ATN biomarkers. Partial correlation and mediation models were employed to investigate the associations among glymphatic function, ATN biomarkers, and cognition. ***Results:*** The AD group has a lower ALPS index than the MCI group and CU, and MCIs are also lower than CUs. The Aβ-positive group had a lower ALPS index than the Aβ-negative group, and the male group had a lower ALPS index than the female group. The ALPS index was negatively associated with amyloid deposition, tau burden and plasma p-tau 181 and neurofilament light (NfL), and positively associated with glucose metabolism and hippocampal volume only in females. ALPS-index showed significant mediation effects between global amyloid deposition and meta-temporal lobe tau burden, between global amyloid deposition and plasma p-tau 181. The ALPS index mediates the associations of Aβ pathology with neurodegeneration and tau pathology with neurodegeneration in the female or Aβ-positive groups. The ALPS index was positively associated with global cognition, memory, language and executive function. The ALPS index mediates the associations of Aβ pathology with global cognition, and tau pathology with global cognition in the female or Aβ-positive groups, and neurodegeneration with global cognition only in the female group. ***Conclusion:*** Compared to CU, a significant reduction in ALPS-indexes in MCI and AD patients, and males exhibit lower ALPS-indexes than females. The ALPS-index was correlated with ATN biomarkers and mediated key relationships among Aβ, tau pathology, neurodegeneration, and cognition in a sex manner. The impaired glymphatic function bridges the link between Aβ pathology, tau pathology, neurodegeneration and cognitive decline in a sex-dependent manner. These findings suggest that glymphatic dysfunction plays a critical role in the pathogenesis of AD in a sex-dependent manner.

OP-306

Amyloid PET/CT could not replace tau PET/CT for Alzheimer's disease in terms of disease staging and predicting outcome: a large cohort single-institutional study

S. Chen, *Y. Leung, K. Wu, Y. Wong, S. Cheung, Y. Yip, K. Cheng, C. Ho;*
Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.

Aim/Introduction: The AT[N] criteria of the 2018 NIA-AA Research Framework specifies that the Alzheimer's disease (AD) pathway is defined by in vivo biomarkers of β-amyloid (A) and tau (T). Amyloid is generally regarded as a Core 1 initiator for early detection of pathological change, while tau is a Core 2 driver as a continuous variable related to symptom severity and prognosis prediction. Existing data on AD PET/CT studies are mostly collected from small multicenter trials, which are inevitably heterogeneous, and largely on amyloid-burden. We therefore performed a large cohort, single-institutional PET/CT study with dual-tracers, ^{11}C-PIB (amyloid) and ^{18}F-T807 (tau), on patients clinically suspected of AD, aiming at comparing head-to-head the diagnostic power and severity correlation/prediction of AD between these 2 tracers. ***Materials and Methods:*** During the last 4 years, 863 patients (M:371, F:492; age range:48-92 years, mean=70.4±8.0 years) with decreased short-term memory, but with no history of other neurodegenerative disease, were consecutively recruited. They all underwent ^{11}C-PIB and ^{18}F-T807 PET/CT in 2 separate days. ^{11}C-PIB PET was scanned at 5 & 35 minutes and ^{18}F-T807 PET began at 85 minutes post injection, each for 10-min static imaging. Global cortical-to-cerebellum SUV ratio (SUVR) was calculated for both ^{11}C-PIB and ^{18}F-T807 PET. ^{11}C-PIB "global-retention">=1.42 was taken as threshold for positive amyloid-burden (by prior studies). In amyloid-positive patients, correlation analysis was performed between global SUVR of ^{11}C-PIB ($SUVR_{amyloid}$) and ^{18}F-T807 ($SUVR_{tau}$). ***Results:*** 530/863 (61.4%) patients had negative ^{11}C-PIB PET (mean $SUVR_{amyloid}$=1.10±0.07, median $SUVR_{amyloid}$=1.10). For these [A-] PET patients, ^{18}F-T807 PET also showed minimal-to-no uptake (mean $SUVR_{tau}$=1.06±0.05, median $SUVR_{tau}$ =1.03), categorized as [T-] PET. The remaining 333/863 (38.6%) patients had positive ^{11}C-PIB [A+] PET with $SUVR_{amyloid}$ ranging from 1.17 to 2.24 ($SUVR_{amyloid}$=1.55±0.21). The head-to-head ^{18}F-T807 PET varied significantly among [A+] patients, ranging from zero to intense ^{18}F-T807 uptake ($SUVR_{tau}$ range:0.9-2.34, mean:1.25±0.24). In these [A+] patients, amyloid-burden showed no significant difference between [T+] (N=177/333) and [T-] patients (N=156/333): $SUVR_{amyloid}$=1.58±0.20 vs. 1.49±0.20, P>0.05; while corresponding $SUVR_{tau}$=1.39±0.23 vs. $SUVR_{tau}$=1.05±0.05, respectively, P<0.05. Correlation analysis also indicated that amyloid-burden did not correlate with tau-burden in AD patients (r=0.260, P>0.05), suggesting that amyloid-PET is less optimal for predicting AD disease severity quantified by tau-PET. ***Conclusion:*** ^{11}C-PIB PET/CT is valuable for diagnosing AD at an earlier phase. In [A-] patients, tau-PET may not be necessary. However, when ^{11}C-PIB PET is positive, integration of tau-PET is highly suggested to refine AD staging, potentially for severity grading and predicting treatment response.

Aim/Introduction: Recently, algorithms have been developed to utilize molecular imaging techniques for evaluating patients presenting with clinical symptoms of Alzheimer's disease (AD). However, there is still no clinical validation of the use of these algorithms in patient series. The aim of this study was to compare the metabolism first versus the amyloid first approach to elucidate the cause of early cognitive decline in patients with suspected early AD. ***Materials and Methods:*** In this prospective multicentre study that recruited patients with possible or probable early AD and MCI due to AD, all patients underwent full neuropsychological examination, MRI, ^{18}F-FDG PET/CT, and determination of amyloid status (PET/CT and/or CSF analysis). The diagnosis made after ^{18}F-FDG or amyloid determination was compared with the

consensus diagnosis which was determined based on metabolic brain pattern and amyloid status. ***Results:*** Out of 133 patients recruited, 96 underwent both ^{18}F-FDG and amyloid determination and were analysed. Thirteen patients were excluded from the further analyses due to discrepant result of amyloid and metabolic brain evaluation. The amyloid status was positive (amy+) in 55/83 patients, while metabolic brain changes were characteristic for AD in 45/83 (all amy+), DLB in 5/83 (all amy +), FTD in 5/83 (all amy-), and with LATE (all amy-) in 2/83. 2/83 had normal brain metabolism (1 amy+), 23/83 had metabolic changes consistent with age related atrophy (10 amy+) and in 1/83 the finding was indeterminate (amy+). ^{18}F-FDG imaging was consistent with the consensus diagnosis in 73/83 patients, while amyloid was consistent in all cases. ***Conclusion:*** While determination of amyloid status could confirm or exclude the diagnosis of AD, ^{18}F-FDG PET provides broader diagnostic insight, differentiating among various neurodegenerative disorders, including AD and DLB. While the combination of both modalities likely provides the most accurate diagnosis, a metabolism-first approach may be especially valuable in resource-constrained countries where amyloid determination is limited.

Multiorgan Metabolic Dysregulation in Alzheimer's Disease: Total-body PET/CT Reveals Systemic Network Interactions with Amyloid Burden

R. Xu[1], *Y. Duan*[2], *L. Gao*[2], *Y. Chen*[1], *H. Han*[1], *Z. Cheng*[2], *Z. Xie*[1,3];
[1]*Institute of Medical Technology, Peking University Health Science Center, Peking University, Beijing, CHINA,* [2]*Department of Nuclear Medicine, The First Affiliated Hospital of Shandong First Medical University Shandong Provincial Qianfoshan Hospital, Jinan, CHINA,* [3]*National Biomedical Imaging Center, Peking University, Beijing, CHINA.*

Aim/Introduction: Alzheimer's disease (AD) is increasingly recognized as a systemic disorder, with pathological changes extending beyond the brain to peripheral organs. A common feature of these systemic processes is disrupted energy metabolism[1]. However, traditional PET imaging has been limited in assessing such information due to its restricted axial field of view. Total-body PET overcomes these limitations, enabling simultaneous imaging of multiple organs. In this study, we utilized two tracers to elucidate the interplay between cerebral amyloid-beta deposition and systemic glucose metabolism, aiming investigate the systemic manifestations of AD. ***Materials and Methods:*** Sixty-four AD patients were enrolled, and data were acquired using uEXPLORER with both [^{18}F]-Flobetapir and [^{18}F]-FDG tracers. A total of 131 whole-body and 83 brain regions were segmented via the MPUM model using CT images, from which SURr values were extracted. To further quantify the amyloid load, the Centiloid (CL) scores were calculated from six representative VOIs (medial orbitofrontal, lateral temporal, parietal, anterior cingulate gyrus, posterior cingulate gyrus, and precuneus), following the AHEAD 3-45 classification (CL ≤20, 20< CL<40, CL≥40)[2,3]. A metabolic connectivity matrix with a size of 214×214 was constructed using FDG tracers, employing Pearson correlation coefficients. This matrix was then analyzed to assess the topological properties of the network across different CL groupings. Additionally, we computed edge correlations between the population-based residual matrix and CL scores, selecting significant edges ($p<0.01$) as positive (Σ^+) or negative (Σ^-) features. An ensemble model for CL prediction was trained using the edge features and validated on test data. ***Results:*** Our study identified CL-dependent brain-body connectivity alterations in amyloid pathology. The CL<20 subgroup exhibited compensatory hyperconnectivity between the inferior parietal lobule and posterior orbital gyrus ($\Delta=0.97$), alongside elevated cardiocentric connectivity ($\Delta=0.98$) , whereas CL>40 subgroup demonstrated uterine-brain hyperconnectivity ($\Delta=1.28$), suggesting potential neuroendocrine dysregulation. Network analysis revealed 18 positive and 37 negative edges. Our predictive model demonstrated strong validity ($R^2=0.912$), robustly linking CL thresholds to these distinct connectivity patterns. ***Conclusion:*** By revealing the relationship between systemic metabolic networks and amyloid burden, our proposed approach characterize AD's systemic pathology, potentially facilitating more precise disease subtyping. ***References:*** ULLAH R, et al. OP-309

PET imaging of βAmyloid Load Across the Spectrum of Dementia with Lewy Bodies

M. Yoshita[1], *S. Tsuji*[2], *K. Yokoyama*[2];
[1]*NHO Hokuriku National Hospital, Nanto, JAPAN,* [2]*Public Central Hospital of Matto Ishikawa, Hakusan, JAPAN.*

Aim/Introduction: Dementia with Lewy bodies (DLB) is characterized by predominant deficits in executive and visuospatial functions, accompanied by clinical features including parkinsonism, fluctuating cognition, visual hallucinations, and REM sleep behavior disorder. The role of β-amyloid (Aβ) plaques in DLB, especially during prodromal stages, remains unclear. This study investigates Aβ load throughout the DLB spectrum, from isolated REM sleep behavior disorder (iRBD) to mild cognitive impairment with Lewy bodies (MCI-LB) and fully developed DLB. ***Materials and Methods:*** A consecutive cross-sectional study was conducted on patients diagnosed iRBD, MCI-LB, or DLB at the Public Central Hospital of Matto Ishikawa Dementia Research Center. Aβ levels were measured using Pittsburgh compound B (PiB) PET, and Centiloid (CL) scale was calculated. Comparisons were made amongst clinical groups. Multiple linear regression tested interactions between sex and APOE ε4 status on PiB CL along the DLB spectrum. ***Results:*** The study included 84 patients: 4 with iRBD, 36 with MCI-LB, and 44 with DLB. Global cortical PiB CL was significantly higher in DLB than MCI-LB and iRBD. The DLB group had the highest proportion of Aβ positive patients (72%), followed by MCI-LB (42%), and iRBD (0%). Woman displayed higher PiB CL with advancing age compared to men. APOE ε4 carriers exhibited higher PiB CL in MCI-LB ($p < 0.03$) and DLB ($p< 0.03$). ***Conclusion:*** Aβ load increases further along the DLB spectrum, with significant elevation in the predementia stage of MCI-LB and DLB compared to iRBD. APOE ε4 carriers and older women tend to have higher Aβ levels. Reducing Aβ levels in DLB clinical trials may benefit early-stage patients or those with certain genetic profiles, aiding in developing disease-modifying treatments.

Prediction value of cingulate gyrus activity by brain FDG PET for sudden cardiac death in patients with HFrEF

***Y. Zhao**[1], M. Yun[1], Z. Shi[1], Y. Bai[2], X. Zhang[1];*
[1]Laboratory for Molecular Imaging, Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, [2]Department of Nuclear Medicine, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: The brain regulates the heart through the autonomic nervous system (ANS). Disruptions in cardio-neural interactions can affect disease prognosis in patients with heart failure. This study investigated the relationship between ANS-linked neuro-metabolism and left ventricular (LV) diastolic dysfunction in patients with heart failure and reduced ejection fraction (HFrEF), as well as its correlation with sudden cardiac death (SCD)-related events. ***Materials and Methods:*** This retrospective study included 196 (age 58.0 years [IQR: 49-65 years], 88.8% men) patients with HFrEF, who underwent gated single photon emission computed tomography (SPECT) myocardial perfusion imaging (G-MPI) and brain ^{18}F-fluorodeoxyglucose positron emission tomography. The parameters of LV systolic and diastolic function, including left ventricular ejection fraction (LVEF), end-diastolic volume (EDV), end-systolic volume (ESV), peak ejection rate (PER), and peak filling rate (PFR), were evaluated by quantitative GMPI. Cingulate gyrus glucose metabolism activity was analyzed by SPM12 software. Relationships between the brain metabolism and SCD-related events were assessed using Cox models and mediation analyses. ***Results:*** Overall, 22 patients (11.2%, median follow-up: 3.8 years) experienced SCD-related events. Compared to those without SCD-related events, patients with SCD-related events had a lower LVEF (15.0 [13.8-19.3] vs. 21.0 [17.0-25.0], $P < 0.001$), PER (0.58 [0.51-0.79] vs. 0.82 [0.66-1.07], $P < 0.001$), PFR (0.59 [0.48-0.76] vs. 0.80 [0.64-1.04], $P < 0.001$), cingulate gyrus activity (1.01 [0.93-1.05] vs. 1.04 [0.97-1.12], $P = 0.019$), and a higher EDV (250.5 [192.5-345.3 vs. 200.5 [156.75-262.5], $P = 0.014$) and ESV (214.5 [148.8-296.0] vs. 156.0 [116.8-215.3], $P = 0.006$). Patients with reduced metabolism in the cingulate gyrus were more likely to exhibit severe LV diastolic dysfunction (PER: 0.76 [0.60-1.01] vs. 0.89 [0.70-1.09]; PFR: 0.75 [0.60-0.96] vs. 0.88 [0.70-1.08], all $P < 0.05$) and had a higher incidence of SCD-related events (52.9% vs. 36.2%, $P = 0.033$). Furthermore, cingulate gyrus metabolism activity showed significant correlations with LV diastolic function (all $P < 0.05$). Cingulate gyrus metabolism activity (HR: 9.286, 95% CI 1.247-69.169, $P = 0.03$) was strongly associated with SCD-related events after adjustment for clinical information and LV functional parameters. Additionally, cingulate gyrus activity was linked to SCD-related events through its relationship with LV diastolic function. ***Conclusion:*** Cingulate gyrus activity displayed significant independent prognostic value for risk stratification of SCD-related events in patients with HFrEF. Impairment in cingulate gyrus metabolism may contribute to the occurrence of SCD-related events, potentially mediated by LV diastolic function.

EPS-095

Serial FDG PET analysis for detection of cardiotoxicity of breast cancer chemotherapy

***Y. Izoe**[1], M. Nagao[2], H. Tsukada[2], S. Watanabe[2], Y. Maekawa[2], A. Yamamoto[2], Y. Satoh[3], H. Saya[1], S. Akashi-Tanaka[2], S. Sakai[2];*
[1]Fujita Health University, Toyoake, JAPAN, [2]Tokyo Women's Medical University, Shinjuku-ku, JAPAN, [3]Fujita Medical Innovation Center Tokyo, Ota-ku, JAPAN.

Aim/Introduction: In breast cancer patients undergoing repeated chemotherapy, cancer therapy-related cardiac dysfunction is an important prognostic factor. However, there are no useful tools for its prediction. Myocardial accumulation on FDG PET is influenced by blood glucose level and insulin activity and fluctuates between individuals with poor reproducibility. Therefore, it is difficult to distinguish physiologic from pathologic accumulation, and myocardial accumulation on FDG PET during oncology has not been used for complication assessment. We quantitatively evaluated myocardial accumulation using FDG PET performed consecutively during breast cancer chemotherapy to assess the potential for cardiotoxicity by chemotherapy regimen. ***Materials and Methods:*** We analyzed 535 FDG PET examinations performed before and after chemotherapy in 108 patients with breast cancer between January 2014 and February 2025. On pre- and post-treatment FDG PET, the mean values within the volume of interest (size 1.5cm3) of myocardium with the highest accumulation and descending aorta on the same cross-section were measured, and the ratio of the two was defined as the myocardial standard uptake ratio (M-SUR). Chemotherapy was classified into four regimens: anthracyclines, human epidermal growth factor receptor 2 (HER2) inhibitors, immune check inhibitors (ICI), and others (eribulin, paclitaxel, and docetaxel, etc.). When single or multiple chemotherapy regimens were administered in the same patient, pre- and post- data sets for each chemotherapy regimen were compared using Wilcoxon matched-pairs signed rank test. Patients with other cancers, cardiac metastases or diabetes were excluded. ***Results:*** The average observation period and number of PET scans per patient is 39 months and 5.0 scans. A total of 309 pre- and post-chemotherapy data sets were obtained, of which 34 were for anthracyclines (n=17), 146 were for HER2 inhibitors (n=40), 20 were for ICI (n=9), and 109 were for others (n=54). M-SUR after chemotherapy was significantly higher than before chemotherapy in the anthracyclines (4.66±3.94 vs. 3.19±2.10, $p<0.0001$) and ICI (4.98±4.27 vs. 3.02±2.21, $p=0.0328$) groups. On the other hand, in the HER2 inhibitor and the other groups, M-SUR tended to be lower after chemotherapy than before, but the difference was not significant (HER2 inhibitor: 4.91±4.44 vs. 4.31±3.22; the other: 4.22±3.16 vs. 3.76±3.01). ***Conclusion:*** Serial analysis of pre- and post-chemotherapy FDG PET revealed different responses to myocardial accumulation depending on the chemotherapy regimen. With anthracycline and ICI, there is a significant increase in myocardial uptake after chemotherapy. Analysis of myocardial accumulation on FDG PET, which has been underutilized, has the potential to detect cardiotoxicity of chemotherapy.

EPS-096

Left ventricular volumes and ejection fraction by [^{13}N]-NH^3 positron emission tomography are dependent on the reconstruction method: A head-to-head comparison with cardiovascular magnetic resonance

***S. Kvernby**[1,2], J. Oddstig[1,2], F. Hedeer[3], S. Akil Engblom[3];*
[1]Radiation Physics, Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Sweden, Lund, SWEDEN, [2]Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN, [3]Clinical Physiology, Department of Clinical Sciences Lund, Lund University, Skåne University Hospital, Lund, SWEDEN.

Aim/Introduction: Myocardial perfusion imaging using positron emission tomography (PET) enables assessment of left ventricular ejection fraction (EF) by determining left ventricular end diastolic volume (EDV), end systolic volume (ESV) and stroke volume (SV). Choice of PET image reconstruction method (OSEM or BSREM) and reconstruction parameters (number of iterations and subsets or penalization factor β) impacts the image quality. The aim of this study was to investigate to what extent the choice of reconstruction method and reconstruction parameters affects the assessment of left ventricular volumes and EF determined by [^{13}N]-NH^3 PET in a head-to-head comparison with cardiovascular magnetic resonance (CMR). ***Materials and Methods:*** Twenty-three patients with suspected or established chronic coronary syndrome were examined with CMR and [^{13}N]-NH^3 PET during rest on the same day. The PET-data were reconstructed into gated images with 8 bins, using six different PET image reconstructions (TOF-OSEM-2 iterations/16 subsets (2/16) - 3 mm post filter, TOF-OSEM-5 iterations/16 subsets (5/16) - 3 mm post filter, TOF-OSEM-6 iterations/24 subsets (6/24) - 3 mm post filter, BSREM-β50, BSREM-β100 and BSREM-β300). EDV, ESV, SV and EF were assessed and compared between all PET reconstruction methods and with CMR findings. Statistical differences were evaluated using paired sample t-Test. ***Results:*** Regardless of reconstruction method, left ventricular volumes by [^{13}N]-NH^3 PET were significantly smaller ($p<0.001$) than the volumes from CMR, where the smallest difference between the two modalities was found when using TOF-OSEM-6/24 or BSREM-β50 (average agreement with CMR; EDV: -54.5 ml, ESV: -19.8 ml, SV: -33.8 ml), while the largest difference was found when using TOF-OSEM-2/16 (average agreement with CMR; EDV: -63.1 ml, ESV: -27.9 ml, SV: -35.0 ml). Compared with CMR, EF by PET was significantly higher ($p<0.001$) using TOF-OSEM-2/16 or BSREM-β300 reconstructions (4.1% increase), while no difference was found for the other reconstructions. A significant smaller ($p<0.01$) EDV and ESV together with a larger EF could be seen for two of the PET reconstruction methods (TOF-OSEM-2/16 and BSREM-β300), when comparing them with the PET reconstruction producing the largest volumes and smallest EF (TOF-OSEM-6/24). No significant difference ($p>0.05$) in SV could be seen between the different PET reconstruction methods. ***Conclusion:*** The choice of reconstruction method affects the assessment of cardiac left ventricular volumes and EF from [^{13}N]-NH^3 ammonia PET. The largest volumes and best agreement with CMR were found with OSEM reconstruction using a high number of iterations and subsets, or with BSREM reconstruction using a low penalization factor.

EPS-097

Clinical Validation of Automated Convolutional Neural Network Screening of Incidental Cardiac Uptake on Bone Scintigraphy

V. Uusitalo, *H. Halme, T. Ahokas, E. Hippeläinen;*
Helsinki University Hospital, Helsinki, FINLAND.

Aim/Introduction: We validate a convolutional neural network tool designed for the automatic detection of incidental cardiac uptake suggestive of transthyretin amyloidosis (ATTR) on bone scintigraphy. In the case of incidental cardiac uptake, our algorithm can alert the nuclear medicine technician to obtain additional cross-sectional imaging and notify the clinical reader of the possibility of ATTR cardiomyopathy. ***Materials and Methods:*** We utilized a previously designed neural network to retrospectively analyze cardiac uptake on 1325 [^{99m}Tc]Tc-HMDP scintigraphs, which were imaged due to non-cardiac indications at Helsinki University Hospital, Finland. Images were read by an experienced nuclear medicine physician and were labeled as negative (Perugini grade 0 or 1) or positive (Perugini grade 2 or 3) for cardiac uptake. ***Results:*** The mean age was 75 ± 12 years, and 37% were female. There were 30 positive cases of cardiac uptake detected by a nuclear medicine physician (2.3%). Four images (0.3%) were excluded for being non-diagnostic for cardiac analysis. The area under the curve (AUC) for automated detection of cardiac uptake compared to the human reference was 0.87. In the automated screening, there were no false negative cases, 997 true negatives, 342 false positives, and 30 true positives, respectively. Thus, the human reader did not reclassify any negative cases by the neural network but downgraded 92% of positive cases to non-significant cardiac uptake. ***Conclusion:*** An automated novel neural network can safely exclude significant incidental cardiac uptake suggestive of ATTR cardiomyopathy on bone scintigraphy. Cardiac imaging specialists should review any positive results from automated screening. Our algorithm can be utilized for online image surveillance to identify incidental cardiac uptake during bone scintigraphy, alerting technicians and reading physicians to the possibility of ATTR cardiomyopathy.

EPS-098

Graph Theory Analysis of Brain Functional and Metabolic Network Alterations in Heart Failure Patients: a simultaneous PET/MR study

C. Zheng[1], *R. Qin*[1], *N. Li*[2], *J. Lu*[1];
[1]*Xuanwu Hospital, Capital Medical University, Beijing, CHINA,*
[2]*Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.*

Aim/Introduction: Graph theory analysis elucidates complex brain network topology, aiding understanding of neurological impacts. Heart failure (HF) is known to impact both brain function and metabolism. This study investigated alterations in brain functional (fMRI-derived) and metabolic (FDG-PET-derived) networks in patients with distinct HF phenotypes (preserved vs. reduced ejection fraction: HFpEF vs. HFrEF) using simultaneous PET/MR and graph theory. ***Materials and Methods:*** The study included 68 subjects, including 27 patients with HFpEF, 27 patients with HFrEF, and 14 healthy controls (HC). All participants underwent integrated 18F-fluorodeoxyglucose ([^{18}F-FDG) PET/MR scans, which included 3D TIWI and resting-state functional MRI sequences. The DPARSFA software and in-house MATLAB scripts were utilized to preprocess fMRI and PET imaging. Brain parcellation was based on the Anatomical Automatic Labeling (AAL) atlas. The individual functional network was constructed by calculating Pearson's correlation of temporal signals between all brain region pairs, and the average is used as the group-level correlation matrix. Additionally, the Pearson's correlation of standardized uptake values ratio (SUVr) across brain regions within the cohort was utilized to generate a group-level metabolic network. To calculate the global characteristic parameters related to graph theory, area-under-the-curve (AUC) was integrated across a range of network sparsity to summarize network properties. The difference of each network property between the three groups was evaluated by using a nonparametric permutation approach with 10000 permutations. ***Results:*** The global connectivity characteristics of brain functional networks and metabolic networks differ significantly in HF. While no significant differences are observed in the global properties of functional networks among the HFpEF, HFrEF, and healthy control groups, the metabolic networks exhibit marked disruption in HF. Compared to HFrEF, HFpEF demonstrates significant alterations in global network metrics, including decreased normalized clustering coefficient (nCp) and small-worldness (sigma), along with increased characteristic path length (Lp), as revealed by permutation testing ($P < 0.05$ for all). Especially when sparsity thresholds exceed 0.3, the small-world index falls below 1, suggesting a shift toward global network segregation and a significant decline in network stability. ***Conclusion:*** HF patients exhibit differential alterations in brain functional and metabolic networks. Metabolic network topology appears more sensitive to HF-related pathological changes, particularly distinguishing between HFpEF and HFrEF phenotypes. These findings suggest

that graph analysis of brain metabolic networks could offer valuable pathophysiological insights, and its topological features hold potential as biomarkers for assessing HF-related brain injury.

EPS-099

Impact of CT-free Attenuation Correction on Left Ventricular Ejection Fraction and Volumes obtained from a dedicated Cardiac CZT SPECT Camera

V. Roelants[1], *M. Hesse*[2], *F. Dupont*[2], *N. Laajimi*[2], *A. Oulad Bouchetta*[2], *R. Lhommel*[2];
[1]*Cliniques Universitaires Saint-Luc, Brussels, BELGIUM,* [2]*Cliniques Universitaires Saint-Luc - Université Catholique de Louvain, Brussels, BELGIUM.*

Aim/Introduction: Attenuation-correction (AC) improves the diagnostic accuracy of myocardial perfusion scintigraphy (MPS). In the CASCTEC study we developed an approach generating CT-free attenuation maps for pinhole CZT cameras (pinhole CZT), based on emission scans only. In this work, we evaluated the effect of CT-free AC on the determination of left ventricular ejection fraction (LVEF), end-systolic (ESV) and end-diastolic (EDV) volumes using a pinhole CZT. ***Materials and Methods:*** Twenty-seven patients (19 male; age: 67 ± 15 years, BMI: 28 ± 6 kg/m2) with suspected or known coronary artery disease referred for a two-day stress/rest MPS have been included at this stage. 5-minute ECG-gated (16 bins) acquisitions were performed on a pinhole CZT 30-60 minutes after injection of 359 ± 18 MBq of a 99mTc-labeled tracer. This acquisition was immediately followed by an additional 5-minute acquisition after retracting the detectors without moving the patient. It allowed to delineate the patient body contour, and together with the first acquisition, enabled the segmentation of soft and lung tissues to produce an attenuation map. Each frame of the ECG-gated acquisition was reconstructed using the manufacturer algorithm without and with AC, then smoothed using a 1-2-1 temporal filter. LVEF, ESV and EDV were calculated from each reconstruction using Quantitative Gated SPECT software (QGS). Results were analyzed using linear regression and Wilcoxon Signed-Rank test, while Bland-Altman plots served to evaluate the level of agreement. ***Results:*** LVEF, ESV and EDV values were automatically obtained for 23 patients. Manual adjustment of the LV contour was required in the remaining 4 patients. The comparison between NC and AC images gave the following results: 60.6 ± 8.9 % vs 54.8 ± 8.4 % (p<0.001) for LVEF; 100.5 ± 30.2 ml vs 104.3 ± 31.4 ml (p<0.001) for EDV and 41.5±19.2ml vs 49.0±20.8ml (p<0.001) for ESV. Linear correlation was excellent for LVEF (R=0.94, p< 0.001) and for both EDV (R=0.98, p<0.001) and ESV (R=0.96, p<0.001). However, Bland-Altman analysis revealed a significant bias of -5.74% for LVEF (95% limit of agreement: -12.0 to 0.54%), of 3.8ml for EDV (95% limit of agreement: -7.4 to 14.9ml) and of 7.6 ml for ESV (95% limit of agreement: -3.4 to 18.5ml). ***Conclusion:*** LVEF and volumes determined by QGS from CT-free AC pinhole CZT MPS strongly correlated with NC values. However, CT-free AC introduced significant bias (underestimation of LVEF and overestimation of LV volumes) making the two methods non-interchangeable.

FAPI SPECT/CT to Evaluate Fibrosis Burden of Right Ventricular in CTEPH: Correlation with Echocardiographic Strain Parameters and Response to BPA

K. Wang*, X. Li, S. Song, W. Fang, L. Wang, C. Yan;*
Chinese Academy of Medical Sciences & Peking Union Medical College, Fuwai Hospital, Beijing, CHINA.

Aim/Introduction: Prognosis in chronic thromboembolic pulmonary hypertension (CTEPH) is strongly determined by right ventricular (RV) function, which deteriorates partly due to myocardial fibrosis. Radiolabeled fibroblast activation protein inhibitors (FAPI) offer a novel way to visualize the fibrosis progression in vivo. This study aims to assess FAPI SPECT/CT as a potential imaging biomarker to evaluate the fibrosis burden and to investigate the association between RV FAPI uptake parameters with RV strain parameters derived from speckle tracking echocardiography, both at baseline and after balloon pulmonary angioplasty (BPA). ***Materials and Methods:*** We enrolled 37 CTEPH patients who completed baseline ^{99m}Tc-FAPI SPECT/CT, strain echocardiography, and right heart catheterization (RHC) before the initial BPA. Baseline FAPI parameters (Fibroblast Activation Volume [FAV], SUV_{peak}, TBR_{peak}) and RV strain parameters (free wall strain [FWS] and global strain [GS]) were collected. RV-pulmonary artery coupling was calculated as RVFWS/sPAP (estimated systolic pulmonary artery pressure). Ten patients underwent complete re-examination (including FAPI SPECT/CT) after the first BPA. ***Results:*** Baseline RV FAPI uptake varied with mean ± SD values of 2.27 ± 0.97 for SUV_{peak} (range: 1.04-4.19), 2.92 ± 0.96 for TBR_{peak} (range: 1.44-4.76), and 128 ± 118 mL for FAV (range: 0-525 mL). Echocardiographic strain analysis yielded a mean FWS of -14.7 ± 6.28 % and a median RVFWS/sPAP of -0.23 ± -0.18. Baseline TBR_{peak} of free wall (FW) correlated with longitudinal diameter of RV (r = 0.541, p = 0.001), FWS (r = 0.386, p = 0.018) and RVFWS/SPAP (r = 0.347, p = 0.026). Response to the first BPA varied among patients; not all showed improvement in hemodynamics or RV strain. Nonetheless, changes (Δ) in FW TBR_{peak} significantly correlated with changes (Δ) in FWS (r = -0.721, p = 0.019) and ΔRVFWS/SPAP (r = -0.636, p = 0.048). This finding reflects a concordance between changes in FAPI uptake and changes in strain parameters: greater reductions in FAPI uptake paralleled greater improvements in strain, while increased uptake was associated with strain deterioration. ***Conclusion:*** FAPI SPECT/CT emerges as a promising imaging biomarker for assessing RV involvement in CTEPH. The significant correlation between RV FAPI uptake with baseline myocardial strain parameters, as well as the association between changes in FAPI uptake and changes in RV strain following BPA suggests its potential utility in assessing response to treatment.

EPS-101

Detection of myocardial metabolic abnormalities by ^{18}F-FDG and preliminary mechanism analysis in mice with Anthracycline cardiotoxicity: A corresponding ^{18}F-FDG PET/MRI observation

T. Yuan[1], *X. Chen*[1], *M. Wei*[1], *X. Lin*[1], *H. Zhu*[1], *Z. Yang*[1], *X. Wang*[2];
[1]*Peking University Cancer Hospital & Institute, Beijing, CHINA,* [2]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), NMPA Key Laboratory for Research and Evaluation of Radiopharmaceuticals (National Medical Products Administration), Beijing, CHINA.*

Aim/Introduction: The present translational study aimed to verify whether serial ^{18}F-FDG PET predicts doxorubicin cardiotoxicity and preliminary mechanistic insights. ***Materials and Methods:*** Twenty mice were allocated into four groups: five received 5-6 weekly intraperitoneal doxorubicin (5 mg/kg) and were sacrificed at week 7; five each underwent 4- or 3-week regimens (terminated at weeks 5/4); and five controls received six weekly intraperitoneal saline injections before sacrifice at week 7. Histopathological changes were identified by light and electron microscopy. Prospective cohort study (NCT04555642) with ethics approval, enrolling lymphoma survivors post ≥3 cycles of anthracycline regimens underwent ^{18}F-FDG PET/CT and PET/MRI. ^{18}F-FDG PET/MRI parameters (including PET and CMR parameters) for toxicity prediction were established via ROC curve analysis. Early cardiotoxicity was observed by ECG within two weeks near-PET/MRI. ***Results:*** In mice, ^{18}F-FDG radiotracer distribution analysis revealed significantly elevated myocardial uptake in the 4 and 5-6 weekly doxorubicin doses compared to control group (P<0.05). Progressive pathological changes were observed with increasing chemotherapy cycles: mice exhibited graded myocardial

injuries ranging from mild subendocardial edema to myocardial disintegration, accompanied by mitochondrial vacuolization and nuclear swelling/vacuolization. Mild subendocardial fibrosis became detectable starting at 4 cycles, persisting through 5-6 cycles. Ultrastructural analysis demonstrated distinct mitochondrial alterations: those receiving 5-6 weekly doxorubicin doses exhibited pronounced mitochondrial swelling, disrupted cristae, and vacuolated structures. The specificity, positive predictive value and accuracy of $SUV_{max\text{-}heart}$ (cutoff 8.8) were 87.1%, 71.4% and 84.1% for the $SUV_{max\text{-}heart}$ were better than $SUV_{max\text{-}heart}/SUV_{max\text{-}mediastinum}$, $SUV_{max\text{-}heart}/SUV_{max\text{-}liver}$, and $SUV_{max\text{-}heart}/SUV_{max\text{-}muscle}$ ratios. There was no available parameters of MRI using ROC curve analysis with P values >0.05. Moreover, myocardial uptake values exhibited an increasing trend with successive chemotherapy cycles. Notably, while no significant differences in these parameters were observed between ECG-positive and negative groups at 3-4 treatment cycles (P>0.05), the ECG-positive subgroup receiving 7-8 chemotherapy cycles showed significantly elevated values across all four PET parameters compared to their ECG-negative counterparts All P<0.05). Cardiac structural analysis revealed that ECG-positive patients post-chemotherapy had significantly lower indexed EDV/BSA. Furthermore, patients completing 7-8 chemotherapy cycles demonstrated reduced LVEF, decreased indexed EDV, and lower septal wall T1 values compared to ECG-negative controls (all P<0.05). ***Conclusion:*** Cumulative chemotherapy induces dose-dependent cardiotoxicity, evidenced by elevated PET metabolic parameters ($SUV_{max\text{-}heart}$ AUC=0.844) and impaired cardiac function in ECG-positive patients, particularly after 7-8 cycles. Animal studies corroborate progressive myocardial damage, from mitochondrial vacuolization to fibrosis, aligning with clinical PET findings. PET/CT demonstrates superior sensitivity over MRI for early detection.

EPS-102

First total-body dynamic imaging and kinetic modeling of ^{18}F-flurpiridaz quantifying perfusion and mitochondrial complex I distribution in healthy volunteers

H. Song[1,2,3], *J. Zhao*[1,2,3], *Z. Xiang*[1,2,3], *Z. Qin*[1,2,3], *Y. Wang*[4], *P. Wu*[1,2,3], *S. Li*[1,2,3];
[1]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [2]*Shanxi Key Laboratory of Molecular Imaging, Shanxi Medical University, Taiyuan, CHINA,* [3]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA,* [4]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: High-resolution mitochondrial complex I-(MC-I) targeting probe ^{18}F-flurpiridaz combined with total-body PET/CT can unleash its potential in future pathological studies beyond myocardial perfusion imaging. Yet the most appropriate kinetic model for total-body ^{18}F-flurpiridaz quantification has not yet been proposed. We aim to obtain preliminary data on total-body pharmacokinetics of ^{18}F-flurpiridaz in healthy volunteers as a potential quantitative biomarker for both perfusion and MC-I activity. ***Materials and Methods:*** Nine healthy volunteers underwent 60-minute dynamic total-body ^{18}F-flurpiridaz PET/CT scans. Multiple normal organ VOIs were generated with an automated CT-based total-body segmentation method on motion-corrected total-body dynamic imaging to obtain time-activity curves (TACs). Descending aorta was chosen as the input function for most of the organs except for lung, where the pulmonary artery was used. Both irreversible (2T3K) and reversible (2T4K) two-tissue compartment model with blood volume and time delay correction were applied to compare their fitting quality using the Akaike Information Criterion (AIC). Logan and Patlak graphical analyses were also used to verify the reversibility of ^{18}F-flurpiridaz kinetics in different organs, as well as providing simplified quantification surrogates for MC-I distribution. ***Results:*** The 2T4K model demonstrated superior fit for most organs compared to 2T3K, excluding liver and lung where irreversibility predominated. The rate constants demonstrated organ-specific pattern. The perfusion rate K_1 ranged from 0.05 ml/cm^3/min in spinal cord to 2.62 ml/cm^3/min in right renal cortex. The backward flux k_2 varied from 0.04 min^{-1} in liver to 1.64 min^{-1} in left lung's upper lobe. The k_3 representing specific binding to MC-I peaked in thyroid as 0.64 min^{-1} vs. 0.00 min^{-1} in liver, and the reversible binding parameter k_4 varied from 0.07 min^{-1} in myocardium to 0.90 min^{-1} in thyroid. The renal cortex has the highest distribution volume (V_T) of 17.71 ml/g, while the middle right lung lobe had the lowest V_T (0.74 ml/g). Logan analysis with t*=10 min demonstrated higher R^2 in most organs compared to Patlak analysis, verifying the reversible kinetics of ^{18}F-flurpiridaz. Strong correlations were observed between Logan-V_T and 2T4K-V_T(r=0.97, P<0.0001), suggesting that they can be used as promising surrogates for MC-I distribution. ***Conclusion:*** This study delivers the first evidence of ^{18}F-flurpiridaz's reversible binding kinetics across multiple organs in human. Total-body ^{18}F-flurpiridaz dynamic imaging exhibits distinct kinetic rates across various organs. Mapping the multi-organ pharmacokinetic parameters of ^{18}F-flurpiridaz has the potential to enable pathological correlation in future perfusion/MC-I studies.

EPS-103

Prognostic Value of Stress Myocardial Perfusion Entropy (MPE) in Patients with Normal Single-Photon Emission-Computed Tomography (SPECT) Myocardial Perfusion Imaging

L. Djaileb[1], *N. De Leiris*[1], *M. Desvignes*[2], *D. Fagret*[1], *C. Ghezzi*[3], *G. Barone-Rochette*[1], *L. Riou*[3];
[1]*University Grenoble Alpes, Grenoble, FRANCE,* [2]*Gipsa-Lab, University Grenoble Alpes, Grenoble, FRANCE,* [3]*Univ. Grenoble Alpes, INSERM, LRB, Grenoble, FRANCE.*

Aim/Introduction: Stress myocardial perfusion entropy (MPE) as computed from routinely acquired SPECT myocardial perfusion images showed an added prognostic value over clinical risk factors, stress test EKG and summed stress score (SSS) in high-risk type 2 diabetic patients (1). The relationship between increased MPE and coronary microvascular dysfunction (CMVD) have been suggested in a preclinical model (2). Our aim was to assess the prognostic value of MPE in low-risk patients with normal SPECT myocardial perfusion imaging. ***Materials and Methods:*** Consecutive patients with normal myocardial perfusion (SSS <4) and a normal left ventricular ejection fraction (> 45%) were retrospectively enrolled in the study. Myocardial perfusion imaging using ^{201}Tl was performed on a CZT cardiac dedicated camera following exercise testing or pharmacological testing. MPE was determined from SPECT myocardial perfusion images as previously described (1). The primary endpoint was the occurrence of a cardiovascular event (cardiovascular death, non-fatal myocardial infarction, coronary angiography with or without revascularization, and stroke). Univariate and multivariable Cox models were performed to assess the prognostic value of MPE for cardiovascular events. ***Results:*** From May 2011 to September 2012, 472 patients were identified. 29/472 (6%) were lost to follow-up. 443 patients were included in this analysis. The primary endpoint occurred in 73 patients during follow-up (3.3 ± 0.4 years). In a multivariate analysis, age (HR 1.04 [1.01; 1.06] p <0.0001) and stress entropy (HR: 1.6 [1.004; 2.56], p=0.04) were independent predictors of cardiovascular events. In survival analysis, patients with elevated MPE (> 4.06) underwent more events than those with a lower MPE (<4.06) (log rank = 0.04). ***Conclusion:*** MPE determined from thallium-201 stress CZT SPECT perfusion imaging improved prognostic risk assessment of cardiovascular event in patients with normal myocardial perfusion scintigraphy. ***References:*** (1) Djaileb, L. et al. Prognostic value of SPECT myocardial perfusion entropy in high-risk type 2 diabetic patients. Eur J Nucl Med Mol

Imaging 48, 1813-1821 (2021). (2) Carabelli, A. et al. Noninvasive assessment of coronary microvascular dysfunction using SPECT myocardial perfusion imaging and myocardial perfusion entropy quantification in a rodent model of type 2 diabetes. Eur J Nucl Med Mol Imaging 49, 809-820 (2022).

EPS-104

Incidence of Cardiotoxicity Assessed with CZT-ERNA in Patients Undergoing Medical Cancer Therapy: A 12-year real-word experience

J. E. Larsson, *M. Ø. Nielsen, B. Zerahn;*
Department of Nuclear Medicine, Copenhagen University Hospital – Herlev, Copenhagen, DENMARK.

Aim/Introduction: Medical cancer therapies (MCT) have undergone a remarkable transformation during the recent decades with the addition of new therapeutic modalities. Nonetheless, adverse effects remain significant. In this context, incidences of cardiotoxicity, as assessed with cadmium-zinc-telluride (CZT) equilibrium radionuclide angiography (ERNA) imaging, are limited. Therefore, the aim of this study was to determine the incidence and risk factors for cardiotoxicity in patients undergoing contemporary MCT under surveillance with CZT-ERNA. ***Materials and Methods:*** We included all adult patients who underwent first-time and follow-up assessment of cardiac function with CZT-ERNA within 6 months in relation to MCT at a European university hospital between 2012 and 2024. The primary outcome was cardiotoxicity, defined as a reduction in left ventricular ejection fraction (LVEF) ≥ 10% from baseline to < 50% during the first year, and was estimated using cumulative incidence functions. Secondary outcomes included the estimated proportion of patients with recovery of LVEF to ≥ 50%, and risk factors for cardiotoxicity. Risk factors were estimated with multiple logistic regression adjusted for age, sex, body mass index, and type of cancer in landmark analyses of survivors > 9 months. ***Results:*** Of 5,937 patients with a first-time CZT-ERNA, 953 patients (54% females, mean age 63 years, SD 14.4) had a follow-up assessment within 6 months and a total of 3,236 examinations during the first year. Most patients had sarcoma (30%), melanoma (23%), and breast cancer (20%). The overall incidence of cardiotoxicity was 115/953 ~ 12.1% (95% CI 10.0-14.1) with best/worst case sensitivity analysis: 1.9-18.0%. Median time to cardiotoxicity was 125 days [Q1-Q3 82-184 days] and reversibility was observed in 61 patients (61/115 ~ 53%). Baseline LVEF (adjusted OR / 10% increase 0.50; 95% CI 0.40-0.62; p <0.001), end-systolic volume (adjusted OR / 10 ml increase 1.47; 95% CI 1.28-1.69; p < 0.001) and end-diastolic volume (adjusted OR / 10 ml increase 1.13; 95% CI 1.03-1.24; p=0.01) were associated with cardiotoxicity. ***Conclusion:*** Cardiotoxicity occurred in approximately 12% of all cancer patients referred for CZT-ERNA surveillance during MCT. Risk factors were larger left ventricular volumes and lower LVEF at baseline.

EPS-105

Clinical Outcomes and Management Following Abnormal SPECT Myocardial Perfusion Imaging

B. Miles, *K. Atieh, K. Mason, U. Oza;*
Baylor University Medical Center, Dallas, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Stress myocardial perfusion imaging with single photon emission computed tomography (SPECT) is a widely implemented imaging choice to assess for inducible reductions in coronary arterial flow during times of increased myocardial demand. While coronary angiography is the gold standard to evaluate flow-limiting coronary blood flow, this invasive imaging modality is associated with risks of traumatic vascular complications and contrast induced complications. Compared to coronary angiography, nuclear stress testing has fewer risks. These complications include short-lived arrhythmias and chest pain which typically subside upon return to resting heart rate. Many patients who present with angina can undergo nuclear stress testing to assess for underlying inducible reduced coronary flow. The purpose of this study was to assess the rate of interventions in patients who underwent nuclear cardiac stress testing and were found to have abnormal findings. ***Materials and Methods:*** This global population-based retrospective cohort study was designed utilizing the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines. We accessed the anonymized medical record information of more than 165 million patients in 144 large healthcare organizations internationally. The patient cohort was created by using International Classification of Disease 10 (ICD-10) codes, Current Procedural Terminology (CPT) codes, and medication codes. Patients in this study had to have no personal history of TIA or stroke (Z86.73), and no history of peripheral vascular disease (I73). They were required to have undergone myocardial perfusion imaging (CPT 78452) with an abnormal outcome (R94.39). This resulted in 88,522 patients. They were then evaluated for the outcomes of angioplasty with or without stents, coronary artery bypass grafting, or medical management (aspirin with either clopidogrel, prasugrel, or ticagrelor) within the subsequent 3 months. ***Results:*** 41.8% of patients with abnormal nuclear medicine stress testing were managed with intervention of any type. The most common intervention was medical management (41.6%), followed by angioplasty with or without stents (5.3%) and coronary artery bypass grafting (2.9%). ***Conclusion:*** Stress myocardial perfusion imaging with single photon emission computed tomography (SPECT) is used to assess for inducible reductions in coronary arterial flow during times of increased myocardial demand and has less risks than coronary angiography. Our study has shown that abnormal nuclear stress myocardial perfusion images often lead to interventions within 3 months of testing in patients, with the most common intervention being medical management. These findings highlight the utility of nuclear stress imaging in the management of patients with chest pain.

EPS-106

Potential link between left ventricular mechanical dyssynchrony (LVMD) and coronary microvascular dysfunction (CMD) in suspected coronary arteries disease (CAD) patients: a preliminary study based on CZT-SPECT

H. Zhang[1], *F. Caobelli*[2], *K. Shi*[2], *F. Yu*[1];
[1]*Tongji University School of Medicine,shanghai Tenth people's hospital, Shanghai, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: It is still unclear whether left ventricular mechanical dyssynchrony (LVMD) is implicitly tied to the pathogenesis of coronary microvascular dysfunction (CMD). This preliminary study aimed to demonstrate the correlation between LVMD and CMD by CZT-SPECT myocardial perfusion imaging (MPI). ***Materials and Methods:*** A cohort of 142 suspected CAD patients who were referred to D-SPECT MPI were retrospectively analyzed and divided into two groups: the CMD group and the non-CMD group. CMD was defined as CFR <2.5 and LVMD was diagnosed through phase bandwidth (PBW) and phase standard deviation (PSD) value exceeded mean+2SD for control patients. ***Results:*** A total of 142 patients were recruited for this study and divided into two groups: CMD group (n =62, 32 males, 30 females; mean age 68.69±9.08 years) and non-CMD group as controls (n = 80, 47 males, 33females; mean age 63.55±11.35 years).Among the 62 CMD patients, 26 (41.9%) had LVMD, including stress LVMD 19 cases, rest LVMD 16 cases, and both stress/rest LVMD 9 cases. The phase analysis parameters of two groups showed statistically significant differences, PBW (P<0.001; P<0.001), PSD (P<0.001; P<0.001) and Entropy (P<0.001; P=0.011) were significantly elevated in the CMD group. Compared with the non-LVMD group, the parameters of stress/rest left ventricular function were worse

in the LVMD group, with left ventricular ejection fraction (LVEF) (P=0.002; P=0.001), perk ejection ratio (PER) (P=0.003; P=0.001), peak fraction ratio (PFR) (P=0.034; P=0.010) were lower, and ESV (P=0.014; P=0.026) was higher. There was a moderate negative correlation between CFR and Stress PBW (r=-0.22, P=0.014), Stress PSD (r=-0.25, P=0.011), Rest PBW (r= -0.19, P=0.037). Meanwhile, multivariate regression analysis suggested that stress LVMD was an independent risk factor for CMD (OR: 22.52, 95% CI: 2.45-206.80, P=0.006). ***Conclusion:*** There is a clear correlation between LVMD and CMD, which provides incremental value for the early diagnosis of CMD in suspected CAD patients.

EPS-107

Functional Evaluation of Cardiac Cell Membrane Transporter P-Glycoprotein in healthy volunteers with [^{18}F]MC225-PET imaging- a feasibility study

W. Liu[1], *J. Somsen*[1], *G. S. d. Souza*[1], *P. Mossel*[2], *A. Bartels*[3], *R. Slart*[1], *G. Luurtsema*[1];
[1]*University Medical Center Groningen, Groningen, NETHERLANDS,*
[2]*Leiden University Medical Center, Leiden, NETHERLANDS,*
[3]*Ommelander Ziekenhuis Groep, Scheemda, NETHERLANDS.*

Aim/Introduction: P-glycoprotein (P-gp) is an efflux transporter that regulates the distribution of various compounds across multiple organs, including the heart and brain. Cardiac P-gp plays a crucial role in protecting against cardiotoxicity and also in modulating the efficacy of P-gp-related cardiovascular drugs, such as beta-blockers and digoxin. [^{18}F]MC225-PET imaging has been identified as a promising tool for assessing P-gp function at the blood-brain barrier (BBB) in the past. This feasibility study aims to assess cardiac P-gp function with [^{18}F]MC225-PET imaging, in healthy volunteers. ***Materials and Methods:*** Six healthy volunteers (3 females, 60.67 ± 3.21 years; 3 males, 66.25 ± 3.59 years, all free of medications affecting P-gp function, underwent 60-minute dynamic [^{18}F]MC225 LAFOV PET scans (injected activity: 214.9 ± 92.36 MBq). Whole-blood time activity curves was derived from the internal aortic arch. The image derived input function (IDIF) was calibrated using the arterial manual samples, and adjusted for the plasma-to-whole blood ratio and corrected for plasma parent fraction. Kinetic parameters were calculated using different compartment models, including the reversible one-tissue compartment model and both reversible and irreversible two-tissue compartment models. ***Results:*** Sixty minutes post-injection, the plasma parent fraction was 64.61 ± 10.17%, with males showing 63.55 ± 16.26% and females 65.66 ± 6.41%. [^{18}F] MC225 PET imaging showed increased uptake in the heart wall. The reversible two-tissue compartment model provides the best fit for characterizing P-gp function in the human heart. Kinetic parameters were used to assess cardiac P-gp function and are presented in Table 1. The volume of distribution (VT) in healthy volunteers was 22.26 ± 2.23 mL·cm-3 for females and 27.12 ± 8.43 mL·cm-3 for males. ***Conclusion:*** This is the first evaluation of cardiac P-gp function in healthy volunteers using [^{18}F]MC225 PET. Although the small sample size limits statistical power, the findings still demonstrate the potential for future applications of [^{18}F]MC225 PET in assessing or predicting cardiotoxicity and the treatment effects of P-gp substrate medications.

EPS-108

Diagnostic Performance of NaI(Tl) SPECT Myocardial Blood Flow Quantification versus Relative MPI in Detecting Hemodynamically Significant Stenosis: A Prospective Study Using ICA with Wire-Based FFR as Reference

R. Sun, *Z. Zhang, K. Han, X. Wang, L. Wang, W. Fang;*
Chinese Academy of Medical Sciences Fuwai Hospital, Beijing, CHINA.

Aim/Introduction: This prospective study compared the diagnostic performance of myocardial blood flow (MBF) quantification derived by NaI (Tl) SPECT with relative myocardial perfusion imaging (MPI) in detecting hemodynamically significant stenosis in patients with coronary intermediate stenosis, using invasive coronary angiography (ICA) with wire-based fractional flow reserve (FFR) as reference. ***Materials and Methods:*** We enrolled 102 patients (age 58 ± 9 years, 64.7% male) with ≥ 1 coronary intermediate stenosis (50% ~ 90% diameter stenosis [DS]) by coronary CTA scheduled for clinically indicated SPECT MPI were prospectively enrolled in this study. All participants underwent both SPECT MPI and SPECT MBF quantification, followed by ICA with FFR measurements for intermediate stenosis. Vessel-level rest MBF, stress MBF and myocardial flow reserve (MFR) were obtained by NaI (Tl) SPECT. A SSS of ≥ 4 was considered abnormal on relative MPI. Hemodynamically significant stenosis was defined as > 90% DS on ICA or wire-based FFR ≤ 0.80. The optimal cut-off values of MBF and MFR were determined by ROC curve analysis and the Youden index. Areas under the curve were compared using DeLong method. The diagnostic indicators were compared using generalized estimating equations (GEE) to adjust for correlation between multiple vessels within the same patient. ***Results:*** Among 301 vessels included in the final analysis, hemodynamically significant stenosis was identified in 71 vessels (23.5%), including: 19 vessels with > 90% DS, 52 vessels with FFR ≤ 0.80 (from 124 vessels with FFR measurements,excluding 5 with missing data) and 158 vessels with < 50% DS. The optimal cut-off value on vessel level was 1.62 mL/min/g for stress MBF (AUC: 0.719; sensitivity: 66.2%, specificity: 79.6%, PPV: 50.0%, NPV: 88.4%, accuracy: 76.4%) and 1.99 for MFR (AUC: 0.691; sensitivity: 62.0%, specificity: 83.5%, PPV: 53.7%, NPV: 87.7%, accuracy: 78.4%). The AUC, sensitivity, specificity, PPV, NPV and accuracy for relative MPI was 0.561, 22.5%, 89.6%, 40.0%, 78.9% and 73.8%, respectively. The diagnostic AUC and sensitivity of stress MBF and MFR were significantly higher than relative MPI (all P < 0.0001). ***Conclusion:*** Quantitative MBF assessment by NaI (Tl) SPECT demonstrated superior diagnostic performance, particularly sensitivity, compared to relative MPI in detecting hemodynamically significant stenosis determined by ICA with wire-based FFR. This study supports its potential as a non-invasive tool for functional evaluation of hemodynamically significant stenosis.

EPS-109

Pre-administration of caffeine anhydrous has the potency to suppress myocardial [^{18}F]-FDG uptake: a feasibility study

C. P. W. Cox, *Q. G. de Lussanet de la Sablonière, T. Mulders, L. H. Graven, F. A. Verburg, T. Brabander;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Positron emission tomography/Computed tomography (PET/CT) with [^{18}F]-2-fluoro-2-deoxyglucose ([^{18}F]-FDG) has an increasingly relevant role in diagnosis and treatment management of cardiac inflammation and infection. A major problem of cardiac [^{18}F]-FDG PET/CT is physiological myocardial [^{18}F]-FDG uptake, which could complicate the differentiation between physiological uptake in the normal myocardium and inflammation. Despite dietary manipulation, extended fasting and possibly additional intravenous heparin to suppress the physiological myocardial uptake, 5-20% of the patients still present inadequate myocardial uptake suppression and further improvement of the protocol is needed. These patients may benefit from additional caffeine anhydrous pre-administration, as it reduces insulin-dependent GLUT4 myocardial glucose uptake and increases free fatty acid levels, which stimulate myocytic free fatty acid oxidation. The aim of this study is to investigate the feasibility of additional caffeine anhydrous pre-administration on myocardial [^{18}F]-FDG uptake suppression. ***Materials and Methods:*** Eight adult patients who showed inadequate myocardial [^{18}F]-FDG suppression with the standard high-fat no-carbohydrate diet and 12 hours fasting on a routine [^{18}F]-FDG PET/CT with indication of inflammation or infection were included. An additional study PET/CT was performed with the standard diet and an additional caffeine anhydrous food supplement

tablet (200 mg) one hour prior to [^{18}F]-FDG injection. Both PET/CT scans were independently scored with a blind assessment of left ventricular myocardial [^{18}F]-FDG uptake for each of the 17 segments, as well as for overall image quality. Additionally, SUV measurements were taken for extra-cardiac image quality. Patients were monitored by measuring blood pressure and heart rate, and blood samples were analyzed for blood glucose and free fatty acid levels. ***Results:*** Additional caffeine supplementation prior to [^{18}F]-FDG administration resulted in a significantly lower total number of segments with inadequate suppression ($p<0.001$). Only three patients still showed inadequate suppression. Among them, two showed a significant decrease in the number of inadequate segments, all of which were in the basal and mid postero-anterolateral segments. No significant differences ($p>0.05$) were found on visual and semi-quantitative extra-cardiac image quality and sarcoid lesions. All patient monitoring parameters remained stable compared to before caffeine intake, except a significant ($p<0.001$) decrease (-8 beats/minutes) in mean heart rate before [^{18}F]-FDG injection and a significant ($p<0.05$) increase (+8 mmHg) of mean systolic blood pressure after PET/CT. Patients did not report any symptoms associated with caffeine. ***Conclusion:*** Additional caffeine anhydrous pre-administration one hour before [^{18}F]-FDG injection has potency to improve myocardial [^{18}F]-FDG uptake suppression, while maintaining extra-cardiac visual and semi-quantitative image quality.

EPS-110

Agreement of ^{68}Ga-DOTANOC PET/CT with ^{18}F-FDG PET/CT and Cardiac MR in sarcoid patients with suspected cardiac involvement

R. Solanki*, A. Sood, B. Mittal;*
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Cardiac magnetic resonance imaging (CMR) and positron emission tomography (PET) are helpful in the early diagnosis and follow-up of cardiac sarcoidosis (CS). ^{18}F-FDG PET/CT in CS is one of the major criteria in diagnosing disease activity of CS, and helps in therapy monitoring however, requires stringent patient preparation/ dietary modifications for suppressing myocardial FDG uptake. ^{68}Ga-DOTANOC imaging for somatostatin receptors (SSTR) expressed in sarcoid granulomas, maybe an alternative, as it shows minimal physiological myocardial uptake & does not require dietary modifications to suppress myocardial radiotracer activity. ***Materials and Methods:*** This prospective study enrolled twenty-three patients, either biopsy-proven pulmonary sarcoidosis patients with suspected cardiac involvement or patients presenting with a primary cardiac abnormality with clinical features & histopathological diagnosis from a systemic site. Patients underwent CMR, ^{13}N-NH_3, ^{18}F-FDG (after low carbohydrate high fat protein diet preparation), and ^{68}Ga-DOTANOC PET/CT studies. Patient wise and cardiac segment wise analysis was done using Cohen's kappa to assess inter-modality agreement among three modalities. Mean SUVmax and target to background blood pool ratio (TBR) for positive lesions on DOTANOC and FDG PET were also calculated. ***Results:*** All patients underwent ^{68}Ga-DOTANOC & ^{18}F-FDG PET/CT, whereas only 19 patients could undergo CMR. ^{68}Ga-DOTANOC & CMR showed almost perfect intermodality agreement on segment-wise analysis [Cohen's kappa 0.88 (p-value 0.004)] and good intermodality agreement on patient-wise analysis [Cohen's kappa 0.51 (p-value 0.003)]. ^{18}F-FDG PET/CT showed almost perfect intermodality agreement with CMR on segment-wise analysis [Cohen's kappa 0.80 (p-value 0.004)] and good intermodality agreement on patient-wise analysis [Cohen's kappa 0.77 (p-value 0.001)]. Mean lesion SUVmax and TBR were not significantly different for ^{68}Ga-DOTANOC (6.6 ± 2.8 & 3.4 ± 1.4 respectively) and ^{18}F-FDG (9.0 ± 5.4 & 3.6 ±1.2 respectively). ***Conclusion:*** In conclusion, ^{68}Ga-DOTANOC PET/CT emerges as a highly effective and convenient imaging modality for diagnosing and managing cardiac sarcoidosis, demonstrating diagnostic performance comparable to ^{18}F-FDG PET/CT and cardiac magnetic resonance (CMR). Its favorable imaging characteristics, including high target-to-background ratios and reduced physiological myocardial uptake, enhance its utility in accurately detecting active cardiac sarcoid lesions. Furthermore, the streamlined preparation process and lack of dietary restrictions offer significant advantages in clinical practice, improving patient compliance and potentially less indeterminate results for reporting physician. The results of this study support the integration of ^{68}Ga-DOTANOC PET/CT into the diagnostic algorithm for cardiac sarcoidosis, warranting further prospective studies to validate its role and optimize its application in routine clinical settings.

EPS-112

The relationship between myocardial blood flow assessed by dynamic CZT-SPECT and the radiomics features of coronary artery calcification in NOCAD patients

K. Zavadovsky*, A. Maltseva, I. Taskaev, A. Dasheeva, A. Mochula;*
Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Coronary artery calcification (CAC) is a marker of cardiovascular disease risk. Although myocardial blood flow (MBF) impairment and CAC have a weak inverse correlation, radiomics analysis of CAC may offer a more informative approach for evaluating MBF compared to the Agatston Calcium Score. Therefore, this study aimed to assess the relationship between MBF and radiomics features of CAC in patients with non-obstructive coronary artery disease (NOCAD). ***Materials and Methods:*** Based on CCTA results, 34 NOCAD patients (stenosis <50%; 23 men; mean age 59.0±9.6 years) were included in the study. We assessed CAC using the Agatston Calcium Score and the Calcium Volume Score. All patients underwent dynamic CZT-SPECT to assess stress and rest myocardial blood flow (SMBF or RMBF) and myocardial flow reserve (MFR) [1,2]. Radiomics features of CAC were additionally estimated using the Pyradiomics module in 3D Slicer 5.7.0. ***Results:*** Based on SMBF values, patients were divided into two groups: reduced SMBF (<1.5; n=19) and normal SMBF (≥1.5; n=15). The Agatston Calcium Score showed no significant difference between groups: 62.0 (44.0; 246.0) vs. 39.0 (17.0; 102.0), whereas patients with reduced SMBF had significantly higher the Calcium Volume Scores: 30.0 (17.0; 90.0) vs. 12.0 (4.0; 28.0) mm3. SMBF demonstrated significant inverse correlations with radiomics features: Glszm-SizeZoneNonUniformity (ρ=-0.37), Firstorder-Energy (ρ=-0.37), Glrlm-RunLengthNonUniformity (ρ=-0.37), Voxel count (ρ=-0.37), Gldm-DependenceEntropy (ρ=0,38), Firstorder-TotalEnergy (ρ=-0.39), Shape-VoxelVolume (ρ = -0.39), Glszm-ZoneEntropy (ρ=-0.40), Shape-MeshVolume (ρ=-0.42), Glcm-Idn (ρ=-0.43), Glcm-Idmn (ρ=-0.44), with a stronger correlation than the Agatston Score (ρ=-0.37). MFR showed significant inverse correlations with Firstorder-Minimum (ρ=-0.40), Shape-Sphericity (ρ=-0.40), Shape-MeshVolume (ρ=-0.39), Glrlm-RunLengthNonUniformity (ρ=-0.39), Glcm-Idmn (ρ=-0.39), Glszm-ZoneEntropy (ρ=-0.39), Shape-MajorAxisLength (ρ=-0.39), Shape-MinorAxisLength (ρ=-0.41), Glszm-GrayLevelNonUniformity (ρ=-0.42), Shape-Maximum3DDiameter (ρ=-0.42), Gldm-GrayLevelNonUniformity (ρ=-0.43), Glrlm-GrayLevelNonUniformity (ρ=-0.44), with a stronger correlation than the Agatston Score (ρ=-0.37) and Calcium Volume Score (ρ=-0.39). ***Conclusion:*** SMBF and MFR had significant inverse relationship with radiomics features of CAC. This approach offers a novel and potentially more effective method for assessing the impact of CAC on myocardial perfusion in NOCAD patients compared to the conventional the Agatston Calcium Score. ***References:*** 1.Mochula A, et al. The Influence of Kinetic Models and Attenuation Correction on Cadmium-Zinc-Telluride Single-Photon Emission Computed Tomography (CZT SPECT)-Derived Myocardial Blood Flow and Reserve: Correlation with Invasive Angiography Data. EPS-113

Early Detection of Anthracycline Combined with Immune Checkpoint Inhibitor Therapy-Related Cardiotoxicity Using [18F]FDG PET MRI

Y. Cai[1], *T. Yuan*[2], *X. Xu*[3], *Y. Sun*[4], *X. Chen*[5], *h. zhu*[3], *T. Wu*[1], *Z. Yang*[3], *X. Wang*[1];
[1]Department of Nuclear Medicine, National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College,, Beijing, CHINA, [2]Department of Nuclear Medicine, Peking University First Hospital,, Beijing, CHINA, [3]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Peking University, Beijing, CHINA, [4]Department of Pathology, Fuwai Hospital, National Cardiovascular Center, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA, [5]Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Nuclear Medicine, Peking University Cancer Hospital, Beijing, CHINA.

Aim/Introduction: To verify whether [18F] F -FDG PET/MRI can predict Anthracycline Combined with immune check point inhibitor Therapy-Related Cardiotoxicity ***Materials and Methods:*** Experimental procedures were carried out on female BALB/c mice, ranging from 6 to 8 weeks in age and weighing 18-20 g. The mice were divided into PD-1group, P-A group (anti-PD-1 + doxorubicin), and control group. Cardiac uptake of radiopharmaceuticals was evaluated via γ-counting and PET/MRI imaging. Combined with light microscopy (H&E, Masson's trichrome, CD68 immunostaining) to observe myocardial pathological changes. Human trials included 29 lymphoma patients undergoing anthracycline and PD-1 therapy. Cardiotoxicity was defined per 2022 ESC criteria, with patients stratified into ECG[+] (n=18) and ECG[-] (n=11) groups. Cardiac toxicity was assessed using [18F] F -FDG PET/MRI. Diagnostic accuracy was determined via ROC curve analysis. Data were analyzed with SPSS and GraphPad Prism ($p<0.05$) ***Results:*** In animal experiments, there was no basic uptake in myocardium in control group, the myocardium showed increased uptake of [18F] F -FDG in 4-week PD-1 group,6-week PD-1 group and P-A groups, The myocardial cell swelling and degeneration and focal macrophage infiltration of the epicardium were observed in 4-week PD-1 group , 6-week PD-1 group and P-A groups by optical microscope. In clinical studies, the [18F] F -FDG SUVmax_heart in ECG(+) group was higher than that in ECG(-) group, and GLS, GRS, GCS in ECG(+) group were lower than that the in ECG(-) group (all P values <0.05). Following 3-4 cycles of PD-1 inhibitor therapy, SUVmax_heart were elevated in the ECG(+) group compared to ECG(-) group. SUVmax_heart exhibited optimal diagnostic performance for cardiotoxicity injury (cut-off: 3.0; AUC=0.768; sensitivity=77.8%; specificity=81.8%; PPV=77.8%; NPV=81.8%; accuracy=79.3%). ***Conclusion:*** [18F] F -FDG PET/MR imaging can identify anthracycline/PD-1-induced cardiotoxicity in lymphoma patients at an early stage. anthracycline Combined with Immune checkpoint inhibitor therapy may induce myocardial damage, manifesting as reduced left ventricular full-thickness wall motion, with SUVmax_heart serving as a sensitive diagnostic parameter for cardiotoxicity.

EPS-114

Low myocardial flow reserve would predict all-cause mortality, cardiovascular mortality, and non-cardiovascular mortality in end stage kidney disease patients

S. Ohshima;
Kaikoukai Nagoya Kyoritsu Hospital, Nagoya, JAPAN.

Aim/Introduction: We have reported that low myocardial flow reserve (MFR) would predict all cause mortality and major cardiovascular event in end stage kidney disease (ESKD) patients. However it is unclear about the prognostic value of low MFR in cardiovascular(CV) or non CV mortality in these patients. In this study, we investigated the prognostic value of low MFR in all-cause mortality, cardiovascular (CV) mortality and non- CV mortality in ESKD patients. ***Materials and Methods:*** 1020 HD patients who underwent N^{13}-NH_3-PET myocardial perfusion imaging (MPI) suspected for ischemic heart disease were included. They are divided into two groups according to median value of MFR (2.0). We collected all-cause mortality, CV mortality and non-CV mortality. We have followed them for 1282 days. ***Results:*** We found any cause of death were 285 cases (the high MFR group vs the low MFR group; 165 (35.5%) vs 118 (21.3%), $p<0.001$), CV death were 121 cases (52 (9.4%) vs 68 (14.6%), $p=0.010$) and non-CV death were 164 cases (66(11.9%) vs 97 (20.9%, $p<0.001$)). Kaplan-Meier curve analysis and Cox regression model showed the low MFR groups had poor prognosis for all-cause mortality (log rank; $p<0.001$, hazard ratio (HR); 1.9964, 95% confidential interval (CI); 1.576-2.529), CV mortality (log rank; $p=0.0009$, HR; 1.834, 95%CI; 1.278-2.633) and non-CV mortality (log rank; $p<0.0001$, HR; 2.213, 95%CI; 1.555-2.907). Furthermore, multivariate cox regression model analysis showed the continuous value of MFR was an independent predictor for both all-cause mortality (HR0.180, 95%CI 0.074-0.435, $p=0.0001$) and non-CV mortality (HR0.553, 95% CI0.397-0.769, $p=0.0004$). ***Conclusion:*** In ESKD patients, low MFR would be an important predictor for all-cause mortality, CV mortality and non-CV mortality.

Filling A Void: An altered teaching method for Nuclear Medicine Technology in Australia

M. Scalzo[1], *K. Metzger*[1], *T. Pearson*[2], *J. Barlow*[3];
[1]RMIT University, Melbourne, AUSTRALIA, [2]Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA, [3]Queensland X-ray, Brisbane, AUSTRALIA.

Aim/Introduction: In response to insights from multiple workforce summits, RMIT University has developed the Embedded Student Model (ESM), a groundbreaking initiative designed to integrate academic theory with Work Integrated Learning (WIL). This transformative framework, created in collaboration with industry partners, equips students with clinical expertise, critical thinking, and professional skills essential for success in Nuclear Medicine imaging. The ESM addresses workforce shortages, combats student "placement poverty," enhances employability, and aspires to establish a replicable model for innovation in higher education. ***Materials and Methods:*** The ESM will balance academic instruction with industry engagement, addressing RMIT's limited presence outside Victoria through collaboration with public and private partners. This innovative apprenticeship-style approach integrates three days of remote learning with two days of practical experience each week, preparing students for professional success. RMIT University ensures quality teaching, learning outcomes, and a supportive student experience for remotely delivered content. Combining theoretical knowledge with hands-on training, the ESM uses capability-based assessments and a real-world capstone project to equip graduates with the academic credentials and practical expertise needed for workforce readiness. ***Results:*** The ESM will deliver immediate impact beyond graduate numbers and job placements by addressing "placement poverty," as highlighted in the 2024 Australian Universities Accord. Through sustained industry partnerships, RMIT University provides students with real-world exposure, mentorship, and networking opportunities,

ensuring they graduate with in-demand skills aligned with workforce needs. This innovative approach not only tackles student hardships but also serves as a scalable and adaptable model for other educational programs. By expanding the ESM to States and Territories lacking undergraduate Nuclear Medicine training, RMIT can benefit the Nuclear Medicine profession Australia-wide. The program's inception, demonstrates how public and private industry collaborations can address shared challenges, enhancing both education and workforce readiness. ***Conclusion:*** The ESM bridges academia and industry, addressing skills gaps and combating placement poverty. By integrating theoretical learning with practical experience, it prepares graduates for meaningful careers. This innovative model has the potential to transform education, foster workforce readiness, and serve as a blueprint for both national and global adoption.

Revisiting SeHCAT: A Familiar Tool with Renewed Clinical Significance in Nuclear Medicine

M. Ryser, *S. Figueiredo, J. O. Prior, P. Ferreira, M. Nicod-Lalonde;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Bile acid malabsorption (BAM) is a prevalent etiology of chronic diarrhea. A sensitive and specific diagnostic method for this pathology is the SeHCAT (selenium-75 homochlic acid taurine) procedure. This test is experiencing a resurgence in the field of Nuclear Medicine, particularly with the introduction of new treatments options. The aim of this work is to describe how we implemented this procedure in our Nuclear Medicine Department and to share our experience. ***Materials and Methods:*** For the successful implementation of the SeHCAT investigation procedure in our Nuclear Medicine Department, we did a comprehensive review of existing literature and a collaborative discussion with a multidisciplinary team, including Nuclear Medicine Physicians, Gastroenterologists, Nuclear Medicine Technologists and the nursing staff. Several criteria had to be considered to establish an optimal protocol: patient preparation, radiopharmaceutical availability, acquisition parameters (timing post-radiopharmaceutical administration, imaging modalities, energy window specifications, collimation technique), interpretation criteria and waste management. ***Results:*** The implementation process in our department for this procedure took us 3 months. After considering all the above-mentioned criteria, a standardized protocol was developed and implemented. Our first patient was assessed in August 2024, and, by March 2025, we had conducted examinations on three patients. Our results revealed that two patients exhibited severe BAM, while one presented with mild BAM. The results of SeHCAT investigation guided subsequent therapeutic management. Specifically, the introduction of Colestyramine, a bile acid sequestrant, in the two patients with severe BAM led to a good response in controlling diarrhea, which was not the case in the patient presenting with mild BAM. ***Conclusion:*** Through the dedicated efforts of our multidisciplinary team, The SeHCAT investigation procedure was safely and efficiently implemented in our department. SeHCAT investigation enables us to effectively address the diagnostic needs of gastroenterologists, thereby enhancing patient care in the context of BAM.

OP-316

Correlating Subjective Evaluations in Equine Nuclear Scintigraphy with Radiomic Profiles, Serum Osteocalcin and C-Terminal Telopeptides of Type I Collagen

P. Tually[1], *J. Meadows*[1], *S. Tagore*[1], *G. Currie*[2];
[1]*TeleMedVET, Perth, Western Australia, AUSTRALIA,* [2]*Charles Sturt University, Wagga Wagga, AUSTRALIA.*

Aim/Introduction: The racehorse industry is facing increasing scrutiny under its social licence to operate, particularly concerning preventable injuries such as stress fractures. Advanced imaging tools like PET and SPECT and the emergence of blood biomarkers offer new opportunities to identify bone fatigue earlier and mitigate musculoskeletal injury (MSI) risk.This study aimed to explore the relationship between serum bone turnover markers and regional radiomic features from planar and SPECT imaging in Thoroughbred racehorses, to assess the potential of combined modalities in improving early detection of subclinical bone stress. ***Materials and Methods:*** A prospective study was conducted across two jurisdictions—Western Australia and Hong Kong—using clinically lame Thoroughbred racehorses undergoing nuclear scintigraphy. Blood samples were collected pre-radiotracer injection and analysed for osteocalcin (OC) and C-terminal telopeptides of type I collagen (CTX) using equine-specific ELISA kits. Samples were processed and analysed at a single laboratory to ensure consistency. In Australia, horses received standardised scintigraphic imaging with a SPECT-capable gamma camera (Millennium MPR, GE Healthcare). Radiomic features were extracted from predefined regions of interest using decay-corrected geometric mean values. Relative radiomic asymmetry (left vs right) and serum marker levels were assessed for association. ***Results:*** Horses with both elevated OC levels and asymmetry in radiomic values above a defined threshold were more likely to demonstrate regions of increased radiopharmaceutical uptake suggestive of developing bone pathology. While CTX alone was not associated with increased radiotracer uptake, the OC:CTX ratio appeared informative. Combined biomarker-radiomic screening identified a subset of high-risk cases not readily apparent from imaging or blood data alone. ***Conclusion:*** This study supports the feasibility of integrating radiomic and serum biomarker data to enhance early MSI risk detection in racehorses. Given the industry's need to address welfare concerns, particularly around preventable injuries, tools like SPECT imaging and OC:CTX analysis could contribute to improved monitoring protocols. Multimodal screening may play a future role in protecting horse welfare and supporting the industry's ongoing social legitimacy.

OP-317

Relationship of point-of-care β-hydroxybutyrate measurements with myocardial glucose uptake: an observational study.

S. Bourouis, *C. Derneden, Q. Shagera, F. Jamar, O. Gheysens, V. Depoortere;*
Cliniques universitaires Saint-Luc, Bruxelles, BELGIUM.

Aim/Introduction: 18F-FDG-PET/CT is widely used to diagnose inflammatory/infectious cardiac diseases. A limitation of 18F-FDG-PET is the physiological myocardial glucose uptake, which may interfere with image interpretation. Adequate suppression of physiological myocardial glucose uptake is crucial. To achieve adequate myocardial glucose suppression (MGS), patients follow a high-fat, low-carbohydrate diet for 24-48 hours combined with prolonged fasting (>12 hours) before FDG injection. Despite this, up to 20% scans remain non-diagnostic due to inadequate suppression. While dietary logs are often reviewed, no consistent link between nutrient intake and MGS was confirmed. Recent studies showed an inverse correlation between β-hydroxybutyrate (BHB) levels - a ketone body produced during fasting - and myocardial glucose uptake. BHB can be measured easily with point-of-care devices, making it a potentially useful tool. This observational study aimed to assess the relationship between BHB levels and MGS 18F-FDG-PET/CT. ***Materials and Methods:*** We studied 102 patients undergoing 18F-FDG-PET/CT for oncologic or cardiac inflammatory/infectious evaluation. All patients had capillary BHB levels checked prior to FDG injection using a point-of-care device. 72 patients with suspected cardiac conditions followed a dietary regimen with prolonged fasting. PET scans were performed 60-90 minutes post-injection and MGS was assessed

visually by experienced nuclear medicine physicians using a 4-point scale : diffuse myocardial uptake (score 0), uptake at the basolateral wall or basal ring sign (score 1), myocardial uptake equal to left ventricular bloodpool (score 2) and myocardial uptake less than left ventricular bloodpool (score 3). Scores 2 and 3 were considered as optimal suppression. ***Results:*** Cardiac 18F-FDG-PET scores were: 0 (19), 1 (12), 2 (35) and 3 (36). Median (IQ range) BHB values were significantly lower for scores 0 and 1 compared to 2 and 3, i.e. 0.1 (0.1-0.7), 0.2 (0.1-0.4), 0.8 (0.4-1.2) and 0.8 (0.4-1.2) mmol/L, respectively. When combining scores 0/1 and 2/3, median (IQ range) BHB values were significantly lower for scores 0/1, 0.2 (0.1-0.4) vs 0.8 (0.4-1.2), respectively; P<0.01. Patients with adequate preparation had higher BHB levels than those without (0.7 vs 0.2 mmol/L; P<0.05). ROC curve analysis yielded an AUC of 0.8, with a BHB cutoff of ~0.45 mmol/L predicting good MGS (sensitivity 73%, specificity 77%). Correlation between BHB and glucose was weak (R = -0.24). ***Conclusion:*** Point-of-care BHB measurement is feasible and levels correlate inversely with myocardial glucose uptake. Dietary preparation increases BHB levels, and BHB monitoring may help optimize the management of patients referred for cardiac inflammatory/infectious evaluation.

OP-318

Design and Fabrication of Spherical Inserts using Stereolithography for 10 L Imaging Validation Phantom

N. Salkica[1], *M. Jusufbegović*[2], *A. Beganović*[3], *A. Skopljak-Beganović*[3], *S. Hadžimusić*[1], *E. Tinjak*[4];
[1]*Clinic of Nuclear Medicine, Sarajevo, BOSNIA AND HERZEGOVINA,* [2]*Clinic of Radiology, Sarajevo, BOSNIA AND HERZEGOVINA,* [3]*Department for Medical Physics and Radiation Protection, Sarajevo, BOSNIA AND HERZEGOVINA,* [4]*Clinic of Oncology, Sarajevo, BOSNIA AND HERZEGOVINA.*

Aim/Introduction: Imaging validation phantoms are commonly used for calibration, resolution testing, and contrast evaluation in imaging modalities such as positron emission tomography (PET), single-photon emission computed tomography (SPECT), and computed tomography (CT). The focus is on achieving dimensional and volumetric accuracy, optical clarity, and mechanical robustness to ensure valid and reproducible experimental outcomes. The aim of this study is to design and construct six spherical inserts for 10 L acrylic phantom with (inner diameters: 10, 13, 17, 22, 28, and 37 mm) using stereolithography (SLA) and clear photopolymer resin. ***Materials and Methods:*** The phantom was designed using parametric computer-aided design (CAD) software, ensuring precise manipulation of geometry and dimensional tolerances. The nominal dimensions of 24.1 × 30.5 × 24.1 cm were chosen to provide a total volume of 10 L. Wall thicknesses between 3-5 mm were selected to optimize the balance between mechanical rigidity and attenuation effects. To reduce resin consumption, the external container was partitioned into multiple panels for bonding. Six spherical inserts, with internal diameters of 10, 13, 17, 22, 28, and 37 mm, were designed with shell thicknesses of 1-2 mm. These inserts were equipped with integrated fill ports or vent channels to facilitate fluid introduction and removal. Mounts or rods inside the main phantom volume ensured stable positioning of the spheres. For the SLA printing process, a clear resin was selected based on compatibility with the SLA machine and its mechanical and optical properties. Post-processing included UV-curing to stabilize the prints, followed by wet-sanding and polishing to enhance optical clarity. Final assembly used UV-curing adhesives or epoxy formulations, with leakage testing conducted under internal pressure. ***Results:*** The assembled 10 L acrylic phantom was dimensionally accurate, with all six spherical inserts positioned securely within the main phantom volume. Attenuation characteristics of materials used for phantom production was assessed and found to be suitable for imaging validation. Leakage testing confirmed the integrity of the seals at all interfaces, and no significant seepage was observed. ***Conclusion:*** The construction of a 10 L acrylic phantom with six spherical inserts using SLA and clear resin is a feasible and effective approach for producing a dimensionally precise and transparent phantom for advanced imaging validation and calibration studies. Attention to design details, material properties, print orientation, support strategies, and post-processing techniques is essential to ensure the phantom's accuracy and reliability. The fabricated phantom is suitable for use in PET, SPECT, and CT imaging applications, offering a robust tool for calibration and testing.

OP-319

Evaluating the Effectiveness of Virtual Reality as a distraction tool in Pediatric Scanning Procedures - To Enhance Image Quality and Reducing Anesthesia use

N. Svendsen*, V. Setterberg;*
Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Distraction during such procedures is essential in pediatric care. Effective techniques reduce anxiety, promote trust, and prevent delays in language and speech development. VR glasses, with healthcare-specific games, offer a promising distraction tool. The glasses feature calming, engaging games to help the child remain still and reduce distress. We have modified the user interface from vertical to horizontal gameplay, so it can now be used during scanning procedures. Including a 180-degree field of view so the child can keep the head in one position. ***Materials and Methods:*** The Pediatric Technologist Team is often consulted within the department when children struggle to cooperate during scanning procedures, due to fear, anxiety, or restlessness. We introduced the VR-glasses for scanning procedures in 30 children aged 5-13 y. as a distraction tool in these cases where standard distraction (movies in the ceiling etc.) was not sufficient. The remote control is functioning with only small movements of the hand, that do not interfere with the scanning procedure. ***Results:*** A total of 30 children used the VR glasses during scanning procedures. During the test period the intervention was ineffective in 4 of the 30 children; with 3 children not being able to distract the children and 1 child declining to use the glasses. And in the remaining 26 children the procedure was performed successfully with satisfied child and parents and a high-quality study. Most of the children had renographies, hepatobiliary scintigraphies or SPECT/CT of the abdomen or the extremities performed. The VR intervention allowed the children to remain still and calm, reducing the need for anesthesiologic support. ***Conclusion:*** In the majority of children that needed extra distraction, VR glasses were more effective than standard distraction methods. Unlike passive techniques, as movie in the ceiling etc., VR allows children to actively engage in an immersive environment, fostering deeper focus, distracted the child, and improved cooperation. This active participation proved more effective in reducing stress compared to standard methods, which is not engaging the child in the same manner. The use of VR glasses furthermore reduced the need for anesthesiologic intervention and rescheduling of the scan. The experience helped children become fully engaged, often losing awareness of time and surroundings. These results suggest that VR is a promising tool in pediatric imaging as an extra tool for distraction.

OP-320

Preclinical PET Imaging of B7-H3 Expression Using Affibody Molecules Labelled with Positron-Emitting Gallium-68

M. Oroujeni[1], *V. Tolmachev*[1], *E. A. Bezverkhniaia*[1], *E. Papalanis*[1], *A. Mujahid Bin Muhammad*[1], *A. Verabyova*[1], *E. Gunneriusson*[2], *S. Klint*[2], *E. Ryer*[2], *M. Carlqvist*[2], *W. Kazmierczak*[2], *A. Orlova*[1], *F. Y. Frejd*[2];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Affibody AB, Stockholm, SWEDEN.*

Aim/Introduction: Affibody molecules, non-immunoglobulin scaffold proteins, have a high potential as probes for molecular imaging of different molecular targets. One of the molecular targets for radionuclide diagnosis and therapy is B7-H3 (known as CD276), which is overexpressed in various cancers, whereas its expression is low in most normal organs and tissues. The visualization of expression levels of B7-H3 has been performed using Affibody molecules labelled with Tc-99m. However, radionuclide molecular imaging using PET offers several advantages such as superior sensitivity, quantitation accuracy, and better spatial resolution compared to SPECT. In this study, we aimed to introduce a radiotracer for PET imaging of B7-H3 using Affibody molecules labelled with Ga-68. ***Materials and Methods:*** To design imaging agents for labeling with the generator-produced positron-emitting radionuclide ^{68}Ga, the macrocyclic triaza chelator (2-[4,7-bis(carboxymethyl)-1,4,7-triazonan-1-yl]acetic acid) (NOTA) chelator was site-specifically coupled to the C-termini of the anti-B7-H3 Affibody molecules. Four different variants of Affibody molecules, ZB7-H3_2, ZB7-H3_3, ZB7-H3_4, and ZAC12 (as control) were produced, characterized, and labelled with ^{68}Ga. In vitro characterization was performed on B7-H3-expressing cell lines. A head-to-head biodistribution of Affibody molecules labelled with ^{68}Ga was studied in mice bearing B7-H3-expressing SKOV-3 xenografts. PET/CT imaging was performed to confirm the biodistribution results. ***Results:*** All variants were successfully labelled with ^{68}Ga with high radiochemical yield and purity and demonstrated specific binding to B7-H3-expressing cells in vitro and in vivo. ^{68}Ga-labelled conjugates bound specifically to B7-H3-expressing cells in vitro and in vivo. Biodistribution demonstrated that the blood concentration of [^{68}Ga]Ga $Z_{B7\text{-}H3\text{—}2}$ (0.24±0.03 %ID/g) and [^{68}Ga]Ga $Z_{B7\text{-}H3\text{—}3}$ (0.27±0.02 %ID/g) was significantly ($p < 0.05$) higher than for the control variant, [^{68}Ga]Ga-Z_{AC12} (0.11±0.01 %ID/g) 2 h after injection. [^{68}Ga]Ga-ZB7-H3_2 had the highest tumor accumulation only 2 h after administration, which was 2.8-fold higher than for the control ZAC12. Tumor-to-liver ratio was significantly ($p < 0.05$) higher for [^{68}Ga]Ga-$Z_{B7\text{-}H3\text{—}2}$ (7.5±0.7) than for [^{68}Ga]Ga-$Z_{B7\text{-}H3\text{—}3}$ (3.9±0.2) and [^{68}Ga]Ga-$Z_{B7\text{-}H3\text{—}4}$ (4.4±0.8). There was a tendency for higher tumor-to-organ ratios compared to the other variants, resulting in higher imaging contrast using [^{68}Ga]Ga-ZB7-H3_2 for preclinical PET imaging of B7-H3-expressing tumors. ***Conclusion:*** The use of an Affibody-based tracer containing a NOTA chelator at the C-terminus provides labeling of the anti-B7-H3 Affibody molecule with ^{68}Ga. The newly introduced Affibody-based tracers are suitable for preclinical imaging of B7-H3 expressing tumors already 2 h after injection. [^{68}Ga]Ga-ZB7-H3_2 could be a promising candidate for further development aiming at clinical imaging in the future.

Using AI to assess PRRT response in ^{177}Lu-DOTATATE post-treatment scans: creation of a Python-based tool to automate inter-cycle comparison

F. Montanini[1], *E. M. Abenavoli*[2], *V. Briganti*[2], *M. Nerattini*[3], *A. Lastrucci*[4], *C. Galeotti*[1], *R. Ricci*[4], *R. Sciagrà*[2,3], *V. Berti*[2,3];

Aim/Introduction: Accurate assessment of treatment response in patients with metastatic neuroendocrine tumors (NETs) undergoing ^{177}Lu-DOTATATE therapy is essential for effective clinical management. Visual comparison of post-treatment whole-body (WB) acquisitions between consecutive cycles is often a challenging procedure, especially when evaluating the liver, due to the complex and variable distribution of lesions. This work aimed to develop an automated Python based software solution to quantitatively compare liver uptake across treatment cycles, overcoming the limitations of subjective visual analysis by providing a standardized and reproducible method to evaluate disease progression or regression. ***Materials and Methods:*** A custom software tool was developed using Python 3.13, leveraging artificial intelligence models to streamline coding. The software imports DICOM files of anterior and posterior WB acquisitions from two ^{177}Lu-DOTATATE treatment cycles. Images are then normalized by dividing pixel values by the mean counts value of a reference region, selectable as either the third lumbar vertebra or spleen. Automatic liver segmentation is performed on both anterior and posterior views of each cycle, with an option for manual adjustment of region-of-interest (ROI) contours to ensure accuracy. The segmented liver ROIs are registered and transformed to align perfectly between cycles, enabling direct comparison. Differences in uptake are calculated, with increased counts indicating lesion progression and decreased counts suggesting lesion response. The software finally generates a numerical and visual report summarizing changes. Extensive testing and debugging ensured robust functionality across various datasets. ***Results:*** The software successfully processed WB acquisitions, accurately segmenting the liver and aligning ROIs between cycles. Normalization using reference regions standardized counts values, ensuring reliable comparisons. The automated analysis highlighted uptake differences, with visual reports clearly depicting areas of increased or decreased counts. Testing confirmed the tool's ability to quantify disease changes rapidly, offering a significant improvement over visual assessment by providing objective data at a glance. ***Conclusion:*** This automated tool enhances the evaluation of ^{177}Lu-DOTATATE treatment response by quantifying liver uptake changes with precision and consistency in patients with metastatic NETs. By overcoming the limitations of subjective visual assessment, the tool offers a robust complement to qualitative evaluation, enabling clinicians to detect subtle variations in disease progression or regression with greater confidence. Future developments aim to expand the software's functionalities to include SPECT/CT acquisitions and whole-body lesion analysis, further broadening its applicability. ***References:*** •Weber et al. (2020). Quantitative imaging biomarkers for nuclear medicine: from SUV to AI. European Journal of Nuclear Medicine and Molecular Imaging, 47(6), 1400-1412.

Development of a Dynamic Flow Phantom for Routine Calibration and Quality Control in [^{82}Rb]RbCl PET imaging.

S. Mallem[1], *M. Bernardini*[2];
[1]*INSERM - U970 PARCC, Paris, FRANCE,* [2]*Hôpital Européen Georges Pompidou AP-HP, Paris, FRANCE.*

Aim/Introduction: [^{82}Rb]RbCl PET is increasingly used for myocardial perfusion imaging due to its ability to provide fast, quantitative assessment of myocardial blood flow. However, its short half-life (76 s) and automated injection systems complicate calibration and PET system quality control. Unlike [^{18}F]FDG, no standard phantom can be manually filled to verify the accuracy of injected activity and image quantification in clinical settings. We developed and validated a simple dynamic flow phantom to enable calibration and routine quality control for [^{82}Rb]RbCl PET. ***Materials and Methods:*** The system included a cylindrical phantom (as used for [^{18}F]FDG), connected to silicone tubing, a peristaltic pump, and a 3D-printed open injection chamber allowing automated injection without air bubble introduction. The circuit provided continuous flow, simulating clinical injection

conditions : early input function and later homogeneous distribution can be visualized. To calculate the total system volume, a known activity of [^{18}F]FDG was injected, and volumic activity was determined via gamma counter measurements after homogenization. PET acquisition started at injection time, and dynamic reconstruction showed tracer homogeneity suitable for quantification at 2 minutes. Quantitative analysis was performed over the 2-5 minute interval, in line with clinical protocols. The same procedure was applied with [^{82}Rb]RbCl at different activity levels. Image-based activity was compared with expected values to assess PET quantification accuracy and the reliability of the injected activity reported by the injector. ***Results:*** With [^{18}F]FDG, mean SUV was 0.97, corresponding to -3% deviation from expected activity. This confirmed both the accuracy of PET quantification for [^{18}F]FDG and the ability of the phantom to achieve homogeneous distribution within 2 minutes. With [^{82}Rb]RbCl, quantification was systematically lower than expected. A correction factor was derived for [^{82}Rb]RbCl acquisitions : the average deviation was −9% at high activity (1,480 MBq) and −5% at low activity (740 MBq), remaining within the commonly accepted ±10% tolerance for PET quantification. ***Conclusion:*** The dynamic flow phantom developed provides a practical and reproducible tool for [^{82}Rb]RbCl PET calibration and quality control. It allows realistic simulation of clinical injection, accurate verification of PET quantification, and consistent comparison between measured and injector-reported activity. The setup is easy to implement and suitable for integration into routine quality control procedures. ***References:*** Jensen, EJNMMI Phys, 2022 Bui, J Nucl Cardiol, 2020 Koenders, J Nucl Cardiol, 2022 Armstrong, J Nucl Cardiol, 2022 van Dijk, EJNMMI Phys, 2022 Gould, J Nucl Cardiol, 2011 Prior, Eur J Nucl Med Mol Imaging, 2012

Aim/Introduction: [^{177}Lu]Lu-PSMA single photon emission computed tomography (SPECT)/CT is a promising early response biomarker for [^{177}Lu]Lu-PSMA therapy in retrospective studies and an affordable alternative to PSMA-PET. ENZA-p is a prospective randomised phase II trial in metastatic castrate resistant prostate cancer (mCRPC). This ENZA-p sub-analysis aims to determine if a week 6 [^{177}Lu]Lu-PSMA-617 SPECT/CT is prognostic for clinical outcomes. ***Materials and Methods:*** Eligible participants (pts) were randomised (1:1) to either enzalutamide 160 mg daily or enzalutamide 160 mg daily +[^{177}Lu]Lu-PSMA-617 7.5 GBq (2 or 4 doses). All patients in the combination arm underwent a 25-minute SPECT/CT 24 hours after each [^{177}Lu]Lu-PSMA-617 therapy, with SPECT/CT imaging acquisition protocols, cameras and image reconstruction parameters standardised across the 15 trial sites. SPECT/CT images were centrally quantified with semi-automated software to derive total tumour volume (TTV) and standardised uptake value (SUV)mean. Reduction of >90% in SPECT-TTV and SUVmean at 6 weeks were considered significant. Change in SPECT/CT quantitative parameters (TTV and SUVmean) between dose 1 and dose 2 were correlated with clinical outcomes. ***Results:*** ENZA-p randomised 162 pts of whom

81 received enzalutamide plus (2 or 4 doses) 7.5Gbq ^{177}Lu]Lu-PSMA-617. 74/81 (91%) had analysable SPECT/CT. Median PSA-PFS was 12 months (95%CI: 10-16) with median overall survival 33 months (95%CI: 27-35). The median change in SPECT-TTV was -57% (IQR: -89% to -38%), with 24% of pts demonstrating a 90% reduction in SPECT-TTV at 6 weeks, 61% a 50% reduction, and 4.1% any rise in SPECT-TTV. Median PSA-PFS for pts with ≥90% volume response was 17 months (95%CI: 9.6-NE) vs 11 months (95%CI: 9.6-15) for <90% volume response, HR=0.56 (95%CI: 0.29-1.09). Median OS for pts with ≥90% volume response was 36 months (95%CI: 33-NE) vs 32 months (95%CI: 27-34) for <90% volume response, HR=0.49 (95%CI: 0.21-1.10). The median change in SUVmean was -30% (IQR: -56% to -13%), with 15% of pts demonstrating a 90% reduction in SUVmean at 6 weeks, 30% a 50% reduction, and 15% any rise in SUVmean. Median PSA-PFS for pts with ≥90% decrease in SUVmean at 6 weeks was 22 months (95%CI: 6.8-NE) vs 11 months (95%CI: 10-15) for <90% decrease, HR=0.45 (95%CI: 0.19-1.06). Median OS for pts with ≥90% decrease in SUVmean was not reached (95%CI: 21-NE) vs 32 months (95%CI: 27-34) for <90% decrease, HR=0.28 (95%CI: 0.08-0.90). ***Conclusion:*** [^{177}Lu]Lu-PSMA SPECT/CT quantitative parameters at 6-weeks is a candidate early prognostic biomarker for PSA-PFS and OS with enzalutamide plus ^{177}Lu]Lu-PSMA-617 therapy.

Aim/Introduction: The ideal imaging modality to guide metastasis-directed therapy (MDT) in oligometastatic castration-resistant prostate cancer (omCRPC) has yet to be fully established. The ARTO trial demonstrated that adding MDT to systemic treatment improves oncological outcomes in omCRPC. However, preliminary data from the MEDCARE trial suggest that the diagnostic accuracy of imaging tools may influence MDT efficacy in this clinical setting. Therefore, we aimed to evaluate the impact of PET-guided versus conventional imaging-guided MDT on clinical outcomes in omCRPC patients. ***Materials and Methods:*** We performed a secondary analysis using data from the PRECISE-MDT study, focusing on omCRPC patients treated with stereotactic body radiotherapy (SBRT) guided by either PET (PSMA or choline) or conventional imaging (CI). All patients received systemic treatment in addition to MDT. Inverse probability of treatment weighting (IPTW) was applied to adjust for AJCC stage, ISUP Grade Group, PSA value at the time of MDT, metastatic site, and number of metastases. Outcomes included progression-free survival (PFS), time to systemic treatment change (PFS2), and overall survival (OS). PSA response rates (PSA50 and PSA90) were also assessed. All survival analyses were censored at 48 months. ***Results:*** The IPTW-adjusted analysis showed significantly improved PFS in the PET-guided group compared to the CI-guided group (median 14.23 vs. 8.30 months; p=0.0422; HR=0.53; 95% CI [0.28, 0.99]) and a trend toward improved PFS2 favoring PET guidance (median 27.10 vs. 12.90 months; p=0.0840; HR=0.49; 95% CI [0.22, 1.12]). No significant difference was observed in OS (median not reached in either group; p=0.4042; HR=0.55). PSA50 response rates were comparable between groups (49.2% PET vs. 47.1% CI), as were PSA90 rates (24.6% PET vs. 23.5% CI). ***Conclusion:*** PET-guided MDT significantly prolongs the time to progression and shows a trend toward delaying systemic treatment change compared to conventional imaging-guided MDT in omCRPC patients, although PSA response profiles were substantially overlapping between groups. These findings support the use of next-generation imaging to optimize patient selection and treatment outcomes in the omCRPC setting, when MDT is chosen to intensify systemic treatment.

Assessment of PARPi-uptake in metastatic castration resistant prostate cancer patients using [^{18}F]PARPi- and [^{68}Ga]PSMA PET/CT

H. Einspieler*, H. Ofner, M. Ozenil, C. P. Spielvogel, I. K. Langrate, M. R. Hassler, L. Nics, K. Bamminger, P. A. T. Baltzer, S. F. Shariat, M. Hacker, G. Kramer, S. Rasul;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: [^{18}F] Poly-ADP-ribose polymerase inhibitors (PARPi) are a novel class of radiotracers that allow non-invasive PET imaging of PARP1 expression. In this study, we aimed to quantify PARPi uptake in tumor lesions of patients with metastatic castration-resistant prostate cancer (mCRPC) and to compare these findings with prostate-specific membrane antigen (PSMA) expression using PET/CT imaging. ***Materials and Methods:*** [^{18}F] PARPi and [^{68}Ga]Ga-PSMA-11 PET/CT scans from 22 male patients with mCRPC were retrospectively analysed. Lesions with relevant PARPi uptake (higher than background) were delineated and correlated with their PSMA-expression using standardized uptake values (SUV). Additionally, a comparison was performed to investigate the effects of homologous recombination deficiency (HRD) alterations on PARPi tumor uptake. ***Results:*** Most metastatic PCa lesions that exhibited PARPi uptake were located in the bones (n=57), with mean SUVmax values of 4.9 ± 1.5 for PARPi and 30.9 ± 28.3 for PSMA. Additionally, 3 local prostate lesions, 14 lymph nodes and 4 further metastatic lesions were detected. Significant correlations were identified between PARPi- and PSMA uptake, as measured by SUVmean (r=0.48, p<0.001), SUVpeak (r=0.48, p<0.001) and SUVmax (r=0.43, p<0.001) of the osseous metastatic lesions and SUVpeak (r=0.49, p=0.04) of extraosseous lesions. No significant differences were found between PARPi uptake of metastatic lesions in patients with or without HRD alterations (all p>0.05). ***Conclusion:*** Considerable uptake of [18F]PARPi was observed in multiple lesions in mCRPC patients, suggesting the potential of using [18F]PARPi as a diagnostic imaging tool in mCRPC patients. Further studies are needed to evaluate the clinical benefit of this innovative radiotracer. In the future, the use of PARPi PET imaging may support personalised treatment strategies and be a helpful tool in clinical decision making.

Aim/Introduction: Acid Phosphatase 3 (ACP3) is an emerging promising theranostic target for prostate cancer (PCa). It is expressed on the surface of PCa cells in most primary and metastatic lesions. ACP3 shows higher and more homogeneous expression

than PSMA in both low- and high-ISUP grade tumours as well as in metastases, while not being expressed in healthy organs such as salivary glands, kidneys, and gastrointestinal tract. We present preliminary data from an ongoing prospective, multicentre, phase I clinical trial investigating safety, dosimetry, pharmacokinetics, and diagnostic performance of [^{68}Ga]Ga-OncoACP3, a novel high-affinity ligand of ACP3 discovered from DNA-Encoded Chemical Libraries, in PCa patients. ***Materials and Methods:*** 20 patients with a confirmed diagnosis of PCa are planned for enrolment starting from April 2025 in two cohorts: Cohort A, 5 patients with primary tumour only; Cohort B, 15 patients with or without metastatic disease. Each patient receives an intravenous administration of 250 MBq [^{68}Ga]Ga-OncoACP3, followed by PET/CT imaging at 0-20, 60-, and 120-min post-injection. Blood and urine samples are collected at predefined timepoints to assess pharmacokinetics. Adverse events are reported according to CTCAE v.5.0. When available, [^{68}Ga]Ga-OncoACP3 PET imaging results are compared to PSMA PET and correlated with pathological findings from biopsy or surgery. ***Results:*** As of April 25th, two patients have been enrolled and completed [^{68}Ga]Ga-OncoACP3 PET imaging. No adverse events have occurred. [^{68}Ga]Ga-OncoACP3 demonstrated a mixed hepatobiliary and renal excretion, with no uptake in salivary glands. Suspect PCa lesions were visible on both 60- and 120-min post-injection acquisitions. Patient 1 previously underwent prostatectomy for ISUP 3 PCa and presented with biochemical relapse (PSA=0.26 ng/mL). PSMA PET showed an area of faint uptake (SUVmax=3.5) below the prostatic bed and an unspecific uptake in one rib (SUVmax=5.3). [^{68}Ga]Ga-OncoACP3 PET revealed intense uptake (SUVmax=16) in the same region of the prostate bed, with no bone uptake. Patient 2 presented with a history of multiple biochemical relapses of ISUP 5 PCa, with no evidence of disease at PSMA PET, subsequently treated with cycles of enantone (last administered on August 2024). [^{68}Ga]Ga-OncoACP3 PET, performed with PSA=5.3 ng/mL, detected intense uptake in a precaval adenopathy (SUVmax=26.4) and a moderate uptake in D9 (SUVmax=10.8). ***Conclusion:*** [^{68}Ga]Ga-OncoACP3 resulted safe and showed favourable biodistribution and targeting characteristics for PET imaging of PCa. [^{68}Ga]Ga-OncoACP3 could represent a valuable advancement over current PSMA-targeting modalities across the whole natural history of the disease, and particularly in theranostic applications.

OP-327

Theranostic targeting of the prostatic acid phosphatase (ACP3) with [^{68}Ga]Ga-OncoACP3-DOTA and [^{177}Lu]Lu-OncoACP3-DOTA in prostate cancer patients

P. Backhaus[1,2], *K. E. Seifert*[2,3], *S. Cazzamalli*[4], *S. Oehler*[4], *F. Migliorini*[4], *A. Ciamarone*[4], *T. Georgiev*[4], *J. Mock*[4], *M. Bögemann*[3], *H. Breyholz*[1], *D. Ventura*[1,2], *F. Landau*[1,2], *F. Büther*[1,2], *E. Puca*[4], *D. Neri*[4], *K. Rahbar*[1], *A. J. Schrader*[3], *M. Schäfers*[1,2];
[1]*Department of Nuclear Medicine, West German Cancer Center, University Hospital Münster, Münster, GERMANY,* [2]*European Institute for Molecular Imaging, University of Münster, Münster, GERMANY,* [3]*Department of Urology, Werst German Cancer Center, University Hospital Münster, Münster, GERMANY,* [4]*Philochem AG, R&D department, Otelfingen, SWITZERLAND.*

Aim/Introduction: Prostatic acid phosphatase 3 (ACP3) shows high expression in prostate cancer (PC) and barely any expression in healthy organs. Recently, a first-in-class high-affinity ACP3 ligand was isolated from a DNA-encoded chemical library [1]. In this retrospective analysis, the first 25 PET with [^{68}Ga]Ga-OncoACP3-DOTA (OncoACP3) and the first patient treated with [^{177}Lu]Lu-OncoACP3-DOTA were analyzed. ***Materials and Methods:*** Chemically pure OncoACP3-DOTA precursor was provided by Cazzamalli et al. [1] The radiotracer was produced and used according to Section 13(2b) of the German Medicinal Products Act. SUV_{mean} of normal organs and PC lesions' SUV_{max} for [^{68}Ga]Ga-OncoACP3 were compared against a PSMA-targeting radioligand (i.e., [^{18}F]F-PSMA-1007 or [^{68}Ga]Ga-PSMA-11) by Wilcoxon rank sum test. Superior diagnostic performance of either tracer was awarded if 50 % higher uptake or 10 % more PC lesions were detected. ***Results:*** 25 male PC patients received PET scans 62 min (mean) after injection of 145 MBq (median) OncoACP3. No side effects were observed. All patients had received PSMA-PET scans (23/25 [^{18}F]PSMA-1007, 2/25 [^{68}Ga]Ga-PSMA-11-PET) 17 days (mean) before the OncoACP3-PET. In comparison to [^{18}F]PSMA-1007, OncoACP3 uptake was significantly lower in the liver, kidney, parotid gland and small intestine (all $p < 0.002$). Blood retention was significantly higher for OncoACP3 ($p < 0.001$). OncoACP3-PET demonstrated PC manifestations in all 25 patients. In 11 patients with locoregional PC, performance was better for OncoACP3 in 6 and for PSMA in 3 patients (mean SUV_{max} OncoACP3 vs. PSMA: 24.1 vs. 11.2, n.s.). In 11 patients with lymph node metastases, performance was better for OncoACP3 in 4 and for PSMA in 2 patients (mean SUV_{max} OncoACP3 vs. PSMA: 20.2 vs. 14.9, p 0.018). In 17 patients with osseous metastases, diagnostic performance was better for OncoACP3 in 5 and for PSMA in 7 patients (mean SUV_{max} OncoACP3 vs. PSMA: 17.7 vs. 18.5, n.s.). OncoACP3 PET impacted further diagnostic work-up in 7 and therapy decisions in 8 patients. One patient was treated with two cycles of [^{177}Lu]Lu-OncoACP3 in compassionate use with 2.4 and 5.0 GBq. Treatment was well tolerated, PSA with a prior doubling time of < 1 month demonstrated response (1st cycle 46.5 ng/ml, 2nd cycle 48.3 ng/ml, 5 weeks after 2nd cycle 23.1 ng/ml). ***Conclusion:*** First theranostic ACP3-targeting demonstrates great potential of the ligand OncoACP3-DOTA in prostate cancer patients. ***References:*** [1] (Cazzamalli et al. Aim/Introduction: To compare PET/CT imaging targeting prostate-specific membrane antigen (PSMA) and fibroblast activation-protein (FAP) in metastatic hormone sensitive (mHS) and castration resistant (mCR) prostate cancer (PC). PSMA imaging is regarded as a game changer in evaluation of metastatic PC owing to its high sensitivity and value in radiotheranostics. However, other molecular targets such as FAP may be useful in patients with metastases showing low affinity for PSMA. ***Materials and Methods:*** FAPStera (EudraCT:2022-003788-13) is an ongoing prospective study, having enrolled 14/15 men with mHSPC and 20/25 men with mCRPC. Patients were required to present with at least one metastasis on conventional imaging (CT/MRI or bone SPECT). The median age was 73 (range, 61-83), 55 % had Gleason 4+5 PC and median pre-scan PSA was 55 ng/mL (range, 2-2000). The patients underwent long-axial field-of-view whole-body PET/CT twice within 2 weeks in random order with fluorine-18 labeled DCFPyL (PSMA) or FAP inhibitor FAPI-74. Each scan was reviewed by two experienced nuclear medicine physicians and the observed metastases were divided in groups as follows: pelvic lymph nodes, extra-pelvic lymph nodes, skeletal and visceral. SUVmax of the metastatic lesions was measured. Positivity on both PET scans was assessed according to predefined criteria. Clinical and tracer uptake data was analyzed using standard non-parametric statistical tests. ***Results:*** A total of 1097 lesions were identified in

34 patients with mPC. There were 9% (n=94) pelvic nodal, 12% (n=127) extra-pelvic nodal, 76% (n=833) skeletal, and 4% (n=43) visceral metastases, respectively. In skeletal, [^{18}F]DCFPyL imaging detected 99% (n=826/833) and [^{18}F]FAPI-74 58% (n=484/833) of the lesions, while that in pelvic nodal was 100% (n=94/94) with [^{18}F]DCFPyL and 52% (n=49/94) with [^{18}F]FAPI-74. In extra-pelvic nodes PSMA detected 86% (n=109/127) and [F]FAPI-74 55% (n=70/127) of lesions, while in visceral metastases [^{18}F]DCFPyL found 93% (n=40/43) and [^{18}F]FAPI-74 72% (n=31/43) lesions. Overall, 3% (n=28/1097) of metastases were negative for PSMA, 14% (n=18/127) of extra-pelvic nodal and 7% (n=3/43) of visceral metastases. Of these PSMA-negative lesions 61% (n=17/28) were positive for [^{18}F]FAPI-74. Generally metastatic lesions had higher SUVmax for [^{18}F]DCFPyL (median 25; range, 0-203) than [^{18}F]FAPI-74 (median 3.1; range, 0.1-23.2), although few cases in visceral lesions showed the opposite pattern of uptake. ***Conclusion:*** PSMA PET/CT remains the preferred molecular imaging method for evaluating metastatic PC. However, [^{18}F]FAPI-74 PET/CT may assist in selection of patients for theranostic approaches using alpha- or beta emitters especially in cases with multiple PSMA-negative lesions showing uptake of [^{18}F]FAPI-74.

Aim/Introduction: Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE) criteria have been established for standardized assessment of PSMA-PET. We aimed to investigate the impact of radiotherapy (RT) on overall survival (OS) across different stages determined by PROMISE using PSMA-PET in prostate cancer patients with biochemical recurrence (BCR). ***Materials and Methods:*** We included prostate cancer patients with biochemical recurrence following definitive therapy, who were recruited from a large international multi-center registry study. All patients underwent PSMA-PET at 20 centers worldwide, with known PSA level at the time of imaging and management plan determined after PSMA-PET. Molecular imaging TNM (miTNM) stages of all patients were determined according to PROMISE. Patients were divided into risk groups based on PSA levels (any PSA level; PSA level between 0-0.5 ng/ml; PSA level >0.5ng/ml). ***Results:*** Our cohort included 2738 patients, who underwent PSMA-PET between May 2013 and October 2024. The median follow-up duration was 5.1 years (3.6-6.8 years). As of data-cutoff, 390 patients (14.2%) had died. miTNM stages were: T0N0M0 in 791 patients (29%), TxNxM0 in 960 patients (35%), TxNxM1 in 987 patients (36%). The median time interval from PSMA-PET to RT was 1.9 months (1.0-3.6 months). Patients with salvage RT eligibility (T0N0M0 or TxNxM0) treated with RT had significantly longer OS compared to patients who were not treated (7 years survival rates: 90% vs 84%, p=0.0395). In the subgroup of T0N0M0, OS was significantly longer in RT group (7 years survival rates: 92% vs 87%, p=0.0179, In TxNxM1 group, RT was associated with significantly better OS at any PSA level as well as in patients who had PSA level>0.5 ng/ml (7 years survival rates: 77% vs 66%, p<0.001). ***Conclusion:*** This study highlights that prostate cancer patients in biochemical recurrent stage, who were treated with RT, had significantly longer OS across different PSMA-PET PROMISE stages. Longer OS was also observed in patients undergoing salvage RT for BCR with negative PSMA findings (T0N0M0) and in patients with PET metastatic disease undergoing palliative RT.

Kinetic Profiling of [^{68}Ga]Ga-PSMA-11 Using Total-Body PET in Suspected Prostate Cancer: Preliminary Results from the Prospective FUPERMAN Study

A. Farolfi[1], *I. Brusa*[1], *D. Dall'Olio*[2], *C. M. P. Sgro*[3], *L. Bianchi*[4], *R. Mei*[1], *C. Nanni*[1], *P. Castellucci*[1], *S. Fanti*[1];
[1]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Department of Medical and Surgical Sciences, Alma Mater Studiorum - University of Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Bologna, ITALY,* [4]*Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Multiparametric MRI (mpMRI) is the cornerstone for prostate cancer (PCa) diagnosis but shows limited sensitivity in PI-RADS 1-3 lesions, risking underdetection of clinically significant prostate cancer (csPCa). The FUPERMAN study investigates the added diagnostic value of PSMA-PET in patients with negative/equivocal mpMRI findings, using real-time PSMA-PET/fusion-target biopsy. In this sub-analysis, we leveraged dynamic total-body PET to explore [^{68}Ga]Ga-PSMA-11 pharmacokinetics, aiming to identify kinetic parameters that distinguish malignant from benign prostate lesions. ***Materials and Methods:*** FUPERMAN is a prospective, single-center study enrolling men with suspected PCa (PSA≥4ng/mL, PSA density≥0.1ng/mL^2, family PCa history) and negative/equivocal mpMRI (PI-RADS 1-3). This sub-analysis included patients who underwent 60-min dynamic [^{68}Ga]Ga-PSMA-11 PET on a total-body system (FOV=194 cm) within 6 months of mpMRI. Volumes of interest (VOIs) were manually delineated on intraprostatic areas with increased uptake and on reference prostate tissue without significant uptake. Lesions were scored using the PRIMARY Score (PS), with PS ≥3 considered positive and targeted with transperineal PSMA-PET/fusion-target biopsy; all patients also underwent systematic biopsy. csPCa was defined as ISUP grade group ≥2. Kinetic analysis included time-activity curves, graphical models (Patlak, RE), and compartment models (1TC, 2TC, 2TiC). Model fit was assessed using mean absolute scaled error and Akaike Information Criterion. ***Results:***

Ten men were enrolled (median age: 62, PSA: 16.09 ng/mL, dPSA: 0.45 ng/mL^2). Among 16 lesions, 2 had PS 2 (0% csPCa), 5 had PS 3 (40% csPCa), 4 had PS 4 (25% csPCa) and 5 had PS 5 (100% csPCa). Eight lesions were negative for csPCa on histology (PET+/csPCa-). Patlak modeling fit 4/5 PS 5 lesions best, suggesting irreversible uptake; all others fit better with reversible models (RE), similar to 8/8 lesions PET+/csPCa- and normal prostate. Compartment analysis revealed that all PS 3-4-5 lesions, PET+/csPCa- lesions and reference prostate were best described by irreversible uptake (2TiC). K1, k3, and Ki were significantly higher in PS 3-4-5 lesions vs reference tissue ($p<0.05$). Ki strongly correlated with SUVmax/SUVmean (Rho>0.8, $p<0.001$), while k_2 inversely (Rho=-0.83, $p=0.0053$). Ki outperformed SUV in sensitivity (89% vs 78%, both at 94% specificity). Among PS 3 lesions, k3 best distinguished csPCa from false-positive PET findings ($p=0.037$). ***Conclusion:*** Dynamic [^{68}Ga]Ga-PSMA-11 total-body PET reveals promising kinetic biomarkers, particularly Ki and k3, for identifying csPCa in patients with inconclusive mpMRI. Kinetic modeling (i.e. k3) enhances specificity in PRIMARY score 3 lesions where visual and SUV-based evaluation often fail. Further validation is ongoing.

^{177}Lu-PSMA-1 applied to ccRCC

***A. Giraudet**, A. Vinceneux, A. Sanchez-Lajusticia, G. Garin, J. Badel, D. Perol, A. Bidaux, C. Cropet, C. Trolliet, D. Kryza; Centre Léon Bérard, Lyon, FRANCE.*

Aim/Introduction: PSMA is over expressed in 86-100% of clear cell RCC (ccRCC)(1). PSMA-PET in ccRCC have demonstrated a greater sensitivity compared to conventional imaging(2). ^{177}Lu-PSMA is safe, increases OS for prostate cancer patients. PRADR is an ongoing prospective phase I/II study evaluating its tolerability and efficacy for metastatic ccRCC (mccRCC) patients pre-treated with immunotherapy and TKI. We report preliminary results of the safety run cohort concerning PSMA-PET and ^{177}Lu-PSMA SPECT-CT findings. ***Materials and Methods:*** This prospective multicentrique phase I/II study planned to include up to 42 patients, including 6 patients in a safety run conducted in Léon Bérard Cancer Center, treated with maximum 4 cycles of 7.4 GBq of ^{177}Lu-PSMA-1 radiolabeled on site. A positive lesion on PSMA PET had to demonstrate a lesion SUV max/liver SUVmean ≥ 1.5. Patient eligibility required at least 50% of positive supracentimetric extrahepatic lesions, and ≥ 80 % of positive supracentimetric liver metastatic in case of liver mets. Whole body SPECT-CT on 360° CZT-CT was repeated at 4h, 24, and D7 after injection at cycle 1 for dosimetry purpose. Lesions uptake was visually compared to background and normal liver uptake. Treatment tolerance and efficacy is still evaluated. ***Results:*** Eleven patients included in the safety run were screened. Six of them fulfilled PSMA-PET positivity criteria and up to day had received at least one cycle of ^{177}Lu-PSMA-1. Treated patients presented with bone (N=5 patients), pleural (N=2), lung (N=4), liver (N=1), peritoneal (N=3), nodal (N=3), soft tissues (N=4), adrenal (N=2), pancreatic (N=2) metastases. In all patients, lesions uptake highly decreased over time on repeated ^{177}Lu-PSMA SPECT-CT and demonstrated a complete clearance of all lesions in 4/6 patients, and almost in the remaining. Despite intense lesions uptake on H4 SPECT-CT, 5/6 patients demonstrated at least 1 supra-centimetric lesion showing no uptake. ***Conclusion:*** In highly selected mccRCC patients on lesions uptake intensity on PSMA-PET, ^{177}Lu-PSMA lesions uptake is highly heterogenous in the same patient, and tends to demonstrate an almost complete wash-out on D7 SPECT-CT in all patients. ***References:*** (1). Optimization and Scale-Up of ^{177}Lu Radiolabeling of PSMA-ALB-56 for Automated Patient Dose Preparation

C. Fersing[1,2], *J. Torchio*[1], *S. Renaud*[1], *L. Rubira*[1], *J. Vanney*[1]; [1]*Montpellier Cancer Institute, Nuclear Medicine Unit, Montpellier, FRANCE,* [2]*IBMM, Univ Montpellier, CNRS, ENSCM, Montpellier, FRANCE.*

Aim/Introduction: Targeted radionuclide therapy using ^{177}Lu-labeled ligands of the prostate-specific membrane antigen (PSMA) is now established as an effective treatment for metastatic castration-resistant prostate cancer. Recently, chemical modification of PSMA radioligands with albumin-binding motifs has shown promise in improving biodistribution and tumor uptake. Among these, PSMA-ALB-56 has demonstrated excellent preclinical results and is now entering clinical evaluation. However, current literature describes its ^{177}Lu radiolabeling using conventional conditions, with limited investigation into process optimization [1]. Thus, a study was conducted to explore key synthesis parameters for [^{177}Lu]Lu-PSMA-ALB-56. Optimized conditions were subsequently scaled up using an automated radiolabeling protocol suitable for clinical dose preparation. ***Materials and Methods:*** Radiolabeling conditions for [^{177}Lu]Lu-PSMA-ALB-56 were evaluated using manual, non-purified syntheses. No-carrier-added $^{177}LuCl_3$ (3.27 GBq/mg) was used. The effect of five different buffer systems on the radiochemical purity (RCP) of the complex was assessed. RCP was determined by high-performance liquid chromatography (HPLC). The influence of four antioxidants on complex stability over 48 h was also evaluated by HPLC. Each condition was tested in triplicate. Optimized parameters were then transferred to an automated procedure using a ^{68}Ga workflow. Three batches were produced and analyzed for RCP, radiochemical yield (RCY), 120 h stability, radionuclidic purity and radionuclide identity. ***Results:*** Twenty-seven radiolabeling reactions were performed manually using 25 µg of PSMA-ALB-56 and 80 MBq of ^{177}Lu, heated at 98 °C for 30 min. Three buffers (1 M ammonium acetate, 1.8 M ascorbic acid, 1.25 M HEPES) yielded excellent RCPs (>98%). Lower molarity buffers (0.1 M ammonium or sodium acetate) gave similar results. Maintaining pH ~4.5 was critical. Methionine and ascorbic acid preserved RCP >97% over 48 h, while 3.5 mM gentisic acid improved peak resolution on HPLC. Cysteine inhibited complexation. Automated syntheses yielded [^{177}Lu]Lu-PSMA-ALB-56 in 30 min with RCP of 98.9 ± 0.1% post-purification on C_{18} cartridge. Methionine 18.75 mg/mL in the reaction medium and ascorbate 3.6 mg/mL in the final formulation maintained RCP >95% over 120 h. Mean radiochemical yield was 86.5 ± 0.5%, with final vial recovery of 87.4 ± 0.5% and apparent molar activity of 40.1 ± 2.3 GBq/µmol. Radionuclidic purity and identity matched ^{177}Lu specifications. ***Conclusion:*** The use of 0.11 M sodium acetate (0.25 mL) and 25.7 mg/mL methionine (1.5 mL) at pH 4.5 (0.65 mL of HCl 0.1 M) enabled efficient automated production of [^{177}Lu]Lu-PSMA-ALB-56. Three test batches (>2 GBq) demonstrated excellent stability over 5 days, and doubling the starting activities would allow GMP-compliant production of patient doses. ***References:*** [1] C. A. Umbricht, et al. Mol Pharm. 2018, 15, 2297−2306.

OP-344

Fully compliant automated cassette-based sterility testing of radiopharmaceuticals on miniAllinOne

T. Vergote[1], *C. Vriamont*[1], *P. Novelli*[1], *F. De Meeus d'Argenteuil*[1], *K. Van Butsele*[1], *G. Zeiske*[2], *M. Nousch*[2]; [1]*Trasis, Ans, BELGIUM,* [2]*CUP Contract Labs, Radeberg, GERMANY.*

Aim/Introduction: Sterility testing is mandatory for all parenteral (radio)pharmaceuticals intended for human use, as required by European and US Pharmacopeias [1,2]. In the US, the test must be conducted within 30 hours post-manufacturing. However, radioactivity introduces unique challenges. Few facilities, like Cup Lab (DE), are authorized to conduct such tests. Radioactivity can also cause false negatives due to bacteriostatic or bactericidal effects, potentially allowing bacteria to proliferate post-administration. A solution is needed that complies with regulations, is simple, robust, economical, and eliminates radioactivity interference to ensure accurate results. ***Materials and Methods:*** A sterile, single-use cassette system was developed, integrating components for immediate, automated sterility testing, including filtration membrane and culture media. The sterility of the setup was evaluated, along with its ability to support aerobic and anaerobic microbial growth. Reference strains recommended by pharmacopeias were introduced into the filtration units, followed by growth media, and microbial growth was monitored. Aerobic (TSB at 25°C) and anaerobic (FTM at 32°C) growth were tested. Initial sterility tests on freshly produced radiopharmaceuticals show promising results. ***Results:*** Unlike manual methods, this approach enables immediate post-production testing in a simple, fully automated way, ensuring operator safety from radiation. The single-use cassette includes four filter units serving as test chambers for sterility and controls, designed to detect biological contaminants. Within a laminar flow hood, the cassette is placed on the miniAllinOne synthesizer and connected to buffers, media, and sample. The automated process then runs independently. Initial sterile runs confirmed absence of growth. When reference microorganisms (≤100 CFU) were added, robust growth occurred for Bacillus spizizenii, Clostridium sporogenes, Pseudomonas paraeruginosa, and Staphylococcus aureus within three days, and for Candida albicans and Aspergillus brasiliensis within five days. Preliminary automated tests on batches of radiopharmaceuticals meet sterility requirements, with approximately 30 minutes needed to prepare both test and control samples for incubation. ***Conclusion:*** This closed, sterile system reduces contamination risks and integrates into automated workflows, minimizing human intervention. It complies with both European and American Pharmacopeia sterility testing standards and supports growth of critical reference microorganisms. This proof-of-concept shows strong potential to standardize sterility testing in radiopharmaceutical quality control, enabling routine implementation across the industry. ***References:*** [1] Ph. Eur., Chapter 2.6.1. Sterility [2] USP, Chapter <71> Sterility Tests

OP-345

^{225}Ac-radiopharmaceuticals and Their Daughters - HPLC-Based Liquid Scintillation Detection for Routine Characterization

***G. Claude**, M. Balzer, W. Brenner, S. Spreckelmeyer;*
Charité – Universitätsmedizin Berlin, Klinik für Nuklearmedizin, Berlin, GERMANY.

Aim/Introduction: Targeted alpha therapies using actinium-225 (^{225}Ac) are gaining momentum. While significant progress has been made in the production and quality control of ^{225}Ac-radiopharmaceuticals, analytical methods for reliable identity assessment as required for the determination of radiochemical purity and stability remain limited.[1] High-performance liquid chromatography (HPLC) with fraction collection has been previously suggested but lacks speed and resolution, making it cumbersome for routine application. We present a streamlined method using HPLC coupled with inline liquid scintillation counting (LSC) to analyze [^{225}Ac]Ac-PSMA-I&T and [^{225}Ac]Ac-DOTATOC (collectively referred to as ^{225}Ac-RPs), enabling the differentiation between ^{225}Ac and its daughter nuclides in a single chromatographic run. ***Materials and Methods:*** ^{225}Ac-RPs were analyzed using a Ramona Star radio-HPLC system equipped with inline LSC detection. Various scintillation cocktail ratios were tested to ensure sufficient signal intensity while minimizing radioactive waste. Chromatograms were analyzed for reproducibility and signal patterns. Different formulations (e.g., reaction formulation, stabilized formulation with DTPA) were tested to probe the stability of the complexes and the behavior of free or recoiled daughter nuclides. ***Results:*** Our method provided reproducible retention times for ^{225}Ac-RPs, allowing clear differentiation between [^{225}Ac]Ac-PSMA-I&T and [^{225}Ac]Ac-DOTATOC. Three distinct peaks were consistently observed in all preparations, corresponding to complexes of ^{213}Bi-RP, ^{209}Pb-RP, and ^{225}Ac-RP. This observation aligns with known coordination chemistry of ^{213}Bi and ^{212}Pb at room temperature.[2,3] Fraction collection followed by gamma spectrometry enabled unambiguous identification of the ^{213}Bi-RP and ^{225}Ac-RP. Upon addition of DTPA, the peaks corresponding to ^{213}Bi-RP and ^{209}Pb-RP eventually disappeared, suggesting either decomplexation or failure of newly formed daughter nuclides to form DOTA or DOTAGA complexes in presence of DTPA. Reducing the volume of the scintillation cocktail successfully limited waste without compromising signal intensity. ***Conclusion:*** We successfully demonstrated the next step towards radiochemical purity determination of ^{225}Ac-radiopharmaceuticals, including their daughter nuclides ^{213}Bi and ^{209}Pb. ***References:*** (1) Hooijman, E. OP-346

Nitrosoarenes for ^{18}F-labeling - insights into substrate scope

***M. Laube**[1], S. Roscales[2], J. Pietzsch[1,3], A. G. Csákÿ[2];*
[1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [2]Instituto Pluridisciplinar, Universidad Complutense de Madrid, Madrid, SPAIN, [3]Faculty of Chemistry and Food Chemistry, School of Science, Technische Universität Dresden, Dresden, GERMANY.

Aim/Introduction: Nitrosoarenes are versatile organic building blocks that are considered both good nucleophiles and electrophiles and therefore offer diverse applications for the formation of new C-N bonds and heterocycles.[1] Herein, we report initial findings on the [^{18}F]fluoro-for-nitroso exchange and systematically investigate the scope and limitations of this completely novel radiofluorination approach. ***Materials and Methods:*** Nitroso compounds were obtained by oxidation of the corresponding anilines with Oxone[2]. Radiofluorination reactions were screened using our recently described microliter scale radiofluorination approach in HPLC vials [3] comprising concentration of K_2CO_3 for QMA elution (29.4 mM (normal) vs. 7.3 mM (¼ base)), reaction temperature (90°C, 110°C, 130°C), and solvent (MeCN, DMF, DMSO) as parameters. The radiochemical conversion (RCC) was determined by radio-TLC and radio-HPLC. Isolated RCY were determined after semi-preparative HPLC. Product identification was performed by standard addition using the authentic non-radioactive reference substances. ***Results:*** A set of 18 nitroso-substituted compounds was synthesized in yields of 56-89% starting from commercially available amines utilizing a simple, high-yielding synthetic strategy towards nitrosoarenes bearing different functional groups. Substrate scope covered the nitroso derivatives of unsubstituted benzene and pyridine, as well as arenes bearing substituents like CN, CHO, CF_3, NO_2, CO_2Et, Cl, OMe, Me, Br, COPh alone or in combination at specified positions to get insights into the effects of electron withdrawing or donating groups. The formation of the ^{18}F-labeled product resulting from [^{18}F]fluoro-for-nitroso exchange could be observed and verified by standard addition and analysis by radio-HPLC. RCC as a measure for radiolabeling efficacy was found to vary in this subset between 2-78% while isolated RCY varied between 2-54% for 13 selected precursors. Application of normal K_2CO_3 concentration and higher temperatures of 110°C or 130°C in DMSO or DMF was found to be advantageous for the reaction. ***Conclusion:*** To the best of our knowledge, this work represents the first example for a [^{18}F] fluoro-for-nitroso exchange which might prove to be a useful tool for ^{18}F-chemistry based on accessibility of nitrosoarenes starting from anilines. The radiofluorination approach tolerates a variety of electron donating or withdrawing groups and can be applied to the radiofluorination of heterocycles like pyridine, too. ***References:*** [1] Roscales, S.; Csákÿ, A. PYTA is the new DOTA - A versatile chelator for targeted radionuclide therapy

***M. Cheveau**[1,2], M. Moreau[2], A. Grohmann[1], S. Robert[1], M. Mendes-Arnaud[1], D. Vivier[2], A. Cochet[2,3], B. Collin[2,3], F. Boschetti[1], S. Poty[2], F. Denat[2];*
[1]Chematech-MDT, Dijon, FRANCE, [2]ICMUB, UMR 6302, CNRS, Université Bourgogne Europe, Dijon, FRANCE, [3]Centre Régional De Lutte Contre Le Cancer Georges François Leclerc, Dijon, FRANCE.

Aim/Introduction: Targeted radionuclide therapy (TRT) is experiencing an exponential growth with rising interests in several radionuclides including: ^{225}Ac (α), ^{177}Lu (β^-) and ^{161}Tb (β^-, AE, IC). Yet, those radionuclides present distinct coordination properties. DOTA remains the gold-standard for those three radionuclides, despite suboptimal coordination properties toward ^{225}Ac and ^{161}Tb. This prompted the quest for a "magic chelate", which would surpass DOTA's versatility: Macropa demonstrated impressive performances with ^{225}Ac but poor affinity for ^{177}Lu, Crown presented valuable chelation properties for ^{161}Tb but showed progressive in vivo release of ^{225}Ac. We recently reported the synthesis and evaluation of PYTA-based bifunctional chelators (BFCs) in a study that highlighted outstanding chelation properties with ^{225}Ac compared to gold-standards. Herein, we exemplify the high versatility of PYTA BFCs with radiochemical and in vivo evaluations with ^{177}Lu, ^{161}Tb, and ^{111}In. ***Materials and Methods:*** PYTA BFCs were conjugated to a PSMA ligand and panitumumab (anti-EGFR IgG_2). Radiochemical performances were compared to gold-standards (DOTA, Macropa, Crown) and stabilities were tested in reference media (PBS, EDTA, serum).

^{177}Lu/^{161}Tb/^{111}In-panitumumab conjugates biodistribution were evaluated in mice bearing EGFR^{+} (BxPC3) subcutaneous tumors up to 15 days post-intravenous injection, along with SPECT/CT imaging. Dosimetry is reported based on biodistribution data. ***Results:*** PYTA-conjugates demonstrated excellent radiochemical yields (>97%) under mild conditions with all radionuclides, with high specific activities (600MBq/mg for ^{111}In, 1.2GBq/mg with ^{177}Lu and ^{161}Tb) and prolonged stabilities (~95% after 7 days in serum). In comparison, Macropa displayed a low affinity for these radionuclides and Crown demonstrated detrimental instability with ^{177}Lu, in line with our previous ^{225}Ac results, and a low affinity for ^{111}In. Finally, DOTA was outperformed in every radiolabeling assays and did not demonstrate enhanced stability compared to PYTA. Biodistribution studies and SPECT/CT images of PYTA-panitumumab radioconjugates revealed a high and specific accumulation in the tumor (40-80%IA/g 6 to 9 days post-injection) and low non-specific accumulation in healthy organs known to accumulate free radiometals, especially liver and bones (<5%IA/g), highlighting the in vivo stability of PYTA radiocomplexes. Dosimetry based on biodistribution data report therapeutic indexes >10 in all organs. ***Conclusion:*** PYTA BFCs display unprecedented radiochemical performances toward ^{225}Ac, ^{177}Lu, ^{161}Tb and ^{111}In, outperforming gold-standards. In vivo assessment revealed the enhanced stability of PYTA radioconjugates, in line with our previous ^{225}Ac study. This study showcases the unmatched versatility of PYTA BFCs, propelling them to the forefront as a transformative breakthrough for the development of TRT. ***References:*** Cheveau, M et al. ChemRxiv. 2025. https://doi.org/10.26434/chemrxiv-2025-q2t1b.

Aim/Introduction: Thorium-227 represents an interesting candidate for targeted alpha therapy (TAT) given its relatively long half-life, 18.7 days, and the cascade of short-lived, high-potency, alpha-emitting daughter progeny in its decay scheme. However, to date few chelators exist which can effectively and stably bind [^{227}Th]Th^{4+} at molar activities high enough for TAT. Furthermore, clinical studies with Th-227 have exclusively focused on antibody-based targeting strategies. We hypothesized that Th-227 could be effectively paired with fast-circulating peptide-based targeting vectors, if a suitable chelator could be identified. We aimed to evaluate the radiolabelling properties of a pool of potential chelators, and investigate for the first time, the feasibility of peptide-based targeting with Th-227 in a preclinical mouse model. ***Materials and Methods:*** An array of potential [^{227}Th]Th^{4+} chelators were screened using freshly purified Th-227 obtained from an ^{227}Ac/^{227}Th generator. Radiochemical yields were determined by radio-TLC and gamma spectroscopy, and the most favourable candidates taken forward for further investigation using concentration-dependent radiolabelling and human serum stability studies. A ^{227}Th-labelled peptide-based bioconjugate, [^{227}Th]Th-noneunpaX-Ahx-TATE, was prepared and characterized using radio-TLC, radio-HPLC, log$D_{7.4}$ measurements, and serum stability studies. Preclinical evaluation of [^{227}Th]Th-noneunpaX-Ahx-TATE was undertaken in male NRG mice bearing AR42J tumours and biodistribution studies performed at 3 h post-injection. Optimised methods for evaluation of Th-227 biodistribution and dissemination between parent and daughter progeny uptake were developed, allowing for routine detection. ***Results:*** An initial screening of potential chelators for [^{227}Th]Th^{4+} identified H_4noneunpaX as an efficient ligand, demonstrating radiolabelling with [^{227}Th]Th^{4+} at concentrations of 10^{-6} M (A_m = 272 kBq/nmol) under mild conditions (ambient temperature, 15 min). The coordination characteristics of [Th(noneunpaX)] were thoroughly investigated through ^{1}H NMR spectroscopy, mass spectrometry, and DFT calculations, indicating the formation of a single monomeric complex. [^{227}Th]Th-noneunpaX-Ahx-TATE was prepared with high molar activities (A_m = 500 kBq/nmol), and fully characterised by radio-TLC, gamma spectroscopy, and radio-HPLC, showing a single peak, with RCP >99.7%. Preclinical evaluation of [^{227}Th]Th-noneunpaX-Ahx-TATE in AR42J tumour bearing mice, showed good tumour uptake (25.8±6.2 %IA/g) at 3 h post injection and fast clearance via the renal pathway. Low retention in non-target organs was seen, with notably low uptake in bone, implying good radiotracer stability in vivo. ***Conclusion:*** H_4noneunpaX was identified as a versatile chelator which can be labelled with [^{227}Th]Th^{4+} under mild conditions and demonstrates high in vivo stability and tumour uptake when coupled to a peptide-targeting vector.

OP-349

Impact of formulation buffers on the radiolysis and stability of RHN001-Tx (^{188}Re-PSMA)

A. Mdlophane[1,2], *S. Mdanda*[1,2], *S. M. Sibiya*[1,2], *M. Qebetu*[1,2], *K. Ramonaheng*[1,2], *M. M. Sathekge*[1,2,3], *F. L. Giesel*[4], *J. Cardinale*[4];
[1]*Nuclear Medicine Research Infrastructure, Pretoria, SOUTH AFRICA,* [2]*University of Pretoria, Pretoria, SOUTH AFRICA,* [3]*Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA,* [4]*Medical Faculty and University Hospital Duesseldorf, Duesseldorf, GERMANY.*

Aim/Introduction: RHN001 is a novel PSMA-targeting theragnostic ligand which can be labelled with Technetium-99m and Rhenium-188. A first in man study with ^{188}Re-labelled RHN001-Tx (formerly GCK01) in the treatment of prostate cancer has been reported(1). The ligand is subject of the recently started RHINO trial - a prospective phase-I/II clinical trial. The objective of the current project was to optimise the formulation by incorporation of suitable stabilizers and reduction of the radiolytic effect of β-emissions. ***Materials and Methods:*** Preparation of RHN001-Tx was conducted as previously reported (1). After cartridge extraction, RHN001-Tx was reformulated in 4 different buffers: Formulation 1 was simple phosphate buffered saline with sodium ascorbate as anti-oxidant; Formulation 2 was a typical ^{225}Ac-formulation buffer based on sodium acetate/ascorbate in saline with additional diethylenetriamine pentaacetic acid (DTPA); Formulation 3 and 4 were composed from sodium acetate and -ascorbate in saline with or without gentisic acid. The impact on radiolytic stability was determined by radioHPLC at the end of synthesis (EoS), 3 h and 6 h post-synthesis. ***Results:*** Formulation 1 resulted in poor and quickly dropping radiochemical purity (RCP, not quantifiable). In formulation 2 the DTPA caused transchelation of the ligand to DTPA increasing over time. Formulation 3 showed improved stability of the labelled product (RT 6.15 min) with 99 % RCP at EoS, dropping to 95.4 % and 92.7 % at 3- and 6 h, respectively. Finally, the addition of gentisic acid in formulation 4 resulted in the best radiolytic stability with 98.9 %, 97.6 % and 96.4 % RCP at EoS, 3- and 6 h, respectively. ***Conclusion:*** Surprisingly, our standard formulations did not work for stabilizing RHN001-Tx. However, we were able to identify a suitable formulation buffer based on an adapted version of a previously used buffer for ^{225}Ac-

Radiopharmaceutical formulations. In the new formulation we were able to validate an excellent shelf-life of up to 6 h for RHN001-Tx. Validation for the more recent preparation procedure and even longer shelf-lives are currently under investigation. ***References:*** (1)Cardinale J, Giesel FL, Wensky C, Rathke HG, Haberkorn U, Kratochwil C. Aim/Introduction: Terbium-161 (^{161}Tb) with simultaneous γ-emissions of 48.9 keV and 74.6 keV is suitable for micro SPECT imaging while its β-emission (154 keV) and Auger-electrons (≤40 keV) are also ideal for therapy. Actinium-225's (^{225}Ac) alpha-emissions of 5.8 MeV make it ideal for therapy against cancers. 3p-C-DEPA is a potential good chelator for both ^{225}Ac and ^{161}Tb. Simultaneous/concomitant use of ^{225}Ac and ^{161}Tb-labelled radiopharmaceuticals are potentially effective for radiotherapy of malignancies because it would take advantage of three potent radionuclide classes (beta, alpha and Auger/conversions electrons). ***Materials and Methods:*** The BFC 3p-C-DEPA$_{-TFP}$-PEG$_4$ was conjugated to the model antibody trastuzumab followed by radiolabeling with [^{161}Tb]TbCl$_3$ or [^{225}Ac]AcCl$_3$ using standard conditions (2 h at 40 °C (^{161}Tb) and ^{225}Ac (37°C)). Benchmarks BFCs, DOTA$_{-SCN}$, 3p-C-DEPA$_{-SCN}$ and Macropa$_{-SCN}$ were used for trastuzumab conjugation and radiolabeling. The in vitro stability of the corresponding radioconjugates was determined in PBS and human serum for a period of 4 (^{161}Tb) to 10 (^{225}Ac) days. The radioimmunoconjugates (RICs) were evaluated in vivo using biodistribution in non-tumor bearing Balb/C mice and will be done in JIMT-1 athymic Balb/C nude mice. Concomitant radiotherapy of [^{161}Tb]Tb-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab and [^{225}Ac]Ac-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab will be done in HCC1954/JIMT-1 xenografts, 4T1-HER2 syngeneic models and patient-derived xenografts. ***Results:*** The HPLC and bioanalyzer analysis of the immunoconjugates 3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab, DOTA$_{-NCS}$-trastuzumab, 3p-C-DEPA$_{-NCS}$-trastuzumab and Macropa$_{-NCS}$-trastuzumab showed 98% purity with less than 2% impurities. A RCC of 93.5% was obtained for [^{225}Ac]Ac-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab, 90.4% for [^{225}Ac]Ac-DOTA$_{-NCS}$-trastuzumab, 97.3% for [^{225}Ac]Ac-3p-C-DEPA$_{-NCS}$-trastuzumab and 95.9% for [^{225}Ac]Ac-Macropa$_{-NCS}$-trastuzumab after 2 h incubation at 37°C. Furthermore, a RCC of 90.8% was obtained for [^{161}Tb]Tb-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab, 83.2% for [^{161}Tb]Tb-DOTA$_{-NCS}$-trastuzumab after 2 h incubation at 40°C. Excitingly, in PBS, 91.3 ± 4.3%, 60.1 ± 0.6%, 48.3 ± 1.2%, and 81.9 ± 5.6% intact radiocomplexes were observed after 10 d for [^{225}Ac]Ac-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab, [^{225}Ac]Ac-DOTA$_{-NCS}$-trastuzumab, [^{225}Ac]Ac-3p-C-DEPA$_{-NCS}$-trastuzumab and [^{225}Ac]Ac-Macropa$_{-NCS}$-trastuzumab, respectively. In contrast, [^{161}Tb]Tb-3p-C-DEPA$_{-TFP}$-PEG$_4$-trastuzumab was found to be less stable with only 36.7 ± 7.9% and 71.1 ± 3.2% of intact radiocomplex remaining after 4 days in PBS and human serum, respectively. There were no major significant differences between the biodistribution profile of [^{225}Ac]Ac-3p-C-DEPA-$_{NCS}$-trastuzumab, [^{225}Ac]Ac-DOTA$_{-NCS}$-trastuzumab and [^{225}Ac]Ac-Macropa$_{-NCS}$-trastuzumab in all organs of interest ($p > 0.05$ for all organs). However, the liver uptake of [^{225}Ac]Ac-DOTA$_{-NCS}$-trastuzumab (14.1 ± 2.9% IA/g) was higher than [^{225}Ac]Ac-3p-C-DEPA$_{-NCS}$-trastuzumab (9.0 ± 3.3% IA/g) ($p=0.04$). Additional in vitro and in vivo experiments are ongoing. ***Conclusion:*** 3p-C-DEPA$_{-TFP}$-PEG$_4$ is a promising chelator especially for ^{225}Ac with a good RCC under mild conditions, and stability in vitro.

OP-351

Bischelate Strategy for a "Pseudo-Theranostic Pair" (PET and RIT): Synthesis and in vivo Evaluation of the First Site-Specific DFO/DOTAGA Immunoconjugate

D. Vivier[1], *M. Grah Kple*[1], *J. Ariztia*[1], *M. Moreau*[1], *M. Claron*[1], *A. Laouafa*[1], *A. Kownacka*[2], *C. Petitot*[2], *J. Simonet*[2], *R. Ruffin*[2], *A. Oudot*[2], *B. Collin*[2], *F. Denat*[1];
[1]*Université Bourgogne Europe, CNRS, ICMUB UMR 6302, Dijon, FRANCE,* [2]*Centre Georges François Leclerc, IMATHERA, BioSanD – UMS INSERM 58, Dijon, FRANCE.*

Aim/Introduction: Targeted radiotherapy (TRT), recently propelled by the approval of Lutathera® and Pluvicto®, offers a promising approach for treating metastatic cancers by delivering therapeutic radionuclides directly to tumor cells, reducing systemic toxicity compared to conventional treatments. To optimize patient selection and monitor efficacy, TRT is often combined with PET imaging under the radiotheranostic paradigm. However, when different radionuclides are used for therapy and diagnosis, the choice of chelator becomes a key limitation, as most are optimized for a single radiometal. To address this, we developed a DOTAGA/DFO dual-chelator platform based on L-lysine, tailored for the pseudo-theranostic pair ^{177}Lu/^{89}Zr. This strategy allows site-specific assembly of bischelate immunoconjugates via microbial transglutaminase (MTGase)-mediated conjugation, offering an efficient solution for accommodating therapeutic and diagnostic radionuclides in one construct. ***Materials and Methods:*** Starting from Boc-L-Lys(Fmoc)-OH, we synthesized a DFO-Lys-DBCO probe combining a deferoxamine (DFO) chelator for PET and a DBCO handle for strain-promoted azide-alkyne cycloaddition (SPAAC). Enzymatic conjugation to trastuzumab (Tzb) via MTGase, followed by SPAAC with an azide-functionalized DOTAGA chelator, yielded the bischelate immunoconjugate ss-Tzb-DFO-DOTAGA. Each step was monitored by mass spectrometry. The resulting immunoconjugate was radiolabeled with either ^{89}Zr or ^{177}Lu, and its stability was evaluated in PBS and plasma over 7 days. In vivo studies were conducted in mice bearing HCC1954 xenografts (HER2-overexpressing cell line, resistant to Tzb). PET or SPECT imaging with [^{89}Zr]Zr-ss-Tzb-DFO-DOTAGA or [^{177}Lu]Lu-ss-Tzb-DFO-DOTAGA were performed at 24, 72, and 168 hours post-injection to monitor biodistribution. An additional group received [^{89}Zr]ss-Tzb-DFO-DOTAGA(Lu) — where DOTAGA was pre-loaded with cold lutetium — to assess the influence of the second chelator occupancy. ***Results:*** The DFO-Lys-DBCO probe was synthesized in four steps (39% overall yield). Enzymatic conjugation yielded ss-Tzb-DFO-DBCO with a grafting ratio of 2; the subsequent SPAAC introduced an average of 1.8 DOTAGA per antibody. Radiolabeling confirmed excellent selectivity of DFO for ^{89}Zr and DOTAGA for ^{177}Lu, with radiochemical purities above 94% before purification. The bischelate conjugate exhibited stability comparable to monochelate controls (≥95% after 7 days). Analysis of biodistribution and imaging data is currently underway. ***Conclusion:*** This work reports the first site-specific, dual-chelator immunoconjugate for theranostic applications. Its modular two-step assembly enables easy adaptation to a range of therapeutic radiometals, including β- and α-emitters. Preliminary findings suggest that the choice of radiometal has minimal impact on the in vivo behavior of the bischelate immunoconjugate, supporting its potential as a versatile radiotheranostic platform pending full data analysis.

Reactive Evaluation - A Novel Alternative to Transfer Learning to Handle Multi-Centric Variations in Prostate Cancer Cohorts

L. Papp[1], *S. Wail*[2], *D. Haberl*[1], *L. Dolezel*[2], *M. Hacker*[1], *R. A. Bundschuh*[3], *C. Lapa*[4], *R. Laudicella*[5], *I. Burger*[6], *W. Drexler*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [3]*Universitätsklinikum Carl Gustav Carus Dresden, Dresden, GERMANY,* [4]*Universitaetsklinikum Augsburg, Augsburg, GERMANY,* [5]*Università di Messina, Messina, SWITZERLAND,* [6]*Kantonspital Baden, Baden, SWITZERLAND.*

Aim/Introduction: Metabolic, imaging apparatus and clinical workflow variations across different medical imaging centres are challenging efforts to build highly-generalisable, multi-centric AI models. Next to techniques e.g. ComBat or cycleGAN harmonisation, transfer learning (TL) can be used to fine-tune a trained model to another data source's characteristics. This, however, complicates clinical adoption and does not result in a singular model. Here, we present a novel technique, called Reactive Evaluation (RE), which dynamically weights model predictions during inference-time, based on a target data source's distribution, without the need to perform any model tuning or TL. ***Materials and Methods:*** Three prostate cancer ^{68}Ga-PSMA-11 image datasets, including a PET/MRI (11 ISUP<2 vs 17 ISUP≥2) from Austria, a PET/MRI (49 ISUP<2 vs. 75 ISUP≥2) from Switzerland and a PET/CT (25 ISUP<2 vs 25 ISUP≥2) from Germany were collected. All cohorts underwent a 2x2x2mm PET resolution normalisation. This was followed by automated prostate and lesion detection and IBSI 1.0 radiomic feature extraction of lesions in the prostate. Automated machine learning was employed to build mixed-stacked ensemble learners to predict low or high risk prostate cancer per-patient. The following scenarios were employed for training: Scenario1 - Switzerland (train)-Austria (validate+test); Scenario 2 - Germany (train)-Switzerland (validate+test); Scenario 3 - Switzerland (train)-Germany (validate+test). In all scenarios, the non-training set was split to 50-50% for validation and test sets, while maintaining a balanced test split ratio of ISUP<2 vs. ISUP≥2 cases. The 50% validate set was the reference dataset for RTE weighting, and the other 50% test set was evaluated by the model, while employing RE at inference-time. The same evaluation was repeated without RE on the test datasets for comparison. ***Results:*** The balanced accuracy (BACC) with RE was 0.84 in Scenario 1, while it was 0.78 without RE. In Scenario 2, BACC was 0.67 with RE and 0.63 without RE. In Scenario 3, BACC was 0.67 with RE and 0.60 without RE. ***Conclusion:*** We demonstrate that RE can yield 3.3 - 7.1% BACC increase in multi-centric prostate cancer cohorts without the need for TL and even when PET/CT and PET/MRI data are mixed. Since RE does not retrain base models, it has the potential to dynamically become increasingly more accurate as additional representative validation samples are provided to it over time. This simplifies efforts to minimise the impact of imaging variability in AI models and allows the generalisability of such models across multiple imaging sites.

OP-353

PSMA PET radiomics in risk stratification of prostate cancer; A machine learning approach

K. Mathiazhagan*, K. B. Chandra, R. Kumar, C. D. Patel, A. Seth, S. Kaushal, G. Priyanka;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Aim of the study was to assess the role of PSMA PET radiomics in risk stratification of prostate cancer. The primary and secondary objective was to assess the feasibility of PSMA PET radiomics in predicting NCCN risk groups and ISUP grades in prostate cancer. ***Materials and Methods:*** Data from pathologically confirmed treatment-naïve prostate cancer patients who underwent 68Ga-PSMA-11 PET/CT between January,2018 - August,2024 were analyzed. Primary target outcome was high-very high NCCN risk. Secondary outcome was identification of high-risk ISUP grade group (≥4), based on pathology. Radiomics features were extracted from primary lesion segmentations using whole prostate Region of interest. A total of 110 and 112 clinico-imaging and radiomics features were analyzed for NCCN risk and ISUP grade group prediction analyses respectively. Sampling with Bootstrapping allocated 189 patients (January,2018 - December,2023) to training set, with 75 patients reserved for validation. An independent cohort of 66 patients (January,2023 - August,2024) was used for testing. Feature selection was performed using Gini Index and 10 ML algorithms were trained via stratified 10-fold cross-validation. After validation, model evaluation for generalizability was tested on unseen testing set. ***Results:*** The study included 255 male patients. High-very high NCCN risk was observed in 142/189 (75.1%) of patients in the training/validation sets and 40/66 (60.6%) in the testing set (P = 0.028). High-risk ISUP grade groups were present in 65.1% (123/189) of the training/validation set and 62.1% (41/66) of the testing set (P = 0.766). For primary objective, eight ML algorithms achieved >0.800 in all performance metrics during cross-validation, with k-Nearest Neighbors (kNN) performing the best (AUC 0.964). On validation, kNN still achieved the highest AUC of 0.785. Testing on the independent dataset showed seven ML models maintained strong performance (AUC >0.700). Gradient Boosting (xgboost) had the highest AUC-0.782, CA-0.712, F1 score-0.782, Precision-0.723, and Recall-0.850. For secondary objective, eight ML algorithms achieved >0.800 performance metrics during cross-validation, with Gradient Boosting (catboost) showing the best results (AUC 0.953). During validation, seven ML algorithms maintained >0.700 in all metrics, with Random Forest achieving the best AUC of 0.795. Seven models in independent test set maintained strong performance (>0.700 in all metrics with Gradient Boosting (xgboost) achieving the highest performance metrics (AUC-0.812, CA-0.803, F1 score-0.840, Precision-0.850, and Recall-0.829). ***Conclusion:*** Machine learning using PSMA PET radiomics can predict high-very high NCCN risk and ISUP grade groups in treatment-naïve prostate cancer patients with robust performance and generalizability.

Aim/Introduction: Deep Learning (DL) is at the forefront of modern nuclear medicine (NM) data research. However, most cohorts are small, which hinders the training and generalizability of highly complex DL models. As such, most NM-specific DL prediction models are either systematically over- or under-fitted to small training data, preventing them to unlock their true potential (1). In this study, we demonstrate that classical DL models can be trained with quantum learning (QL), requiring significantly less trainable parameters than conventional learners (CL). This technique is called variational quantum-classical computing. Furthermore, we show that QL trains models with better predictive DL performance than relying on conventional DL learners, due to the reduced

number of trainable parameters. ***Materials and Methods:*** Two open-access PET/CT and clinical multi-centric datasets, including diffuse large b-cell lymphoma (DLBCL) to predict two-years survival and the head and neck dataset (HECKTOR) to predict HPV status were utilized. DLBCL had 40-44, and HECKTOR had 158-74 train-test splits from different centers. A one hidden layer classical neural network was trained with 16 neurons, and 305 weights for DLBCL. In case of HECKTOR, 25 neurons and 951 weights were trained. These trainings with CL were done with Adam optimizer through 100 epochs. The same classical model schemes were also independently trained with QL through 10-epochs where a 9 and a 10-qubit circuit were optimized for DLBCL and HECKTOR, respectively. In these circuits, the number of parameters to train was 36 and 40 for DLBCL and HECKTOR, respectively. In the trained models, confusion matrix analytics were utilized, from which sensitivity (SNS), specificity (SPC) and balanced accuracy (BAcc) were calculated over test cases. ***Results:*** In DLBCL, QL yielded 63% SNS, 86% SPC, and 74% BAcc, while CL yielded 59% SNS, 85% SPC and 72% BACC. In HECKTOR, QL yielded 93% SNS, 53% SPC, and 73% BAcc, while CL yielded 91% SNS, 52% SPC and 71% BAcc. ***Conclusion:*** Quantum learning was capable to train classical DL models with significantly less parameters compared to classical learning algorithms, while also yielding a higher predictive performance. This parameter advantage is larger as the model complexity increases, making our findings scalable to larger DL models. With these findings, we demonstrated not only the technical feasibility but also the disruptive potential of QL in future NM-DL applications. ***References:*** 1. Aim/Introduction: Dynamic [18F]FDG-PET is an emerging imaging modality that captures the temporal metabolic behavior of lesions. This study aimed to evaluate whether the intrinsic information embedded in time activity curves (TACs), when analyzed with artificial intelligence, can improve the differentiation between benign and malignant pulmonary lesions. ***Materials and Methods:*** A total of 229 patients with clinically suspected lung cancer were enrolled, comprising both representative subtypes of lung cancer and benign pulmonary lesions. Among them, 187 patients from the same institution were randomly assigned to training (n = 149) and internal validation (n = 38) cohorts using an 8:2 split. An independent external testing set of 42 patients was collected from a different institution. TACs were extracted from manually segmented lung regions of interest (ROIs). An unsupervised clustering algorithm was first used to divide the TACs within each ROI into high- and low-metabolism groups. A deep learning model combining Long Short-Term Memory (LSTM) and Convolutional Neural Networks (CNN) was subsequently trained to generate a risk score per patient based on the clustered TACs. Receiver Operating Characteristic (ROC) analysis was performed to evaluate classification performance. ***Results:*** The proposed TAC-based model significantly distinguished between benign and malignant lesions across both datasets ($p < 0.05$). It outperformed conventional static metrics such as SUVmax and Ki. In the internal validation set, the model achieved an AUC of 0.909, with a sensitivity of 0.818, specificity of 1.000, and F1-score of 0.914. In comparison, SUVmax showed lower diagnostic accuracy (AUC = 0.727), as did Ki (AUC = 0.703). For the external test set, the TAC model maintained high performance (AUC = 0.892), outperforming SUVmax (AUC = 0.716) and Ki (AUC = 0.714). ***Conclusion:*** We proposed a novel diagnostic model that integrates time-series learning models. This approach demonstrated superior performance over conventional quantitative PET parameters in differentiating benign from malignant lung lesions, and holds promise for enhancing clinical diagnostic decision-making in pulmonary oncology.

Machine Learning-Based Prediction of Radiochemotherapy Response in NSCLC Using ^{18}F-FDG PET/CT

R. Da-ano[1], *O. Tankyevych*[2], *Y. Mtazaoui*[2], *C. Cheze Le Rest*[2], *D. Visvikis*[1];
[1]*INSERM - DR GRAND OUEST/ LaTIM U1101, Brest, FRANCE,* [2]*Nuclear Medicine, University of Poitiers, Poitiers, FRANCE.*

Aim/Introduction: Predicting the response to concurrent chemoradiotherapy in stage III non-small cell lung cancer (NSCLC) is essential for personalized treatment planning. This study aimed to explore the use of ^{18}F-FDG PET/CT imaging alongside machine learning techniques, to predict radiochemotherapy response in NSCLC patients. The hypothesis was that combining clinical parameters with PET/CT data, could effectively predict pathological response with high accuracy. ***Materials and Methods:*** The clinical data of 158 patients with stage III NSCLC from 2 institutions (105 from Poitiers and 53 from Tours) were collected. The primary endpoint was the response to concurrent chemoradiotherapy assessed using RECIST criteria (complete response, partial response, stable disease vs progression). Random Forest (RF) was employed as the machine learning algorithm to predict the response based on radiomics derived from PET/CT combined with clinical parameters (age, gender, histology, stage). The model's performance was evaluated using accuracy and Area Under the Curve (AUC) metrics for both untransformed and combat-version PET/CT data. ***Results:*** The RF model showed a significant difference in performance between the untransformed and combat-version PET/CT data on the test set. The combat-version showed an increased performance with an AUC of 0.78 and accuracy of 92% compared to its untransformed counterpart with an AUC of 0.75 and an accuracy of 91%. These results demonstrate that applying the combat harmonization to the PET/CT data issued from different institution resulted in a slight but consistent improvement in the model's ability to predict radiochemotherapy response, suggesting that data preprocessing plays a role in enhancing the predictive accuracy. ***Conclusion:*** Using ^{18}F-FDG PET/CT data, this study shows that machine learning models can accurately forecast how NSCLC patients would respond to radiochemotherapy. The advantage of data preprocessing approaches was demonstrated by the combat-version PET/CT data's better predictive accuracy when compared to untransformed data. These results provide credence to the generalizability of PET/CT imaging in conjunction with machine learning as a non-invasive way of enhancing individualized treatment plans for non-small cell lung cancer. ***References:*** [1] Yoo J, Lee J, Cheon M, Woo SK, Ahn MJ, Pyo HR, Choi YS, Han JH, Choi JY. Predictive Value of ^{18}F-FDG PET/CT Using Machine Learning for Pathological Response to Neoadjuvant Concurrent Chemoradiotherapy in Patients with Stage III Non-Small Cell Lung Cancer. Cancers (Basel). 2022 Apr 14;14(8):1987. doi: 10.3390/cancers14081987. PMID: 35454899; PMCID: PMC9031866.

Dual-Attention Deep Learning Framework for Non-Invasive Histological Subtyping of Lung Cancer Using ^{18}F-FDG PET/CT Imaging

Y. Jia[1], *X. Zhu*[2], *M. Hacker*[1], *X. Li*[1], *Y. Wu*[2], *S. Xue*[1];
[1]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Nuclear Medicine, Peking University Cancer Hospital Inner Mongolia Hospital/Cancer Hospital Affiliated to Inner Mongolia Medical University, Hohhot, CHINA.

Aim/Introduction: Accurate histological subtyping of lung cancer is essential for selecting appropriate, subtype-specific therapies. Yet current diagnostic practice relies on invasive biopsies, which carry procedural risks and may fail to capture tumor heterogeneity. To address these limitations, we developed a dual-attention deep learning framework that non-invasively classifies lung cancer subtypes using baseline ^{18}F-FDG PET/CT imaging. This diagnostic model also serves as the first component of our multi-modal foundation model for lung cancer, with future applications in predicting therapeutic response and survival to support personalized treatment planning. ***Materials and Methods:*** We retrospective included 1,042 patients with pathologically confirmed lung cancer from two independent clinical centers. All patients underwent baseline ^{18}F-FDG PET/CT imaging prior to any therapeutic intervention, and only untreated primary tumors were analyzed. We developed a dual-stream convolutional neural network comprising: (1) modality-specific branches for extracting metabolic (PET) and anatomical (CT) features, (2) lesion-guided spatial attention using annotated tumor masks to enhance focus on diagnostically relevant regions, and (3) bidirectional cross-modality attention for effective PET/CT feature fusion. Performance was evaluated using accuracy, F1-score, and area under the receiver operating characteristic curve (AUROC). ***Results:*** Our model achieved robust performance in lung cancer subtyping, with an overall accuracy of 82.3% (95% CI: 79.3-88.2%), an F1-score of 0.81, and an AUROC of 0.89 across all classes. Subtype-specific performance was consistent: ADC reached 85.4% accuracy (F1-score: 0.85; AUROC: 0.91), SCC 86.1% accuracy (F1-score: 0.85; AUROC: 0.91), and SCLC 75.6% accuracy (F1-score: 0.74; AUROC: 0.83). ***Conclusion:*** The proposed dual-attention deep learning framework enables accurate, non-invasive subtyping of untreated primary lung tumors using preoperative PET/CT imaging. By combining interpretability and generalizability, this work serves as a critical diagnostic component in the development of a larger lung cancer foundation model designed to support personalized prognostication and therapy planning.

Evaluating tumour heterogeneity and therapy response with AI-assisted longitudinal analysis of FDG- and PSMA-PET/CT

L. Förner[1,2], *K. Tehlan*[1,2], *E. Gastreich de Llanes*[1], *J. Enke*[1], *Z. Reinke*[1], *K. Hildebrand*[1], *P. Hoffmann*[1], *M. Trepel*[1], *R. Claus*[1], *C. Lapa*[1], *T. Wendler*[1,2], *LF and KT are first authors with equal contribution;*
[1]University Hospital Augsburg, Augsburg, GERMANY, [2]Technical University of Munich, Munich, GERMANY.

Aim/Introduction: The introduction of AI-assisted image analysis tools and liquid biopsies where genetic traces such as circulating tumour DNA (ctDNA) are analysed opens new possibilities to track heterogeneity and treatment response in metastatic cancer patients. In the frame of the Augsburg Longitudinal Plasma Study (ALPS) [1], we set up an automatic imaging pipeline to evaluate FDG- and PSMA-PET/CT (FPC and PPC) over time and evaluate it in a first cohort. ***Materials and Methods:*** 29 metastasized castration-resistant prostate cancer patients enrolled in ALPS underwent multiple FPC and PPC, as well as Lu-177-PSMA radioligand therapy (RLT), external beam radiation therapy of the metastases (EBRT), ARPI or chemotherapy (CTx). We used the AutoPET III automatic tumour segmentation [2], implemented multiple PET/CT metrics, and applied them on all available FPC and PPC at patient and organ level. We then analysed the trends in the view of the dates RLT were applied. ***Results:*** Patients got 2-5 FPC, 2-11 PPC, 3.8±2.5 (0-8) RLT cycles or 0.4±0.9 (0-4) EBRT over 51±39 (2-148) weeks, with 7 of them deceasing and 13 dropping-out. 8 patients got ARPI and 5 CTx. During the RLT, SUVmean, SUV standard deviation (SUVstd), and Dmax dropped significantly in PPC (-24.8%, -48.7% and -2.2% respectively). For FPC, while RLT reduced most tumour metrics (-9.8%, -13.2% and +2.2% respectively) no reduction was significant. Matched comparison of FPC and PPC during RLT showed significant differences in SUVstd (p=5.4E-5), Dmax (p=6.6E-4) and total tumour surface area (p=6.4E-8). ***Conclusion:*** Significant drops in tumour metrics for PPC confirm therapy effectiveness and reduced heterogeneity in PSMA-avid disease after RLT, while FDG-avid heterogeneity does not follow the same decreasing pattern. Matched analysis shows significant differences between the two tracers' heterogeneity profiles, growth patterns, and lesion size distribution during RLT. This highlights the potential emergence or selection of aggressive tumour subpopulations inherently resistant to PSMA-targeted therapies or potentially driven by therapeutic selection pressure. While we did not annotate tumours manually, the segmentations were qualitatively evaluated and the longitudinal curves derived from the pipeline agree with the development of the patients. Including radiology reports as validation for the segmentation, correlating the results with dosimetry, PSA and ctDNA values, and repeating the analysis for other therapies are next steps towards better understanding heterogeneity and correlation between image findings and genetic biomarkers in metastatic prostate cancer. ***References:*** [1] Sommer S et al. J Lab Med. 2024 Jun 1;48(3):107-19.[2] Rokuss M et al. arXiv preprint arXiv:2409.09478, 2024.

AI-Assisted Detection of Prostate Cancer Lesions on 18F-Flotufolastat PET/CT: Agreement with Expert Readers.

P. Blanc-Durand[1], *C. Besnier*[1], *A. Dujardin*[2], *R. Penny*[3], *E. Itti*[1];
[1]CHU Henri Mondor, Créteil, FRANCE, [2]PAIRE, Paris, FRANCE, [3]Blue Earth Diagnostics, Oxford, UNITED KINGDOM.

Aim/Introduction: Assistance in diagnosis and lesion detection using artificial intelligence is rapidly expanding, particularly in PET/CT diagnostic imaging. The aim of this study is to evaluate the detection performance of an algorithm for identifying high uptake foci on 18F-flotufolastat PET/CT. ***Materials and Methods:*** Patients were included from the LIGHTHOUSE study (NCT04186819)[1], which enrolled those with newly diagnosed unfavourable intermediate-, high-, or very high-risk prostate cancer. Three expert nuclear medicine physicians independently annotated lesions consistent with prostate cancer, forming a consensus ground truth (any lesion identified by at least one reader). The evaluated algorithm, Pionus v1.5.0 (PAIRE, Paris, France), is a convolutional neural network trained on 4,872 FDG PET/CT scans and fine-tuned on 525 PSMA PET/CT scans from the AUTOPET challenge.Predicted lesions were compared to the consensus read and classified as true positives, false positives (detected by the algorithm but not by any physician), or false negatives (missed by the algorithm but detected by at least one physician). Performance was assessed at lesion and patient levels using agreement, positive predictive value (PPV), and false positive rate (FPR). No pathology-based gold standard was used for comparison. ***Results:*** Imaging data from 352 patients enrolled in the LIGHTHOUSE study were analyzed. The algorithm achieved an overall lesion-level agreement of 90% versus the ground truth, of the human reviewers. Agreement for prostate lesions was 90%, for nodal lesions 73%, and for metastatic lesions 80%. The positive predictive value was 47%,

corresponding to a median of 2 false positives per scan and an estimated false positive rate of 53%. At the patient level, the algorithm demonstrated excellent performance, with an overall agreement versus the physician reads of 98%. Agreement for detecting prostate involvement was 98%, for nodal involvement 92%, and for metastatic disease 98%. ***Conclusion:*** These results indicate that the algorithm performs reliably in identifying both primary and secondary prostate cancer lesions and shows lesion-level agreement comparable to expert human readers, particularly in the detection of metastatic disease. ***References:*** 1) Surasi DS, Eiber M, Maurer T, Preston MA, Helfand BT, Josephson D, Tewari AK, Somford DM, Rais-Bahrami S, Koontz BF, Bostrom PJ, Chau A, Davis P, Schuster DM, Chapin BF; LIGHTHOUSE Study Group. A phase I/II study of [^{61}Cu]Cu-NODAGA-LM3 for the detection of neuroendocrine tumours: Preliminary results of the COPPER PET in NET Trial

G. Nicolas[1], *A. Chirindel*[1], *F. Kaul*[1], *L. McDougall*[1], *A. Johayem*[2], *A. Llamazares*[2], *M. Baier*[3], *N. Schubert*[3], *F. De Rose*[3], *B. Pais*[3], *L. Jaafar-Thiel*[3], *M. Alejandre Lafont*[1], *A. Bauman*[1], *M. Fani*[1], *D. Wild*[1]; [1]*Department Theragnostics, University Hospital Basel, Basel, SWITZERLAND,* [2]*Department of nuclear Medicine, University Hospital Zurich, Zürich, SWITZERLAND,* [3]*Nuclidium AG, Basel, SWITZERLAND.*

Aim/Introduction: (Pre)clinical data suggest that somatostatin receptor (sstr) antagonists, when radiolabelled with gallium-68, offer superior imaging performance over agonists in patients with neuroendocrine tumours (NETs). [^{61}Cu]Cu-NODAGA-LM3 is a novel PET tracer targeting sstr subtype 2 that may overcome the production, resolution, and logistics limitations of [^{68}Ga]-based tracers. Copper-61 is cyclotron produced and has a longer half-life compared to Ga-68 or F-18, which are currently used for sstr2-targeting PET tracers, enabling delayed imaging and easier logistics. Additionally, Cu-61 has a high positron fraction enhancing image quality per administered activity. We report first-in-human data on safety, biodistribution, dosimetry, blood pharmacokinetics, image quality, and lesion detection with [^{61}Cu]Cu-NODAGA-LM3. ***Materials and Methods:*** This ongoing, randomized, controlled, reader-blind, phase I/II PET/CT study (NCT06455358) includes 22 patients with sstr2-positive well-differentiated gastroenteropancreatic or bronchopulmonary NETs. Each patient undergoes both [^{61}Cu]Cu-NODAGA-LM3 (1h and 3h post-injection) and [^{68}Ga]Ga-DOTA-TOC (1h p.i.) PET/CT imaging on the same scanner within 28 days and, if applicable, 14±2 days after somatostatin analogue injection. Co-primary endpoints are safety and sensitivity of [^{61}Cu]Cu-NODAGA-LM3. Sensitivity will be tested for noninferiority against [^{68}Ga]Ga-DOTA-TOC using a mixed-effects logistic regression model. Biopsy and/or composite imaging during 2-7 months of follow-up serve as gold standard. Adverse events will be monitored up to one day after administration using the Common Terminology Criteria for Adverse Events version 5.0. Main secondary outcomes are biodistribution, pharmacokinetics, dosimetry, and lesion detection. Six patients undergo additional PET/CT 18h p.i for dosimetry. The PET/CT results at 1h and 3h p.i. are compared to determine optimal imaging time. ***Results:*** To date, 9 patients have completed imaging and 4 completed full dosimetry without any adverse events. [^{61}Cu]Cu-NODAGA-LM3 demonstrated rapid blood clearance (median half-life: 15.3 minutes [13.4-25.3] and a residence time of 77.1 minutes [67.9-101.3]). Biodistribution was favourable, with 53% lower median liver SUVmax 2.7 [2.5-3.2]) and 63% lower median spleen SUVmax (9.0 [6.4-10.3]) compared to [^{68}Ga]Ga-DOTA-TOC (liver: 5.8 [4.2-6.7], spleen: 24.0 [18.9-25.8]). Median of the mean SUVmax for the three hottest matched lesions, tumour uptake was 21% higher with [^{61}Cu]Cu-NODAGA-LM3 (19.6 [8.9-22.5] vs. 16.2 [11.7-19.3]), improving lesion detectability and tumour-to-background contrast. The median effective dose was 5.0 mSv [4.2-5.7]. Image quality was rated superior in 8/9 cases in blinded review. ***Conclusion:*** [^{61}Cu]Cu-NODAGA-LM3 demonstrated excellent safety, favourable pharmacokinetics, biodistribution, dosimetry, and superior lesion detectability in patients with NETs. These preliminary findings support the clinical potential of sstr2 antagonists and suggest potential for broader clinical use.

OP-362

Head-to-head comparison of [^{18}F]AlF-NOTA-TATE and [^{68}Ga]Ga-DOTA-TATE PET/CT in Patients with Neuroendocrine Tumors: a prospective study

H. Liu*, G. Ma, H. Wen, X. Zhang, R. Wang, J. Zhang; Department of Nuclear Medicine, The First Medical Centre, Chinese PLA General Hospital, Beijing, CHINA.*

Aim/Introduction: A prospective comparison was made between [^{18}F]AlF-NOTA-TATE and the routinely used clinical imaging agent [^{68}Ga]Ga-DOTA-TATE in patients with neuroendocrine tumors (NETs) regarding diagnostic performance, pharmacokinetic features, and safety, and the clinical application potential of the former as an alternative was explored. ***Materials and Methods:*** The [^{18}F]AlF-NOTA-TATE was synthesized automatically by employing the self-developed direct purification technology of column chromatography, and the quality control standards were stringently adhered to. A clinical comparative study enrolled 20 patients with suspected or confirmed NETs (median age 52 years). All patients accomplished PET/CT imaging of [^{18}F]AlF-NOTA-TATE (dose 7.8 ± 1.8 mCi) and [^{68}Ga]Ga-DOTA-TATE (dose 3.9 ± 0.6 mCi) within 3 days. Image analysis encompassed parameters such as the detection rate of lesions, the maximum standardized uptake value (SUVmax), the tumor/background ratio (TBR), etc., while the radiation dosimetry and the characteristics of biodistribution were simultaneously evaluated. ***Results:*** Among the 20 patients, 13 were diagnosed as NETs and 7 showed negative imaging results or were diagnosed with non-NET lesions. The total detection rate of lesions by [^{18}F]AlF-NOTA-TATE was consistent with that of [^{68}Ga]Ga-DOTA-TATE, but the former showed higher uptake in the liver (SUVmax: 63.9 ± 24.9 vs. 37.2 ± 6.2, P = 0.009), lymph nodes (SUVmax median: 33.8 vs. 22.4, P = 0.021), and bone metastases (SUVmax: 112.9 ± 20.7 vs. 66.1 ± 6.7, P < 0.001). In terms of TBR, [^{18}F]AlF-NOTA-TATE was superior to the control group in liver lesions (77.8 ± 32.4 vs. 57.3 ± 17.6, P = 0.040) and bone metastasis lesions (135.2 ± 28.6 vs. 89.3 ± 18.9, P = 0.001). The biodistribution showed that the physiological uptake of [^{18}F]AlF-NOTA-TATE was higher in normal organs such as the pituitary gland and spleen, but lower in the brain and cardiac ventricles. Dosimetry assessment indicated that the effective dose was 0.021 ± 0.007 mSv/MBq, with the highest absorbed dose in the spleen (0.109 ± 0.059 mGy/MBq), and the safety was good. ***Conclusion:*** [^{18}F]AlF-NOTA-TATE exhibits comparable lesion detection rate to [^{68}Ga]Ga-DOTA-TATE in NETs diagnosis, and has higher tumor uptake and better TBR, especially in the detection of micrometastases. Its automated

synthesis process is simple, with a long half-life, and can overcome the supply limitation of gallium-68 imaging agents. It is expected to become a new alternative solution for the diagnosis and treatment of NETs.

OP-363

Intra-individual Comparison of 68Ga-DOTA-TOC PET/CT and 18F-SiTATE PET/CT: Frequency of Pitfalls in patients with neuroendocrine tumors (G1-G2)

K. Hansen, *J. Q. Petzold, M. C. M. Gammel, A. Richter, W. A. Weber, M. Eiber, I. Rauscher, S. Notohamiprodjo;*
TUM Klinikum Rechts der Isar, Munich, GERMANY.

Aim/Introduction: 18F-SiTATE is a promising new SSTR-PET tracer for imaging neuroendocrine tumors (NET). We retrospectively evaluated the frequency and characteristics of non-tumor-related uptake in comparison to 68Ga-DOTA-Toc. ***Materials and Methods:*** 40 NET patients (G1-G2) were included, who underwent 68Ga PET/CT and, as a follow-up 12.5 ± 6.4 months later 18F-SiTATE PET/CT. All PET/CT scans (n=80) were reviewed by 2 nuclear medicine physicians. PET positive focal findings attributed to a benign origin based on known pitfalls and information from CT were analyzed. The maximum and mean uptake intensity (SUVmax/mean) of these benign findings was measured using a 50% isocontour volume of interest and compared between tracers. For intra-individual comparison, the same benign lesion was analyzed on both scans. Paired differences were approximately normally distributed (Shapiro-Wilk), allowing statistical evaluation using a two-tailed paired t-test. ***Results:*** Overall, a total of 365 benign focal findings were identified: 164 on 68Ga-DOTA-TOC PET/CT and 201 on 18F-SiTATE PET/CT. In 56% this was due to focal uptake by normal organs with somatostatin receptor expression in 20% due to benign osseous lesions, and in 24% due to inflammatory lesions. 68Ga-DOTA-TOC SUVmax values for findings in these three categories were 7.48 ± 6.29, 3.10 ± 1.50, and 7.45 ± 4.81, respectively, while the corresponding values for 18F-SiTATE were 7.95± 6.66, 4.30 ± 1.75, and 6.22 ± 2.98, respectively. Regionally, SUVmean and SUVmax values across specific anatomical sites—including the processus uncinatus, and cervical and presacral ganglia—were largely similar between 18F-SiTATE and 68Ga, with minimal variation. However, 18F-SiTATE demonstrated prominent gallbladder uptake in 22 out of 28 patients (SUVmax 13.57 ± 5.40), whereas no such uptake was observed with 68Ga. In a paired comparison of the highest-uptake benign osseous lesion per patient, 18F-SiTATE showed significantly higher SUVmax values than 68Ga-DOTA-TOC (mean difference: 1.37; 95% CI: 1.88 to 0.86; $p < 0.0001$). ***Conclusion:*** In this preliminary analysis physiological findings were largely similar between 18F-SiTATE and 68Ga-DOTA-TOC. Yet 18F-SiTATE showed significantly higher uptake in the gallbladder and benign osseous findings compared to 68Ga-DOTA-TOC. These differences should be considered when evaluating 18F-SiTATE PET/CT studies.

OP-364

High versus Low Specific Activity in the Biodistribution of [18F]SiTATE: A Matched-pair Analysis of clinical PET Data

J. Petzold[1], *S. Notohamiprodjo*[1], *A. Richter*[1], *A. Wurzer*[1], *P. Bösl*[1], *S. Fischer*[1], *S. Lindner*[2], *J. Allmann*[1], *W. Weber*[1], *M. Eiber*[1], *I. Rauscher*[1];
[1]*TUM University Hospital, Munich, GERMANY,* [2]*LMU University Hospital, Munich, GERMANY.*

Aim/Introduction: [18F]SiTATE is a novel somatostatin receptor-targeting PET-agent with potential clinical advantages based on its F18-label consisting in longer half-life and large batch production. This potentially opens up the possibility of centralised production with distribution to peripheral PET centres without their own cyclotron. However, longer transport routes and thus longer time periods between batch production and injection lead to lower specific activities. We have therefore investigated, whether the specific activity influences its normal organ uptake. ***Materials and Methods:*** A total of 40 patients with gastroenteropathic and pulmonal neuroendocrine tumors (G1-G3) were retrospectively selected based on the specific activity of injected [18F]SiTATE and sub-grouped in patients receiving high (mean value, 114,09 MBq/µg, n=20) versus low specific activity (mean value, 29,02 MBq/µg, n=20). SUVmean was determined within standardized isocontour volumes of interest with 50% of the SUVmax and a diameter of 3 cm in the submandibular gland, thyroid gland, blood pool, lung, spleen, liver, adrenal gland, kidney, pancreas, urinary bladder, prostate, bone and muscle. Differences in mean SUVmean values were compared using a student t-test. ***Results:*** In the sub-group of patients with high specific activity the median SUVmean in the submandibular gland, thyroid gland, blood pool, lung, spleen, liver, adrenal gland, kidney, pancreas, urinary bladder, prostate, bone and muscle were 2.29, 3.87, 1.38, 0.35, 40.46, 7.37, 21.50, 17.87, 8.59, 18.13, 5.43, 1.32, 0.88, respectively. In the sub-group of patients with low specific activity the median SUVmean in the submandibular gland, thyroid gland, blood pool, lung, spleen, liver, adrenal gland, kidney, pancreas, urinary bladder, prostate, bone and muscle were 1.94, 3.39, 1.22, 0.32, 39.10, 6.52, 21.79, 20.21, 8.12, 15.50, 5.36, 1.16, 0.76. Of all regions tracer uptake in the submandibular gland, musculature and blood pool were slightly but statistically significantly higher in the high-specific-activity group (median SUVmean: 2.29 vs. 1.94, $p = 0.047$; 0.88 vs. 0.76, $p = 0.038$; 1.38 vs. 1.22, $p = 0.024$ respectively). No other statistically significant differences were found for normal organs. ***Conclusion:*** A 4-fold decrease in specific activity has only minor effects on the biodistribution of [18F]SiTATE, which are most likely not clinically relevant. These findings suggest that [18F]SiTATE can be centrally produced and transported to PET clinics in a similar way to [18F]FDG.

OP-365

First histological ex vivo validation of the novel [18F]SiTATE SSTR PET tracer

N. Trautwein[1], *S. Mattern*[2], *M. Hinterleitner*[3], *G. Reischl*[4], *R. Schirrmacher*[5], *V. Steger*[6], *S. Nadalin*[7], *K. Nikolaou*[8], *J. Schwenck*[1], *S. Singer*[9], *C. la Fougère*[1];

Aim/Introduction: The utilization of radiolabeled somatostatin analogs (SSAs), exemplified by [68Ga]Ga-DOTA-SSAs, has profoundly impacted imaging and therapeutic methodologies. However, their utilization is limited by the high cost of generators and the brief half-life of 68Ga. Conversely, [18F]SiTATE emerges as a compelling alternative, boasting the advantages of the prolonged half-life of 18F and the high output of cyclotron-based production. This study aims to provide the first histological ex vivo validation of [18F]SiTATE. ***Materials and Methods:*** 47 patients (57% male, mean age 66.9 ± 14.9 years) with histologically confirmed well-differentiated neuroendocrine neoplasms (NENs) who underwent [18F]SiTATE PET scan followed by surgery within four months were retrospectively included in this study. The quantification of lesion uptake was performed using SUVmean, SUVpeak, SUVmax, and the tumor-to-liver ratio (TLR). The histological SSTR2 expression levels were determined using H-scores, with thresholds delineating SSTR scores 1-3. The accuracy of PET imaging for preoperative metastatic detection was evaluated against surgical histology. ***Results:*** The findings revealed a significant correlation between [18F]SiTATE uptake (SUVmean and TLR) and SSTR2 H-scores ($r = 0.618$, $r = 0.622$; $P < 0.0001$). Furthermore, a SSTR score of 3 was

found to be associated with elevated SUVmean and TLR levels (P < 0.0001). Among the 35 patients who underwent primary resection and lymphadenectomy, PET imaging exhibited a sensitivity of 73.9% and a specificity of 100%. ***Conclusion:*** [^{18}F]SiTATE PET imaging demonstrated a strong correlation with histological SSTR expression, underscoring its potential application in staging and guiding therapeutic decisions in NENs. This novel ^{18}F-labeled tracer demonstrates comparable specificity to historical [^{68}Ga]Ga-DOTA-SSA data, while also exhibiting the potential to enhance sensitivity in detecting locoregional metastases. Further head-to-head comparisons of [^{18}F]SiTATE with [^{68}Ga]Ga-DOTA-SSA and histological validation are warranted to optimize its diagnostic accuracy and clinical impact. ***References:*** Leupe H, Ahenkorah S, Dekervel J, et al. OP-366

Retrospective Evaluation of [^{18}F]AlF-NOTA-Octreotide PET/CT in 288 Patients Referred for SSTR PET/CT

H. Leupe[1], *S. De Buyst*[1], *J. Dekervel*[1], *F. Cleeren*[2], *C. Dooms*[1], *K. Goffin*[1], *S. Jentjens*[1], *L. Boeckxstaens*[1], *F. Van Herpe*[1], *E. Van Cutsem*[1], *P. Clement*[1], *G. Rasschaert*[1], *G. Bormans*[2], *C. Verslype*[1], *C. Deroose*[1];
[1]*UZ Leuven, Leuven, BELGIUM,* [2]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: [^{18}F]AlF-NOTA-octreotide has emerged as a reliable tracer for somatostatin receptor (SSTR) PET/CT in patients with neuroendocrine neoplasms (NENs). Although effective and logistically advantageous, there remains limited data on its routine clinical application, particularly for specific NEN subtypes less represented in the prospective trials that evaluated its diagnostic accuracy (e.g. NET G3) (1-3). This study aims to assess the real-world clinical use of [^{18}F]AlF-NOTA-octreotide PET/CT, with an emphasis on uptake characteristics and referral patterns at our institution. ***Materials and Methods:*** A retrospective analysis was conducted on all patients referred for SSTR PET/CT at University Hospitals Leuven between March 1, 2023, and January 18, 2024. Relevant clinical and demographic data, along with procedural details, were collected. PET/CT imaging data was analyzed to quantify uptake parameters. Image analysis was performed using MIM version 7.3.4 (MIM Software Inc., Cleveland, Ohio). SSTR-positive lesions were delineated semi-automatically using a relative threshold based on SUV_{mean} of the liver (1.5 x SUV_{mean} + 2 SD). ***Results:*** A total of 322 [^{18}F]AlF-NOTA-octreotide PET/CT scans from 288 patients were evaluated, with besides 175 patients with gastroenteropancreatic (GEP) NET, 15 patients presenting with G3 NET, 15 with paraganglioma/pheochromocytoma (PPGL), 5 with neuroendocrine carcinoma (NEC) and 40 with lung NET (table 1). In total, 4677 lesions were analyzed. Average injected activity was 208.5 ± 73.6 MBq (2.8±0.88 MBq/kg), and the mean uptake time before imaging was 121 ± 14 minutes. Analysis of the referral patterns by SNMMI appropriate use criteria (AUC) showed that the majority of patients were referred for 'Monitoring of NETs seen predominantly on SSTR PET', followed by 'Initial staging after histologic diagnosis'. Mean SUV_{max} ± SD per WHO tumor grade show comparable uptake in G1 (12.1±9.8), G2 (16.0±17.9), G3 (13.0±12.3) NET and NEC (13.4±5.5). Mean SUV_{max} per NET lesion organ site was highest for pancreas (23.0±28.9), followed by liver (16.0±15.5), small intestine (15.9±15.6) and lymph node (15.6±14.3). Mean SUV_{max} per primary tumor was highest for appendixNET (29.9±29.4), followed by gastricNET (20.4±18.2), rectumNET (17.5±13.6), pancreasNET (14.7±16.7) sigmoidNET (14.5±13.0), smallintestineNET (13.5±13.6) and lungNET (8.7±9.0). ***Conclusion:*** This study provides essential real-world data supporting the routine clinical use of [^{18}F]AlF-NOTA-octreotide PET/CT in NET patient management. Quantitative analysis shows sufficient tracer uptake in NET lesions irrespective of tumor grade, lesion organ and primary tumor origin. ***References:*** 1. Pauwels E,JNuclMed.2023Apr;64(4):632-638.PMID:36265911. 2. Pauwels E,EJNMMI.2020Dec;47(13):3033-3046.PMID: 32617641. 3. Boeckxstaens L,EJNMMIRes.2023Jun;13(1):53.PMID: 37261615.

OP-367

[^{68}Ga]Ga-FAPI PET/MR Imaging for Predicting Invasive Potential in Pituitary Neuroendocrine Tumors

Y. Xi[1], *J. Li*[2], *X. Wang*[2], *Y. Lu*[2], *W. Sun*[1], *X. Zhang*[1], *W. Hai*[1], *B. Li*[1], *S. Lin*[2];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiaotong University, School of Medicine, Shanghai, CHINA,* [2]*Department of Neurosurgery, Ruijin Hospital, Shanghai Jiaotong University, School of Medicine, Shanghai, CHINA.*

Aim/Introduction: Pituitary neuroendocrine tumor (PitNET) is a common benign tumor in the brain, which exhibits benign behavior. But about 35% of them show invasive growth. This study aimed to use [^{68}Ga]Ga-FAPI PET/MR for early detection of tumor invasion, which beneficial for guiding the development of treatment strategies for reducing recurrence rates. ***Materials and Methods:*** Twenty Patients who found a pituitary mass with KNOSP Level II-IV or suspicion bone invasion were collected from December 2023 to November 2024. All patients underwent [^{68}Ga]Ga-FAPI PET/MR, and then performed transnasal hypophysectomy within one week. Region of interests (ROIs) were drawn to obtain the maximum standardized uptake value (SUV_{max}) in five areas for each tumor: Left cavernous sinus; Right cavernous sinus; Bottom of the tumor; Top of the tumor; The sphenoid sinus mass if the tumor invaded. The invasion into surrounding tissues in each area was evaluated during hypophysectomy. Then, Drew ROC curve and calculated Youden Index to obtain the best cut-off value of SUV_{max} for prediction the invasiveness and the diagnostic accuracy. Pathological diagnosis was obtained to differentiate tumor type. ***Results:*** 85 areas were evaluated in 20 patients. The tumor size was correlated with SUV_{max} in the bilateral cavernous sinus (p=0.002 and p=0.046). The KNOSP level of the bilateral cavernous sinuses was significant correlated with SUV_{max} (p<0.001). The SUV_{max} of area with KNOSP ≥ 2 was significantly higher than that with KNOSP < 2 (p=0.006). The pathological types of high invasive potential PitNETs (PIT-1 / T-PIT / null cell) had a greater impact on [^{68}Ga]Ga-FAPI radioactive uptake with a higher SUV_{max} (p<0.001). Then, this study found a correlation between SUV_{max} and the percentage of Ki67 expression (p=0.021). The SUV_{max} with Ki67 > 1% was significantly higher than that with Ki67 ≤ 1% (p=0.009). Importantly, SUV_{max} of invasive tumors was significantly higher than that of non-invasive ones (p<0.001). To predict the invasiveness of pituitary tumors through SUV_{max}, drew ROC curve and obtained AUC as 0.88 (p<0.001). Calculated Youden Index as the maximum value 0.68 while cut-off value of SUV_{max} was 1.7. In this cut-off value, the diagnostic accuracy was 92.31%, and sensitivity, specificity was 90.70%, 94.29%, respectively. ***Conclusion:*** [^{68}Ga]Ga-FAPI PET/MR accurately evaluated the invasiveness and site of invasion of pituitary tumors. [^{68}Ga]Ga-FAPI radioactive uptake was affected by tumor size, The relationship between tumors and cavernous sinus, and tumor type.

OP-368

Validation of PET Response Evaluation Criteria in Neuroendocrine Tumors (PERCIN) in an Independent Cohort.

A. Chaban[1], *L. Unterrainer*[2], *R. Werner*[2], *A. Holzgreve*[2], *L. Bodei*[3], *W. Weber*[1], *G. Sheikh*[2];
[1]*Klinik und Poliklinik für Nuklearmedizin, Klinikum Rechts der Isar, Technische Universität München, München, GERMANY,* [2]*Klinik und Poliklinik für Nuklearmedizin, LMU Klinikum München, München, GERMANY,* [3]*Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, USA, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: We have recently proposed criteria for assessment of tumor response to therapy by measuring changes of the somatostatin receptor-positive tumor volume (SRV) with PET (PERCIN). In the development cohort, tumor response according to PERCIN had a higher prognostic value than tumor response according to morphologic imaging (RECIST). The goal of the present study was to externally validate the prognostic value of PERCIN in an independent patient population imaged and treated at another medical center. ***Materials and Methods:*** This retrospective, single-center validation study included 100 patients with gastroenteropancreatic neuroendocrine tumors (GEP-NETs, G1: 35, G2: 62, G3: 3), who underwent somatostatin receptor PET/CT (SSR-PET/CT) before and after four cycles of SSR-targeted radiopharmaceutical therapy. SRV was delineated by using background tissue-dependent threshold values (for liver metastases, voxels with a SUVbw more than 2.2 g/ml higher than the maximum liver SUVbw were included in the total tumor volume; for lung and bone metastases, voxels with a SUVbw of more than 3.0 g/ml; and for all other metastases, voxels with a SUVbw higher than the maximum liver SUVbw). Based on these volumes, treatment response was evaluated according to PERCIN as follows: complete response (CR) - absence of any uptake on follow-up PET; partial response (PR) - no new lesions and ≥40% decrease in SRV; progressive disease (PD) - new lesion on follow-up PET and/or ≥20% increase in SRV; stable disease (SD) - no new lesions with <40% decrease or <20% increase in SRV. Patient groups defined by PERCIN were correlated with progression-free survival (PFS). For comparison, response was also evaluated using RECIST (CT-based) and PERCIST (PET-based). ***Results:*** After a follow-up time of 4.2-137.8 months (median = 27.8 months), the median PFS was 35.6 months. PERCIN demonstrated the highest concordance with PFS (p<0.001, c-index=0.75). Median PFS for PERCIN PR, SD, and PD was 48,5 months (45 patients), 34 months (34 patients), and 12.5 months (20 patients). Tumor response according to PERCIST also had significant prognostic value but showed a lower concordance level than PERCIN (p<0.001, c-index=0.69), whereas tumor response according to RECIST failed to achieve statistical significance (p=0.84, c-index=0.52). ***Conclusion:*** External validation of the PERCIN criteria confirmed its strong prognostic value in patients with GEP-NETs undergoing somatostatin receptor-targeted radiopharmaceutical therapy. The prognostic value of tumor response according to PERCIN was superior to existing PET and CT-based criteria.

OP-369

Impact of peptide dose on tumor and normal organ somatostatin receptor expression at PRRT; Measurements on ^{68}Ga-DOTATOC-PET in a simulated therapy setting

E. Ilan[1,2], *U. Jahn*[3], *A. Sundin*[3];
[1]*Medical Physics, Uppsala University, SWEDEN,* [2]*Nuclear medicine & PET, Department of Surgical Sciences, Uppsala University, SWEDEN,* [3]*Radiology & Molecular Imaging, Department of Surgical Sciences, Uppsala University, SWEDEN.*

Aim/Introduction: Disseminated small intestinal neuroendocrine tumors (SI-NET) are primarily treated with long-acting somatostatin analogs (SSA) and peptide-receptor- radionuclide-therapy (PRRT). Debate remains about whether SSA block the uptake of ^{177}Lu-DOTATATE at PRRT and their influence on the tumor versus normal organ receptors. This study aimed to assess whether previously observed uptake differences between large (>4cm) and small (>1cm to<4cm)SI-NET metastases versus normal organs persist in a simulated PRRT setting, when injecting intravenous SSA at amounts comparable to PRRT, before and after a preload of 400µg intravenous octreotide(Sandostatin), and measured on ^{68}Ga-DOTATOC-PET. ***Materials and Methods:*** Ten patients with SI-NET, underwent three ^{68}Ga-DOTATOC-PET/CT examinations (dynamic and static whole-body (WB) PET). Each PET/CT session started by infusion of 167±21MBq(mean±SD) of ^{68}Ga-DOTATOC. Before the last two PET/CT scans an extra intravenous infusion of 150µg octreotide, was administered to mimic the PRRT, and five hours prior to the last PET/CT, a single intravenous infusion of 400µg octreotide. In each patient, the median tumor SUV and tumor net-influx-rate(K_i) of all tumors, large tumors and small tumors, respectively, were determined using 50% iso-contour VOIs. For normal organs (liver,right and left kidney, spleen, pancreas and bone marrow) SUV was determined placing a spherical VOI (1.5cm in diameter) in a representative healthy part of the respective organs. ***Results:*** In the large tumor group, SUV and K_i remained stable across all peptide concentrations (p>0.05), while the remaining tumor groups demonstrated progressive SUV reductions. K_i values declined consistently in all median tumors, while small tumors showed a reduction between the first and second dynamic scans but stabilized following additional peptide at the third time-point. Across all peptide concentrations, SUV and K_i was consistently lower in small tumors than in large tumors. For healthy organs, a significant SUV decline was observed after the first octreotide injection (150µg), in the second WB scan, with the spleen showing further reduction after peptide pre-loading prior to the third WB. The spleen showed the largest SUV decrease(50%), followed by the liver(45%), pancreas(30%), kidneys(20%) and bone marrow(25%).Tumor-to-kidney ratios were stable in large tumors but decreased in small tumors after preloading. Tumor-to-spleen ratios increased initially, then decreased only in small tumors. Ratios to liver, pancreas, and bone marrow were high due to their low baseline uptake. ***Conclusion:*** Large SI-NETs are not influenced by high amounts of injected peptide,while small NETs appear to reduce their uptake in the presence of higher peptide amounts, equivalent to receptor down regulation.

Correlation analysis of ^{68}Gallium-FAPI- and ^{18}Fluor-FDG-uptake of joints and periarticular tissue with structured pain anamnesis in 171 patients

M. Röhrich[1], *L. Brückner*[2], *A. Spektor*[1], *P. Kvacskay*[3], *M. Schreckenberger*[1], *H. Lorenz*[3], *U. Haberkorn*[2], *W. Merkt*[4];
[1]*University Hospital Mainz, Mainz, GERMANY,* [2]*University Hospital Heidelberg, Heidelberg, GERMANY,* [3]*University Hospital Heidelberg, Mainz, GERMANY,* [4]*University Hospital Düsseldorf, Düsseldorf, GERMANY.*

Aim/Introduction: In both ^{68}Gallium-FAPI-PET and ^{18}Fluor-FDG-PET, joint-associated tracer uptake is a common finding. While ^{18}Fluor-FDG reflects glucose metabolism of inflammatory cells, ^{68}Gallium-FAPI-PET reflects activation of fibroblasts involved in chronic, fibrotic processes. To date, it is not clear, which of these tracers is superior with respect to the depiction of articular pain, the major symptom of joint diseases like osteoarthritis or rheumatoid arthritis. In this retrospective analysis, we correlate ^{68}Gallium-FAPI- and ^{18}Fluor-FDG-PET-imaging findings with a structured joint-related pain anamnesis in 171 patients. ***Materials and Methods:*** Patients, who underwent either 68Gallium FAPI-PET/CT (85 patients) or 18Fluor-FDG-PET/CT (86 patients), filled in a structured anamnesis form, which covered history of joint diseases, pain medication, the presence, localization and intensity of joint-related pain as well as clinically established quality of life-centered scoring systems: 1. Shoulder Pain and Disability Index (SPADI), 2. Western Ontario and McMaster Universities Arthritis

Index (WOMAC), which depicts hip- and knee related pain and 3. Knee Injury and Osteoarthritis Outcome Score (KOOS). PET-signals of shoulders, hips and knees as well as corresponding periarticular tissues were delineated by isocontouring and SUVmax and SUVmean were extracted. Imaging and anamnesis results were analyzed descriptively and the results of the scoring systems were correlated with PET-imaging parameters. ***Results:*** Joint-related pain was present in 41/85 (68Gallium FAPI-PET/CT) and 49/86 (18Fluor-FDG-PET/CT) patients. Differences in PET-signal intensities between pain-affected and pain-free joints and periartcular tissue (shoulder, hip and knee) were markedly more pronounced in 68Gallium FAPI-PET/CT than in 18Fluor-FDG-PET/CT. For instance, 68Gallium FAPI-uptake in pain-positive shoulder-joints was significantly: higher than in pain-negative ones (average SUVmax / mean 2.56+/-0.99 and 0.90+/-0.56 (pain-positive) versus 1.87+/-0.94 and 0.66+/-0.27 (pain-negative). However, 18Fluor-FDG-uptake of shoulder joints was mostly independent from pain (average SUVmax / mean 2.27+/-0.83 and 1.20+/-0.31 (pain-positive) versus 2.46+/-1.06 and 1.11+/-0.36 (pain-negative). Hips and knees showed similar results. Correlations between 68Gallium FAPI-PET/CT / 18Fluor-FDG-PET/CT signalling parameters and results of corresponding established scoring systems (SPADI, WOMAC, KOOS) were positive and significant for almost all parameters in both tracers. However, 68Gallium FAPI-PET/CT showed markedly higher positive correlations for periarticular tissue than 18Fluor-FDG-PET/CT. ***Conclusion:*** Overall, 68Gallium-FAPI-PET showed a more pronounced positive correlation with joint-related pain than 18Fluor-FDG-PET/CT. Thus, it appears promising to include 68Gallium-FAPI-PET into the assessment and therapy response evaluation of diseases with joint-related pain, such as osteoarthritis and rheumatoid diseases.

OP-372

Diagnosis of Prosthetic Loosening Following Total Knee Arthroplasty: A Quantitative SPECT/CT Approach

J. Rei da Cruz Escaleira[1,2], *R. Sá e Silva*[1], *M. Oliveira*[1], *L. Costa*[1], *A. Vilaça*[3];
[1]*Department of Nuclear Medicine, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL,* [2]*Unit for Multidisciplinary Research in Biomedicine (UMIB), Oporto, PORTUGAL,*
[3]*Department of Orthopedics, Unidade Local de Saúde (ULS) de Santo António, Oporto, PORTUGAL.*

Aim/Introduction: Single-photon emission computed tomography/computed tomography (SPECT/CT) has emerged as a promising modality for assessing prosthetic loosening after total knee arthroplasty (TKA). However, persistent postoperative physiological uptake can obscure interpretation, making early diagnosis particularly challenging. This study aimed to evaluate the role of quantitative SPECT/CT in enhancing diagnostic accuracy and supporting clinical decision-making. ***Materials and Methods:*** We retrospectively analyzed patients with cemented total knee prostheses (TKPs) under follow-up by orthopedic specialists at a single center who underwent ^{99m}Tc-labeled bisphosphonate SPECT/CT within the past two years. Knees were stratified by time since surgery into early(<5 years) and late(≥5 years) groups. Suspected loosening was defined by the presence of periprosthetic radiolucent lines (RL)≥2 mm on knee radiographs in the early group, and by visual assessment of increased periprosthetic tracer uptake on SPECT/CT without an alternative cause in the late group. Peak standardized uptake value (SUV_{peak}) was calculated using dedicated software, with spherical volumes of interest (VOIs) placed in five component regions: the tibial stem (TS) tip, medial and lateral tibial plateaus (TP), and medial and lateral femoral condyles (FC). ***Results:*** Forty-seven patients were included (85.9% women, 54.7% obese), with a median age of 74 years[IQR: 67-76]. Sixty-four TKPs were evaluated; 36 (56.3%) were imaged <5 years post-surgery, and 28 at ≥5 years. In the early group, SUV_{peak} values were significantly higher in TKPs with suspected loosening than in radiographically normal implants across all assessed regions, with the most pronounced differences at both TP(p<.001). In the late group, SUV_{peak} was significantly elevated in scans with loosening suspicion at the TS tip(p=.002) and lateral TP(p=.033), with close but non-significant trends in other regions, except the lateral FC(table I). Receiver operating characteristic (ROC) analysis identified optimal SUV_{peak} thresholds for detecting TKPs loosening (table II). In the early group, the medial TP showed the highest diagnostic performance, with a cut-off of 4.8 yielding 70.0% sensitivity and 96.2% specificity(AUC=0.900). In the late group, the TS tip provided the best accuracy, with a cut-off of 2.3 achieving 61.5% sensitivity and 100% specificity (AUC=0.831). Varus-aligned knees(n=42) demonstrated a significantly higher medial-to-lateral SUVpeak ratio compared to neutrally aligned knees (1.17 vs. 1.03, p=.028). ***Conclusion:*** This study supports the use of quantitative SPECT/CT as a practical tool for evaluating suspected prosthetic loosening following TKA. Time-based SUV_{peak} cut-offs may enhance interpretation across postoperative phases—particularly in the early period—by increasing diagnostic accuracy and potentially optimizing patient management while avoiding unnecessary interventions.

OP-373

Usefulness of Quantitative 99mTc-WBC SPECT/CT for Infection Detection

A. Skriabina*, M. Jreige, J. O. Prior, N. Schaefer, M. Nicod-Lalonde; CHUV, Lausanne, SWITZERLAND.*

Aim/Introduction: WBC scintigraphy is a well-known imaging modality for detecting infection. The diagnosis of infection is made by visual and semi-quantitative assessment on planar and/or SPECT/CT images. We aimed to investigate the added value of SPECT/CT quantification for the detection of infection. ***Materials and Methods:*** We retrospectively evaluated all patients with suspicion of infection undergoing ^{99m}Tc-Scintimun or in vitro ^{99m}Tc-labelled WBC scintigraphy with quantitative SPECT/CT (4h and/or 24h post-injection). Patients who refused the hospital's general consent and who did not have available follow-up were excluded from the analysis. Microbiological results and radiological follow-up were retrieved from the patient's electronic file. For planar semi-quantitative analysis, regions of interest (ROI) were drawn on the suspected site of infection and on the contralateral limb at 4 and 24 hours, and static ratio (ROI lesion/ROI contralateral at 24h)/(ROI lesion/ROI contralateral at 4h) was calculated. Lesion SUV_{max} and SUV_{peak} were measured from 4h and 24h SPECT/CTs. ROC analysis was performed to compare diagnostic accuracy of the different parameters. ***Results:*** In total, 55 WBC scans in 52 patients (39M/13F, aged 23 to 87 years) were included. Follow-up showed infection in 16/55 (29%) (15 on biological samples and 1 on radiological follow-up). The AUCs of the static ratio, SUV_{max}@4h and SUV_{max}@24h were not statistically different: 0.79 [95%CI 0.62-0.96], 0.71[0.57-0.86] and 0.71 [0.57-0.85], respectively. Similar results were found for SUV_{peak}. In a subgroup of 45 patients with no bone marrow surrounding the lesion suspected of infection, the AUCs of the static ratio, SUV_{max}@4h and SUV_{max}@24h were 0.76 [0.56-0.95], 0.79 [0.65-0.94] and 0.82 [0.69-0.96], respectively. In this subgroup, quantitative SPECT/CT parameters at a single timepoint @24h had a higher diagnostic accuracy than planar analysis using two timepoints @4 and @24h, although the difference was not statistically significant. ***Conclusion:*** Our preliminary data show similar specificity and sensitivity of quantitative SPECT/CT parameters at a single timepoint either 4h or 24h for the diagnosis of infection compared to standard dual-time planar imaging. Quantitative SPECT parameters may replace the time-consuming dual-acquisition protocol on 2 separate days, particularly in patients with no bone marrow surrounding the suspected infected lesion. These promising results remain to be confirmed in a larger population sample.

OP-375

A prospective observational study on long-term results of ^{90}Yttrium and 166-Holmium radiosynoviorthesis of chronic knee synovitis in rheumatoid arthritis.

M. Szentesi, *E. Takács, A. Radácsi;*
Hospital of the Hospitaller Brothers of St. John of Budapest, Budapest, HUNGARY.

Aim/Introduction: Examination of anti-inflammatory effect of 90-Yttrium and 166-Holmium injections in Rheumatoid Arthritis (RA) patients. ***Materials and Methods:*** After the treatment, we performed a long-term, prospective follow-up. In our present work We report the 10-year results of 345 RA patients. All patients provided written informed consent. In all patients inflammatory knee joint disease was diagnosed on the basis of the American College of Rheumatology. 312 of 345 patients with RA were seropositive, 33 seronegative. Mean age of 108 male and 237 female patients was 61.6 years (range 40-84) years. In 180 patients the right knee, in 165 the left knee was treated by RSO. Steinbrocker functional stadium II was observed in 165, stadium III in 165 and stadium IV in 15 of them. By radiography grades I (n= 9), II (n=201), III (n= 135) were observed. Grading was done according to Steinbrocker anatomic score. Mean duration of disease was 7.3 years (0.5-25), of synovitis (6.4 years (0.5-24) Mean number of punctions of the treated joint prior to radiosynovectomy was 12.3 per patient and of steroid administrations prior to radiosynovectomy 10.2. In 25 patients a systemic steroid therapy has been performed. Evaulation was based on the criteria as described by Müller, Rau and Scütte the score system was developed by the authors. ***Results:*** Excellent and good results in RA patients were achieved in 78.5% in the first 5 years and 65.8% in 10 years after RSO. Excellent and good results were achived in 89,6%/5 years and 79,2%/ 10 years in local stadium II, in the first 5 years, while excellent and good results were found in 62,3% in local stadium III. Ten years after RSO 70,43% of patients did not need another punction. These results prove that RSO must be done in the early X-ray phase I-II. The effectiveness is worsened significantly by the stadium of the disorder and the local x ray phase and diagnosis. P 0.00001. ***Conclusion:*** RSO is as effectiv method of treating chronic synovitis as surgical synovectomy. Even after a ten-years period 78,5% the findings were rated as excellent or good. 70,43% of the patients do not need another punction even after a ten years period. The treatment must be done in RA Steinbrocker stadium I-II, local stadium I-II.

OP-376

Somatostatin Receptor-directed PET/CT: A key factor in diagnosis and treatment of tumour-induced Osteomalacia

M. Heinrich[1], *A. Kosmala*[1], *A. Dierks*[2], *F. Genest*[3], *S. Achtziger*[3], *P. Raab*[3], *A. K. Buck*[1], *C. Lapa*[2], *L. Seefried*[3], *K. Michalski*[1];
[1]*Universitätsklinikum Würzburg, Würzburg, GERMANY,* [2]*Universitätsklinikum Augsburg, Augsburg, GERMANY,* [3]*Universität Würzburg, Würzburg, GERMANY.*

Aim/Introduction: To evaluate the efficacy of somatostatin receptor (SSTR)-directed positron emission tomography/computed tomography (PET/CT) in localizing phosphaturic mesenchymal tumours (PMT) in patients with tumour-induced osteomalacia (TIO) and to explore relationships between imaging parameters and biochemical markers. ***Materials and Methods:*** This retrospective analysis included 20 patients with suspected TIO who underwent SSTR-directed PET/CT. PET/CT parameters and findings were analysed in combination with biochemical markers and clinical outcome. Patients with a delineable SSTR-positive tumour on PET underwent surgical resection, while those without a discernible tumour but persistent renal phosphate wasting were continued or initiated on medical treatment. Follow-up assessments included laboratory values and clinical examinations. ***Results:*** PMT were detected in 12 out of 20 patients (60 %) on PET and were subsequently resected. Phosphorus levels (0.56 mmol/l vs 0.84 mmol/l; U = 20.5; r = 0.26; p = 0.03), tubular reabsorption of phosphate (TRP; 62 % vs 87 %; U = 4; r = 0.77; p < 0.01) and tubular maximum of phosphate reabsorption over GFR (TmP/GFR; 0.58 mmol/l vs 0.87 mmol/l; U = 16.5; r = 0.44; p = 0.07) were lower in patients with detected PMT compared to those without. Fibroblast growth factor 23 (FGF23) elevation was not higher in PMT positive patients with 253 % vs 134 % above the upper limit of normal (ULN; U = 47; p = 0.97). Total lesion uptake (TLU) of the tumours showed a significant negative correlation with TmP/GFR (r = - 0.71; r = 0.02; p = 0.03). A maximum standardized uptake value (SUVmax) threshold of 7.6 differentiated PMT from bone fractures with 83 % sensitivity and 100 % specificity. All resected tumors showed histological expression of SSTR2. Post-resection follow-up confirmed clinical cure in all cases with improvements in phosphate levels, TmP/GFR and TRP, while FGF23 levels varied. ***Conclusion:*** Patients with a lower TmP/GFR show a higher TLU in SSTR-directed PET/CT for PMT. In SSTR-directed PET/CT, a clear distinction between PMT and bone fracture is possible with a SUVmax threshold of 7.6. The integration of PET derived TLU, along with TmP/GFR could improve diagnosis and treatment planning for TIO.

OP-377

'New Normal': Reporting Bone SPECT/CT scans reconstructed with a Bayesian Algorithm using Anatomical Information

H. McMeekin, *H. Mohan, A. Syed;*
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Anatomical information from a CT can be used in Bayesian SPECT reconstruction algorithms to reduce noise and increase resolution. The superior quantitative performance of these algorithms has been demonstrated (1); we investigated the impact of a Bayesian algorithm with an anatomically guided relative difference prior (AMAP-R) based on visual assessment for routine clinical reporting. ***Materials and Methods:*** 20 patient Tc-99m HDP bone SPECT/CT scans were independently reviewed by two experienced nuclear medicine consultants. A Bayesian SPECT reconstruction algorithm (AMAP-R) using anatomical prior information based on the patient's CT scan was optimised and implemented retrospectively using vendor neutral reconstruction software. CT attenuation correction, Monte-Carlo scatter correction, and resolution recovery were applied during the iterative reconstruction loop of 6 iterations and 15 subsets. After an initial optimisation study for visual assessment, the following parameters were used for the AMAP-R algorithm: Bayesian weight 0.1; RDP gamma 1; similar neighbours 8. The images were scored for image quality and diagnostic confidence compared to the current clinical reconstruction: the camera manufacturer OSEM algorithm with CT attenuation correction using 4 iterations, 8 subsets, and a 9mm Gaussian FWHM post-filter. Any change in clinical interpretation was noted and described. ***Results:*** Averaged results from both reviewers were: 75% had better image quality; 23% had higher diagnostic confidence; 18% clinical interpretation may change. Facet joint uptake was more clearly localised in some cases, and there was increased visibility of degenerative change. No scans were found to have worse image quality or lower diagnostic confidence. ***Conclusion:*** Bayesian SPECT reconstruction for bone SPECT/CT scans offers increased image quality and diagnostic confidence in some cases, as well as impacting clinical interpretation. The 'new normal' must be established for these images, which could offer increased sensitivity for identifying facet joints and other degenerative disease sites as possible pain generators. ***References:*** 1. Kangasmaa, T.S., Constable, C. & Sohlberg, A.O. Quantitative bone SPECT/CT reconstruction utilizing anatomical information. EJNMMI Phys 8, 2 (2021). https://doi.org/10.1186/s40658-020-00348-1

Diagnostic Performance of 360° CZT-SPECT/CT Using [^{99m}Tc]Tc-HDP for Detecting Active Lumbar Inflammation in Degenerative Disc Disease: Correlation with MRI Findings

S. Peralta[1], *F. Mínguez*[1], *M. Romera*[1], *A. Basanta*[1], *M. Rodríguez-Fraile*[1], *V. Betech-Antar*[1], *F. Pareja*[1], *A. F. Hendy*[1], *G. Quincoces*[1], *R. Cuevas*[1], *A. Martínez*[1], *V. Rodrigo*[1], *N. Varela*[1], *E. F. Guillén*[2], *J. J. Rosales*[1], *J. Arbizu*[1];
[1]*Clinica Universidad de Navarra, Pamplona, SPAIN,* [2]*Clinica Universidad de Navarra, Madrid, SPAIN.*

Aim/Introduction: To evaluate the correlation between semiquantitative parameters of [99mTc]Tc-HDP 360° CZT-SPECT/CT (SPECT/CT) and active inflammatory changes on Magnetic Resonance Imaging (MRI) in patients with lumbar pain and degenerative disc disease. ***Materials and Methods:*** We included patients with lumbar pain who underwent SPECT/CT using a VERITON-CT version 300 (Spectrum Dynamics Medical) and MRI. SUVmax was measured by placing a rectangular Volume of Interest (VOI) that included the superior and inferior vertebral endplates from T12 to S1. Active inflammation was classified as present or absent based on MRI findings. Groups were compared using the Mann-Whitney U test. Optimal SUVmax cut-off values for detecting active inflammation were determined by ROC curve analysis. ***Results:*** A total of 61 patients (mean age: 60.9 ± 15.8 years; 55.7% female, 44.3% male) and 366 lumbar vertebral segments were analyzed. Active inflammation was identified on MRI in 41 segments from 26 patients (42.6%), while 325 segments from 35 patients showed no inflammatory changes. The most frequently affected spinal level was L5-S1, accounting for 13 out of 41 segments with inflammation (31.7%). Segments with active inflammation exhibited significantly higher SUVmax values, with a median of 9.0 (IQR: 7.4-11.2), compared to 6.4 (IQR: 5.0-7.4) in non-inflammatory segments ($p < 0.001$). An optimal SUVmax cut-off of 7.9 provided a sensitivity of 68.2%, specificity of 83.7%, positive predictive value (PPV) of 34.5%, negative predictive value (NPV) of 95.4%, and overall accuracy of 81.2% (AUC: 0.830; 95% CI: 0.758-0.902). ***Conclusion:*** Semiquantitative analysis of [99mTc]Tc-HDP using 360° CZT-SPECT/CT demonstrates good diagnostic performance in identifying active inflammatory changes in the lumbar spine of patients with degenerative disc disease. The high negative predictive value (95.4%) supports its use as a complementary imaging modality to rule out active inflammation when MRI is unavailable or contraindicated.

TROP Session - Thyroid Committee: An Overview on Nuclear Medicine Therapy of DTC Patients: Radioiodine and Beyond

OP-379

rTSH vs Endogenous Stimulation: Different Roads, Same Destination in Thyroid Cancer Treatment

S. Paiva*, S. Barata, I. Casimiro, D. Carvalho, J. Rebelo, G. Costa; ULS Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is the most common endocrine malignancy, with an excellent prognosis and 5-year survival rate. However, recurrence risk persists, particularly among intermediate and high-risk groups. Current guidelines recommend individualized strategies for postoperative radioiodine (RAI) therapy, with TSH stimulation achieved either by thyroid hormone withdrawal or recombinant human TSH (rTSH). The optimal stimulation method regarding disease control remains under investigation. This study aimed to compare disease recurrence rates (that required adicional RAI treatments) and progression-free survival (PFS) between stimulation methods in patients with no RAI uptake outside the thyroid bed in the whole-body post-RAI treatment scan. ***Materials and Methods:*** This retrospective cohort study included 315 patients with DTC who underwent total thyroidectomy followed by RAI therapy. Patients were stratified according to TSH stimulation: endogenous (n=163) or rTSH (n=152). Collected data included age, gender, histological type, AJCC/TNM staging and RAI activity. PFS was defined as time from RAI therapy to recurrence or last follow-up, with patients without recurrence censored at last contact. Statistical comparisons used the Chi-square test and Kaplan-Meier survival analysis with the log-rank test. Statistical analysis was performed using SPSS-Statistics v.30.0. $P<0.05$ were considered statistically significant. ***Results:*** There were no significant differences between the endogenous and rTSH groups regarding gender distribution (female 71.8% vs 76.3%, p=0.74), mean age at first RAI treatment (50.9 vs 53.6 years, p=0.07), histological type (papillary carcinoma 85.3% vs 85.5%, p=0.45), or AJCC staging (Stages I-II in 98.8% vs 97.4%, p=0.58). Recurrence that required additional RAI treatments, occurred in 11.7% of patients in the endogenous group and 11.8% in the rTSH group (p=0.934). Mean time to recurrence was 21.8 months (range: 4.4-98.1) for endogenous stimulation and 27.5 months (range: 2.6-79.2) for rTSH. Kaplan-Meier analysis showed no significant difference in PFS between groups (log-rank p=0.925). ***Conclusion:*** In this cohort, the method of TSH stimulation did not significantly influence recurrence rates or progression-free survival. These results support rTSH as an effective and safe alternative, particularly for patients with comorbidities, aligning with current recommendations for individualized management of DTC. ***References:*** Avram AM, Giovanella L, Greenspan B, et al. Aim/Introduction: In low-to-intermedite risk papillary thyroid cancer (PTC), multifocality is no longer considered "per sè" as an additional risk factor suggesting post-operative adjuvant iodine-131 administration. However, many studies showed a significantly different prognosis in patients with larger total diameters (i.e. obtained by summing the diameter of any single

foci). This study was prompted to evaluate if total diameter (sumD) should be taken into account to administrate radioiodine in PTC patients. ***Materials and Methods:*** The records of 115 multifocal PTC patients (mPTC) [F=83, M=32] affected by low-to-intermediate risk PTC were reviewed. All patients underwent (near)-total thyroidectomy followed by risk-adapted iodine-131 therapy (RIT). A post-therapy whole-body scan (pT-WBS) integrated with single photon emission tomography-computed tomography (SPECT/CT), was obtained in all cases 2-5 days after RIT. In all patients, the response to initial treatments was assessed 8 to 12 months after RIT according to 2015 American Thyroid Association (ATA) guidelines. Patients were monitored in a mean follow-up of 20.6 months. ***Results:*** In our cohort, the mean sumD size was 22.67±15.25 mm. In 24 out of all (20.9%) mPTC patients, loco-regional lymph node metastasis were ascertained by histopathological analysis (i.e., pN1). Interestingly, the mean sumD was larger in these patients compared with pN0 ones (23.9±4.4 mm vs 21.9±4.1mm, p= 0.043). Overall, 87 (75.6%) and 28 (24.4%) out of 115 patients presented an ER or a less than ER, respectively. Noteworthy, the sumD was larger in patients having a less than ER compared to patients with ER [27.1 mm±14.2 vs 21.3 mm±12.3, respectively (p=0.039)]. At receiver operating characteristic (ROC) analysis, the optimal sumD cutoff to predict a less than ER to initial treatments was set at 21.5 mm (AUC= 0.783). Accordingly, the overall sensitivity, specificity, accuracy, positive predictive value (PPV), and negative predictive value (NPV) were 96.43, 59.77, 68.70, 43.55, 98.11 respectively .The risk of having a less than ER is about 96.4% (27/28) higher in mPTC patients with a total mean size ≥21.5 mm than in other patients 40.2% (35/87) (OR=40.11; 95%C.I. 5.21-308.93). Interestingly, sumD overperformed gender, age, histological variant, pT-staging, lesions topography, and BRAF mutation in predicting less than ER. ***Conclusion:*** In low-to-intermediaterisk mPTC patients, the sumD significantly predicts the response to adjuvant treatment and we suggest to take it into account in postoperative decision making. In particular, a sumD≥21.5 mm identifies patients having a higher prevalence of residual lymph node metastasis after surgery with attached worse response to adjuvant therapy.

OP-381

Comparison of long-term survival with and without radioiodine therapy in low-risk differentiated thyroid cancer (ESTIMABL2-like): A SEER based analysis.

H. Weis[1], *K. Schmidt*[1], *M. Hellmich*[2], *J. Heilinger*[1], *A. Drzezga*[1], *M. Schmidt*[1];
[1]*Department of Nuclear Medicine, Faculty of Medicine and University Hospital of Cologne, Cologne, GERMANY,* [2]*Institute of Medical Statistics and Computational Biology, Faculty of Medicine and University Hospital of Cologne, Cologne, GERMANY.*

Aim/Introduction: In patients with low-risk differentiated thyroid cancer (DTC, i.e. papillary- and follicular thyroid cancer (PTC, FTC)) postsurgical radioiodine therapy (RAI) is matter of controversial debate. Long-term survival data are scarce and partially conflicting. A single prospective study showed that a treatment avoiding RAI was non-inferior compared to RAI for a composite of low-risk DTC patients, yet follow-up time was relatively short (<5 years) and FTC were underrepresented (only 3.1 % of patients (n=24)) [ESTIMABL2, (1,2)]. We analysed long-term relative survival (> 10 years) of low risk DTC patients based on the large Surveillance, Epidemiology, and End Results Program database (SEER). ***Materials and Methods:*** We retrospectively analysed survival relative to the proportion of expected survivors in a comparable set of cancer free individuals (relative survival, RS) as a robust measure of net survival. We compared survival with and without RAI in cohort of low risk DTC patients (pT1am, pT1b, N0, NX). 199,789 patients with thyroid cancer were identified from the year 2000 until 2021. Patients were subdivided based on histology (PTC and FTC) and TNM. Lymph node involvement (N1) was additionally analysed. Relative survival was compared for each subgroup with and without RAI by a specific z-test. Additionally, overall survival was analysed. ***Results:*** Relative survival was higher even in certain low-risk subgroups after RAI in case of a long enough follow-up time: For PTC without lymph node involvement no relevant difference between subgroups could be detected. In contrast, if lymph node involvement prevails, relative survival was higher in the RAI-group after a long follow-up time of ten years (2.6 % difference, p=0.023). For FTC, in an ESTIMABL2-like cohort, relative survival was significantly higher by 0.5 % with RAI after 5 years (p=0.029), which could not be detected after only three years (0.38 % difference, p=0.15). The relative survival benefit increased up to 4.4% after eleven years. In addition, overall survival was higher by 3.6% after five years, increasing up to 7.3% after 11 years. ***Conclusion:*** Subgroups of patients with low-risk differentiated thyroid cancer in an ESTIMABL2-like cohort have, depending on histology, a higher survival after RAI compared to patients not undergoing RAI during long term follow-up. ***References:*** [1] Leboulleux S et al., N Engl J Med. 2022;386:923. OP-382

Development and Validation of a Dynamic Risk-Adaptive Algorithm for Radioactive Iodine (RAI) Dosimetry in Thyroid Cancer: Integrating Clinical Guidelines and Machine Learning

W. Song, *X. Zhang, M. Li, X. Lan;*
Union Hospital, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Radioactive iodine (RAI) therapy is critical for differentiated thyroid cancer (DTC) management, yet optimal dosing remains challenging, particularly for patients requiring multiple treatments. Current approaches often rely on static empirical protocols, neglecting dynamic risk stratification, individualized biomarker trends (e.g., Tg kinetics), and evolving guidelines (e.g., 2021 Chinese RAI Guidelines).To develop and validate a computational algorithm integrating real-time treatment response assessment, quantitative imaging biomarkers, and guideline-based clinical rules to optimize RAI dosing for both initial and repeat therapies. ***Materials and Methods:*** A hybrid model was constructed using retrospective data from 600 DTC patients, incorporating: XGBoost-based prediction of baseline dose using features including Tg slope, nodal metastasis ratio, and SPECT/CT-derived iodine avidity. Dose adjustments based on Guidelines (e.g., renal function limits, pediatric BSA scaling, lung metastasis fractionation). Bone marrow dose estimation (threshold ≤2 Gy) and dynamic TSH suppression targets. Validation was performed prospectively in 200 patients, comparing algorithm recommendations to expert panel decisions. ***Results:*** The algorithm demonstrated high concordance (92%) with guideline-recommended dosing ranges, evidenced by strong inter-rater reliability (κ=0.85). For patients requiring repeat therapies, the model reduced over-dosing instances (>200 mCi) by 40% compared to traditional protocols, while preserving equivalent biochemical response rates (Tg reduction ≥25% in 78% vs. 75%, p=0.32). Critically, safety outcomes improved significantly: real-time dose fractionation alerts reduced post-treatment bone marrow suppression from 18% to 6% (p<0.01), underscoring its capacity to balance efficacy with reduced hematologic toxicity. These results validate the algorithm's dual role in standardizing dose selection and enhancing patient safety in complex multi-therapy scenarios. ***Conclusion:*** This dynamic risk-adaptive algorithm enables precision RAI dosing by harmonizing guideline mandates, quantitative biomarkers, and patient-specific safety thresholds. It addresses critical gaps in managing multi-therapy patients and provides a scalable framework for integrating evolving evidence into clinical workflows. ***References:*** 1. Patterns of Use,

Single-time-point Iodine-124 PET/CT imaging for patients with differentiated thyroid carcinoma to predict therapeutic efficacy

***M. Sadeghi Panah**, W. Jentzen, H. Hautzel, R. Görges, W. P. Fendler, K. Herrmann, I. Čiučiulkaitė, P. Fragoso Costa, D. Kersting; University Hospital, Essen, GERMANY.*

Aim/Introduction: A two-time-point ^{124}I-PET/CT lesion dosimetry protocol has been performed for years at our institution in selected DTC patients prior to planned radioiodine therapy (RIT). These scans were conducted approximately 24-h and 96-120-h after ^{124}I administration. The aim of this work was to utilise only the 24-h-time-point ^{124}I PET/CT data set to statistically predict therapeutic efficacy using standard activities. This simplified approach has advantages for patient comfort and logistics. ***Materials and Methods:*** Dosimetry data from 397 patients with 796 lesions were analysed retrospectively (2009 to 2023). The following lesion characteristics were recorded: (a) histology (papillary and follicular), (b) lesion type (residual thyroid tissue, lymph node metastases, lung metastases, bone metastases), (c) RIT for initial ablation or after completed first RIT, (d) predicted ^{131}I lesion absorbed doses (in Gy/GBq) derived from two-time-point ^{124}I dosimetry and (e) ^{124}I SUVmax. The lesions were then categorised into subgroups based on their histology, lesion type and therapeutic RIT state. Their ^{124}I 24-h SUVmax was correlated with the ^{131}I lesion absorbed dose estimated by the two-time-point ^{124}I dosimetry. Reaching established target absorbed doses (100 Gy for lymph node metastases, 85 Gy for lung metastases, 300 Gy for residual thyroid tissue and 350 for bone metastases) by using standard ^{131}I activities of 3.7 GBq, 7.4 GBq and 11.1 GBq was considered to be therapeutically effective. Spearman correlation coefficients (CC) and their confident intervals (CI) were determined for each subgroup. Histology was not considered for residual thyroid tissue. ***Results:*** A significant correlation of SUVmax with lesional absorbed dose was found for 4 subgroups: residual thyroid tissue (CC=0.93, n=214) and lymph node metastases in papillary DTC (CC= 0.93, n=182) before first RIT as well as residual thyroid tissue (CC=0.90, n= 36) and lymph node metastases in papillary DTC (CC=0.82, n= 67) after at least one RIT. For example, a 24h SUVmax >120 for thyroid remnant or >60 for lymph node metastases (papillary) and a planned activity of 3.7 GBq will achieve the target dose in 90% of the lesions. ***Conclusion:*** Single-time-point ^{124}I PET allows the prediction of therapeutic efficacy for selected subgroups. For lesions with low SUVmax the pretherapeutic dosimetry can be completed by performing the second PET imaging after 96-120-h.

Aim/Introduction: This prospective study aims at demonstrating that the first treatment with ^{131}I of metastatic differentiated thyroid cancer (MDTC), optimized with dosimetric treatment planning with ^{124}I, provides an objective response rate on soft tissue metastases at 6 months higher than the fixed activity administration schema. ***Materials and Methods:*** Patients are enrolled if they have known DTC metastases to soft tissues, if they were not treated in the previous 5 years, except with surgery or radiotherapy. They are prepared with hormone withdrawal both for treatment planning and therapy. Oral administration of liquid ^{124}I (100 MBq) is followed by blood sampling and whole body counting at 2, 6, 24, 96 h. PET scans are taken at 24 and 96 h. Lesion post-therapy dosimetry is performed on dead time corrected SPECT/CT taken at 24 and 96 h. A composite response is assessed with ^{18}F-FDG-PET, contrast-enhanced CT/MRI, ^{124}I PET and thyroglobulin level, 6 months after one or two optimized treatments. ***Results:*** We studied 28 patients with ^{124}I. Eleven (39%) were dropped out for absence of ^{124}I uptake by metastases. Seventeen patients received 26 optimised treatments with median 11 GBq, IQR 8-13.5 GBq, range 4-20 GBq. In 10/26 (38%) administrations, the limit of 2 Gy to blood prevented us to administer more than our standard activity for MDTC (8 GBq). In 14/26 (54%) treatments, we administered almost the maximum tolerable activity. Treatment planning modified our standard activity in 22/26 treatments (85%). Three females over 70 exhibited G2/G3 haematological toxicity. Moderate sialadenitis was reported by 5 patients. Among 8 patients who reached the end of the study, we had 3 CR (one with a massive skull metastases), 4 PR and 1 PD. ***Conclusion:*** ^{124}I PET showed extraordinary diagnostic sensitivity, higher than post-therapy ^{131}I SPECT/CT. This was essential for a perfect staging before the first treatment. Known the high threshold necessary to reach CR with bone metastases (350-650 Gy [1]), a correct staging allowed to plan the maximal tolerable activity in presence of bone lesions. Lesion dosimetry was less impacting than blood dosimetry, since intra-patient heterogeneity, their number and their undetectability on CT made global prediction of absorbed dose unfeasible in many cases. This fact remarks the clinical usefulness with bone lesions in MDTC of maximization based on pre-treatment blood dosimetry with ^{131}I, feasible even in absence of ^{124}I. The study is funded by the AIRC Foundation. ***References:*** [1] Jentzen et al J Nucl Med. 2016 Oct;57(10):1499-1504

OP-385

Redifferentiation of Radioiodine-Refractory Thyroid Cancer following Genotype-Guided MAPK/BRAF Inhibition

***C. Laschinsky**[1], M. M. Weber[2], B. Riemann[3], T. Brandenburg[1], D. Führer-Sakel[1], D. Gröner[4], M. C. Kreissl[5], F. Weber[1], K. Herrmann[1], W. Jentzen[1], H. Grafe[1], C. Rischpler[6], S. Theurer[1], A. Bockisch[1], J. Nagarajah[7], W. P. Fendler[1], D. Kersting[1];*
[1]Universitätsklinikum Essen, Essen, GERMANY, [2]Medizin Center Bonn, Bonn, GERMANY, [3]Universitätsklinikum Münster, Münster, GERMANY, [4]Universitätsklinikum Frankfurt, Frankfurt, GERMANY, [5]Universitätsklinikum Magdeburg, Magdeburg, GERMANY, [6]Universitätsklinikum Stuttgart, Stuttgart, GERMANY, [7]Röntgeninstitut, Düsseldorf, GERMANY.

Aim/Introduction: In patients with BRAF-wild type (BRAF-WT) radioiodine-refractory thyroid cancer, inhibition of the mitogen-activated protein kinase (MAPK) pathway using a mitogen-

activated protein kinase (MEK) inhibitor can restore iodine uptake. In contrast, patients with BRAFV600E mutations typically require specific BRAF inhibition to achieve similar effects. This report presents the final analysis of the ERRITI trial's primary endpoint—redifferentiation rate—for a genotype-guided MAPK modulation strategy: trametinib (a MEK inhibitor) for BRAF-WT patients and a combination of trametinib with dabrafenib (a BRAF inhibitor) for BRAFV600E patients. Additional outcomes related to clinical redifferentiation outside the study and survival are also described. ***Materials and Methods:*** ERRITI was a prospective, interventional, single-center, two-arm phase II trial (NCT04619316) including 29 patients with radioiodine-refractory thyroid cancer. Patients received redifferentiation therapy for at least 21 ± 3 days. Additionally, outcomes from seven patients treated with comparable clinical protocols outside the trial were included. The primary endpoint was the redifferentiation rate, evaluated via ^{123}I scintigraphy and ^{124}I PET imaging. Redifferentiation rates between BRAF-WT and BRAFV600E groups were compared using the X2 test. Patients demonstrating restored radioiodine uptake underwent dosimetry-guided high-activity ^{131}I therapy. Time to treatment failure (TTF) was defined from the start of redifferentiation therapy to disease progression, initiation of new therapy, or death. Cox regression analysis was used to assess the associations of redifferentiation success and BRAF status with TTF and overall survival (OS), reporting hazard ratios (HR) with 95% confidence intervals (CI). Adverse events (AEs) were reported from trial participants who underwent active AE monitoring. ***Results:*** Redifferentiation was successful in 16/36 patients (44.4%), with similar rates for BRAF-WT (42.9%) vs. BRAFV600E (46.7%) groups (p=1.0). Among ERRITI trial participants, 11/29 (37.9%) achieved redifferentiation. Radioiodine therapy was administered at a mean activity of 10.1 GBq. AEs occurred in 22/29 patients (75.9%), only 3 grade 3/4, all resolved completely. Patients with successful redifferentiation had significantly longer TTF (median: 19.4 months vs. 12.8 months, HR: 0.42, 95%-CI: 0.179-0.997, p=0.049), while OS did not differ significantly (median: 57.9 months vs. not reached, HR: 2.39, 95%-CI: 0.672-8.499, p=0.178). Similarly, no significant differences in TTF or OS were observed between BRAF-WT and BRAFV600E patients. ***Conclusion:*** Genotype-guided MAPK modulation achieved redifferentiation in nearly half of patients, with comparable efficacy in BRAF-WT and BRAFV600E subgroups. Redifferentiation in combination with radioiodine therapy was associated with prolonged TTF, supporting its potential in managing radioiodine-refractory thyroid cancer. ***References:*** doi: 10.1158/1078-0432.CCR-22-0437

OP-386

From Resistance to Response: BRAF/MEK Inhibition Revives RAI Uptake in RAIR-DTC

M. Demirkol[1], *G. Kaya*[2], *H. Seymen*[3], *F. Alagöl*[3], *F. Selçukbiricik*[3];
[1]*Amerikan Hospital, Istanbul, TÜRKIYE,* [2]*Republic of Turkiye, Ministry of Health, Yozgat State Hospital, Nuclear Medicine Dept., Yozgat, TÜRKIYE,* [3]*Koc University Hospital, Istanbul, TÜRKIYE.*

Aim/Introduction: Differentiated thyroid cancer (DTC) is commonly diagnosed early, but some patients develop metastatic disease. Locoregional metastases are surgically treated, while distant ones, especially to lung and bone, often require radioactive iodine (RAI) therapy. A subset develops RAI-refractory (RAIR) disease, where lesions fail to uptake iodine. Interestingly, redifferentiation with targeted agents like BRAF and MEK inhibitors may restore RAI avidity, but optimal management remains unclear. ***Materials and Methods:*** We retrospectively analyzed patients with metastatic papillary or follicular thyroid carcinoma treated at Koç University (2018-2025). Inclusion required prior RAI post-thyroidectomy and RAIR disease, defined by lack or loss of RAI uptake, progressive lesions, rising thyroglobulin (Tg), or FDG uptake. Imaging included whole-body scintigraphy, [^{18}F]FDG PET/CT, and CT/MRI. Patients received trametinib alone or with dabrafenib/vemurafenib for 4-6 weeks. RAI therapy followed redifferentiation. Uptake and dosimetry were evaluated with standard software. Tg trends, imaging, and response (RECIST 1.1) were assessed. Toxicity was graded by CTCAE v5. ***Results:*** Nine patients (2 male, 7 female; median age >55 in 66%) were analyzed. Most (66%) had classical papillary DTC; 77% had BRAF mutations. Combination redifferentiation was used in all BRAF-mutant cases. After a median 6-week therapy, 88% showed restored RAI uptake and received RAI (5.5-9.1 GBq). Median follow-up was 27 months. Post-RAI, 75% achieved partial response, 12.5% had stable disease, and 12.5% progressed. No grade ≥3 toxicity occurred. ***Conclusion:*** Redifferentiation, particularly in BRAF-mutant RAIR-DTC, can re-enable effective RAI therapy, with most patients showing clinical benefit. Restoration of iodine uptake is necessary but not always predictive of response. Even without major tumor shrinkage, redifferentiation revealed occult disease, aiding treatment planning. Anti-Tg interference was clarified in 3 patients. Therapy was well tolerated, even in older patients. Future directions include optimizing redifferentiation duration, integrating genomic profiling, and leveraging personalized dosimetry to enhance outcomes. Redifferentiation using BRAF/MEK inhibitors is safe and effective in selected RAIR-DTC patients, enabling RAI therapy and meaningful responses. Personalized approaches based on tumor biology are essential to advance care.

OP-387

First-in-Human SPECT/CT Imaging and Dosimetry of [^{211}At]NaAt in Refractory Thyroid Cancer in Alpha-T1 Trial

T. Watabe[1], *H. Sasaki*[2], *T. Kamiya*[2], *K. Mukai*[1], *S. Naka*[2], *A. Fukuhara*[1], *Y. Shirakami*[1], *K. Ooe*[1], *H. Haba*[3], *A. Toyoshima*[1], *K. Isohashi*[1], *I. Shimomura*[1], *N. Tomiyama*[1];
[1]*The University of Osaka, Suita, JAPAN,* [2]*The University of Osaka Hospital, Suita, JAPAN,* [3]*RIKEN, Wako, JAPAN.*

Aim/Introduction: Radioactive iodine (RAI) therapy with ^{131}I has long been used to treat patients with differentiated thyroid cancer. However, some patients develop resistance to repeated RAI therapy, even in regions with adequate iodine uptake. Astatine (^{211}At), a cyclotron-produced alpha emitter, has garnered attention as a novel NIS-targeted alpha therapeutic agent. In this first-in-human clinical trial (Alpha-T1 trial), we aimed to evaluate dosimetry of [^{211}At]NaAt using SPECT/CT imaging in patients with RAI-refractory thyroid cancer. ***Materials and Methods:*** Patients with metastatic differentiated thyroid cancer who had received at least three prior RAI treatments were enrolled (n = 11). A single intravenous administration of [^{211}At]NaAt was performed under recombinant human TSH (rhTSH) stimulation. Dose escalation followed a modified 3+3 design, with dose levels of 1.25 MBq/kg (n=2), 2.5 MBq/kg (n=3), and 3.5 MBq/kg (n=6). SPECT/CT imaging was conducted at 1, 3, and 24 hours post-administration using the VERITON-CT system (Spectrum Dynamics Medical) equipped with a full-ring cadmium zinc telluride detector, targeting the 79 keV X-rays emitted by the daughter nuclide ^{211}Po. Regions of interest were manually delineated in major organs using PMOD software, and residence times were derived from time-activity curves using the trapezoidal integration method. Absorbed doses were estimated using IDAC-Dose 2.1. Adverse events were evaluated according to CTCAE v5.0 criteria. ***Results:*** At 3 hours post-administration, physiological uptake was observed in the stomach (SUVmean = 3.47 ± 1.35) and bladder (3.62 ± 0.68), followed by the spleen (2.70 ± 0.51) and salivary glands (2.21 ± 0.66). Relatively high absorbed doses were recorded in the stomach (2.75 ± 1.46 mGy/MBq) and salivary glands (1.96 ± 0.80 mGy/MBq), while the red bone marrow received 0.57 ± 0.15 mGy/MBq. Dose-limiting toxicity (grade 3 lymphopenia or leukopenia persisting for more than one week) was observed at the 3.5 MBq/kg dose level (50%). The common adverse events were anemia (Grade 1: 55%), leukopenia

(Grade 2: 27%, Grade 3: 36%), thrombocytopenia (Grade 1: 18%), salivary gland swelling (grade 1: 9%, grade 2: 64%), xerostomia (grade 1: 36%, grade 2: 18%), and gastrointestinal symptoms such as nausea (grade 1: 9%, grade 2: 82%), anorexia (grade 2: 27%), and vomiting (grade 2: 36%). ***Conclusion:*** This study demonstrates the feasibility of performing dosimetry for targeted alpha therapy with [^{211}At]NaAt in patients with RAI-refractory thyroid cancer. Similar to ^{131}I and ^{177}Lu, ^{211}At enables SPECT imaging, making it a promising for predicting treatment-related toxicities during dose escalation and assessing therapeutic efficacy. ***References:*** NCT05275946

Alzheimer's Disease Detection Using FDG-PET and Clinical Data with a 3D CNN and Grad-CAM Visualization

Z. Tekgul[1], *E. Balci*[2], *O. Akdemir*[2], *S. Sagiroglu*[1], *L. Atay*[2];
[1]*Gazi University Faculty of Engineering, Department Of Computer Engineering, Ankara, TÜRKIYE,* [2]*Gazi University Medical Faculty, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Early and accurate detection of Alzheimer's disease (AD) is critical for timely intervention and patient care. We propose a 3D convolutional neural network (3D CNN) that integrates full volumetric FDG-PET scans with demographic and clinical variables to classify amyloid PET positivity. Our dataset comprises 212 subjects from ADNI, including age, sex, APOE genotype, and MMSE scores, which are concatenated with imaging features to improve both accuracy and explainability. ***Materials and Methods:*** Data from patients with mild cognitive impairment obtained from the ADNI dataset confirmed by 2 experienced nuclear medicine experts were used and 10 Fold Cross Correlations were applied in training. The created 3D CNN models have 3x3D-Conv layers, each followed by Max Pooling and Batch Normalization. After them, 1xAverage Pooling layer exists. Demographic information is given into a Dense layer. The output of the convolution layers and demographic data were combined and passed through 3xDense and 2xDropout layers. Adam Optimizer and Cross Entropy were used as error function in model optimization. 3D Grad-CAM was used as XAI method to make the decision-making process of the models interpretable. ***Results:*** Two models were trained with 212 and 159 patient data because of imbalance data among classes. Two models showed promising results in predicting amyloid PET positivity by achieving 80.66% and 96.86% Accuracy and 85.20% and 97.58% F1 Scores, respectively. The model having more balanced data achieves the task with high accuracy. Additionally, the trained models, unlike traditional 2D slice-based models, process full volumetric data, thus preserving spatial continuity and eliminating possible information loss in the third dimension. As a result of the visualization obtained with Grad-CAM in both 2D slice and full 3D volumetric format, the brain features that provide the most important contribution to the model estimation were successfully determined and insights were provided regarding the neurobiological patterns associated with amyloid positivity. ***Conclusion:*** Combining full-volume PET with clinical data in a 3D CNN substantially enhances classification performance and provides transparent, regional insights via explainable AI. This framework may support earlier, more reliable detection of amyloid pathology and deepen understanding of underlying neurobiological patterns.

EPS-117
Robustness of the Centiloid Scale Against Different Reconstructions and Reference Regions

K. Hirschmüller[1], *E. Prieto*[1], *F. Mínguez*[1], *R. Fahmi*[2], *E. F. Guillen*[3], *R. Cuevas*[1], *A. Martínez*[1], *B. Echeveste*[1], *M. Riverol*[1], *J. Arbizu*[1];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,* [2]*Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA,* [3]*Clínica Universidad de Navarra, Madrid, SPAIN.*

Aim/Introduction: Centiloid (CL) scale is a standardised metric for quantifying amyloid-PET acquired with different tracers. The aim of this study was to test the impact of different technical factors on the calculated CL values. ***Materials and Methods:*** Sixty-eight (N=68) amyloid PET images acquired at our institution were retrospectively reviewed. Two different tracers were included: 16 ^{18}F-florbetaben (FBB) and 52 ^{18}F-flutemetamol (FMM) datasets. Images were processed using a commercially available solution to calculate Centiloid. Four different options were considered for each tracer, including two different reconstructions (Rec1: OSEM3D, 3i21s, with TOF and 5 mm Gaussian filter, and Rec2: OSEM3D, 3i21s, with PSF+TOF and 2mm Gaussian filter) and two different reference regions (RR) (pons and whole cerebellum (WCb) for FMM, and the cerebellar grey matter (GMCb) and WCb for FBB). Statistical analyses were performed to evaluate the impact of the reconstruction and the choice of RR on the calculated CL values. Bland-Altman plots, Lin's concordance correlation coefficient (CCC) and Wilcoxon tests were used. ***Results:*** When WCb was used as RR, concordance between CL values corresponding to the two considered reconstructions was almost perfect, with CCC > 0.99 and with 95% limits of agreement (LoA) within ±10 CL. However, this was not the case when the pons (for FMM) and the GMCb (for FMM) were used as RRs with 0.95 < CCC < 0.99 and with 95% LoA reaching ± 20 CL. Concordance between pons- and WCb-derived CLs was poor for FMM, with mean differences of 16.2 CL for Rec1 and 24.4 CL for Rec2. However, the concordance between FBB CL values obtained with GMCb and those obtained with WCb was much higher and with much lower mean differences (i.e., -7.6 CL for Rec1 and -2.1 CL for Rec2). ***Conclusion:*** The CL metric is more robust against differences in reconstruction when the WCb is used as RR. CL derived from FMM images using the pons as RR show the highest sensitivity to image resolution. Significant differences were obtained between CL values calculated with pons and WCb for our FMM cohort, and more so with PSF reconstruction.

EPS-118
Glymphatic system dysfunction and retinal vascular changes in Alzheimer's disease

Z. Chen[1], *S. Yan*[1], *S. Bi*[1], *Z. Qi*[1], *B. Cui*[1], *N. Li*[2], *Y. Hu*[3], *J. Lu*[1];
[1]*Department of Radiology & Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA,* [2]*Beijing United Imaging Intelligence Imaging Technology Research Institute, Beijing, CHINA,* [3]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: This study investigated the mediating role of glymphatic system dysfunction in the relationship between retinal vascular alterations and cognitive impairment in Alzheimer's disease (AD). By integrating multimodal neuroimaging and retinal assessments, we explored the eye-brain axis as a non-invasive biomarker for early AD detection. ***Materials and Methods:*** Thirty-one AD patients and 24 healthy controls (HC) underwent 3D T1-weighted imaging (3D T1WI), diffusion tensor imaging (DTI), and retinal fundus photography. Glymphatic metrics included hippocampus_perivascular space (Hip_PVS), basal ganglia_PVS, white matter_PVS, free water and diffusion tensor image analysis along the perivascular space (DTI-ALPS) index, and. Retinal vascular parameters (RVPs) comprised fractal dimension (FD) and vascular density (VD), mean arterial caliber, and mean venous caliber. Using the minimum bounding circle of the optic disc as the diameter (papilla-diameter, PD), VD (total, 0.5-1.0 PD, 1.0-1.5 PD, 1.5-2.0 PD,

2.0-2.5 PD) was calculated, as well as for mean arterial caliber and mean venous caliber. Statistical analyses included group comparisons, spearman correlations, mediation analysis. Bagged Trees models were trained to distinguish AD patients from HC, and area under the curve (AUC) of receiver operating characteristic (ROC) was performed to evaluate classification performance. Covariates included age, gender, education, hypertension, diabetes, hyperlipidemia. Multiple comparisons correction was performed using the false discovery rate (FDR). ***Results:*** AD patients exhibited elevated Hip_PVS ($P_{FDR} < 0.001$), reduced DTI-ALPS index ($P_{FDR} = 0.008$), and higher free water ($P_{FDR} < 0.001$) compared to HC. FD, VD (total), VD (0.5-1.0 PD), and VD (1.0-1.5 PD) were significantly lower in AD (all $P_{FDR} < 0.05$) and correlated with Hip_PVS (r = -0.353 to -0.434, $P_{FDR} < 0.05$). Mini-Mental State Examination (MMSE) score showed negative correlation with Hip_PVS (r = -0.647, $P_{FDR} < 0.001$), while positively correlating with FD, VD (total), VD (0.5-1.0 PD), and VD (1.0-1.5 PD) (r = 0.306 to 0.410, $P_{FDR} < 0.05$). Mediation analysis revealed that Hip_PVS mediated the effects of FD, VD (total), VD (0.5-1.0 PD), and VD (1.0-1.5 PD) on MMSE score with indirect effect ranging from 27.580 to 123.584. The retinal combination model, incorporating FD, VD (total), VD (0.5-1.0 PD), and VD (1.0-1.5 PD), achieved AUC of 0.768 for distinguishing AD from HC, and the retinal combination + Hip_PVS model yielded higher AUC of 0.877. ***Conclusion:*** Hip_PVS-mediated glymphatic dysfunction bridges retinal vascular changes and cognitive decline in AD. Integrating retinal and glymphatic biomarkers enhances diagnostic performance, underscoring the retina as a non-invasive window for early AD detection.

EPS-119

Multi-site, prospective trial of FET-PET In Glioblastoma (FIG) Study (TROG 18.06):Results of central review of FET-PET biologic target volume delineation for radiation planning.

A. Scott[1], *R. Francis*[2], *S. Lee*[1], *E. Lau*[3], *E. Thomas*[2], *A. Moore*[4], *D. Pattison*[5], *T. Akhurst*[6], *E. Hsiao*[7], *G. Schembri*[7], *P. Lin*[8], *I. Kirkwood*[9], *D. Krishna*[10], *S. Ngai*[11], *S. Beuzeville*[12], *D. Wong*[13], *N. Barry*[14], *M. Ebert*[2], *H. Gan*[1], *S. Ng*[1], *M. Pinkham*[11], *D. Bailey*[7], *E. Koh*[15];
[1]*ONJCRI and Austin Health, Heidelberg, AUSTRALIA,* [2]*Sir Charles Gairdiner Hospital, Perth, AUSTRALIA,* [3]*Austin Health, Heidelberg, AUSTRALIA,* [4]*TROG, Newcastle, AUSTRALIA,* [5]*Royal Brisbane and Womens Hospital, Brisbane, AUSTRALIA,* [6]*Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [7]*Royal North Shore Hospital, St Leonards, AUSTRALIA,* [8]*Liverpool Hospital, Sydney, AUSTRALIA,* [9]*Royal Adelaide Hospital, Adelaide, AUSTRALIA,* [10]*Canberra Hospital, Canberra, AUSTRALIA,* [11]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [12]*St George Hospital, Sydney, AUSTRALIA,* [13]*Wesley Hospital, Brisbane, AUSTRALIA,* [14]*University of Western Australia, Perth, AUSTRALIA,* [15]*Liverpool Hospital, Liverpool, AUSTRALIA.*

Aim/Introduction: To update regarding the prospective multi-site trial evaluating O-(2-[^{18}F]-fluoroethyl)-L-tyrosine Positron Emission Tomography (FET-PET) in Glioblastoma (FIG) study, and to report the impact of central Nuclear Medicine physician (NMP) review of prospective FET-PET1 delineation of the biological target volume (BTV) for radiotherapy (RT) planning. ***Materials and Methods:*** Adult GBM participants across 11 Australian sites undergo FET-PET post-surgery/pre-chemo-RT [CRT] (FET-PET1), one month post CRT (FET-PET2) and at suspected progression vs pseudoprogression evaluation timepoint (FET-PET3). Group 1 participants enter at timepoint 1 (FET-PET1 with MRI1), with Group 2 at timepoint 2. Adjuvant RT target volumes are derived per standard contrast MRI, with hybrid post-hoc RT volumes then incorporating the FET-PET1 NM-derived BTV utilising MiM version 7.0 to evaluate the impact of FET PET on potential treatment planning. All trial sites and NMP have passed credentialling which included three benchmarking cases involving FET1-BTV delineation. ***Results:*** Recruitment commenced in January 2021, with 247 (n=156 Group 1 and n=91 Group 2) participants enrolled to date with n=143 evaluable Group 1 data. Trial credentialling demonstrated variations in FET-PET1-derived BTV in 25/72 (34.7%)-13 minor and 12 major. Currently, 121/143 participant FET-PET1 with BTV delineation cases across 11 sites have undergone central NMP review, with 18/121 (14.9%) requiring resubmission. Reasons for resubmission/protocol deviation included incorrect imaging sequence selection within MiM workflow (n=3), static GTV overcontouring (n=12), dynamic volume of interest change in size/position during workflow (n=1) and static FET interpretation issues (n=2). ***Conclusion:*** This trial has demonstrated the importance of credentialling and central review of prospective FET-PET-derived BTV delineation in ensuring protocol adherence. The FIG study is the largest prospective multi-site study of its kind addressing FET-PET's impact on radiation planning and in management of pseudoprogression and prognostication. Analysis of trial FET-PET BTV data is continuing, as is recruitment for evaluable patients to address progression vs pseudoprogression post CRT.

EPS-120

Metabolic activity of proton radiation therapy related effects in gliomas measured with [18F]FET PET imaging

K. Madsen[1], *A. Muhic*[2,3], *J. Skjøth-Rasmussen*[4], *J. Carlsen*[5], *D. Scheie*[6], *I. Law*[1], *O. Henriksen*[1];
[1]*Department of Clinical Physiology, Nuclear Medicine and PET, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [2]*Department of Oncology, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [3]*Danish Centre for Particle Therapy, Aarhus University Hospital, Aarhus, DENMARK,* [4]*Department of Neurosurgery, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [5]*Department of Radiology, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK,* [6]*Department of Pathology, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: Proton radiation therapy (PRT) has since 2019 become a treatment option alongside photon therapy in Denmark. PRT reduces doses to normal brain structures and for gliomas PRT has been considered in oligodendroglioma WHO grade 2-3 (O2-3) and astrocytoma IDH mutated WHO grade 2-4 (A2-4). Concerns have been raised regarding the frequency of proton treatment-related effects (PTRE). We previously found the metabolic activity measured by [18F]FET PET imaging separates tumor relapse from PTRE at an early stage with an optimal TBRmax cut-off at 2.2. The aim of this study is to characterize the time course of metabolic activity within PRTE lesions verified by histopathology. ***Materials and Methods:*** Forty-nine patients (mean age 41 years range 23-65) from Rigshospitalet, Copenhagen, Denmark suffering from glioma were treated with PRT at the Danish Centre for Particle Therapy until October 2022 and followed for minimum 2.5 years until March 2025. At regular follow-up MRI new contrast enhancing lesions were found in 29 patients of which eight patients fulfilled the inclusion criteria for the study, i.e. [18F]FET PET imaging and biopsy showing only PTRE (initial pathology O3 n=5, A3 n=2 A4 n=1). Patients were subsequently followed with regular MRI and median four [18F]FET PET scans (range 1-8). ***Results:*** Regarding the eight included patients PTRE emerged at MRI median 10 months after PRT (range 7-24), and all but one subsequently developed multiple lesions during the follow-up period. The TBRmax peaked at a median of 11 months (range 0-22) after PTRE emerged at MRI. Regarding the majority of lesions TBRmax remained below the cut-off at 2.2, however, three patients each developed one lesion with higher intensity, with a peak TBRmax at 2.5-3.5. ***Conclusion:*** Our study indicates that PTRE may emerge relatively late after PRT and might also have a prolonged course. The metabolic activity of PTRE lesions usually stays below 2,2 but lesions may develop higher metabolic intensity. However, our study only included patients where biopsy was required, which might select the most severe cases.

Aim/Introduction: To assess the possible effect of concurrent immunotherapy with immune check point inhibitors (ICIs) on 18F-FDOPA PET/MRI imaging, in patients with brain metastases (BM) treated and suspected of tumor relapse (TR) versus treatment related changes (TRC). ***Materials and Methods:*** A retrospective analysis was performed on 37 ^{18}F-FDOPA PET/MRI (FDOPA-PET) scans from 37 patients (including 53 BM), from different primary tumors. Patients had received surgery combined with hypofractionated stereotactic radiation therapy or radiosurgery alone. A subset of patients had received, immunotherapy using ICI. Images were analyzed visually and quantitatively. Semiquantitative evaluation included measurement of SUVmax and lesion-to-striatum (L/S) and lesion-to-cortex (L/C) SUVmax ratios. Patients were categorized based on whether they were undergoing ICI at the time of imaging. Lesion etiology for TR vs TRC interpretation was determined through clinical-radiological follow-up (at least 6 months) and/or histopathology. Statistical analysis was performed using non-parametric tests (Mann Whitney test) to compare differences between groups (immunotherapy vs. no immunotherapy). ***Results:*** The most common primary malignancy was lung adenocarcinoma (23/37, 62.%), followed by breast cancer (6/37), renal cancer (3/37), melanoma (2/37), small cell lung cancer (1/37), pulmonary neuroendocrine tumor (1/37) and colon neuroendocrine tumor (1/37). At the time of the PET/MRI 17/37 (46%) of patients (23 lesions) were receiving ICIs. Among the 53 analyzed lesions, 22 were finally considered as TR. A mean L/S of 1.12vs0.92 and L/C of 2.00vs1.67 differentiated TR from TRC in no ICI patients. A mean L/S of 1.24vs0.90 and L/C of 2.02vs1.41 differentiated TR from TRC in patients on ICI. No statistically significant differences ($p > 0.05$) between the two groups were observed regardless of lesion classification. However, both visual and semiquantitative analysis showed an overall trend towards higher uptake in patients undergoing ICI with higher SUVmax values and L/S ratios, this difference was even more pronounced in PET/MRI-positive cases both in SUVmax (U=53.0, p=0.118) and L/E ratio (U=64.0, p=0.316). The results of lower L/C ratio in patients receiving immunotherapy in PET/MRI-negative lesions this could be related to the increased cortical uptake under the influence of ICIs. ***Conclusion:*** Despite slightly higher FDOPA-PET activity in BM undergoing ICIs was observed, the preliminary analysis do not show significant differences. Nevertheless, studies with larger samples should be performed to confirm these negative results. Our findings support the utility of FDOPA-PET imaging for BMs assessment, regardless of the patient's immunotherapy status.

Parini, Aosta, ITALY.*

Aim/Introduction: The analysis of 18F-FET Time Activity Curves (TAC) based on SUVmax uptake patterns is useful to differentiate between high-grade and low-grade gliomas. Typically, high-grade gliomas exhibit an early peak followed by a decrease, while low-grade gliomas tend to show a gradual increase over time. Some lesions may plateau after an initial rise. However, visual interpretation of these curves can be challenging due to image noise affecting SUVmax measurements and ambiguous curve trends in some cases. Our study aimed to develop an objective method for characterizing 18F-FET TAC uptake patterns through analytical curve processing. ***Materials and Methods:*** 51 patients affected by different grade gliomas (2021 WHO classification) underwent a 40-minute dynamic 18F-FET PET/CT scan. Of these, 19 patients were evaluated at initial diagnosis, and 32 at disease relapse. Overall, 59 lesions were analyzed: 35 were high-grade (12 glioblastomas and 1 astrocytoma at diagnosis; 19 glioblastomas and 3 astrocytomas at relapse), and 24 were low-grade (2 astrocytomas, 2 oligodendrogliomas, and 2 gangliogliomas at diagnosis; 11 astrocytomas, 6 oligodendrogliomas, and 1 ganglioglioma at relapse). SUVmax TACs were extracted from dynamic imaging data using a 40% threshold VOI on the lesions. The final 20 minutes of each TAC were fitted with a linear regression model to calculate the angular slope. In particular, we defined a plateau as any slope within the range of ±5°; while slopes >5° were considered increasing, and those <−5° decreasing. ***Results:*** None of 13 high-grade lesions at diagnosis showed an increasing uptake pattern: 10/13 showed decreasing curves (mean slope: −13.4°), and 3/13 plateau patterns (mean slope: −0.02°). In the relapse group, 13/22 high-grade lesions exhibited plateau curves (mean slope: −0.9°), 3/22 increasing curves (mean slope: 7.6°), and 6/22 were decreasing (mean slope: −8.9°). 5/6 low-grade lesions at diagnosis showed plateau curves (mean slope: −0.3°), and 1/6 was decreasing (slope: −11.5°). In contrast, 5/18 low-grade lesions at relapse exhibited increasing curves (mean slope: 9.8°), 10/18 plateau curves (mean slope: 0.7°), and 3/18 decreasing curves (mean slope: −8.5°). ***Conclusion:*** Evaluating TAC slopes allows for a more objective classification of uptake patterns. Our findings revealed distinct TAC behaviour between diagnosis and relapse, particularly among high-grade gliomas. Notably, relapsed high-grade lesions exhibited all curve types, including increasing patterns traditionally associated with low-grade gliomas. Our results showed a kinetic shift at relapse in the TAC patterns, which could help clinicians for identifying glioma patients who are likely to benefit from treatments.

EPS-123

Noninvasive Assessment of IDH Mutation Status and WHO Grade in Untreated Prospective Glioma Patient Cohort using Integrated ^{18}F-FET PET/MR

B. Yu[1], *W. Zhou*[1], *M. Li*[1], *Z. Lin*[2], *Y. Wei*[2], *X. Chen*[2], *Y. Yang*[3], *T. Hua*[1];
[1]*Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [2]*United Imaging Healthcare Co., Ltd., Shanghai, Shanghai, CHINA,* [3]*Beijing United Imaging Healthcare Co., Ltd., Beijing, Beijing, CHINA.*

Aim/Introduction: Isocitrate dehydrogenase (IDH) mutation status and WHO grade are essential markers for glioma stratification and therapeutic decision-making. This study aimed to evaluate the diagnostic performance of multiparametric PET/MR, combining O-(2-^{18}F-fluoroethyl)-L-tyrosine positron emission tomography (^{18}F-FET PET) and intravoxel incoherent motion (IVIM) imaging, for the noninvasive assessment of IDH mutation status and WHO grade. ***Materials and Methods:*** 86 untreated prospective glioma patients (IDH-mutant type: 46; IDH-wild type: 40) underwent simultaneous ^{18}F-FET PET and IVIM imaging using an integrated PET/MR (uPMR790, United Imaging Healthcare, Shanghai, China). The max, peak, and mean tumor-to-brain ratio (TBR_{max}, TBR_{peak}, TBR_{mean}), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were derived from whole-tumor segmentations based on PET images. IVIM metrics of the tumor, including the standard

apparent diffusion coefficient (sADC), true diffusion coefficient (D), pseudo diffusion coefficient (D*), perfusion fraction (f), relative blood flow (rBF), distributed diffusion coefficient (DDC) and water molecular diffusion heterogeneity index (α) were measured. Logistic regression and receiver operating characteristic (ROC) analysis were performed to evaluate the predictive value of PET indicators, IVIM indicators and their combined use for IDH mutation and WHO grade. ***Results:*** Univariate logistic regression showed that TBR_{max} (p = 0.015), TBR_{peak} (p = 0.016), and TBR_{mean} (p = 0.007) were significantly negatively associated with IDH mutation status, indicating lower uptake in IDH-mutant gliomas. Among IVIM parameters, IDH-mutant gliomas exhibited lower f (p = 0.003), rBF (p = 0.003), but higher α (p = 0.001). Age was a significant predictor of IDH mutation (p = 0.027), with mutations more common in younger patients. A multivariate model combining TBR_{mean}, f, rBF, α, and age achieved the highest predictive performance for IDH mutation status, with an AUC of 0.8147. TBR_{max} (p = 0.001), TBR_{peak} (p = 0.003), TBR_{mean} (p =0.006), and age (p = 0.003) were positively associated with WHO grade, while D (p = 0.038) and sADC (p = 0.048) were negatively associated. A combined model incorporating TBR_{max}, D, and age yielded the best diagnostic performance, with an AUC of 0.8322. ***Conclusion:*** Multiparametric ^{18}F-FET PET/MR imaging demonstrates significant promise for the noninvasive evaluation of IDH mutation status and WHO grade in glioma patients. The combination of metabolic and diffusion-perfusion parameters enhances evaluation performance, supporting its clinical utility in glioma management.

EPS-124

MRI radiomic analyses to predict the clinical utility of additional [^{18}F]FET PET imaging in glioblastoma patients

L. Kaiser[1], *A. J. Zounek*[1], *E. Istrefi*[1], *J. Isakaj*[1], *E. Barci*[1], *J. Reis*[2], *R. Forbrig*[2], *B. Wiestler*[3], *K. J. Müller*[1], *L. von Baumgarten*[4], *M. J. Mair*[1,5], *S. Ziegler*[6,1], *N. L. Albert*[1];

Aim/Introduction: MRI remains the primary imaging modality for managing glioblastoma, and contrast-enhancement on MRI usually represents the target volume for local therapies such as surgical resection or irradiation. However, MRI may fail to capture the full extent of the tumor, while [^{18}F]FET PET imaging can help to reveal metabolically active tumor parts beyond those visible on contrast-enhanced MRI in a significant number of cases. This study explores whether radiomic features extracted from MRI can predict the presence of tumor parts outside the contrast-enhancing volumes, thus identifying patients who may benefit from additional [^{18}F]FET PET imaging for local therapy planning. ***Materials and Methods:*** The study cohort consisted of 239 patients newly diagnosed with glioblastoma. All patients underwent preoperative [^{18}F]FET PET scans. PET tumor boundaries were determined using a 1.6-fold background intensity threshold. MRI tumor volumes, including regions of contrast enhancement and T2 signal hyperintensity, were delineated using the BraTS toolkit. The spatial overlap and maximum Hausdorff distance between PET and MRI-defined tumor volumes were assessed. Radiomic features were derived from T1-weighted contrast-enhanced and T2-weighted MRI images. A logistic regression model with nested cross-validation (5 folds, 50 repeats) was employed to classify cases where [^{18}F]FET PET revealed more than 1 ml of tumor tissue beyond the MRI-defined region and with a Hausdorff distance exceeding 1 cm. ***Results:*** 145/239 patients (61%) exhibited PET-detected tumor exceeding the MRI-defined areas, while the remaining 94 patients (39%) showed PET activity confined within or marginally exceeding contrast-enhancing MRI volumes. The overall Dice similarity coefficient between MRI and PET volumes was 0.37. The radiomics-based model achieved an area under the curve (AUC) of 0.78 in identifying patients with PET volumes significantly exceeding MRI (positive predictive value of 0.80 and negative predictive value of 0.60). ***Conclusion:*** MRI radiomics demonstrated moderate performance in predicting glioblastoma patients in whom additional [^{18}F]FET PET visualizes tumor tissue beyond contrast enhancement on MRI. Future studies are warranted to assess whether this strategy can enhance local therapy planning by enabling more selective application of [^{18}F]FET PET in clinical practice.

EPS-125

Can radiomics from conventional MRI forecast [^{18}F]FET PET positivity in patients with suspected low-grade gliomas?

L. Kaiser[1], *A. J. Zounek*[1], *E. Istrefi*[1], *J. Isakaj*[1], *E. Barci*[1], *J. Reis*[2], *R. Forbrig*[2], *B. Wiestler*[3], *K. J. Müller*[4], *L. von Baumgarten*[5], *M. J. Mair*[1,6], *S. Ziegler*[7,1], *N. L. Albert*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Institute of Neuroradiology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [3]*Department of Neuroradiology, Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY,* [4]*Department of Neurology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [5]*Department of Neurosurgery, LMU University Hospital, LMU Munich, Munich, GERMANY,* [6]*Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, AUSTRIA,* [7]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY.*

Aim/Introduction: In patients with suspected low-grade glioma on MRI, [^{18}F]FET PET is regularly performed to localize regions for targeted biopsy. Nevertheless, approximately one-third of these non-enhancing gliomas do not exhibit elevated tracer uptake on [^{18}F]FET PET. Given the growing demand for PET scans, the prediction of PET negativity could avoid performing scans with negative outcome. This study, therefore, sought to determine whether radiomics derived from standard MRI sequences could forecast [^{18}F]FET positivity in patients with suspected low-grade gliomas. ***Materials and Methods:*** The study included 282 individuals with newly diagnosed gliomas who underwent preoperative [^{18}F]FET PET and exhibited no contrast enhancement on MRI. Tumor regions were segmented using the BraTS toolkit, and radiomic features were extracted from both contrast-enhanced T1 and T2-weighted MRI images. A logistic regression model with nested cross-validation (5 folds, 50 repeats) was employed to predict [^{18}F]FET positivity, defined as tumor regions exhibiting significant uptake (> 1.6 times the background activity). ***Results:*** 192/282 cases (68%) demonstrated positive [^{18}F]FET uptake, while 90 cases (32%) did not meet the threshold for significant uptake and were classified as [^{18}F]FET-negative. The radiomics-based classification model achieved an area under the curve (AUC) of 0.64, with a positive predictive value of 0.78 and a negative predictive value of 0.45. ***Conclusion:*** Radiomics derived from MRI provided only a limited predictive power in identifying [^{18}F]FET positivity among non-enhancing gliomas, suggesting that PET should be performed in all patients. Further research is needed to determine whether deep learning approaches can enhance predictive accuracy, or whether these findings instead indicate that morphologic texture features from MRI are insufficient to predict if [^{18}F]FET PET can provide additional information to guide biopsy in patients with suspected low-grade glioma.

EPS-126

SSTR-PET Characteristics of Meningiomas: a Retrospective Comparison of Gallium-68- and Fluorine-18-labelled Tracers

L. Degryse[1], *L. Teles*[2], *S. De Vleeschouwer*[1], *L. Boeckxstaens*[1], *S. Jentjens*[3], *W. Deckers*[1], *G. Schramm*[1], *M. Lambrecht*[1], *J. Daisne*[4], *K. Van Laere*[1], *P. Clement*[1], *K. Goffin*[1], *C. M. Deroose*[1];
[1]*University Hospitals Leuven, Leuven, BELGIUM,* [2]*Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS,* [3]*Maastricht University Medical Center, Maastricht, NETHERLANDS,* [4]*ZAS, Antwerp, BELGIUM.*

Aim/Introduction: Meningiomas frequently overexpress somatostatin receptor (SSTR) subtype 2, which is targeted on SSTR-PET imaging [1]. While [^{68}Ga]Ga-DOTATATE/TOC are well-established radiotracers for this purpose, emerging fluorine-18-labelled agents such as [^{18}F]AlF-NOTA-Octreotide (^{18}F-AlF-OC) offer practical advantages, including a longer physical half-life and centralized production [2-4]. We retrospectively studied quantitative uptake metrics across different delineation strategies using both gallium-68 and fluorine-18-labelled tracers. ***Materials and Methods:*** Patients with SSTR-PET imaging at our institution between 1/01/2007 and 1/03/2024, either demonstrating a meningioma or referred for its evaluation, were included. For individuals with multiple scans, only the first scan was analysed. Three radiotracers were used over the study period: [^{68}Ga]Ga-DOTATATE/TOC (N=137, 2.2 MBq/kg, scan 30-60 minutes post-injection), and ^{18}F-AlF-OC (N=15, 2-4 MBq/kg depending on yield, scan 120 minutes). SSTR uptake in meningiomas measuring ≥ 1 cm^3 was quantified using 3 lesion delineation strategies [5]: (1) a fixed SUV threshold of 2.3; (2) a relative threshold of 1.73×SUV_{peak} of a reference meningeal region; (3) a relative threshold of 11% of the SUV_{max}. Physiological uptake was quantified using spherical VOIs in non-pathological spleen, liver, left ventricle, vertebrae and meningeal tissue. ***Results:*** Overall, 171 distinct SSTR-expressing meningiomas (97.7%) and 4 non-SSTR-expressing meningiomas (2.3%) were documented in 152 patients. Most SSTR-expressing meningiomas were localised at the convexity (43.3%), skull base (32.7%) or falx (18.7%). Two patients had an optic nerve sheath meningioma (1.2%) and one had a spinal meningioma (0.6%). Quantitative analysis of lesions ≥1cm^3 revealed robust uptake for both ^{18}F-AlF-OC (N=7) and [^{68}Ga]-DOTATATE/TOC (N=79), with mean SUV_{max} values of 12.8, 12.8, and 13.5 for the former and 13.4, 13.4, and 15.5 for the latter across the three delineation strategies, respectively. Corresponding SUV_{mean} values were 5.2, 3.2, and 4.6 for ^{18}F-AlF-OC and 5.0, 3.0, and 4.8 for [^{68}Ga]-DOTATATE/TOC, respectively. Physiological uptake in all organs was comparable between both tracers. Across all delineation strategies, both tracers achieved high tumourtomeningeal ratios, yielding excellent lesiontobackground contrast. Tumourtoliver ratios exceeded 1 in every 18F-AlF-OC scan and in > 50 % of [^{68}Ga] GaDOTATATE/TOC scans, corresponding to a Krenning score ≥ 3. ***Conclusion:*** SSTR-PET imaging reveals high and consistent uptake in meningiomas across both [^{68}Ga]-DOTATATE/TOC and ^{18}F-AlF-OC. Quantitative parameters were robust across delineation strategies, and no relevant differences in uptake were observed between both tracers. These findings support the clinical interchangeability of ^{18}F-AlF-OC and [^{68}Ga]-labelled tracers for meningioma imaging.

EPS-127

Calibration of 3D ring-design SPECT/CT system to ENC-DAT database

T. Noponen*, H. Suoraniemi, A. Rissanen, M. Seppänen;*
Turku University Hospital, Turku, FINLAND.

Aim/Introduction: 3D ring-design SPECT/CT (3D-SPECT) is a desirable system for imaging small objects such as striatum in [^{123}I]-FP-CIT dopamine transporter (DAT) imaging. The reporting of DAT images relies nowadays on a reliable reference database to quantify precisely whether the striatal uptake level is normal. Widely accepted European Normal Control database of DaTscan (ENC-DAT) has been acquired using dual-head SPECT systems (2D-SPECTs) and requires a striatal phantom based calibration to adjust the specific SPECT system to that database. In this study, 3D-SPECT with the optimized reconstruction protocol is calibrated to the ENC-DAT database and compared with the calibration results of 2D-SPECTs. ***Materials and Methods:*** A brain phantom with realistic head and striatal structures was filled with ^{123}I solution so that the right striatum has 28% higher activity concentration than the left striatum. Three different background activity levels were used and on each level the phantom was imaged using three different imaging systems, 3D-SPECT, analog and digital 2D-SPECT. The six striatum-to-background activity concentration ratios (SBR) (ranging from 2.7 to 11.6) were verified using a well counter. The images were reconstructed and the SBRs quantified from the SPECT images as well. The optimal image reconstruction parameters were defined for the 3D-SPECT by maximizing the SBR in SPECT images. The linear equation was fitted between the well counter and image based SBRs and the slope and r^2 values of the equation were calculated for each SPECT measurement. The slope values will be used to adjust the measurements of each SPECT system to the ENC-DAT database. ***Results:*** Optimal reconstruction (Bayesian penalized-likelihood algorithm with a novel scatter correction, beta = 0.01 and gamma = 3.0) increased the contrast in 3D-SPECT images 26% compared to a standard manufacturer reconstruction. The 3D-SPECT images had the highest slope (s) values and SBRs (s=0.510, SBRs = 1.8-6.3) compared to the values of analog (s=0.413, SBRs = 2.1-5.6) and digital 2D-SPECT (s=0.408, SBR = 1.7-5.3) meaning that 3D-SPECT images have the highest striatal contrast. The r^2 values of the slope fits were very high for each system (3D-SPECT: 0.993, analog 2D-SPECT: 0.995, and digital 2D-SPECT: 0.998) proving that the calibration procedure succeeded reliably. ***Conclusion:*** Our results show that 3D-SPECT can be reliably calibrated to the ENC-DAT database. This makes possible the utilization of well-established database for clinical reporting of 3D-SPECT DAT images. An optimized 3D-SPECT provides the higher SBRs than 2D-SPECTs showing the advantage of 3D-SPECT for DAT imaging.

EPS-128

Clinical Impact of Dual-Biomarker PE2I-PET in the Differential Diagnosis of Parkinsonian Syndrome: A Retrospective Study

T. Crnic Bojkovic[1], *L. Falk*[1], *L. Appel*[1], *C. Widström*[1], *D. Nyholm*[2], *J. Sörensen*[1], *T. Danfors*[1], *M. Lubberink*[1], *M. Jonasson*[1];
[1]*Department of Surgical Sciences, Molecular Imaging and Medical Physics, Uppsala University, Uppsala, SWEDEN,* [2]*Department of Medical Sciences, Neurology, Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: Dynamic PE2I-PET assesses both dopamine transporter (DAT) availability and cerebral blood flow ratio (CBFR), the latter as an alternative to FDG as a marker of brain function. It may support differential diagnosis of early-stage parkinsonian disorders, where clinical assessment is challenging. This study aims to explore the impact of [^{11}C]PE2I-PET on clinical diagnosis in patients evaluated for parkinsonism or related neurodegenerative disorders. ***Materials and Methods:*** We retrospectively reviewed 432 patients (mean age 72; 35% females) who underwent 40-min dynamic [^{11}C]PE2I-PET at Uppsala University Hospital (2015-2023). Patients were included for whom diagnoses by a referring clinician were available from the Uppsala County diagnosis register both prior to and after the PET scan. Parametric images of specific binding ratio (30-40 min; DAT) and CBFR were calculated using a basis function implementation of the simplified reference tissue model with cerebellum as reference region. These images were read by experienced nuclear medicine physicians to obtain the most probable image-based differential diagnosis[1]. Pre- and post-

PET diagnoses were based on the last relevant clinical diagnosis before and after PET. Patients were classified into six diagnostic categories: Parkinson's disease (PD), Lewy body dementia (LBD), progressive supranuclear palsy (PSP), multiple system atrophy (MSA), other dementias, and other non-parkinsonian/unspecified disorders. For comparison with clinical diagnosis, a 'normal scan' PET reading was grouped with the latter for diagnostic comparison. Diagnostic agreement and change were assessed by comparing clinical diagnoses and PET reading overall and within diagnostic groups. Diagnostic changes were interpreted as shifts in clinical confidence. ***Results:*** Pre-PET, PET reading and post-PET diagnoses were distributed as PD: 20%, 30%, and 27%; LBD: 1%, 15% and 11%; PSP: 1%, 5% and 3%; MSA: 1%, 4% and 5%; other dementias: 4%, 5% and 8%; other non-parkinsonian/unspecified disorders: 74%, 42% and 47%. The post-PET diagnosis differed from the pre-PET diagnosis in 42% of cases. Of these, the post-PET diagnosis agreed with the PET reading in 62% of cases ($\kappa = 0.53$, $p < 0.001$). Overall, the post-PET diagnoses agreed in 67% of cases with the PET reading ($\kappa = 0.53$, $p < 0.001$). Non-parkinsonian/unspecified cases decreased markedly after PET from 318 to 202, a 37% reduction. ***Conclusion:*** In this retrospective study, [^{11}C]PE2I PET was associated with changes in clinical diagnoses in more than 40% of patients, and increased agreement with post-PET diagnoses, suggesting a role in refining and supporting clinical decision-making. ***References:*** [1]Crnic Bojkovic et al, EANM Technologist Guide 2024, Chapter 5

EPS-130

A Head-to-head Comparison of ^{18}F-DPA714 PET and ^{18}F-FDG PET in the diagnosis of Autoimmune Encephalitis

M. Zhang[1], *H. Meng*[2], *S. Chen*[2], *H. Wang*[1], *B. Li*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,*
[2]*Department of Neurology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: The positive detection rate of MRI in autoimmune encephalitis (AIE) patients is relatively low, often failing to make a rapid and accurate localization diagnosis. Both ^{18}F-DPA714 [1] and ^{18}F-FDG [2] PET demonstrated their advantages in the diagnosis of AIE by characterizing microglial TSPO expression and glucose metabolism levels, respectively. Therefore, the aim of this study was to conduct a head-to-head comparison of the diagnostic value between ^{18}F-DPA714 and ^{18}F-FDG PET in patients with AIE. ***Materials and Methods:*** This cross-sectional study included 23 antibody-positive and 2 possible antibody-negative AIE patients, along with 10 healthy controls (HCs). All patients underwent sequential ^{18}F-DPA714 PET/MRI and ^{18}F-FDG PET/CT examinations within one week. A follow-up of 6 to 12 months after the baseline examinations was performed to assess the change of patients' clinical symptoms. Positive findings for ^{18}F-DPA714 PET were defined as Z-score above 2.0 in the corresponding brain regions of HCs. Positive results for ^{18}F-FDG PET were indicated by the Z-score above 2.0 or below -2.0 obtained after comparison with the normal population database. ***Results:*** Both ^{18}F-FDG PET and ^{18}F-DPA714 PET showed higher positivity rates than MRI (81% vs 44%, $P = 0.006$ and 76% vs 44%, $P = 0.008$, respectively). A statistically significant association was found between the ^{18}F-DPA714 but not ^{18}F-FDG uptake and the mRS scores ($P = 0.032$) or CASE scores ($P = 0.006$). Patients with epilepsy showed a significantly higher uptake in the whole-cortex of both ^{18}F-DPA714 ($P = 0.001$) and ^{18}F-FDG ($P = 0.005$) as well as in the temporal lobe of ^{18}F-FDG ($P = 0.022$) compared to those patients without. Higher ^{18}F-DPA714 standardized uptake value ratio (SUVR, $P<0.001$) and lower ^{18}F-FDG SUVR ($P<0.001$) in the whole-cortex of patients with long-term cognitive impairment than those patients without were observed. ***Conclusion:*** ^{18}F-DPA714 PET showed its better correlation with disease severity of AIE than ^{18}F-FDG PET, serving as a supplementary tool to ^{18}F-FDG PET and MRI. ***References:*** 1. Aim/Introduction: Gold standard PET quantification implies arterial blood sampling. This procedure is invasive and involves a number of constraints and contraindications. There are alternative methods that avoid arterial samples, one of which uses reference or pseudo-reference regions. The choice of this reference region is critical to the validity and accuracy of the analysis. The synaptic vesicle glycoprotein 2A (SV2A) radiotracer [^{11}C]UCB-J has ideal imaging characteristics to quantify synaptic loss in Alzheimer's disease (AD). The pseudo-reference region conventionally used for this radiotracer is the centrum semiovale (CS). However, recent studies suggest that using the whole cerebellum as an alternative reference region would provide a more robust signal than the small centrum semiovale region.[1] ***Materials and Methods:*** Fifty-two subjects (33 AD patients and 19 healthy controls) underwent a 70 min PET/MR after i.v. injection of [^{11}C]UCB-J (314±30 MBq). Anatomical MRIs were segmented using FastSurfer and 6 potential pseudo-reference regions were drawn (after erosion to avoid partial volume effect): whole cerebellum, cerebellar gray matter, pons and CS defined in 3 different ways: i) from MNI template applied to subject after normalization with ANTs library (mean vol ± SD: 1.6±0.2 mL), ii) from individual MRI eroded total white matter (15.7±8.5 mL), iii) and after exclusion of the white matter lesions (10.7±7.4 mL). SUV values (50-70 min) of each reference region were analyzed for all subjects. DVR using SRMT2 model and SUVr (50-70 min) were calculated with each reference region and investigated for 13 cortical regions of interest. ***Results:*** Mean SUV values between AD patients and controls did not differ in any of the pseudo-reference regions. Coefficient of variation of SUV were comparable across pseudo-reference regions except for the Pons where it was more variable. DVR values were significantly decreased in temporo-parietal regions in AD patients compared to controls with both whole cerebellum and individually defined CS (Cohen's $d>1$). Results were less pronounced (NS in the left temporal mesial ROI) with the CS from the template (Cohen's $d=0.9$), and non-significant in most regions with the pons. The SUVr

(50-70min) showed similar results to DVR. ***Conclusion:*** SUVs in CS and whole cerebellum showed good stability between controls and patients. Careful CS definition by delineation on individual MRI instead of applying a template improved robustness for its use as a reference region. Under these conditions, the CS and whole cerebellum reference regions lead to similar results using DVR and SUVR quantification. ***References:*** 1.Mecca AP et al. 2020.

EPS-132

^{18}F-SynVesT-1 PET Imaging Reveals Synaptic Density Abnormalities and Brain Network Alterations in Tinnitus Patients: A Pilot Study

J. Zhong, *S. Hu;*
Xiangya Hospital,Central South University, Changsha, CHINA.

Aim/Introduction: The prevalence of tinnitus is as high as 10% to 30% of the population, and it has become a major global health problem.At present, the pathogenesis of tinnitus is not completely clear, and its neurophysiological basis needs to be further studied.The hypothesis of increased neuronal activity is confirm by ^{18}F-fluorodeoxyglucose (^{18}F-FDG) in primary and chronic tinnitus patients, but the abnormalities of synaptic density has not been tested directly by synaptic vesicle protein 2A (SV2A). In this positron emission tomography (PET) study with the new tracer ^{18}F-SynVesT-1, we evaluated SV2A abnormalities in patients with primary and chronic tinnitus and compared the pattern to ^{18}F-fluorodeoxyglucose (^{18}F-FDG). ***Materials and Methods:*** 28 patients with acute and chronic tinnitus and 24 healthy controls were recruited. Acute and chronic tinnitus patients underwent magnetic resonance imaging (MRI) and static PET imaging with both ^{18}F-SynVesT-1 and ^{18}F-FDG, while the controls only PET with ^{18}F-SynVesT-1 and MRI. Brain network assessment of PET with ^{18}F-SynVesT-1 was undertaken. Standardized uptake value (SUV) of ^{18}F-SynVesT-1 and ratio (SUVr) were computed between regions of interest. Electroencephalographs (EEGs)was applied in tinnitus patients and healthy controls. Correlations between synaptic density and clinical features in tinnitus were also analyzed. ***Results:*** Chronic tinnitus patients showed increased ^{18}F-SynVesT-1 uptake in 14 brain areas, including the limbic lobe, temporal lobe, and parahippocampal gyrus, corresponding to high metabolism detected by ^{18}F-FDG. Acute tinnitus patients had decreased synaptic density in five brain areas, including the bilateral frontal lobe and left occipital lobe. ^{18}F-SynVesT-1 uptake had a broader pattern than ^{18}F-FDG ($P<0.05$). SUVR of the two tracers was positively correlated in the insula lobe but not in the parahippocampal gyrus, temporal lobe, paracentral lobule, or occipital lobe. Brain network connectivity was enhanced in tinnitus patients, with better connectivity in acute vs. chronic patients. EEG microstate analysis showed alternating patterns in both groups.THI scores were negatively correlated with bilateral hippocampus, amygdala, left putamen, and medial cingulate gyrus. ***Conclusion:*** SV2A PET with ^{18}F-SynVesT-1 represents a promising tool for elucidating the synaptic basis of tinnitus and its associated brain network changes. SV2A PET with 18F-SynVesT-1 is the first in vivo evidence confirming to the hypothesis of changed neuronal activity in tinnitus. Our findings provide further incentive to evaluate interventions that restore synaptic connections to treat tinnitus.

EPS-133

Evidence for brain glial activity in chronic migraine patients: A [^{11}C] PBR28 PET/MR study

Y. Chang, *R. Wang;*
Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: Although neuroinflammation may play a key role in the pathology of migraine and the process of chronification, with implications for disease treatment, the role of microglia in chronic migraine (CM) remains unknown. We investigated whether neuroinflammation is involved in the pathophysiology of CM and whether pro-inflammatory signals are associated with clinical features. ***Materials and Methods:*** This study is divided into two parts. The first part comprises an animal experiment using a chronic migraine (CM) mouse model induced by repeated nitroglycerin (NTG) injections. The distribution pattern of activated microglia in the brains of these mice was evaluated using [^{11}C]PBR28 micro-positron emission tomography (Micro-PET). To further verify the spatial specificity of TSPO (translocator protein) signals, [^{11}C]PBR28 autoradiography was performed. The second part of the study involves a clinical research trial. Nineteen individuals with CM and 10 healthy controls (HCs) underwent integrated brain positron emission tomography (PET)/magnetic resonance (MR) via the translocator protein (TSPO) radioligand [^{11}C] PBR28, a marker of glial activation, together with the quantification of blood plasma inflammatory cytokine/chemokine. The volume in regions of interest (ROI) was calculated using MRI data. The standardized uptake value ratio (SUVR) was extracted for ROI in [^{11}C] PBR28 uptake. The Spearman's rank correlation coefficient between [^{11}C] PBR28 SUVR and changes in plasma factors was calculated. ***Results:*** Micro-PET imaging demonstrated that during the chronicization process of CM induced by repeated NTG injections, there was an increased uptake of radioactivity in the pons, hypothalamus, and amygdala. Complementary in vivo autoradiography revealed a concentrated accumulation of radioactive signals in the medulla oblongata, cerebellum, hypothalamus, midbrain, and basal ganglia, indicating elevated TSPO expression in brain microglia. CM patients had a significantly higher Hamilton Depression Rating Scale (HAMD) and Hamilton Anxiety Rating Scale (HAMA) scores than that in HCs ($p<0.05$). Participants with CM exhibited reduced volume in the thalamus ($p=0.012$), compared with HCs. [^{11}C] PBR28 binding was significantly increased in the midbrain, occipital lobe and vermis, along with increased interictal plasma interleukin-8 (IL-8) and CX3CL1 levels, in individuals with CM compared with HCs. The midbrain levels of TSPO were negatively correlated with the headache frequency ($r=-0.462$, $p=0.046$). ***Conclusion:*** The present findings demonstrated increased central inflammation in CM participants compared to HCs, providing imaging evidence implicating inflammation in the pathophysiology of CM. The reduction in volume within the thalamus may contribute to migraine chronification.

EPS-134

Simplified Quantification of Brain Estrogen Receptors with Fluoroestradiol PET: Evidence Supporting a 30-60 Minute Window for SUVR Calculation

M. Nerattini[1], *V. Berti*[1], *D. C. Matthews*[2], *S. Williams*[3], *C. Andy*[3], *F. Fauci*[3], *C. Boneu*[3], *T. Ajila*[3], *S. Pahlajani*[3], *M. Battista*[3], *R. Andrews*[2], *A. Pupi*[1], *R. Diaz Brinton*[4], *J. P. Dyke*[3], *L. Mosconi*[3];
[1]*University of Florence, Florence, ITALY,* [2]*ADM Diagnostics, Northbrook, IL, UNITED STATES OF AMERICA,* [3]*Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA,* [4]*University of Arizona, Tucson, AZ, UNITED STATES OF AMERICA.*

Aim/Introduction: 17β-estradiol (E2), the most potent endogenous estrogen, modulates neurophysiology and neuropathology via estrogen receptors (ERs) in the brain. The menopause-related decline in E2 has been linked to neurological symptoms and conditions, including Alzheimer's disease. Positron Emission Tomography (PET) with 16α-[18F]fluoro-17β-estradiol (18F-FES) is the only in vivo technique available to assess ER expression in the human brain. However, brain 18F-FES PET studies in women remain limited and typically rely on complex kinetic modeling. Here, we aim to evaluate simplified standardized uptake value ratio (SUVR)-based methods and to identify an optimal static imaging window to enhance clinical feasibility. ***Materials and Methods:*** Fifty-five healthy women (ages 40-65)—18 premenopausal, 18 perimenopausal, and 19 postmenopausal—underwent 90-minute dynamic 18F-FES PET imaging. Parametric binding potential (BPnd) maps were generated using voxel-wise Logan plots with cerebellar gray matter as the reference region. Static images were extracted

for five 20-minute intervals (30-50, 40-60, 50-70, 60-80, and 70-90 minutes post-injection). The pituitary was selected as the primary region of interest (ROI) based on consistent evidence of specific ER binding. Exploratory ROIs included ER-rich hypothalamus, hippocampus, amygdala, caudate, frontal, and cingulate cortex. SUVRs were computed using the same cerebellar reference and compared to distribution volume ratios (DVR = BPnd + 1) via Pearson correlations, intraclass correlation coefficients (ICC), and model selection procedures (stepwise regression and LASSO with AIC). The reference ROI was restricted to cerebellar crus II gray matter, refined with supervised clustering to ensure low, exposure-invariant uptake, thus satisfying normalization criteria. Group differences in SUVRs between pre- and postmenopausal women were also tested. ***Results:*** Pituitary SUVRs showed strong agreement with DVRs, performing best in earlier time intervals. All correlations were significant ($p < 0.001$), peaking at 30-50 minutes ($r = 0.96$, ICC = 0.973). Data-driven analyses identified 30-50 minutes as optimal, closely followed by 40-60 minutes. Findings align with 18F-FES pharmacokinetics—rapid uptake in ER-rich tissue within 20-30 minutes and return to sub-physiological levels by ~1 hour. The selected intervals revealed significantly higher pituitary SUVRs post-menopause ($d = 0.927$, $p = 0.021$ for 30-50 minutes; $d = 0.911$, $p = 0.023$ for 40-60 minutes), consistent with prior evidence of ER upregulation post-menopause. Similar results were observed in exploratory ROIs. ***Conclusion:*** The 30-60 minute SUVR window provides a reliable and practical alternative to kinetic modeling for quantifying pituitary 18F-FES uptake, supporting broader clinical and research application.

EPS-135

Precision Diagnostics in Neurodegeneration via AI-Augmented PET/MRI Fusion of ASL, DTI, and PET

J. Strobel[1], *J. Kassubek*[2], *G. Grön*[3], *A. J. Beer*[4], *M. Beer*[5], *H. Müller*[1], *N. Sollmann*[1];
[1]*Department of Nuclear Medicine and Department of Diagnostic and Interventional Radiology, University Hospital Ulm, Ulm, GERMANY,* [2]*Department of Neurology, University Hospital Ulm, Ulm, GERMANY,* [3]*Department of Psychiatry and Psychotherapy III, University Hospital Ulm, Ulm, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY,* [5]*Department of Diagnostic and Interventional Radiology, University Hospital Ulm, Ulm, GERMANY.*

Aim/Introduction: This study explores a novel approach to neuroimaging for neurodegenerative diseases (NDD) using a hybrid PET/MRI platform that combines Arterial Spin Labeling (ASL), Diffusion Tensor Imaging (DTI), and Positron Emission Tomography (PET). The goal was to integrate these modalities for a comprehensive analysis of NDDs in patients with conditions like Alzheimer's disease, frontotemporal dementia, and primary progressive aphasia. By leveraging the strengths of each imaging technique—ASL for measuring cerebral blood flow, DTI for assessing white matter integrity, and PET for evaluating metabolic and molecular activity—the study aims to enhance diagnostic accuracy, facilitate early detection, and improve understanding of disease-specific patterns. This multimodal strategy may offer valuable insights into the complex pathophysiology of NDDs and support the development of targeted therapeutic interventions. ***Materials and Methods:*** In this study, 76 patients with NDD were examined using the Siemens Biograph PET/MRI system. The standardized acquisition and analysis protocols allowed comparisons between patients and a control group. Specific brain structures of interest were identified based on prior research, and region-of-interest (ROI) analysis was conducted. An artificial intelligence (AI)-based support vector machine (SVM) was employed to categorize different neurodegenerative pathologies. ***Results:*** PET imaging achieved 92.0% accuracy in distinguishing NDD patients from controls and 78.1% for differentiating among NDD types. Combined ASL/DTI matched or exceeded PET accuracy for nfvPPA (81.0%) and lgPPA (94.7%), but was lower for AD (76.3%) and svPPA (88.9%). Voxel-wise analysis revealed overlap between PET and ASL clusters, especially in left-lateralized regions for svPPA and lgPPA. ***Conclusion:*** The study reveals significant differences in PET, ASL, and DTI measurements between neurodegenerative disease (NDD) patients and healthy controls. PET imaging demonstrated a high overall classification accuracy of 92% in distinguishing NDD cases, while ASL and DTI offered comparable or even superior performance in identifying specific subtypes, particularly non-fluent variant primary progressive aphasia (nfvPPA) and logopenic variant PPA (lgPPA). Voxel-wise analysis highlighted notable spatial overlap between PET and ASL signal clusters, especially in left-lateralized brain regions associated with semantic variant PPA (svPPA) and lgPPA. Furthermore, DTI detected complementary white matter alterations in these areas, emphasizing the structural underpinnings of disease progression. This integrated, multimodal imaging strategy underscores the potential of combining MRI and PET to provide a more comprehensive diagnostic picture—targeting both structural and molecular biomarkers in a single session. Such a "one-stop-shop" approach enhances diagnostic precision while streamlining the evaluation process for NDDs.

Preclinical Evaluation of 3B031: A Novel FAP-Targeting Peptide Radioligand with High Tumor Retention and Promising Tumor-to-Kidney Ratio
***W. XU**, J. Zhang;*
PepLib, Metuchen, NJ, UNITED STATES OF AMERICA.

Aim/Introduction: Fibroblast activation protein (FAP) is a membrane-bound serine protease highly expressed in cancer-associated fibroblasts across various solid tumors, making it a compelling target for peptide-based radioligand therapy. However, existing agents such as FAP2286 show notable off-target uptake, particularly in the kidneys, which may limit their clinical utility. We have developed an integrated peptide discovery

platform that combines disulfide-rich peptide phage display with AI-driven in silico peptide design platform to accelerate the development of highly specific and stable peptide radioligands. Using this platform, we developed 3B031, a novel FAP-targeting peptide radioligand with enhanced tumor selectivity and low kidney uptake. ***Materials and Methods:*** 3B031 was discovered through in house peptide library screening and computational design, followed by conjugation with DOTA and radiolabeling with Gallium-68. Surface plasmon resonance was used to determine binding affinity to recombinant human FAP. Plasma stability was evaluated in mouse serum. For in vivo evaluation, BALB/c nude mice bearing subcutaneous HT1080-FAP xenografts were injected intravenously with ^{68}Ga-3B031. PET/CT imaging and ex vivo biodistribution were conducted at 4 hours post-injection. A head-to-head comparison with Novartis's FAP2286 was performed under matched conditions. ***Results:*** 3B031 demonstrated high binding affinity to human FAP with a K_D of 3.7 nM and excellent serum stability. In vivo PET imaging revealed strong tumor localization and minimal non-target organ accumulation. Biodistribution analysis showed high tumor uptake and significantly reduced renal accumulation, resulting in a tumor-to-kidney ratio of approximately 5 at 4 hours post-injection. In comparison, FAP2286 showed a tumor-to-kidney ratio of approximately 2. Under identical conditions, 3B031 outperformed FAP2286 in terms of higher binding affinity, greater tumor retention, lower kidney uptake, and superior tumor-to-kidney ratio. ***Conclusion:*** 3B031 represents a promising next-generation FAP-targeting peptide radioligand with significantly improved pharmacokinetics and tumor selectivity compared to FAP2286. These preclinical results support its advancement into IND-enabling studies and clinical evaluation for diagnostic imaging and potential radiotherapeutic applications in FAP-expressing tumors. ***References:*** 1. mRNA Display-enabled De Novo Discovery of Covalent Macrocyclic Peptide Radiotracers Targeting Fibroblast Activation Protein

X. Cui[1], *P. Liu*[1], *Y. Yang*[2], *Y. Yin*[2], *Z. Liu*[1,3];
[1]*Changping Lab, Beijing, CHINA,* [2]*Shandong University, Qingdao, CHINA,* [3]*Peking University, Beijing, CHINA.*

Aim/Introduction: Current targeted radionuclide therapies (TRT) face challenges with radioligands such as rapid clearance and off-target uptake. This study aimed to exploit mRNA display technology to engineer macrocyclic peptide-based covalent targeted radioligands (CTRs)[1] targeting fibroblast activation protein (FAP), a tumor stromal marker, to achieve prolonged intratumoral retention and enhanced therapeutic precision. ***Materials and Methods:*** A library of >10^{12} macrocyclic peptides incorporating 4-fluorosulfonyloxy-L-phenylalanine (FSY) was ribosomally synthesized using the Flexible In vitro Translation (FIT) system. The Random non-standard Peptide Integrated Discovery (RaPID)[2] platform enabled de novo screening against human FAP. High-affinity hits were conjugated with DOTA for radiolabeling (^{68}Ga/^{177}Lu). Covalent binding kinetics were assessed via SDS-PAGE/autoradiography and surface plasmon resonance (SPR). Pharmacokinetics, stability, and tumor targeting were evaluated in HT-1080-FAP xenograft models using PET/CT imaging, with lipophilicity (Log P) and in vitro stability under radiolabeling conditions (pH 4.0, 90°C) further characterized. ***Results:*** Three CTRs—DOTA-4D-2, -4D-5, and -4D-12—exhibited subnanomolar affinity (K_D = 0.12-0.22 nM) and rapid covalent engagement with FAP (>50% yield within 30 min in vitro). [^{68}Ga]Ga-DOTA-4D-5 demonstrated superior tumor retention, with uptake increasing from 1.77-fold (30 min) to 4.24-fold (5 h) compared to its non-covalent analog, alongside optimal tumor-to-muscle ratios (50.3 ± 21.1). Log P values (−1.92 to −2.15) correlated with reduced non-specific organ uptake, while tandem MS confirmed irreversible binding to tyrosine Y541 in FAP. Stability assays revealed <5% hydrolysis for DOTA-4D-5 under radiolabeling conditions, underscoring robustness. In contrast, non-covalent controls showed rapid washout (tumor uptake decline >60% at 5 h), highlighting the critical role of FSY-mediated covalent bonding. ***Conclusion:*** This study establishes mRNA display as a powerful tool for developing FAP-targeted covalent macrocyclic peptide radiotracers. The integration of FSY enables durable tumor retention through tyrosine-selective sulfur(VI) fluoride exchange (SuFEx), overcoming limitations of conventional non-covalent agents. The optimized CTRs, particularly DOTA-4D-5, exhibit exceptional pharmacokinetic profiles and imaging contrast, positioning them as promising candidates for clinical TRT. This platform broadens the scope of covalent drug design to non-cysteine residues, offering a transformative strategy for precision oncology. ***References:*** (1) Cui, X.-Y. et al. Aim/Introduction: Lymphoma remains a major global health concern. Despite therapeutic advances, managing advanced and relapsed cases, particularly aggressive T-cell lymphoma subtypes, remains an unmet clinical need. Radioimmunotherapy (RIT) with terbium-161 offers a promising strategy, especially for patients at advanced stages of disease. Terbium-161 emits both β^--particles and conversion and Auger electrons, enabling the targeted elimination of large tumor masses as well as small lesions and single cancer cells. In this study, we preclinically evaluate a novel terbium-161-labeled anti-CD30 RIT in comparison to the clinical benchmark lutetium-177 in various T-cell lymphoma models, including a newly developed, clinically relevant disseminated mouse model. ***Materials and Methods:*** The DOTA-conjugated anti-CD30 antibody cAC10 was radiolabeled with terbium-161 or lutetium-177, achieving high specific activities. In vitro cytotoxicity and clonogenic survival were assessed in CD30+ T-cell lymphoma cell lines. In vivo biodistribution and dosimetry were evaluated in a lymphoma xenograft mouse model. Therapeutic efficacy was studied in both localized and disseminated lymphoma models. For the latter, EL4 murine T-cell lymphoma cells were stably transduced with human CD30 (EL4-hCD30+) and inoculated intravenously into immunocompetent mice. Engraftment and disease distribution were assessed via SPECT/CT imaging,

autoradiography, and immunofluorescence staining. ***Results:*** [^{161}Tb]Tb-cAC10 demonstrated superior CD30-specific cytotoxicity across all tested lymphoma cell lines, with IC_{50} values up to 43-fold lower than [^{177}Lu]Lu-cAC10. Clonogenic assays confirmed a markedly stronger reduction in survival with terbium-161. In vivo, both radioimmunoconjugates displayed comparable biodistribution with high tumor uptake (31.0 ± 7.4 %IA/g at 48 h) and low background accumulation. Terbium-161 delivered a 1.5-fold higher tumor-absorbed dose compared to lutetium-177 counterpart. In a localized lymphoma model, a single dose of [^{161}Tb]Tb-cAC10 significantly prolonged median survival (41 days) compared to lutetium-177 (21 days) and controls (12-15 days). The disseminated model showed successful engraftment in clinically relevant sites, including bone marrow. Therapeutic studies in this model are ongoing, and we anticipate an even greater therapeutic benefit for terbium-161 due to its capacity to effectively irradiate single cells and smaller tumor lesions. ***Conclusion:*** To our knowledge, this study presents the first evaluation of terbium-161 RIT for the treatment of hematological malignancies, introducing a novel disseminated mouse model that better reflects the clinical landscape of advanced-stage lymphomas. Terbium-161 RIT demonstrates superior therapeutic potential offering a promising therapeutic option for T-cell lymphomas.

OP-414

Tb, or Not Tb - Exploring Terbium-161 for CD44v6-Targeted Radionuclide Therapy

A. Gustafsson[1], *S. S. Rinne*[1], *T. Xu*[1], *K. Bratteby*[2,3], *A. Lundgren Mortensen*[1,2], *P. Bernhardt*[4,5], *M. Nestor*[1];

Aim/Introduction: Pancreatic cancer remains among the deadliest malignancies, with limited treatment options and poor prognosis. [^{177}Lu]Lu-DOTA-AKIR001, a lutetium-177-labeled full-length human IgG1 antibody targeting CD44v6, has demonstrated therapeutic potential for targeted radionuclide therapy of several malignancies, including pancreatic cancer. Terbium-161, a promising alternative to lutetium-177, emits not only medium-energy beta particles but also conversion and Auger electrons, potentially offering complementary therapeutic benefits. This study evaluated [^{161}Tb]Tb-DOTA-AKIR001 as an alternative CD44v6-targeted therapeutic agent. ***Materials and Methods:*** AKIR001 was labelled with terbium-161 from PRISMAP. Radiochemical stability of [^{161}Tb]Tb-DOTA-AKIR001, with and without 50 mg/ml ascorbate, was assessed in PBS, mouse serum, and EDTA using ITLC or HPLC. CD44v6 expression and binding specificity were validated in vitro. Biodistribution was assessed in immunodeficient BALB/c nu/nu mice bearing subcutaneous human pancreatic ductal adenocarcinoma xenografts. Dosimetry calculations were based on TIACs from bi-/tri-exponential fits and absorbed energy per decay from MOBY phantom or Monte Carlo models; marrow activity concentration was estimated at 36% of blood activity concentration. Therapeutic efficacy was assessed in xenograft-bearing animals receiving either 4 MBq, 2 × 4 MBq(fractionated one week apart), or 8 MBq of [^{161}Tb]Tb-DOTA-AKIR001 and compared to 4 MBq and 12 MBq [^{177}Lu]Lu-DOTA-AKIR001. Tumour uptake was verified via small-animal SPECT imaging, and haematologic toxicity was monitored through serial blood sampling. ***Results:*** [^{161}Tb]Tb-DOTA-AKIR001 showed high radiochemical yields (>95%) and stability (>95% at 24 h) in presence of 50 mg/ml ascorbate. In vitro assays confirmed specific, picomolar-affinity binding to CD44v6-positive cells. [^{161}Tb]Tb-DOTA-AKIR001 tumor uptake exceeded 150% IA/g at 96 h p.i., with favourable tumour-to-organ ratios. The mean absorbed tumour dose was calculated to be 32 Gy/MBq, with a tumour-to-bone marrow absorbed dose ratio of 28. An activity-dose-dependent anti-tumour effect was observed, with greatest tumour regression in the 8 MBq single-dose group. At equivalent activity (4 MBq), [^{161}Tb]Tb-DOTA-AKIR001 outperformed [^{177}Lu]Lu-DOTA-AKIR001. Comparable efficacy was observed between 8 MBq [^{161}Tb]Tb-DOTA-AKIR001 and 12 MBq [^{177}Lu]Lu-DOTA-AKIR001. Mild to moderate haematological effects, including lymphopenia and anaemia, were observed in an activity-dose-dependent manner. Animal weights remained stable. ***Conclusion:*** [^{161}Tb]Tb-DOTA-AKIR001 demonstrated excellent radiochemical stability, favorable biodistribution and dosimetry, and promising therapeutic efficacy. Hematologic changes were more pronounced compared to previous observations with [^{177}Lu]Lu-DOTA-AKIR001; however, the observed anti-tumor effects and potential therapeutic benefits of terbium-161 support its continued exploration alongside of [^{177}Lu]Lu-DOTA-AKIR001. The emission profile of terbium-161 may offer added advantages in certain therapeutic contexts, highlighting [^{161}Tb]Tb-DOTA-AKIR001 as a highly promising candidate for further preclinical development in targeted radionuclide therapy.

OP-415

A feasibility study of SmartCC platform for a two-step pretargeted radioimmunotherapy (PRIT): taking GD2-expressing neuroblastoma as an example

Z. Qiao*, H. Qi, Y. Yang, C. Wei, T. Xu;*
SmartNuclide Biotech, Suzhou, CHINA.

Aim/Introduction: To improve the therapeutic index (TI) of the pretargeted radioimmunotherapy (PRIT), we developed a bispecific fusion protein for two-step PRIT, comprising (i) a tumor-targeting domain, (ii) a lanthanide metal (Ln)-DOTA binding domain, and (iii) a novel tetramerization domain derived from human. There, home-made tetramerization domain library, referred to as SmartCC, mediate the self-assembly and disassembly of the bispecific fusion protein. The tetramer demonstrated high avidity for tumor binding while exhibiting rapid blood clearance upon disassembly into small monomers (<70 kDa). Furthermore, the SmartCC can modulate the pharmacokinetics of proteins, consequently, enhancing the biologic effect of radiation dose to tumor and widening therapeutic window. In this present study, we tested the feasibility of SmartCC platform for PRIT using GD2-expressing neuroblastoma as a model. ***Materials and Methods:*** A library of SmartCCs capable of modulating the pharmacokinetic properties of tumor-targeting antibodies was established and used for in vivo screening to identify GD2-SmartCCs exhibiting the favorable TI. In a typical PRIT, protein was intravenously administrated to IMR32 tumor-bearing mice, followed by the injection of a ^{177}Lu-DOTA-Bn. The PRIT parameters were optimized, including protein dose, ^{177}Lu-DOTA-bn dose, and the time interval between protein and ^{177}Lu-DOTA-Bn administration. Ex vivo biodistribution, dosimetry, tumor inhibition, and toxicity studies were evaluated to assess the effects of PRIT. ***Results:*** The selected bispecific fusion protein (SNA025) was identified through in vivo screen studies. The optimized PRIT parameters of SNA025-PRIT were: 1) 1.0 nmol of protein dose, 2) 48-hour injection intervals, 3) 18.5 MBq of ^{177}Lu- DOTA-Bn. The ex vivo biodistribution studies showed the tumor and kidney uptake were 16.60 ± 2.51 and 1.33 ± 0.18 %ID/g at 24 h postinjection, respectively, with significant tumor retention of 32.58 ± 3.68 %ID/g at 120 hours post-injection. The adsorbed dose of tumor, blood and kidney was 399 cGy/MBq, 0.7 cGy/MBq (TI=589) and 13.1 cGy/MBq (TI=30.5), respectively. Complete IMR32tumor growth inhibition was observed using two doses of SNA025-PRIT (18.5 MBq). Notably, no obvious toxicity or body weight decrease was observed during the PRIT ***Conclusion:*** In summary, we established a SmartCC library with ability to modulate antibody pharmacokinetics and tumor uptake. Taking GD2 as an example, we identified SNA025-PRIT with high tumor

uptake, prolonged retention, low normal tissue uptake, and a favorable safety profile. These preclinical findings highlight the potential of our SmartCC platform for PRIT in diverse tumor targets.

OP-416

Novel SSTR2 RPT agent RYZ401 demonstrates significant improvement in Biodistribution and Efficacy compared to DOTATATE

T. Lo, *T. Chung, L. Nyiranshuti, N. Bakes, S. Richardson, S. Richardson, A. Noncovich, A. Hudson, P. Napier, N. Smith, A. Bhat; RayzeBio, a subsidiary of Bristol-Myers Squibb, San Diego, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Somatostatin receptor type 2 (SSTR2) is found in various cancers, including gastroenteropancreatic neuroendocrine tumors (GEP-NETs), lung, and breast cancers. [^{177}Lu]Lu-DOTATATE is a radiopharmaceutical therapy (RPT) for SSTR2-positive GEP-NETs but has limitations due to prolonged kidney retention, raising the risk of radiation-induced nephropathy. To mitigate such risk, a long Lys-Arg infusion was required during the treatment of [^{177}Lu]Lu-DOTATATE. In addition, high kidney retention restricts the dose that can be safely administered to GEP-NET patients which further impacts the therapeutic efficacy. RYZ401 is a highly selective SSTR2 agonist conjugated with DOTA-chelator allowing labeling with various radioisotopes including ^{177}Lu and ^{225}Ac. RYZ401 was designed to improve tumor retention and accelerate renal clearance compared to DOTATATE. The aim of this study was to use multilayer imaging approaches to evaluate the biodistribution and treatment efficacy of RYZ401 in SSTR2-positive tumor xenograft model compared to DOTATATE based RPT agents. ***Materials and Methods:*** An SSTR2 expressing, non-small cell lung cancer (NSCLC) xenograft mouse model was used in the following in vivo studies. To evaluate the in vivo biodistribution between [^{177}Lu]Lu-RYZ401 and [^{177}Lu]Lu-DOTATATE, a comparative longitudinal Single Photon Emission Computed Tomography (SPECT) imaging combined with Area Under the Curve ($AUC_{2\text{-}168h}$) of Time Activity Curves (TAC) between 2h to 168h post-injection was performed. To validate the treatment efficacy, a head-to-head ^{225}Ac efficacy study between [^{225}Ac]Ac-RYZ401 and [^{225}Ac]Ac-DOTATATE in mice bearing large tumors (410-1300mm^3) was conducted and ^{225}Ac treatment outcome was monitored by SSTR2-targeting Positron Emission Tomography (PET) imaging using [^{68}Ga]Ga-DOTATATE. ***Results:*** Longitudinal SPECT imaging with [^{177}Lu]Lu-RYZ401 displayed a 62% lower kidney uptake (Kidney AUC_{RYZ401}=103; Kidney $AUC_{DOTATATE}$=166) and 303% longer tumor retention (Tumor AUC_{RYZ401}=1619; Tumor $AUC_{DOTATATE}$=534) compared to [^{177}Lu]Lu-DOTATATE. An ^{225}Ac efficacy study was conducted by injection of 111 kBq of [^{225}Ac]Ac-RYZ401 and [^{225}Ac]Ac-DOTATATE in an SSTR2 expressing NSCLC xenograft mouse model. Both [^{225}Ac]Ac-RYZ401 and [^{225}Ac]Ac-DOTATATE showed tumor volume suppression by 4 weeks post-treatment. However, the recurrence of [^{68}Ga]Ga-DOTATATE-positive tumors were detected only in the [^{225}Ac]Ac-DOTATATE-treatment group by week 7. On the other hand, no detectable [^{68}Ga]Ga-DOTATATE-positive PET signal was observed in the [^{225}Ac]Ac-RYZ401 treatment group while maintaining tumor volume suppression. ***Conclusion:*** Preclinical in vivo imaging reveals that RYZ401 has an improved biodistribution profile compared to DOTATATE. [^{225}Ac]Ac-RYZ401 further demonstrates an effective treatment outcome compared to [^{225}Ac]Ac-DOTATATE. Therefore, [^{225}Ac]Ac-RYZ401 as a therapeutic agent has the potential to deliver more effective ^{225}Ac treatment to tumors while reducing kidney radiation dose.

OP-417

Tumor-stroma dynamics define FAP optimum imaging and therapeutic windows in the management of glioblastoma

A. Bilinska[1], *N. Kumar*[1], *E. Menéndez*[1], *T. Läppchen*[1], *F. Rösch*[2], *A. Rominger*[1], *E. Gourni*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Chemistry—TRIGA site, Johannes Gutenberg University of Mainz, Mainz, GERMANY.*

Aim/Introduction: Glioblastoma is one of the most aggressive cancers, with a poor survival rate. The transforming growth factor-beta (TGF-β) signaling pathway plays a significant role in regulating glioblastoma and is known to induce fibroblasts activation, leading to the expression of Fibroblast Activation Protein (FAP). This study investigates the natural tumor-stroma interactions in glioblastoma, identifying an optimal window for FAP-targeted radiopharmaceutical imaging and therapy. ***Materials and Methods:*** PET/CT scans were performed on U87MG xenografts using [^{68}Ga]Ga-DATA.SA.FAPI and [^{68}Ga]Ga-DOTAGA.Glu.$(FAPI)_2$ on days 7, 11 and 15 following tumor cell implantation. PET/CT images were obtained 1hour p.i.. On day 11, an additional cohort of U87MG xenografts was injected with [^{18}F]F-FDG and PET/CT was performed under identical conditions. To monitor tumor-stroma interactions, immunohistochemical staining and qPCR were performed. ELISA was conducted on murine blood samples, collected on the same days. A 48-hour co-culture experiment was conducted using U87MG cells with either cancer-associated fibroblasts (CAFs) or normal fibroblasts (NAFs). Following the co-culture, gene expression analysis was performed, focusing on key genes involved in glioblastoma progression, including FAP and TGF-β. ***Results:*** Tumor uptake significantly increased from day 7(3.7±0.4 %IA/g) to day 11 (7.7±1.3 %IA/g) to day 15 (13.8±1.4 %IA/g), and both radiotracers displayed the same pattern. In contrast, the FDG scan did not show any increase in tumor uptake at day 11 (4.14±1.5%IA/g). The tumor sizes did not significantly change throughout the entire experiment. The levels of murine and human circulating FAP were at the same level at the three tested days, being 130 and 10 µg/ml, respectively. Both human and FAP protein levels increase over days was detected by immunohistochemistry. These was consistent with the significantly increased relative mRNA levels of FAP detected by qPCR. The relative levels of human TGF-β were stable in all the tumors while murine significantly increased, pointing the stroma activation. Co-culture of U87MG cells with CAFs caused the upregulation of FAP expression in cancer cells. Meanwhile, co-culture of U87MG with NAFs led to the upregulation of FAP, CD44 and TGF-β expression in NAFs, indicating their activation. Addition of TGF-β inhibitor to the co-culture of U87MG and NAFs, decreased the mRNA levels of FAP however remained higher than those in NAFs alone. ***Conclusion:*** Our results highlight the role of tumor-stroma dynamics in shaping FAP expression, offering a strategic imaging and therapeutic windows for FAP-based theranostics. These insights provide a biological basis for enhancing clinical translation of FAP-based approaches in glioblastoma.

OP-418

Novel CAIX-Targeted Radiotracer for Precision PEC/CT Imaging of Renal Cell Carcinoma

S. Cheng[1], *X. Niu*[2], *Y. Zhang*[1], *X. Lan*[1], *P. Teng*[2], *D. Jiang*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*College of Pharmaceutical Sciences, National Key Laboratory of Advanced Drug Delivery and Release Systems, Zhejiang University, Hangzhou, CHINA.*

Aim/Introduction: Carbonic anhydrase IX (CAIX) is a well-established marker of hypoxia that has been famed as a promising target for solid malignancies. In renal cell carcinoma (RCC), CAIX expression is unique as it is driven by the loss-function mutations in the VHL gene and subsequent accumulation of downstream HIF-1α in the nucleus, even in the absence of hypoxia. Limited theragnostic options are available for advanced or metastatic RCC, spurring the development of CAIX-targeted radiopharmaceuticals. However, substantial physiological uptake in the gastrointestinal and biliary system remains a persistent concern. This study aims to develop novel CAIX-targeted PET/CT imaging tracers and explore their potential for RCC detection

and metastasis visualization in preclinical models. ***Materials and Methods:*** CAIX expression was analyzed across several tumor cell lines using western blot. Fourteen novel CAIX-specific cyclic peptides were synthesized, functionalized with DOTA chelators, and radiolabeled with gallium-68 (^{68}Ga, $T_{1/2}$ ~ 68 min). Their in vivo distribution was initially evaluated by PET/CT imaging. Mice bearing subcutaneous OS-RC-2 clear cell RCC xenograft were intravenously injected with 4.63 ± 0.93 MBq of radiotracer and images acquired at 15, 30, 60, and 120 min post-injection. Region of interest (ROI) analyse of the images and ex vivo biodistribution, following the last imaging time point, quantified the tumor and major tissue uptake as percent of injected dose per gram of tissue (%ID/g; mean ± SD). Tumor tissues were subsequently collected for immunohistochemistry. ***Results:*** All the radiotracers were synthesized with high radiolabeling yields and radiochemical purity exceeding 95%. Longitudinal in vivo PET/CT screening of OS-RC-2 human xenograft mouse models identified [^{68}Ga]Ga-RCC78 as the most promising candidate, displaying high and sustained tumor uptake alongside rapid background clearance. Biodistribution studies revealed tumor uptake as 4.65 ± 1.00 %ID/g, yielding a tumor-to-background ratio of 41.30 ± 7.01 at 2 h post-injection. Notably, normal tissue uptake was minimal, with gastrointestinal background uptake recorded at only 0.17 ± 0.04 %ID/g at 2 h post-injection. The renal accumulation related to drug excretion remained with acceptable limits (4.40 ± 1.36 %ID/g at 2 h post-injection). Western-blot and immunohistochemical results confirmed CAIX expression in tumor tissues. ***Conclusion:*** We have successfully developed several CAIX-specific radiotracers with outstanding imaging profiles. Among them, [^{68}Ga]Ga-RCC78 stand out for its high tumor contrast and negligible gastrointestinal background. These results lay the groundwork for further optimization of [^{68}Ga]Ga-RCC78 and its progression toward clinical translation in CAIX-targeted RCC imaging.

OP-419

Nectin-4 targeted PET imaging of advanced urothelial carcinoma: tracer development and preclinical evaluation

X. Long*, X. Nian, Y. Zhang, R. An, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Nectin cell adhesion molecule 4 (Nectin-4), a type I transmembrane cell adhesion protein, has been demonstrated to be overexpressed in a variety of tumors, making it an attractive marker for targeted therapies such as antibody-drug conjugates (ADCs). Of great note, the FDA-approval of the first Nectin-4 targeted ADC drug, enfortumab vedotin (EV) offers a promising future for patients with advanced urothelial cancer (UC). However, successful patient selection with PET imaging to noninvasively quantify nectin-4 expression would help to predict treatment response and improve overall therapeutic efficacy. Here, we aim to develop two novel Nectin-4 targeting single-domain antibody (sdAb) tracers and evaluate their diagnostic performance in preclinical UC xenograft models. ***Materials and Methods:*** Two sdAbs, namely the sdAb monomer BS8 and homodimer BS11 were successfully obtained, and their purities and binding kinetics were determined by SDS-PAGE and HPLC. By labeling the two sdAbs with ^{68}Ga ($t_{1/2}$ = 1.1 h), we developed two Nectin-4-targeted PET imaging probes [^{68}Ga]Ga-NOTA-BS8 and [^{68}Ga]Ga-NOTA-BS11. Subcutaneous and orthotopic xenograft models were prepared using Nectin-4 positive sw780 and HT1376 cell lines, respectively. ImmunoPET imaging and ex vivo biodistribution studies were performed in tumor-bearing mice to evaluate imaging performance and systemic distribution of two radiotracers. IHC staining was used to screen the expression of Nectin-4 in UC tissues. ***Results:*** The molecular weight of BS8 and BS11 were approximately 15 kDa and 30 kDa, respectively. [^{68}Ga]Ga-NOTA-BS8 and [^{68}Ga]Ga-NOTA-BS11 showed high radiochemical purities. PET/CT imaging with [^{68}Ga]Ga-NOTA-BS8 and [^{68}Ga]Ga-NOTA-BS11 demonstrated a high tumor-to-background ratio in sw780 subcutaneous models at 2 h post-injection, with the latter showing better diagnostic potential supported by higher tumor uptake (2.10 ± 0.32 %ID/g vs. 3.09 ± 0.44 %ID/g, n=3). Apart from high uptake in the kidney, minimal radioactivity was detected in other healthy tissues and organs. In the orthotopic xenograft models, ex vivo PET imaging and biodistribution studies clearly delineated tumors in the bladder wall, suggesting great potential of transforming BS11 from diagnostic PET imaging to targeted radiotherapy of primary UC lesions, by either bladder irrigation or systemic administration. ***Conclusion:*** In this study, we successfully developed two sdAb-based PET tracers for Nectin-4 imaging in vivo. ImmunoPET of UC xenograft models demonstrated high tumor uptakes, supporting the application of [^{68}Ga]Ga-NOTA-BS11 as a companion diagnostic tool for optimizing treatments targeting Nectin-4, which may further support Nectin-4 targeted radiotherapy and personalized UC cancer management.

Cutting Edge Science Track - TROP Session - Dosimetry Committee: Personalised Dosimetry and Predictive Modeling

OP-420

Predictive Dosimetry in PSMA-targeted Radiopharmaceutical Therapies Guided by Physiologically-Based Pharmacokinetic (PBPK) Modeling and Artificial Intelligence

H. Abdollahi*, A. Rahmim, J. Fowler, C. Uribe;*
BC Cancer Agency, Vancouver, BC, CANADA.

Aim/Introduction: Predictive dosimetry from pre-therapy PET/CT remains a key challenge for optimizing radiopharmaceutical therapy (RPT). We developed a computational framework combining PBPK modeling and AI to predict absorbed dose and biologically effective dose (BED) in tumors and organs-at-risk for PSMA-targeted RPT. By analyzing time activity curves (TACs) from various radiopharmaceuticals, the framework enables systematic in silico evaluation of predictive dosimetry. ***Materials and Methods:*** We used a PBPK modeling approach, representing each organ with vascular, interstitial, binding, and intracellular compartments, with exchanges governed by ODEs. These models simulated PSMA PET and SPECT TACs for 640 virtual patients, focusing on tumors, kidneys, and salivary glands. For each patient, F-18, Ga-68, and Cu-64 TACs were matched to Lu-177 TACs by varying parameters such as association, dissociation, release, and receptor binding rates. Radiomics and kinetic features were extracted, and a nested ML pipeline using Random Forest, Extra Trees, Ridge, and SVR with RFE, LASSO, and RF importance was applied to predict absorbed dose and BED. Performance was evaluated via 5-fold nested cross-validation using MAPE. ***Results:*** Cu-64 consistently yielded the best mean MAPE values for both dose (7.1%, 8.2%, 6.7%) and BED (7.3%, 9.0%, 5.9%) across all tumor volumes (TV = 1, 0.01, 0.001 Liters), outperforming F-18 and Ga-68. Across all evaluated organs and volumes, Cu-64 demonstrated least prediction errors compared to the other radiopharmaceuticals. For dose, MAPE in the kidney decreased from 8.5% at TV = 1 to 3.5% at TV = 0.001, and in the salivary gland from 9.9% to 3.8%. For BED, MAPE in the kidney ranged from 9.3% to 3.7%, and in the salivary gland from 9.2% to 4.4%. Tumor predictions also showed favorable trends,

with Cu-64 achieving the lowest MAPE values of 7.1%, 8.2%, and 6.7% for dose, and 7.3%, 9.0%, and 5.9% for BED at TV = 1, 0.01, and 0.001, respectively. Cu-64 consistently showed the lowest error rates across all tumor volumes and organs. ***Conclusion:*** Cu-64 showed the highest overall accuracy in modeling both dose and BED across all tumor and organs. While Ga-68 performed similarly for tumor BED at intermediate volume, Cu-64 consistently had the lowest prediction errors, likely due to its longer half-life and enhanced delayed imaging capabilities, supporting its selection as the most reliable radiotracer. Clinical validation is ongoing. This integration of modeling and AI enables systematic in silico assessment of radiopharmaceutical behavior and offers a robust platform for predictive dosimetry and optimized RPT.

OP-421

Optimization of ^{177}Lu-PSMA Dosimetry Imaging Schedules using Physiologically-Based Pharmacokinetic (PBPK) Modeling

J. Fowler[1,2], *M. Sabouri*[1,2], *A. Rahmim*[1,2], *C. Uribe*[1,2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Absorbed dose calculations in radiopharmaceutical therapies (RPTs) rely on fitting single photon emission computed tomography (SPECT) data. The timing and frequency of SPECT acquisitions strongly influence the fitting process, and therefore the estimated doses. This study optimized 2-, 3-, and 4-time-point sampling schedules for ^{177}Lu prostate-specific membrane antigen (PSMA) RPTs using a diverse dataset generated via advanced computational modeling. ***Materials and Methods:*** Using our validated physiologically-based pharmacokinetic (PBPK) model, we simulated the biodistribution of ^{177}Lu-PSMA (7.4 GBq) in 100 virtual patients with varied pharmacokinetics. This model, originally developed in MATLAB SimBiology, was adapted and implemented in Python (publicly available) to enable flexible, large-scale studies. Time-activity curves (TACs) were generated for the kidneys, salivary glands, and a primary tumor in each patient. To correctly simulate noise propagation in expectation maximization reconstructions, log-normal noise was added with a standard deviation proportional to the square root of the activity, scaled by a factor α derived from phantom studies and simulations. Three noise realizations per patient yielded 300 virtual studies. Activity sampling occurred hourly for 6 hours, every 2 hours to 48 hours, and every 24 hours to 144 hours. All possible 2-, 3-, and 4-time-point combinations resulted in 465, 4495, and 31465 unique schedule combinations, and were evaluated using the Levenberg-Marquardt least-squares method. A mono-exponential model was applied to all 2-, 3-, & 4-point schedules, while a 3-term bi-exponential model was applied to 3- & 4-point schedules. The optimal schedule in each category minimized the relative error in the estimated time-integrated activity (TIAC) (proportional to the estimated dose when neglecting cross-radiation). ***Results:*** Mean absolute percent error (MAPE) varied across sampling schedules. The optimal 2-point schedule was [12, 72] hours (MAPE: 4.42%). The optimal 3-point schedule was [12, 72, 144] hours, with MAPEs of 3.40% (mono-exponential) and 3.06% (bi-exponential). The best 4-point schedule was [10, 12, 72, 144] hours, yielding MAPEs of 3.39% and 3.06%, respectively. ***Conclusion:*** Validated computational modeling (specifically, PBPK modeling) holds significant potential in guiding optimized RPTs. This work demonstrates that the timing and frequency of SPECT scans have a significant impact on the accuracy of absorbed dose calculations in radiopharmaceutical therapy. Optimizing imaging schedules should be a key consideration in the design of clinical trials and treatment protocols. Thoughtful selection of time points can increase dosimetry accuracy, ultimately supporting more informed clinical decision-making and potentially improving patient outcomes.

OP-422

Progress Update on Personalized Single-Timepoint Kidney Dosimetry in 177Lu-DOTATATE PRRT Using Deep Learning-Based Segmentation: A Multi-Center Study

M. Reymann[1], *L. Bönsel*[1], *S. M. Montenegro*[1], *D. L. Bailey*[2], *A. H. Vija*[3];
[1]*Siemens Healthineers AG, Forchheim, GERMANY,* [2]*Royal North Shore Hospital, Sydney, AUSTRALIA,* [3]*Siemens Medical Solutions USA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA.*

Aim/Introduction: Due to inter-patient variability, especially in kidney radiosensitivity, personalized dosimetry is recommended for [^{177}Lu]Lu-DOTATATE PRRT. Single-timepoint dosimetry (1TP) offers a practical alternative to full time-activity sampling (FTP) by reducing burden on patients and clinics [1, 2]. As part of a multi-center study, we are evaluating the feasibility of a population-based 1TP approach [3]. This update summarizes project status and challenges in aligning heterogeneous data. ***Materials and Methods:*** Over five years, patient data were collected from three clinical sites using Symbia Intevo Bold SPECT/CT systems with medium-energy collimators. Imaging protocols varied: two sites acquired at 0.5, 24, 48, and 72 h post-injection, while the third used 0.5, 4, 24, and either 96 or 120 h. Patient preparation varied: amino acid infusions ranged from 25-30 g lysine/arginine over 3-4 hours; premedication included IV or oral ondansetron, with or without dexamethasone. Some patients also received capecitabine-based radiosensitizers per local protocols. SPECT images were reconstructed at a core laboratory using CG reconstruction with attenuation-correction, scatter-correction, and varying PSF, then smoothed with a 16 mm FWHM Gaussian. Kidney segmentation used a deep learning-based model [4]. Ongoing efforts aim to standardize imaging and patient management across centers for comparability and model-based analysis. The impact of protocol differences on 1TP feasibility will inform optimal protocol design. ***Results:*** A total of 65 patients were included across three clinical centers. Of 177 available treatment cycles, 134 included four measurement timepoints and were eligible for single- vs. four-timepoint dosimetry comparison. Mean injected activities were 6.46±0.44 GBq (D1), 7.41±0.04 GBq (D2), and 7.90±0.12 GBq (AUS), reflecting protocol and delivery differences. Imaging timepoints clustered consistently within centers, with protocol variations evident in relative acquisition times. Projection durations also varied across sites. Registration quality was impacted by CT availability: at a site with only baseline CT, 91% of registrations required adjustment, versus 45-71% at sites with CT at each timepoint - highlighting the influence of protocol design on alignment and motion correction. ***Conclusion:*** The curated dataset is ready for evaluating biodistribution and dosimetry across platforms and timepoints. Preliminary analysis shows that imaging schedules, injected activity, and patient preparation affect data consistency. Addressing these variations is essential before robust evaluation of single-timepoint dosimetry. Future work will focus on harmonizing data across sites for reliable analysis under real-world conditions. ***References:*** [1]: Willowson et al., EJNMMI Phys, 2018. Towards Personalised Dosimetry: Predicting Radiological Response in Neuroendocrine Tumours Treated with [^{177}Lu]Lu-DOTATATE Using Cyclic Changes and Absorbed Dose

M. Macsuka[1], *B. Driscoll*[2], *I. W. T. Yeung*[3], *J. Publicover*[4], *U. Metser*[5], *R. Juergens*[6], *S. D. Myrehaug*[7], *D. Laidley*[8], *R. K. Wong*[2], *D. R. McGowan*[1], *K. A. Vallis*[1];
[1]*Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM,* [2]*Radiation Medicine Program, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, CANADA,*

[3]Southlake Regional Health Centre, Newmarket, ON, CANADA, [4]University Health Network, Toronto, ON, CANADA, [5]Joint Department of Medical Imaging, University Health Network, Toronto, ON, CANADA, [6]Division of Medical Oncology, Juravinski Cancer Centre, Hamilton, ON, CANADA, [7]Department of Radiation Oncology, Odette Cancer Centre, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, CANADA, [8]University of Western Ontario, London, ON, CANADA.

Aim/Introduction: Current [^{177}Lu]Lu-DOTATATE treatment protocols for neuroendocrine tumours (NETs) apply fixed administered activities without individual optimisation. Given the late-responding nature of NETs, identifying biomarkers that predict treatment efficacy could enable adaptive therapeutic strategies. ***Materials and Methods:*** Patients with positive [^{68}Ga]Ga-DOTATATE scans and confirmed NETs were enrolled in the OZMOSIS OZM-067 trial (NCT02743741) and were treated with 4 cycles of [^{177}Lu]Lu-DOTATATE and imaged at 4, 24, and 72 hr post-injection after each cycle. The injected activity varied depending on the kidney dose. Out of the 90 patients in the full dataset, 73 patients and 140 tumours were included in this analysis, after excluding tumours less than 10 ml in volume. Eligible tumours were segmented using a semi-automatic adaptive thresholding method. Partial volume correction was based on recovery coefficients from phantom data. Dose rate curves were fitted using a monoexponential clearance model. Absorbed dose to tumours (Gy) and administered activity (GBq) were recorded for all treatment cycles. Patients were considered responders if they exhibited a partial response (PR) at any time point, as defined by RECIST 1.1. The average total tumour dose and the average change in Gy/GBq across all eligible tumours per patient were also recorded. ***Results:*** A systematic and statistically significant ($p<0.0001$) serial decline in Gy/GBq was observed across treatment cycles, with reductions of approximately 9%, 21%, and 31% in cycles 2, 3, and 4, respectively, relative to cycle 1. A greater reduction in Gy/GBq correlated with an increased likelihood of PR. Specifically, 65% of patients with an average Gy/GBq decrease of at least 50% had PR. A dose-response relationship was also established, starting from 4% probability of PR at low doses, increasing to 28% at 100 Gy before finally plateauing at 45% at the highest doses. Total absorbed dose and Gy/GBq decrease were observed to be uncorrelated. Interestingly, we found that 10 out of 11 patients with an average absorbed dose of at least 100 Gy to their tumours and a decrease in Gy/GBq of at least 50% presented with PR. Ongoing analysis is focused on modelling optimal injected activities based on imaging data, considering organ dose limits and radiobiology. ***Conclusion:*** Cyclic changes in absorbed dose combined with total absorbed dose could serve as a simple and meaningful predictive imaging biomarker that is easily translatable to existing clinical practice. Monitoring these changes could inform personalised treatment adaptations, enhancing therapeutic efficacy and guiding early treatment decisions.

Systematic Comparison of Reported PRRT Tumour Dose-Response Relationships in an Independent Cohort; Pilot Results for Tumour Absorbed Dose

M. Kvassheim[1,2], *H. Ramsvik*[1], *T. Husevåg*[1], *J. Blakkisrud*[1], *C. Stokke*[1,3];
[1]*Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [2]*Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY,* [3]*Department of Physics, University of Oslo, Oslo, NORWAY.*

Aim/Introduction: A systematic review revealed thirteen publications (1-13) investigating PRRT tumour dose-response relationships. We aim to investigate if the correlations can be reproduced with our patient data. This work presents results for a pilot cohort. ***Materials and Methods:*** The methods for dosimetry and response evaluation were implemented as described in each publication in Slicer (v5.6.0), adapted as closely as feasible with our data (SPECT/CTs day 0, 1, 4, and 7 (cycle 1), day 1 (cycle 2-4), day 0 or 7 (cycle 4)). We implemented eight dosimetry methods (1-9) for a pilot cohort of 4 patients and 10 lesions. For publications reporting Pearson correlations we estimated the required sample size to achieve statistical power of 0.80 and 0.90 (alpha = 0.05) using G*Power (v3.1). ***Results:*** The percentage difference between the smallest and largest C1 tumour dose across methodologies varied between 65% and 129% (mean difference 91%). Differences in segmentation, integration methods, and imaging timepoints were contributors to variations in absorbed dose. For activity quantification by spherical VOIs of diameters 1.2 cm and 2 cm as used in (1) and (2), single-timepoint dosimetry (1) on average gave a 26% higher cycle 1 lesion dose compared to the 3-timepoint dosimetry in (2). (4-6) fit a monoexponential to threshold-based activity concentrations from day 1, 4, and 7, while (7) used CT-based segmentations and trapezoidal integration combined with a monoexponential to day 1 and 7, and the average absolute percentage difference in C1 tumour dose was 19%. Sample size calculations for Pearson correlation coefficients with p-values < 0.2 indicated that 236 or 177 lesions and 94 or 71 patients are required for power of 0.9 or 0.8, respectively. When restricting to coefficients with p-values < 0.05, the required sample sizes decreased to 113 or 85 lesions and 36 or 27 patients, for power of 0.9 or 0.8, respectively. ***Conclusion:*** Preliminary investigations in the pilot cohort indicate marked variability in tumour doses calculated across methods, which may explain reported differences in dose-response relationships. Ongoing analysis will assess the reproducibility of the dose-response relationships using an expanded cohort and response data. ***References:*** (1) Ha, EJNMMIPhys. 2024;11(1):14. OP-425

RADIO-MARKER Study: Biomarker identification of radionuclide therapy-induced radiation responses

J. Nonnekens[1], *N. Becx*[1], *P. Morvay*[2], *T. de Wolf*[1], *P. Davies*[2], *G. Tamborino*[1], *R. Brandt*[1], *G. O'Brain*[2], *T. Heredia Genestar*[1], *M. Konijnenberg*[1], *H. Hofland*[1], *C. Badie*[2], *L. Cruz Garcia*[2];
[1]*Erasmus MC, Rotterdam, NETHERLANDS,* [2]*UK Health Security Agency, Chilton, UNITED KINGDOM.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTATATE is an internal radiation treatment for patients with a neuroendocrine tumor (NET). Exposure to ^{177}Lu-DOTATATE induces cellular responses, including DNA damage response activation and gene expression changes. Understanding these radiobiological effects may facilitate biomarker identification for predicting PRRT toxicity and efficacy. Prior studies have shown correlation between radiation dose to the blood and DNA double strand break induction in peripheral blood mononuclear cells (PBMCs) or DNA damage response activation in the blood for PRRT-like treatments. This pilot study investigated the feasibility of liquid biopsies to assess radiation-induced DNA damage and transcriptional changes following PRRT. These irradiation responses could serve as potential biomarker for predicting PRRT outcomes. ***Materials and Methods:*** Patients with gastroenteropancreatic NET receiving their first cycle of 7.4 GBq ^{177}Lu-DOTATATE were included. Blood samples were collected at baseline, 4 hours, 24

hours and 8 weeks post-PRRT. PBMCs were isolated to assess DNA damage using 53BP1 immunofluorescence staining as marker for DNA double strand breaks in 10 patients. The absorbed dose to the blood was calculated by converting radioactive levels measured in a gamma counter using the MIRD formalism. Transcriptomic effects of selected genes were analyzed in whole blood by qPCR, and full transcriptome analysis was performed in 3 patients using cDNA nanopore sequencing (PromethION 2 Solo, Oxford Nanopore Technologies). ***Results:*** Following PRRT, the average number of 53BP1 foci per nucleus increased by 0.57±0.07 (mean±SEM) ($p<0.001$) and 0.34±0.13 (mean±SEM) ($p=0.02$) at 4 and 24 hours, respectively, compared to baseline. The absorbed dose to blood was on average 34.61±13.49 mGy (mean±SD) at 4 hours and 93.98±33.60 mGy (mean±SD) at 24 hours. A significant correlation was found between the number of radiation-induced foci and absorbed dose to the blood. Despite the low dose to circulating PBMCs, qPCR analysis showed significant upregulation of DNA damage response genes FDXR, MDM2, GADD45 and DDB2 after 24 hours. For the first time, full transcriptome sequencing showed significant upregulation of DNA damage response genes at 4 and 24 hours post-PRRT, alongside a striking downregulation of immune response genes at 8 weeks. ***Conclusion:*** Our results here show for the first time direct evidence that PRRT with ^{177}Lu-DOTATATE induces measurable transcriptional changes in PBMCs, linking radiation dose to molecular response. These findings introduce novel biomarkers candidates for predicting clinical outcomes of PRRT and highlight the potential of sequencing-based liquid biopsies for radiation response monitoring.

OP-426

Comparison of radiation-induced DNA damage in PBMCs and absorbed dose to the blood between two therapy cycles with [^{177}Lu]Lu-PSMA-617

N. Zindler[1], *H. Scherthan*[2], *S. Schumann*[1], *P. E. Hartrampf*[1], *I. Strobel*[1], *M. Lassmann*[1], *U. Eberlein*[1];
[1]*University Hospital Würzburg, Würzburg, GERMANY,*
[2]*Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.*

Aim/Introduction: The aim was to compare radiation-induced DNA double strand break (DSB) damage and repair in peripheral blood mononuclear cells (PBMCs) in-vivo and ex-vivo, as well as the absorbed doses to the blood between the first and third cycles of [^{177}Lu]Lu-PSMA-617 therapy in patients with prostate cancer. ***Materials and Methods:*** Blood samples were collected from eight patients before therapy for ex-vivo analysis and to obtain background values. Ex-vivo irradiation with [^{177}Lu]$LuCl_3$ solution was performed to result in 50mGy absorbed dose to the blood. PBMCs were isolated and fixed with ethanol before and immediately after irradiation or after 3h, 6h or 24h. After administration of 7.4GBq [^{177}Lu]Lu-PSMA-617 blood samples were collected at 1h and 24h for in-vivo analysis. All samples were analyzed for DSB foci by manually enumerating γH2AX+53BP1 colocalizing foci in 100 cells per sample. The number of radiation-induced foci (RIF) was determined by subtracting the average number of foci per cell of each non-irradiated sample from the corresponding irradiated samples. The absorbed dose to the blood was calculated for each patient at 1h, 24h and the total absorbed dose using blood sample measurements with a calibrated germanium detector, patient-specific dose rate measurements, and whole-body imaging. To account for inter-patient variability, RIF numbers at 1h post-therapy were normalized to the absorbed dose to the blood. Paired t-tests were used to test for differences in all parameters between the first and third treatment cycles. ***Results:*** RIF numbers were quantified in both ex-vivo and in-vivo samples across the first and third therapy cycles. In the ex-vivo analysis, RIF values decreased with repair time for both cycles: 0h(n=8): 0.75±0.25(first cycle), 0.60±0.18(third cycle); 3h(n=8): 0.41±0.16, 0.31±0.21; 6h(n=7): 0.21±0.21, 0.21±0.14; 24h(n=7): 0.15±0.25, -0.02±0.16. In-vivo RIF numbers at 1h and 24h post-injection were similar for both cycles: 1h(n=7): 0.46±0.21, 0.49±0.10; 24h(n=7): 0.51±0.33, 0.45±0.20. The absorbed dose to the blood was similar for both cycles:1h: (28±6)mGy, (29 ±7)mGy;24h: (225±65)mGy, (245±65) mGy; total: (293±70)mGy, (298±62)mGy. Normalized RIF/mGy values were similar: 1h: (0.016±0.006)mGy^{-1}, (0.017±0.003)mGy^{-1}. No statistically significant differences were observed between the two cycles ($p>0.05$) for all parameters, indicating consistent levels of radiation-induced DNA damage and absorbed dose to the blood across repeated treatment cycles. ***Conclusion:*** Further patient recruitment is needed to increase the statistical power of the study. In addition, clinical parameters, tumor doses and organ doses will be analyzed across treatment cycles to identify potential correlations between these variables and the observed DNA damage and repair.

OP-427

Potential for home-based blood sampling for estimating maximum tolerated activity for [131I]-NaI dosimetry-patients

S. Synnes Lindseth[1], *L. T. G. Mikalsen*[1], *A. Tulipan*[2,3], *E. Hernes*[2], *C. Stokke*[1,4];
[1]*Department of Physics and Computational Radiology, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [2]*Department of Nuclear Medicine, Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [3]*Department of Radiology, Nuclear medicine/PET-centre, Haukeland University Hospital, Bergen, NORWAY,* [4]*Department of Physics, University of Oslo, Oslo, NORWAY.*

Aim/Introduction: Patients at Oslo University Hospital (OUS) undergoing pre-therapeutic [131I]-NaI dosimetry for differentiated thyroid cancer currently visit the hospital four times over the course of one week for venous blood sampling and whole-body probe measurements. These measurements are used to estimate blood and whole-body retention times (τ_b and τ_{wb}, respectively) to calculate the maximum tolerated activity (MTA), in accordance with EANM guidelines. We present a simulation study investigating a novel approach in which patients collect capillary blood samples at home. The aim is to assess whether this procedure can produce MTA-estimates comparable to the current clinical protocol, thereby demonstrating the feasibility for future clinical studies. ***Materials and Methods:*** In a retrospective data analysis of 56 patients who underwent MTA estimation at OUS between 2020 and 2025, we divided the patients into a training set (n = 40) and a validation set (n = 16). A linear regression model to predict the dose factor (D/A) from τ_b was developed using the training set and validated via five-fold cross-validation. For each patient in the validation set, 1500 bootstrap samples of τ_b were generated to simulate 20 µL capillary microsampling based on the measured activity concentration in the collected venous blood samples. Uncertainty in each simulated τ_b was modelled by incorporating a 5% relative standard error in sample volume, expected count rate, and acquisition time. Simulated MTA-values (MTA_{home}) were computed by dividing the 2 Gy absorbed dose limit by the simulated D/A-values and compared to the reference MTA-values. ***Results:*** Reference MTA-values for the 56 patients ranged from 5 to 30 GBq (6 to 26 GBq for the validation patients). The regression model showed strong predictive performance, with an $R^2 = 0.96 \pm 0.02$ across the five cross-validation folds. Predicted MTA_{home}-values had a mean relative error of 10 ± 8 % across all iterations with a root mean squared error of 1.57 GBq compared to the reference values. ***Conclusion:*** Our analysis suggests that home-based capillary blood sampling for MTA estimation may provide estimates comparable to those obtained through the current

hospital-based protocol. This new approach could significantly reduce the need for hospital visits, and further evaluation in a prospective clinical study is planned.

OP-428

Long-Term Renal Safety of Personalized [^{177}Lu]Lu-DOTA-TATE PRRT: Evidence from the NCT02754297 trial Supporting Absorbed Doses Beyond Conventional Limits

S. Kurkowska[1], *P. L. Esquinas*[2], *A. Rahmim*[1], *X. Hou*[2], *F. A. Buteau*[3], *A. Beaulieu*[3], *G. April*[3], *F. Arsenault*[3], *J. M. Beauregard*[3], *C. Uribe*[2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA,* [3]*CHU de Québec – Université Laval, Quebec City, QC, CANADA.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTA-TATE is a well-established therapy for neuroendocrine neoplasms. Fixed-activity injections lead to substantial absorbed dose variability in tumors and organs and can leave many patients undertreated. To address this limitation, the Phase II P-PRRT clinical trial (NCT02754297) evaluated a personalized approach designed to maximize tumor irradiation while preserving renal function, using individualized dosimetry to achieve a targeted renal dose of 26.5Gy (updated from 23Gy after SPECT recalibration). We present the long-term kidney safety outcomes of this personalized approach. ***Materials and Methods:*** We analysed 189 treatment-naïve patients who underwent four cycles of PRRT. Administered activity was individually tailored: initial cycles were personalized based on glomerular filtration rate (GFR) and body surface area, subsequent cycles were based on SPECT/CT kidney dosimetry. Dose reductions (25-50%) were applied to patients with renal/hematologic risk factors. Kidney dosimetry used simplified small-sphere VOI segmentation, monoexponential modelling and OLINDA-derived S-values. Renal safety was monitored via serial eGFR measurements and CTCAE grading. Longitudinal kidney function changes were evaluated using mixed-effects modelling with random intercepts and slopes, adjusting for baseline function, follow-up time, and cumulative renal dose. ***Results:*** Patients received a median cumulative injected activity of 34.97 GBq (range: 5.89-102.67 GBq), resulting in a median cumulative renal absorbed dose of 26.16 Gy (range: 9.54-36.96 Gy). Over a median follow-up duration of 20 months (range: 6-81 months), clinically significant renal toxicity occurred in only four patients: one progressed from baseline Grade 3 to Grade 4 (5.89 GBq; 20.4 Gy, cumulative) and three progressed from baseline Grade 2 to Grade 3 (6.3-13.7 GBq; 18.7-21.8 Gy, cumulative). The cohort showed a 4.68% annual decline in eGFR ($p<0.001$), with substantial interpatient variability. Mixed-effects modelling identified baseline eGFR as the strongest predictor of renal outcome ($\beta=-0.161$, $p<0.001$). Cumulative renal absorbed dose showed no significant association with kidney function changes ($p = 0.178$), likely reflecting the intentional prescription of injected activities to achieve doses below the toxicity threshold. Notably, over half of the patients safely received a cumulative activity exceeding the standard 29.6 GBq (4×7.4 GBq). ***Conclusion:*** Personalized PRRT approach demonstrates long-term renal safety, challenges the conventional 23Gy renal absorbed dose limit, and underscores radiobiological differences from external beam radiotherapy, suggesting current limits may unnecessarily restrict therapeutic potential. The strong association between baseline kidney function and renal outcomes emphasizes the need for careful patient stratification, while supporting dose escalation beyond traditional thresholds for patients with preserved renal function.

Aim/Introduction: COMPETE is a Phase 3, multicentric, randomised, controlled and open-label trial, comparing efficacy and safety of [^{177}Lu]Lu-edotreotide with everolimus in patients with grade 1 or grade 2 gastroenteropancreatic neuroendocrine tumours (GEP-NETs). This is the first Phase 3 trial reporting dosimetry assessments in all patients treated with a radiopharmaceutical therapy ([^{177}Lu]Lu-edotreotide). Here, we report the dosimetry assessments with regard to efficacy and safety of [^{177}Lu]Lu-edotreotide. ***Materials and Methods:*** Patients (aged ≥18 years) with grade 1 or grade 2 inoperable, progressive, somatostatin receptor-positive GEP-NETs (Ki-67 ≤20%) were randomised (2:1) to receive [^{177}Lu]Lu-edotreotide (max. 4 cycles of 7.5 GBq/cycle every 3 months, or until disease progression) versus everolimus (10 mg daily up to 30 months, or until disease progression). The primary endpoint was progression free survival (PFS) per RECIST v1.1. Absorbed dose (AD) for target tumours and all organs besides red marrow were determined imaging based (planar and SPECT) at cycle 1. Red marrow dosimetry was performed in a subset of patients (n=20) with additional blood samples at prespecified timepoints to determine the time-activity curves of blood. ***Results:*** A total of 309 patients were randomised to [^{177}Lu]Lu-edotreotide (n=207) versus everolimus (n=102). The median PFS for [^{177}Lu]Lu-edotreotide was significantly prolonged compared to everolimus (23.9 versus 14.1 months, p=0.022; HR: 0.67, 95% CI: 0.48-0.95). Dosimetry evaluations were performed

in all the patients treated with [^{177}Lu]Lu-edotreotide. Mean AD and AD coefficient in evaluable tumour lesions (n=157) were 27.5 Gy/7.5 GBq and 3.67 Gy/GBq, respectively. The mean AD coefficients in kidneys, whole body, liver, spleen, urinary bladder wall and red marrow were 0.42, 0.03, 0.03, 0.31, 0.63, 0.02 Gy/GBq, respectively. Corresponding ADs were 3.1, 0.2, 0.2, 2.4, 4.7 and 0.1 Gy/7.5 GBq, respectively. Additionally, the moderate AD levels in normal organs support the favourable safety profile of [^{177}Lu]Lu-edotreotide. A lower frequency of renal treatment-emergent adverse events was observed with [^{177}Lu]Lu-edotreotide versus everolimus (14.7% versus 21.2%); haematuria and proteinuria being the most common. Similarly, haematological treatment-emergent adverse events were comparable with [^{177}Lu]Lu-edotreotide versus everolimus (40.1% versus 41.4%), with the most common events being anaemia, lymphopenia and thrombocytopenia. ***Conclusion:*** The results showed that ADs to normal organs were lower than the established thresholds[1]. Substantially higher AD in tumour lesions compared to normal organs suggests a favourable therapeutic index. The dosimetry assessments are in agreement with the efficacy and safety outcomes of the trial. ***References:*** 1. Wahl RL et al, 2021. J.Nuc.Med 62:23-35S.

Aim/Introduction: 177Lu-DOTATATE (PRRT) has become a cornerstone in the treatment of advanced and unresectable gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Objective: To describe the accumulated clinical experience with PRRT in a real-life context. ***Materials and Methods:*** Data were obtained from the SEPTRALU registry which includes consecutively recorded patients with NETs treated with 177Lu-DOTATATE across 26 Spanish hospitals. Survival was evaluated using Kaplan-Meier estimates, and toxicity was graded according to CTCAEv3.0. ***Results:*** A total of 919 patients were recorded (December 2017/April 2025) with a mean age of 66 years (range, 12-91) and 58% were male. Functioning NETs were present in 28%, including 5% carcinoid syndrome. Most tumors were well-differentiated (90%), with a median Ki67 of 6% (range: 1-80%). Primary tumor sites included the pancreas (35%), small intestine (31%), lung (9%), pheochromocytoma/paraganglioma (PPGL) (5.5%), other digestive tract locations (5.5%), and unknown origin (7%). Metastases were most frequently located in the liver (88.8%), lymph nodes (65%), bone (28%), peritoneum (18%), and lung (9%). Prior treatments included primary tumor resection (53%), metastasectomy (24%), and locoregional liver therapies (12%). Radiologic response was: partial response (23%), disease control (76%), progression (9%), and unavailable or non-measurable lesions (15%). Pancreatic NETs had higher response rates (30.4%) compared to intestinal NETs (16%). Progression-free survival was 33.3 months, with site-specific variation: intestine (42.5), PPGL (33.6), pancreas (28), and lung (19.6 months). Overall survival was 52.7 months, similar between pancreatic NETs (61.23, 95% CI, 53.5-69.0 months) and ileal NETs (57.9, 95% CI, 49.1-66.7 months; p=0.17). Grade 3-4 toxicity was low (2.3%). The most common adverse effects were nausea (20%), hematologic (18%), emesis (14%), asthenia (13%), urticaria (9%), and alopecia (6%). ***Conclusion:*** This large real-world series confirms the efficacy and safety profile of 177Lu-DOTATATE in the treatment of advanced and unresectable NETs of various origins.

OP-431

Safety and Efficacy of ^{177}Lu-LNC1010 in Advanced SSTR-Positive Neuroendocrine Tumors: A Single-Center, Single-Arm, Phase II Study

W. Guo[1], *Y. Chen*[1], *H. Fu*[1], *L. Zhao*[1], *J. Zhang*[2], *X. Chen*[2], *H. Chen*[1];
[1]*The first affiliated hospital of Xiamen University, Xiamen City, CHINA,* [2]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: This open-label, single-arm, single-center phase II clinical trial evaluated the safety and efficacy of ^{177}Lu-LNC1010, an optimized long-acting somatostatin analog (SSA), in patients with metastatic neuroendocrine tumors (NETs). ***Materials and Methods:*** A total of 20 patients with histologically confirmed, unresectable metastatic NETs and progressive disease after prior treatment with SSA and/or tyrosine kinase inhibitors were enrolled. Participants received up to four cycles of peptide receptor radionuclide therapy (PRRT) with a fixed dose of ^{177}Lu-LNC1010 (3.33 GBq per cycle) administered at 8-week intervals, as recommended by a prior phase I clinical trial. Adverse events (AEs) and treatment-related adverse events (TRAEs) were graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), version 5.0. Treatment response was assessed using RECIST version 1.1. Kaplan-Meier analysis was performed to estimate progression-free survival (PFS) and overall survival (OS). ***Results:*** A total of 20 patients (9 males, 11 females; median age 53 years) received 62 cycles of ^{177}Lu-LNC1010 PRRT. Grade 3 or 4 treatment-related hematotoxicities occurred in six patients (30%), with thrombocytopenia, leukopenia, and neutropenia being the most common. One patient (5%) developed grade 3 TRAE-related hepatotoxicity after three cycles of PRRT. No grade ≥3 nephrotoxicity was observed. According to RECIST 1.1, disease control was achieved in 19 of 20 patients (95%). Among the 16 patients evaluable by imaging, 15 (93.8%) achieved disease control, including six with partial response (PR) and nine with stable disease (SD). After a median follow-up of 19.5 months (range 0-29), 8 patients (40%) had died, while 12 patients (60%) survived. The median PFS was 12 months (95% confidence interval [CI]: 9.82-14.18), and the median OS was 22 months (95% CI: 17.16-26.84). Disease control was significantly associated with prolonged PFS and OS ($P < 0.001$). ***Conclusion:*** PRRT with 3.33 GBq of ^{177}Lu-LNC1010 was well tolerated and demonstrated an acceptable safety profile. A high disease control rate (93.8%) was achieved, which was positively correlated with improved PFS and OS.

OP-432

Radiolabeled Somatostatin Receptor (SSTR) Antagonist versus Agonist for Peptide Receptor Radionuclide Therapy in Patients with SSTR positive Neuroendocrine Tumors - a retrospective Basket study

A. Mushaweh[1], *C. Eigler*[1], *L. McDougall*[1], *A. Bauman*[1], *E. Christ*[2], *P. Bernhardt*[3], *G. Nicolas*[1], *M. Fani*[1], *D. Wild*[1];
[1]*Department Theragnostics, University Hospital of Basel, Basel, SWITZERLAND,* [2]*Department of Endocrinology, Diabetology and Metabolism, University Hospital of Basel, Basel, SWITZERLAND,* [3]*Department of Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, SWEDEN.*

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) with lutetium-177 labeled somatostatin receptor (SSTR) ([^{177}Lu]Lu-DOTATOC or -DOTATATE) has limited response rate and durability. The SSTR antagonist [^{177}Lu]Lu-DOTA-JR11 offers potentially increased tumor doses with better efficacy. Our aim was to conduct an intrapatient comparison of tumor and organ absorbed doses, safety, and median progression free survival (PFS) after therapy with [^{177}Lu]Lu-DOTATOC and [^{177}Lu]Lu-DOTA-JR11 in patients with early relapsing metastatic neuroendocrine tumors (NETs) after standard PRRT. ***Materials and Methods:*** In this preplanned retrospective, single-center, open label study, 15 consecutive patients with metastatic NETs and progression ≤ 12 months after last PRRT with [^{177}Lu]Lu-DOTATOC (2-4 cycles, 5.6- 7.5 GBq/cycle, total 39 cycles) were included. The patients received a rechallenge PRRT with 1-2 cycles [^{177}Lu]Lu-DOTATOC (standard injected activity: 5.1- 7.4 GBq/cycle, total 18 cycles) followed by 1-2 cycles [^{177}Lu]Lu-DOTA-JR11 (2 GBq/m2 × body surface area: 2.7-4.8 GBq/cycle, total 18 cycles) in an interval of 10±1 weeks. Endpoints: Progression free survival (follow-up with imaging every 3-6 months), safety (CTCAE V 5.0), and imaging-based tumor and organ absorbed doses (3D dosimetry using Olinda). ***Results:*** The median (range) of the mean tumor, kidney and bone marrow absorbed doses of one treatment cycle were 18.5 (1.0-354), 2.2 (1.1-6.7) Gy/cycle and 0.54 (0.32-0.66) for [^{177}Lu]Lu-DOTA-JR11 and 12.9 (0.8-223), 2.0 (0.9-4.1) and 0.21 (0.11-0.41) Gy/cycle for [^{177}Lu]Lu-DOTATOC, respectively. Tumor-to-bone marrow dose ratios of both compounds were in the same range. There were two reversible grade 3 adverse events (lymphopenia, hypoalbumenia) after [^{177}Lu]Lu-DOTATOC therapy, and six reversible grade 3 adverse events (anemia, lymphopenia) after [^{177}Lu]Lu-DOTA-JR11 therapy. No grade ≥4 events occurred. Median PFS was 11 months (95% CI: 9-13) after standard therapy with 2-4 cycles [^{177}Lu]Lu-DOTATOC and 14 months (95% CI: 10-18) after 1-2 cycles [^{177}Lu]Lu-DOTATOC plus 1-2 cycles [^{177}Lu]Lu-DOTA-JR11 (Hazard ratio 0.34, p=0.007) in the same NET patients. ***Conclusion:*** The median (range) tumor absorbed dose per cycle is 2.1 (0.9-6.4) times higher with [^{177}Lu]Lu-DOTA-JR11 compared to [^{177}Lu]Lu-DOTATOC in the same patients resulting in a median PFS benefit of 3 months (95% CI: 1.4-10.8) for early relapsing NET patients following standard PRRT. No relevant or persistent adverse events were detected which justifies further prospective evaluation of [^{177}Lu]Lu-DOTA-JR11 in early relapsing NET patients.

OP-433

Safety Profile of [^{177}Lu]Lu-DOTATATE: A Disproportionality Analysis of Adverse Events from the WHO Global Pharmacovigilance Database

J. Vigne*, T. Ladrière, B. Chrétien, A. Bignon-Bretagne, K. Bouhier-Leporrier, C. Dolladille;*
University Hospital of Caen, Caen, FRANCE.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTATATE has become an effective treatment for patients with metastatic or inoperable neuroendocrine tumors (NETs), owing to its targeted action on somatostatin receptors. While clinical trials, such as NETTER-1[1], have demonstrated its efficacy and overall safety in a limited population of selected patients, real-world safety data remain scarce. ***Materials and Methods:*** This study utilized VigiBase®, the World Health Organization›s global database of individual case safety reports (ICSRs), to evaluate the safety profile of [177Lu]Lu-DOTATATE under real-world conditions. A retrospective disproportionality analysis was performed on all reports submitted up to March 1st, 2024, after deduplication. Safety signals were identified using the Information Component (IC) metric, which estimates the strength of association between a drug and a specific adverse event. A positive lower limit of the 95% confidence interval (IC025 > 0) was considered indicative of a statistically robust association. ***Results:*** Among 3,984 reports analyzed, 86% were submitted between 2021 and 2024, predominantly from the Americas (65%), and primarily by physicians (45%). Adverse events were categorized into 13 main classes and 37 subclasses. The most significant associations were observed with hematologic disorders (IC025 = 2.15), hepatic disorders (IC025 = 1.43), renal failure (IC025 = 1.16), infections (IC025 = 0.91), and malignant hematologic neoplasms (n = 43, IC025 = 2.48). Temporal relationships between treatment and event resolution were supported by dechallenge data in multiple cases. The most frequently co-reported adverse events included hematologic and gastrointestinal disorders within the top 25 co-occurrence patterns. Median time-to-onset ranged from 16 days (metabolic disorders) to 815.5 days (hematologic malignancies). ***Conclusion:*** This global pharmacovigilance study provides valuable insights into the real-world safety profile of [177Lu]Lu-DOTATATE and may contribute to optimizing its clinical use in NET management. ***References:*** 1.Strosberg Jonathan, El-Haddad Ghassan, Wolin Edward, Hendifar Andrew, Yao James, Chasen Beth, et al. OP-434

Impact of ^{18}F-FDG PET in Patients with Advanced Metastatic Neuroendocrine Tumors Undergoing Rechallenge PRRT: Final Results from a Multicenter WARMTH Study

G. Santo[1], *M. Rodrigues*[1], *D. Paez*[2], *L. Kabasakal*[3], *K. Kairemo*[4], *C. Grana*[5], *R. Baum*[6], *G. di Santo*[1], *I. J. Virgolini*[1];
[1]*Department of Nuclear Medicine, Innsbruck Medical University, Innsbruck, AUSTRIA,* [2]*Nuclear Medicine and Diagnostic Imaging Section, Division of Human Health, International Atomic Energy Agency, Vienna, AUSTRIA,* [3]*Department of Nuclear Medicine, Faculty of Medicine, Yeditepe University School of Medicine, İstanbul, TÜRKIYE,* [4]*Nuclear Medicine & Theragnostics, Docrates Cancer Center, Helsinki, FINLAND,* [5]*Radiometabolic Therapy Unit, IRCCS IEO European Institute of Oncology, Milan, ITALY,* [6]*Theranostics Centre for Molecular Radiotherapy and Precision Oncology, Zentralklinik,, Bad Berka, GERMANY.*

Aim/Introduction: The aim of this multicenter study was to evaluate the impact of metabolic status and its changes measured by ^{18}F-FDG PET on treatment response and survival in advanced/metastatic NET patients undergoing rechallenge PRRT. ***Materials and Methods:*** A total of 100 patients were retrospectively included. All patients received two PRRT courses and underwent both ^{68}Ga-DOTA-TOC/TATE and ^{18}F-FDG PET/CT (before PRRT, 3-months after PRRT, and every 6-9 months thereafter). Baseline patient characteristics were correlated with FDG-positivity at baseline and during treatment. Metabolic status and its changes (no change vs. FDG+/FDG– vs. FDG–/FDG+) at baseline, after the first and the second treatment course were correlated with response, time-to-progression(TTP), and overall survival(OS). ***Results:*** In 43/100 patients(G1:17%, G2:67%, G3:19%), primary tumor site was pancreas, liver was involved in 90% of cases. 50% of patients were FDG-positive prior to treatment. There was a trend toward significance for a higher prevalence of FDG-positivity in patients with pancreatic-NETs compared to other primary sites (60% vs.

42%,p=0.053). After the first PRRT course, 37% were FDG-positive:20 patients became metabolically negative, while 7 became FDG-positive. Post-treatment metabolic status correlated significantly with NET grade (FDG+ G1:19%, G2:33%, G3:66%;p=0.009). There was a trend toward significance in G1/G2 patients converting from FDG+ to FDG− compared to G3 patients (p=0.054). After the rechallenge, 41% were FDG-positive: 27 patients converted to FDG−, 16 became FDG+. The correlation between NET grade and metabolic status persisted after rechallenge (FDG+ G1:25%, G2:31%, G3:89%;p<0.0001), indicating that FDG+ status increased progressively in G3 patients (p=0.023). Conversely, in G2-NET there was an increase in those who became FDG− after rechallenge compared to the first course (+7patients). At a median follow-up of 24 months after the initial treatment, 39% of patients had progressed. FDG-status after the first treatment was significantly correlated with TTP (FDG+12 months [95%CI:8.7-15.3] vs. FDG− not reached,p<0.0001). Also changes in glucose metabolism were associated with TTP (p<0.001). After a median follow-up time of 117.6 months(range:38.4-180), FDG-status after the first treatment was significantly correlated with OS (mOS:FDG+94.8 months[95%CI:85.1-104.5] vs. FDG−144 months[95%CI:142.2-145.7],p<0.0001). Patients who became metabolically negative after the initial treatment had the best mOS(p=0.034). Overall response after rechallenge correlated significantly with survival (p=0.002). ***Conclusion:*** Assessment of metabolic status before PRRT and during follow-up allows prediction of TTP and OS, even in patients considered for rechallenge. NET grade influences changes in metabolic status. Standardization of the use of dual-tracer imaging in patients receiving PRRT could guide clinical management.

OP-435

[^{177}Lu]Lu-DOTA-LM3 for PRRT in Metastatic NET: Dosimetry, Response and Safety

T. Speicher, *A. Schaefer-Schuler, M. Mavrommatis, M. B. Bastian, A. Blickle, S. Maus, M. Bartholomä, C. Burgard, F. Rosar, S. Ezziddin; Nuclear Medicine, Saarland University Hospital, Homburg, GERMANY.*

Aim/Introduction: Recently, somatostatin receptor (SSTR) antagonists have gained attention for peptide receptor radionuclide therapy (PRRT) due to their higher receptor binding capacity and promising preclinical results. This study aimed to evaluate the dosimetry, response and safety of the ^{177}Lu-labeled SSTR antagonist [^{177}Lu]Lu-DOTA-LM3 in patients with metastatic NET. ***Materials and Methods:*** This retrospective study included 12 patients with advanced NET undergoing [^{177}Lu]Lu-DOTA-LM3 PRRT; hybrid dosimetry using serial planar whole-body and SPECT/CT imaging at 24 h, 48 h, and beyond 72 h post-injection; absorbed dose estimation for kidneys and spleen through IDAC 2.1 in combination with the IDAC reference man model. Tumor absorbed doses based on sphere model with ^{177}Lu dose factors interpolated according to mass of each lesion (determined by CT imaging). Adverse events according to CTCAE v5.0, response by EORTC and RECIST 1.1 criteria. ***Results:*** A total of 21 treatment cycles were administered (mean activity: 5.02±0.66 GBq per cycle). The primary tumor site was pancreatic (33%), intestinal (42%), or other (25%). Tumor grading was G1 (18%), G2 (45%), and G3 (36%). According to RECIST 1.1, partial response was observed in 28%, stable disease in 57%, and progression in 14%. EORTC criteria showed response in 33%, stable disease in 44%, and progression in 22%. Metastatic lesions were predominantly hepatic (34 lesions in 10/12 patients), with lymph node and bone involvement in 5/12 patients each**.** Tumor lesion dosimetry revealed considerable intra- and inter-patient variability, with a mean absorbed dose of 3.12±1.9 Gy/GBq (range: 0.36-7.59 Gy/GBq). The mean absorbed doses to the kidneys and the spleen were 1.08±0.53 Gy/GBq and 1.08± 0.75 Gy/GBq, respectively. Three patients showed renal doses ≥2.0 Gy/GBq. Tumor-to-organ dose ratios averaged 3.15±1.99 (kidneys) and 3.72±3.28 (spleen). Alongside several low-grade adverse events, one patient developed hepatotoxicity (CTC-3). No grade 4 or 5 toxicities occurred, despite elevated renal doses in some patients. ***Conclusion:*** [^{177}Lu]Lu-DOTA-LM3 therapy delivers high absorbed doses to tumor lesions with a favorable tumor-to-kidney dose ratio and benign toxicity profile. These findings support exploration of this promising therapeutic option in patients with advanced NET.

OP-436

Novel FAP-Targeted Radiopharmaceutical Therapy with ^{177}Lu/^{90}Y/^{225}Ac-3BP-3940 in Patients with Pancreatic Ductal Adenocarcinoma (PDAC)

J. Zhang[1], *J. Li*[1], *A. Eismant*[2], *L. Greifenstein*[2], *A. Klega*[2], *C. Landvogt*[2], *C. Mueller*[2], *T. Zhao*[1], *O. Klein*[3], *B. Jaeschke*[3], *R. P. Baum*[2]; [1]*National University of Singapore, Singapore, SINGAPORE,* [2]*Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY,* [3]*Helios DKD Klinik, Wiesbaden, GERMANY.*

Aim/Introduction: Pancreatic ductal adenocarcinoma (PDAC) is characterized by poor prognosis and limited treatment options in advanced stages. Fibroblast activation protein (FAP) is a promising theranostic target due to its high stromal expression in PDAC. This study reports first-in-human results of FAP-targeted radiopharmaceutical therapy (FRT) using ^{177}Lu-, ^{90}Y-, and ^{225}Ac-labelled 3BP-3940 in 26 patients with metastatic, treatment-refractory PDAC. ***Materials and Methods:*** Between March 2021 and March 2025, 26 patients with metastatic, treatment-refractory PDAC were treated with 3BP-3940-based FRT. Patient selection was based on FAP expression assessed by pre-treatment ^{68}Ga-3BP-3940 PET/CT imaging. Treatments involved either monotherapy or tandem administration of ^{177}Lu-, ^{90}Y-, or ^{225}Ac-labelled 3BP-3940. Adverse events were evaluated using CTCAE version 5.0. Tumor response was assessed by molecular imaging, and overall survival was measured from the initiation of FRT. ***Results:*** FRT with ^{177}Lu-/^{90}Y-/^{225}Ac-3BP-3940 was well tolerated in all patients. The mean cumulative radioactivity/patient were 18±13 GBq for ^{177}Lu, 10±5 GBq for ^{90}Y and 18±10 MBq for ^{225}Ac. Reported side effects included pain in 6/26 patients, 6/26 nausea, 2/26 vomiting, 1/26 diarrhoea, 3/26 partial alopecia, and 1/26 intensified fatigue. One patient experienced Grade 3 toxicity (CTCAE) after the second treatment cycle. No other clinically relevant adverse effects or pharmacologic abnormalities were observed. Post-therapy whole-body imaging and SPECT/CT scans showed intense tumor uptake and prolonged retention, with consistently high tumor-to-background ratios across all patients. Among the 12 patients evaluated after one FRT cycles, molecular imaging responses included partial remission in 58%, mixed response in 8%, stable disease in 25%, and progressive disease in 8%; responses in 13 patients after two cycles included partial remission in 38%, mixed response in 15%, stable disease in 15%, and progressive disease in 31%. Until the study cutoff date in early April 2025, 22 of 26 patients (85%) with PDAC died. The median follow-up time was 17 months, and the median overall survival from the start of FRT was 7 months. ***Conclusion:*** FAP-targeted PTRT using 3BP-3940 labeled with ^{177}Lu, ^{90}Y, or ^{225}Ac is feasible and well tolerated in patients with advanced pancreatic ductal adenocarcinoma. The therapy demonstrated favorable safety, low off-target uptake, and high tumor retention with excellent tumor-to-background contrast. Molecular imaging confirmed objective responses in a subset of patients, and the observed median survival of 7 months from the start of FRT in this heavily pre-treated population is highly encouraging. These first-in-human findings support further clinical evaluation of 3BP-3940 FRT in larger, randomised controlled trials.

OP-437

Changes in Brain Glucose Metabolism Induced by Long-Acting Somatostatin Analogues Therapy in Patients with Neuroendocrine Tumors: a ^{18}F-FDG PET Study

A. Martini[1], *F. De Lauro*[2], *G. Bianciardi*[3], *S. Fanti*[4], *S. Lastoria*[2], *S. Sestini*[1];
[1]*Unit of Nuclear Medicine, Department of Diagnostic Imaging, N.O.P. - S. Stefano, U.S.L. Toscana Centro, Prato, ITALY,* [2]*Nuclear Medicine Unit, Istituto Nazionale Tumori di Napoli, IRCCS "G. Pascale", Naples, ITALY,* [3]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [4]*Nuclear Medicine, Alma Mater Studiorum University of Bologna,IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: although analogues of the peptide somatostatin (SSA) present a high binding to brain SSR2-5, the low entry-rate of SSA into the brain has favored the idea that they cross the blood-brain-barrier (BBB) not in amount sufficient to affect brain functions. In contrast, no work has been done to confirm this hypothesis. Aim of this study was to investigate the potential off-target clinical and regional brain metabolism effects produced by the long-lasting stimulation of low entry-rate of SSA on brain somatostatin receptors in patients with NETs who were candidates for radioligand therapy. ***Materials and Methods:*** we included 25 patients (mean age 59 ± 12 y) with NETs treated with SSA from 6 up to 84 months. All patients underwent a baseline [^{18}F]-FDG PET together with neurological cognitive assessment. Brain hypo- and hypermetabolism were analysed using an optimised and validated voxel-based SPM method at the single-subject and group levels, based on comparisons with a large and well-selected dataset of healthy controls. A Pearson correlation analyses was performed to investigate the relationship between treatment duration and both the cluster extent and severity (mean T-score) of affected brain regions. ***Results:*** singlesubject and grouplevel analyses showed hypometabolism in cortical and sub-cortical regions including the bilateral OFC (BA11), DLPFC (BA9,10,46), VLPFC (45,47), the bilateral middle temporal pole (BA38) and hyppocampus (BA36), the left superior middle inferior temporal gyrus (BA22, 21, 20) and amygdala (BA28), and the bilateral caudate nuclei. The hypometabolism commonality analysis showed the left fronto-temporal cortices and caudate nuclei as the hypometabolic hallmark for the "whole group", with more limited involvement of the right middle temporal cortex and OFC. Correlation analysis demonstrated that patients with longer treatment with SSA present a higher extension and severity of hypometabolism. Besides, patients with longer SSA exposure reported new-onset mood instability, irritability and slight motor disturbances. ***Conclusion:*** this study provides the first evidence that exposure of low but long-lasting entry-rate of SSA in patients with NETs yields a dysfunction of brain regions expressing SSR2-5. The severity of neural dysfunction appears to correlate with treatment duration and could result in the emergence of positive neuropsychiatric symptoms. According with current knowledge of somatostatinergic networks in the brain, this effect could reflect an excessive inhibition of glutamatergic fronto-temporal pathways, e.g. low concentrion of SSA may cross the BBB and could enhance the inhibitory effect of endogenous SST-14 released by SST-INs interneurons and long-range SST-neurons.

Spatial match and mismatch of tau pathology and hypometabolism at individual level

C. Boccalini[1], *D. E. Peretti*[1], *A. Mendes*[1], *M. Scheffler*[2], *N. Ashton*[3], *H. Zetterberg*[3], *K. Blennow*[3], *G. B. Frisoni*[1], *V. Garibotto*[1];
[1]*University of Geneva, Geneva, SWITZERLAND,* [2]*Geneva University Hospitals, Geneva, SWITZERLAND,* [3]*University of Gothenburg, Gothenburg, SWEDEN.*

Aim/Introduction: Neurodegeneration seems to be mostly driven by tau pathology in Alzheimer's disease (AD). However, despite the similar topographies, there is still variability in the tau accumulation and neurodegeneration patterns across the brain with some regions being more vulnerable to one or another pathology. This study aimed to investigate the spatial mismatch between regional tau pathology and brain metabolism as a measure of neurodegeneration at the individual level and evaluate its impact on patients' clinical and biomarker profiles. ***Materials and Methods:*** We included 137 amyloid-positive and clinically impaired patients from Geneva Memory Clinic (N=57) and ADNI (N=80), who underwent both 18F-Fluorodeoxyglucose (FDG)-PET to assess brain metabolism and 18F-Flortaucipir Tau-PET for tau burden within 1 year. The single-subject procedure (involving a voxel-wise comparison versus a group of amyloid-negative cognitively unimpaired subjects) was applied to calculate hypometabolism and tau maps and their spatial overlap by the Dice coefficient. Hypometabolic and tau maps' extents and delta (Δ) scores were used to classify the prevalent pathology. Differences in demographic and clinical features, neuroimaging-derived features, fluid biomarkers and cognitive trajectories were tested between match and mismatch groups. ***Results:*** We identified 22 patients with spatial match and 115 with mismatch, of which 23 showed hypometabolism-predominant mismatch and 92 tau-predominant mismatch. Patients with hypometabolism/tau match were younger and more cognitively impaired, with higher amyloid, neocortical tau, cortical atrophy, and level of glial fibrillary acidic protein (GFAP) in plasma than both mismatch groups ($p<0.005$). When we focus on differences between hypometabolism- and tau-predominant cases, we found the former showing less amyloid and tau burden ($p<0.005$), but a trend for higher inflammation as measure by GFAP than tau-predominant cases. However, we did not find differences in copathologies as measured by white matter lesion volumes and alpha-synuclein in cerebrospinal fluid ($p>0.05$). Match cases showed a significantly steeper cognitive decline than both mismatch cases, controlling for other imaging biomarkers ($p<0.001$). ***Conclusion:*** Spatial overlap between hypometabolism and tau deposition was associated with a severe clinical and biomarker phenotype with the worst prognosis, whereas spatial decoupling between tau and hypometabolism showed a slower cognitive decline. Patients with greater hypometabolism than tau deposition had lower amyloid and neocortical tau burden than tau-prevalent patients suggesting other contributors to neurodegeneration in addition to AD pathologies. Spatial match between tau and hypometabolism can provide additional information in AD identifying different phenotypes.

Ltd, Suzhou, CHINA.*

Aim/Introduction: Despite growing recognition of clinical-biological construct of Alzheimer's disease (AD), evidence supporting the prognostic and monitoring utility of Tau-PET in real-world settings remains limited. This study aimed to bridge the translational gap between Tau-PET research and clinical practice and offer insights into optimizing AD management with ^{18}F-Florzolotau Tau-PET in memory clinic populations. ***Materials and Methods:*** Memory clinic outpatients and cognitively unimpaired volunteers who accepted assessment of AD core biomarkers, Amyloid-PET or plasma p-tau 217 (core 1) and ^{18}F-Florzolotau Tau-PET (core 2), and longitudinal follow-up were included. The prognostic utility was explored in 242 participants with clinical follow-ups (median [range] interval: 1.42 [0.60 ~ 5.93] years) using binary clinical outcomes (progressive versus stable) and the annualized cognitive declines as endpoints. The disease monitoring potential was explored in the subset with Tau-PET follow-ups (n = 81, median [range] interval: 1.94 [0.87 ~ 5.35] years) by comparing the tau trajectories between clinically progressive and stable groups, and the correlation between annualized cognitive declines and annualized tau increases. ***Results:*** Baseline Tau-PET predicted the binary clinical outcomes and the annualized cognitive declines, with continuous measurement, neocortical standardized uptake value ratio (SUVR), showing the best incremental prognostic value to demographic characteristics in the entire cohort (AUC [95% CI] = 0.83[0.77 ~ 0.88] versus 0.67 [0.60 ~ 0.74], p-value < 0.001). Longitudinal Tau-PET analysis depicted a diffuse spatiotemporal pattern of tau accumulation, with tau trajectories closely paralleling clinical cognitive trajectories. Within the AD spectrum sub-cohort, clinically progressive individuals exhibited accelerated tau accumulation than stable cases, most notably in later-involved regions, namely, the precentral gyrus (β [95% CI] = 0.07 [0.02 ~ 0.11] SUVR/year, p-value = 0.007) and supplementary motor area (β [95% CI] = 0.08 [0.02 ~ 0.14] SUVR/year, p-value = 0.017). The annualized rates of tau accumulation correlated with annualized rates of cognitive declines in both traditional (medial temporal lobe and neocortical area) and later-involved regions. ***Conclusion:*** The memory clinic-based longitudinal study confirmed the prognosis and disease monitoring potential of ^{18}F-Florzolotau Tau-PET in AD. Later-involved cortical regions demonstrated greater sensitivity to progression than canonical tau-vulnerable areas, highlighting their potential clinical utility in tracking trajectories and reinforcing the critical need for stage-specific biomarker frameworks tailored to the real-world settings.

Aim/Introduction: Primary age-related tauopathy (PART) is typically limited to the medial temporal lobe, but in rare cases it can also show a more extensive distribution that associates with cognitive deficits mimicking Alzheimer's disease (AD), a condition that has been termed tangle-predominant dementia. It remains unknown whether this condition can be detected in-vivo using PET imaging. ***Materials and Methods:*** We first studied the ante-mortem tau- and Aβ-PET imaging (Flortaucipir, Florbetapir), CSF biomarker, and cognitive characteristics of an autopsy case with neuropathologically-confirmed tangle-dominant disease (Braak V, Thal 0, CERAD 0). We then used a large in-vivo cohort of 2402 older individuals to screen Aβ-PET-negative ('A-'; <24.4 Centiloids) individuals for those with elevated neocortical tau-PET (Flortaucipir) signal ('T+', positive visual read), and studied their cognitive, genetic, and CSF biomarker characteristics. ***Results:*** In PET scans acquired 1.8 years before death, the tangle-dominant autopsy case had a negative Aβ-PET (-7 Centiloids) but showed clearly elevated tau-PET signal in temporo-parietal regions, leading to a positive visual read (Fig-1). Repeated CSF measurements (N=8, 2-13 years before death) were constantly negative for $A\beta_{42}$ (>2000 pg/ml) but positive for p-tau_{181} (>30 pg/ml). Last clinical diagnosis before death was aMCI. In the in-vivo cohort, only 3.6% (45/1264) of A- individuals were T+, but this proportion was significantly higher (9.9%) in cognitively impaired individuals (aMCI/AD dementia). A-T+ showed a temporo-parietal tau-PET signal that was spatially similar but less pronounced compared to A+T+. CSF p-tau_{181} levels were significantly elevated in A-T+ compared to A-T- (p=0.01), but $A\beta_{42}$ levels did not differ (p=0.60). APOE-ε4 frequency in A-T+ (37%) was markedly lower than for A+T+ (69%, p<0.001). ***Conclusion:*** We provide converging neuropathologic and fluid biomarker evidence that tau-PET can detect advanced forms of PART (i.e., tangle-dominant disease), a condition that is phenotypically similar to early-stage AD but has a different genetic background.

OP-441

Inhibitory and Promotive Effects of Amyloid-β on Tau Growth: A Stage-dependent Analysis in Alzheimer's Disease

T. Zhang, *B. Nie, B. Shan;*
Institute of High Energy Physics, CAS, Beijing, CHINA.

Aim/Introduction: Alzheimer's disease (AD) is characterized by β-amyloid (Aβ) plaque and tau neurofibrillary tangles. However, the interaction between these two pathologies remains unclear. This study investigates how tau growth rates are influenced by local Aβ standardized uptake value ratio (SUVR), Aβ accumulation rates, and pre-existing tau deposition. ***Materials and Methods:*** Data were sourced from the Alzheimer's Disease Neuroimaging Initiative. Participants (n = 847) who underwent Aβ and tau PET scans within six months were included to compute individual spatial Pearson correlations between the Aβ and tau SUVR. These spatial correlations were examined against Aβ plaques burden (Centiloid). Participants with multiple Aβ (n = 973) or tau (n = 428) PET scans were used to estimate SUVR values and annual growth rates using linear regression at each subject's midpoint age (baseline age plus half follow-up duration). Subjects were classified as healthy controls (HC), cognitively normal (CN), mild cognitive impairment (MCI), or dementia (AD) based on clinical diagnosis. Path analyses using standardized regression coefficients (β) assessed the influence of Aβ SUVR, Aβ accumulation rates, and tau deposition on tau growth rates at both group and individual levels. ***Results:*** A significant negative correlation was observed between Aβ-tau spatial correlation and Aβ burden (r = -0.719, P < 0.001). Group-level analysis revealed Aβ SUVR negatively

influenced tau growth in HC, CN, and MCI (β = -0.581, -0.487, -0.303 respectively, all P < 0.001), but not AD (β = -0.048, P = 0.560). Tau deposition positively affected tau growth across all groups (HC: β = 0.795; CN: β = 0.640; MCI: β = 0.543; AD: β = 0.265; all P < 0.001). Aβ accumulation rates were also positively associated with tau growth (HC: β = 0.430; CN: β = 0.620; MCI: β = 0.650; AD: β = 0.693; all P < 0.001). At the individual level, the path coefficients from Aβ SUVR to tau growth rates were significantly associated with cognitive measures (β vs CDRSB: r = 0.385; β vs MMSE: r = -0.332; both P < 0.001) and Aβ burden (r = 0.317, P < 0.001). ***Conclusion:*** Tau growth is driven by both self-replication and Aβ accumulation rates, the latter of which may reflect underlying levels of Aβ oligomers. Conversely, Aβ SUVR—potentially capturing both plaques and nonspecific binding—was associated with suppressed local tau growth, though this inhibitory effect weakened with advancing disease. These findings highlight stage-dependent nature of Aβ-tau interactions in AD.

OP-442

Correlation between Tau PET imaging and fluid biomarkers in individuals with Down syndrome

P. Stefaneli Mormandi[1], *V. Camacho*[1], *L. Vaqué-Alcázar*[2,3], *M. Calls-Calahorro*[1], *Y. Delisau*[1], *B. Serrallonga*[1], *I. Barroeta*[2,4], *D. Alcolea*[2,5], *M. Carmona-Iragui*[4,2,5], *J. Fortea*[2,4,5], *A. Fernández-León*[1], *S. Asadurova*[1], *M. Velasco-Nuño*[1], *A. Flotats-Giralt*[1];
[1]Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Sant Pau Memory Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [3]Department of Medicine, Faculty of Medicine and Health Sciences, Institute of Neurosciences, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, SPAIN, [4]Barcelona Down Medical Center, Fundació Catalana de Síndrome de Down, Barcelona, SPAIN, [5]Center of Biomedical Investigation Network for Neurodegenerative Diseases (CIBERNED), Madrid, SPAIN.

Aim/Introduction: Down syndrome (DS) arises from chromosome 21 trisomy, leading to extra APP gene copy and triggering early-onset Alzheimer's disease (AD) pathology. Almost all individuals over 40 years of age with DS display the neuropathological features of AD. Understanding AD biomarker trajectories is necessary for DS-specific clinical interventions and interpretation of eventual drug-related changes. The aim of this study is to correlate Tau ([18F]PI2620) PET findings with biomarkers in cerebrospinal fluid (CSF) and plasma in adults with DS. ***Materials and Methods:*** Fifty-eight subjects with DS who underwent brain [^{18}F]PI2620 PET/CT were included (38% women; mean age 46.6 years [30-63.8]). Brain Tau quantification was based on analysis of the standardized uptake value ratio (SUVr) for each Braak stage. Biomarkers were determined using ultrasensitive immunoassay techniques: glial fibrillary acidic protein (GFAP) in plasma (n=27); p-Tau181 in CSF (n=18) and plasma (n=27); p-Tau217 in plasma (n=44); amyloidβ42/40 ratio in CSF (n=18); neurofilament light (NfL) in CSF (n=9) and plasma (n=21). Spearman's correlation coefficient was used to evaluate the relationship between [^{18}F] PI2620 uptake in Braak stages and biomarkers. ***Results:*** A positive correlation was observed between [^{18}F]PI2620 uptake for all Braak stages and values of GFAP in plasma, p-Tau181 in CSF, p-Tau181 in plasma and p-Tau217 in plasma (all p-values <0.01). A negative correlation between [^{18}F]PI2620 uptake and Aβ42/40 ratio values in CSF was noted for all Braak stages (all p-values <0.01). No significant correlation was found between [^{18}F]PI2620 uptake and NfL values in CSF or in plasma. ***Conclusion:*** The results reinforce the interconnectedness of tau deposition, neuronal injury, and inflammatory responses throughout AD progression. Interestingly, the absence of correlation with NfL levels suggests a differential sensitivity or temporal relationship of this marker. Taken together, our findings support the combined use of [^{18}F]PI2620 PET and fluid biomarkers for understanding AD in DS and aiding diagnosis, monitoring, and treatment evaluation.

OP-443

Comparability of [^{18}F]-FDG and Early-Phase amyloid and tau PET in detecting LATE Pattern in in amnestic mild cognitive impairment

G. Mathoux[1], *C. Boccalini*[2], *D. E. Peretti*[2], *M. Scheffler*[1], *G. B. Frisoni*[1], *V. Garibotto*[1];
[1]Hôpitaux Universitaires de Genève, Genève, SWITZERLAND, [2]Geneva University, Genève, SWITZERLAND.

Aim/Introduction: In the lack of specific biomarkers for limbic-predominant age-related TDP-43 encephalopathy (LATE), [18F]-FDG-PET can provide supportive information revealing characteristic hypometabolic patterns involving medial temporal and limbic regions and a relative sparing of the inferolateral temporal cortex.Early-phase PET (ePET), derived from dual-phase amyloid or tau PET protocols, can replace 18F-FDG-PET imaging in most neurodegenerative cases, showing typical disease patterns. This study aimed to investigate the ability of ePET in detecting the characteristic LATE-like pattern using [18F]-FDG-PET as gold standard in amnestic mild cognitive impairment (aMCI). ***Materials and Methods:*** We included 61 aMCI patients who underwent both FDG-, amyloid-, and tau-PET, with a dual-phase protocol (either from [18F]-Florbetapir, or [18F]-Flutametamol or [18F]-Flortaucipir). Two trained raters independently and blindly visually assessed FDG and ePET images with single-subject maps, classifying each scan into: Normal, Alzheimer's disease (AD)-like, LATE-like, or Other; discrepancies were resolved by consensus. Concordance between FDG and ePET classifications was evaluated using Cohen's κ. Standardized uptake value ratios (SUVR) were extracted, and the inferior-to-medial temporal (IMT) ratio was calculated by dividing the SUVR of the inferior temporal lobe by the combined SUVR values of the amygdala and hippocampus to evaluate the correlation of ePET and their respective ^{18}F-FDG PET scans. ***Results:*** FDG-based classification identified 23 Normal, 23 AD-like, 8 LATE-like, and 7 "other" patterns and ePET 24 Normal, 12 AD-like, 14 LATE-like, and 11 "other".Overall concordance between ePET and [^{18}F]-FDG PET was fair (κ=0.35), improving to κ=0.42 when "Other" patterns were excluded. Discordant cases mainly involved (n=14) scans classified as AD-like on FDG but reclassified by ePET; notably, 11 of these 14 were amyloid and tau positive, consistent with AD etiology.We found significantly lower IMT ratio in AD-like than in LATE-like patients with both FDG and ePET (p<0.05). Strong correlations were found between IMT measured by perfusion and by FDG (r=0.67, p<0.05). ***Conclusion:*** The fair agreement between ePET and [^{18}F]-FDG-PET classifications and the significant correlation in IMT ratio might support the use of ePET to identify LATE-like patterns. Without TDP-43-specific biomarkers, dual-phase amyloid or tau PET offers a broadly accessible, cost-effective strategy to raise clinical suspicion for LATE. However, these findings represent preliminary data from aMCI subsample, which we plan to extend to a larger cohort. Moreover, methodological differences and the relatively small size of ePET control database could have contributed to discordant cases and highlight the need of larger and harmonized datasets to refine and validate this approach.

OP-444

Neuropathological Tau Deposition Mediates the Relationship Between Glymphatic dysfunction and Hippocampal Neurodegeneration in Patients with Mild Cognitive Impairment

X. Xu[1], *B. Zhang*[2], *W. Zhang*[2], *J. Chen*[2];
[1]Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, CHINA, [2]Department of Radiology, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, 210008, China, Nanjing, CHINA.

Aim/Introduction: The glymphatic system, an astrocytic aquaporin 4 (AQP4)-dependent clean system, is a network of functional conduits in the brain for removing metabolic waste and protein deposition. While extensive studies have found Aβ

is closely associated to the glymphatic system, the role of tau pathology in glymphatic dysfunction and its association with neurodegeneration in the Alzheimer Disease (AD) spectrum remain unclear. The aim of this study was to assess how regional tau deposition affect the relationship between glymphatic dysfunction and neurodegeneration in early AD. ***Materials and Methods:*** Cognitively normal (CN, n = 52) controls, mild cognitive impairment (MCI, n = 38) patients, and those with significant memory concern (SMC, n = 46) were included from the Alzheimer's Disease Neuroimaging Initiative database. Regional tau deposition was assessed using positron emission tomography. The glymphatic activity was evaluated using diffusion tensor image analysis along the perivascular space (DTI-ALPS), and neurodegeneration determined by hippocampal volume measured in MRI. Correlation analysis and mediation analysis were used to evaluate the relationship between regional tau SUVR and DTI-ALPS cognitive function scores. Additionally, this study explored how Aβ and APOEε4 status infuence the associations between altered glymphatic activity and tau uptake using hierarchical moderated multiple regression. ***Results:*** Our results showed a significant correlation between tau PET in the right fusiform gyrus and parahippocampal gyrus, and diffusion tensor image analysis along the perivascular space (ALPS) index, which was independent of Aβ and APOE genes statue. Pathological tau deposition could mediate the relationship between glymphatic function and neurodegeneration (indirect effect: 0.012, 95%CI: 0.001, 0.029) rather than ALPS mediates the relationship of tau and neurodegeneration. The relationship between glymphatic function and cognitive decline was fully mediated by tau deposition in specific brain region and neurodegeneration (indirect effect: -1,935, 95%CI: -3.416 — -0.687). ***Conclusion:*** In patients with mild cognitive impairment, the combination of tau PET and MRI provides a powerful approach to identify vulnerable brain regions to tau pathology and its association with glymphatic dysfunction, which appears to be independent of Aβ and APOE ε4 status. Although neural atrophy is irreversible, enhancing glymphatic drainage to mitigate tau-associated neurodegeneration could be a promising therapeutic approach. Our results suggest that targeting tau pathology in the right fusiform gyrus and inferior temporal lobe, along with improving the glymphatic drainage, could offer a potential therapeutic strategy in the early stage of AD.

OP-445

Amyloid and tau changes in preclinical autosomal dominant Alzheimer's disease mutation carriers: a dual-tracer PET/MRI qualitative and quantitative analysis

L. Fu[1], *Z. Zhou*[2], *J. Gao*[1], *Q. Wang*[3], *Q. Wang*[3];
[1]Department of Nuclear Medicine,China-Japan Friendship Hospital, Beijing, CHINA, [2]Department of Neurology,China-Japan Friendship Hospital, Beijing, CHINA, [3]Innovation Center for Neurological Disorders and Department of Neurology, Xuanwu Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: Autosomal dominant Alzheimer's disease (ADAD) offers a distinct framework to study the preclinical phase of Alzheimer's disease (AD), given its predictable symptom onset and high penetrance of causative mutations. The study aims to investigate the spatial distribution and temporal progression of amyloid-beta (Aβ) and tau pathologies, and to assess the application of the centiloid scale (CLs) of PIB-PET in evaluating asymptomatic ADAD patients. ***Materials and Methods:*** Participants were recruited from the Chinese Familial Alzheimer's Disease Network, comprising 19 asymptomatic ADAD mutation carriers and 21 cognitively normal healthy controls (CN). We conducted 20-minute PIB-PET scans (40-60 min uptake) and 20-minute MK6240-PET scans (70-90 min uptake). The cortical-to-cerebellum standardized uptake value ratio (SUVR) was calculated, and CLs of PIB-PET were calibrated using GAAIN datasets. Qualitative analysis categorized ADAD carriers with significant ^{18}F-MK6240 uptake in intracranial regions as Group 2 (both PIB-PET and MK6240-PET positive); others were Group 1(PIB-PET positive or negative; MK6240-PET negative). ***Results:*** Compared to CNs and Group 1, Group 2 participants exhibited significantly higher ^{11}C-PIB uptake in the neocortex but predominant in the striatum (F=20.727, P<0.05) and increased ^{18}F-MK6240-PET uptake in the medial temporal (MTL, P<0.001) and other cortical regions (P<0.05). No statistic difference in the radioactive accumulation of both tracers were observed between CNs and Group 1. In mutation carriers, higher Tau PET binding in MTL and other cortical regions were correlated with shorter estimated years to onset (P=0.02). A 45-year-old female subject with a PSEN2 gene mutation and an MMSE score of 24 had a CL value of 9.25 and an SUVR of 1.10, with visibly increased ^{11}C-PIB uptake in the striatum and MK6240 retention in the MTL. ***Conclusion:*** This study elucidates the spatiotemporal progression of Aβ and tau pathologies in preclinical ADAD, supporting the hypothesis that Aβ accumulation precedes tau pathology. The prominent Aβ deposition in the striatum but less in the cortex in preclinical ADAD may lead to false-negative results in quantitative analysis. Caution should be exercised in early diagnosis and patients' management for ADAD using Centiloid quantification.

OP-446

Could [^{18}F]PI-2620 be used as a biomarker for progressive supranuclear palsy?

A. Bronte[1,2], *E. Prieto*[1], *G. Martí-Andrés*[3], *D. Pigg*[4], *F. Mínguez*[1], *F. Pareja*[1], *G. Quincoces*[1], *M. Erro*[3], *J. Arbizu*[1];
[1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Hospital Universitari de Son Espases, Palma, SPAIN, [3]Hospital Universitario de Navarra, Pamplona, SPAIN, [4]Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a primary 4-repeat (4R) tauopathy. [^{18}F]PI-2620 is a second-generation tau-PET tracer with high affinity to 4R deposits, that has been described to aid in the diagnosis and differentiation of patients with suspected PSP. The aim of our study was to investigate the 4R-tau deposition in patients with clinically diagnosed PSP. ***Materials and Methods:*** We conducted a prospective study in probable or possible PSP patients (diagnosed according to Movement Disorder Society PSP criteria) and controls (healthy and Parkinson disease (PD) controls). All individuals underwent a dynamic [^{18}F]PI-2620 PET scan from 0 to 60 minutes post-injection. Carotid artery image-derived input functions were generated over the 60-minute dynamic [^{18}F] PI-2620 PET. Volume of distribution was calculated using Logan plot, and referred to inferior cerebellum grey matter distribution volume ratios (DVR) were achieved in putamen (P), globus pallidus (GP), globus pallidus externus (GPe), globus pallidus internus (GPi), substantia nigra (SN), subthalamic nucleus (StN), dentate nucleus (DN), dorsomedial (MPF) and dorsolateral prefrontal cortex (LPF). Differences in DVRs among patients with Richardson's syndrome variant of PSP (PSP-RS), non-Richardson variants of PSP (PSP-Non-RS) and control patients were explored using SPSS version 20. ***Results:*** 31 patients were included (18 men; Age 72.3 ± 5.9): 28 PSP (PSP Rating Scale score 38.1 ± 15.5) and 3 Controls (2 Healthy and 1 PD controls). PSP patients were subclassified as 18 PSP-RS and 10 PSP-Non-RS (2 Parkinsonian, 1 Speech&language, 5 Frontal, 1 Oculomotor, 1 Postural instability). PSP-RS DVRs (mean±SD): P (1.23±0.10), GP (1.30±0.12), Gpe (1.32±0.11), Gpi (1.28±0.17), SN (1.22±0.12), StN (1.24±0.16), DN (1.21±0.08), MPF (0.93±0.10), LPF (1.00±0.06). PSP-Non-RS DVRs: P (1.30±0.08), GP (1.36±0.12), Gpe (1.39±0.13), Gpi (1.33±0.16), SN (1.20±0.10), StN (1.25±0.12), DN (1.20±0.05), MPF (0.97±0.05), LPF (1.03±0.05). And Controls DVRs: P (1.14±0.13), GP (1.21±0.11), Gpe (1.23±0.12), Gpi (1.17±0.11), SN (1.23±0.10), StN (1.21±0.05), DN (1.19±0.07), MPF (0.97±0.01), LPF (0.97±0.02). The statistical analysis identified a significant overall

group difference for the Putamen DVR (p = 0.039), with post-hoc testing indicating significant higher DVR values in the PSP-Non-RS group compared to the Control group (p = 0.043). No other differences in DVR values were found among groups. ***Conclusion:*** [^{18}F]PI-2620 PET imaging may aid the diagnosis of patients with PSP by providing greater specificity for 4R tau deposition. In our study, we observed that PSP patients, particularly those with PSP-Non-RS, exhibit differential increases in specific subcortical structures related to PSP-associated tau 4R deposition.

A Novel Substance P Derivative Labeled With Ga68 and Lu177 as Candidates for diagnosis and Therapy of Glioblastoma Tumor
J. Abedi[1]*, s. Mozaffari*[1]*, H. Khoshhosn*[1]*, R. Nami*[1]*, N. Soltani*[1]*, M. Mehrazi*[2]*, M. Mokhtari*[1]*;*
[1]Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Trauma and Injury Research Center, Iran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Glioblastoma (GBM) is a highly aggressive brain tumor with limited effective treatment options. Substance P (SP) and its receptor, neurokinin-1 (NK1R), are known to be overexpressed in GBM, making them promising targets for novel therapies. In this study, we designed and synthesized a new SP-derived compound containing DOTA chelator. Then, we aimed to validate the methods for the labeling and quality control of it with gallium (^{68}Ga) and Lutetium (^{177}Lu) to enhance its diagnostic and potential therapeutic applications. In-vivo bio distribution studies on normal mice were done ***Materials and Methods:*** A new SP-based analog was designed and evaluated by docking software, then synthesized and radiolabeled with Ga68 and Lu177. The labeling process and quality control of this new compound were validated through a series of experiments. The stability, protein binding and partition coefficient were examined. Furthermore, biodistribution studies in normal mice and dosimetry investigations were performed. ***Results:*** The novel SP derivative was significantly interacted with crystal structure of NK_1R from PDB and displayed binding energies around -8 kcal/mol. The radiolabeling method showed an average radiochemical yield of 65% and the radiochemical purity more than 98% after work up preparation for ^{68}Ga. Also, the average radiochemical yield and purity (without any work up) was more than 98% for ^{177}Lu. Protein binding to human serum was 51% and 63% for ^{68}Ga and ^{177}Lu respectively. It was stable up to 4 h after labeling with ^{68}Ga and was stable up to 5 days with ^{177}Lu in saline and human serum. A value of -1.26 log P was calculated for radiolabeled peptide with ^{68}Ga and -0.82 log P was calculated with ^{177}Lu. The most accumulation of ^{68}Ga activity in normal organs were done in kidneys, intestines and salivary glands regions 1 h and 2 h post-injection of radiopeptide. ***Conclusion:*** Our newly synthesized SP derivative demonstrates good radiolabeling capability and stability make it a promising candidate for future GBM diagnostics and targeted radionuclide therapy of GBM metastatic cancers. Also, our studies on GBM cell lines and preclinical investigations using xenograft mice models to assess tumor uptake are on going for further analysis and conclusions. ***References:*** Glioblastoma Multiforme: A Review of its Epidemiology and Pathogenesis through Clinical Presentation and TreatmentSynthesis and evaluation of a novel 64Cu/67Ga-labeled neurokinin 1 receptor antagonist for in vivo targeting of NK1R-positive tumor xenografts

EPS-137
Streamlining [^{18}F]F-JK-PSMA-7 production: A GMP-compliant alternative to HPLC purification using solid-phase extraction
E. Cazzola, *C. Favaretto, L. Pennacchio, J. Amico, D. Peruzzi, N. Bergamaschi, P. Bovone, M. Malachini, G. Gorgoni;*
Ospedale Sacro Cuore, Negrar, ITALY.

Aim/Introduction: [^{18}F]F-JK-PSMA-7 is a fluorinate-18 PSMA alternative tracer used for PET imaging of prostate cancer. Thanks to its high specificity and affinity for PSMA, it enables effective detection, staging, and monitoring of disease progression as well as treatment response [1]. Currently, its production involves nucleophilic aromatic substitution followed by acid deprotection and High-Performance Liquid Chromatography (HPLC) purification in a Trasis AllinOne (AIO) module. However, HPLC purification is a bottleneck due to limited module availability and potential technical failures. This study explores an alternative purification pathway to streamline the production by reducing synthesis steps and time. ***Materials and Methods:*** [^{18}F]F-JK-PSMA-7 was synthesized using a Trasis AIO module, following the standard AIO protocol up to the crude reactor step. At this stage, the reaction was quenched and transferred outside the module for further processing. Various solid-phase extraction (SPE) systems, including C-18, HLB, and CM cartridges, were tested for purification. The obtained purified solutions were analyzed via HPLC and Thin Layer Chromatography (TLC) to compare yields, radiochemical purity (RCP), and chemical purity against the non-purified crude product. ***Results:*** After the synthesis, HPLC analysis of the crude reaction mixture identified impurities, including unbound fluorine-18, partially deprotected intermediates and unknown species. Among all the processes tested, purification of [^{18}F]F-JK-PSMA-7 using C-18 cartridges effectively trapped the product, with water washes efficiently removing inorganic impurities while retaining the desired compound on the cartridge. Additional washing steps with water and 20% ethanol further eliminated residual impurities. The final elution with 2 mL of 50% ethanol achieved a recovery yield of approximately 70%, a radiochemical purity (RCP) exceeding 99%, and chemical impurity levels compliant with the limits specified in the draft monograph reported in Pharmeuropa [2] . The same process using HLB cartridges resulted in high purity product, though recovery was initially low (55%). Recovery efficiency was significantly improved by replacing

water with saline in all solutions. ***Conclusion:*** Cartridge-based SPE purification presents a robust and GMP-compliant alternative to HPLC for the production of [^{18}F]F-JK-PSMA-7. This method streamlines operations, reduces the risk of cross-contamination and operator errors, and improves the overall reliability of synthesis. Furthermore, it significantly shortens production time and enhances yield while maintaining full compliance with the draft European Pharmacopoeia monograph for [^{18}F]F-JK-PSMA-7. ***References:*** [1] B. D. Zlatopolskiy et al., J Nucl Med, 2019, 60:6. [2] Pharmeuropa vol 36.1., 2024.

Quality control of Actinium-225: Francium-221 to be or not to be?

D. Abou[1,2], *M. Toro-Gonzalez*[1], *L. Wheeless*[1], *L. Van Epern*[1], *M. Hommen*[1], *V. Tangadanchu*[1], *C. Hawkins*[1], *T. Drum*[1], *D. Devries*[1]; *[1]Northstar Medical Radioisotopes LLC., Beloit, WI, UNITED STATES OF AMERICA, [2]Washington University School of Medicine, Mallinckrodt Institute of Radiology, St. Louis, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: Actnium-225 radiopharmaceuticals have drawn great interest in cancer therapy due to their tumor-specific delivery of cytotoxic alpha-particles. Detection and quality control (QC) is a critical issue for these potent agents. Direct ^{225}Ac (9.92 days) detection is challenging, however gamma-emitting progeny include ^{221}Fr (4.8 min, 218 keV) and ^{213}Bi (45 min, 440 keV). There is no consensus for best practice of ^{225}Ac QC. We compared multiple analytical methods for accurate quantification of ^{225}Ac and Drug Product (DP) radiochemical purity (RCP%) across several techniques. ***Materials and Methods:*** Accurate ^{225}Ac quantification was first evaluated using both ^{221}Fr and ^{213}Bi in gamma-ray spectroscopy over 30 d. In a DP context, the RCP% of an ^{225}Ac-labeled DOTA-peptide was defined by Thin Layer Chromatography (TLC) at secular equilibrium for ^{221}Fr and ^{213}Bi. We compared two TLC plate readers: a gas proportional counter, under mixed emission and alpha specific parameters; and a plastic silicon photomultiplier detector. TLC sections were also evaluated using High Purity Germanium (HPGe), liquid scintillation (LS) and NaI gamma-well counting. We correlated these methods to gamma counting of HPLC fractions measured at both equilibriums utilizing multiple energy windows. All instruments were checked for suitability of ^{225}Ac detection with determination of linearity (R^2>0.99) and limit of quantification (LOQ). ***Results:*** ^{225}Ac decay measured using HPGe demonstrated alignment to the reported half-lives for both ^{213}Bi and ^{221}Fr. Each instrument reported different LOQs with 0.5 nCi for NaI, 20 pCi for LS, and 400 pCi (^{213}Bi)/980 pCi (^{221}Fr) for HPGe. These values placed LS and HPGe as the most sensitive tools to quantify ^{225}Ac on TLC. TLC plate-reader using the plastic silicon detector resulted in significant RCP% differences between 30 min and >5h readings, whereas the gas proportional counter showed no-significant differences between alpha-specific (30 min) and the mixed-isotope setting (>5h). HPGe-TLC demonstrated equivalent RCP% for both ^{221}Fr and ^{213}Bi at equilibrium. NaI and LS significantly underestimated RCP% at 30 min. Finally, gamma counting of HPLC fractions resulted in 3-5 % underestimation at ^{221}Fr equilibrium. ***Conclusion:*** ^{225}Ac half-life determination was equivalent using ^{221}Fr or ^{213}Bi gamma-rays. Early measurements at 30 min accurately reported RCP% using HPGe and the gas proportional TLC reader. However, all other techniques required ^{213}Bi equilibrium for accurate determination. With the low radioactive concentration of ^{225}Ac radiopharmaceutical, the ultra-low sensitivity of HPGe or LS meet the requirement of detection at 0.5% ^{225}Ac impurities, where other instruments fail.

EPS-139

Direct Alpha Spectroscopy for Detection of ^{225}Ac Radiopharmaceuticals in Cancer Cells

M. Farasat[1], *B. Saeedi Saghez*[1], *L. Wharton*[1], *S. Shapiro*[2], *C. Vinnick*[3], *M. Daignault*[3], *M. Kostashuk*[4], *N. Pranjatno*[3], *M. Weiman*[1], *C. Andreoiu*[3], *H. Yang*[1], *P. Kunz*[1]; *[1]TRIUMF, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA, [3]Simon Fraser University, Burnaby, BC, CANADA, [4]McMaster University, Hamilton, ON, CANADA.*

Aim/Introduction: Targeted alpha therapy (TAT) employs alpha-emitting radionuclides conjugated to tumour-specific ligands to deliver highly localized cytotoxic radiation, offering significant potential for treating metastatic cancers. Among these radionuclides, Actinium-225 (^{225}Ac, $t_1/_2$ = 9.9 days) stands out due to its emission of four high-energy alpha particles through its decay chain, resulting in potent, localized tumour cell damage. However, complete retention of ^{225}Ac and its radioactive daughters at the target site is uncertain due to nuclear recoil, leading to redistribution and potential off-target toxicity. Thus, there is a critical need for methods that allow direct, real-time observation of alpha-emitting radiopharmaceuticals in live cells to better understand uptake, retention, and redistribution dynamics. This study aims to address these challenges by developing a direct alpha spectroscopy method for in vitro investigation of ^{225}Ac radiopharmaceuticals. ***Materials and Methods:*** AR42J rat pancreatic tumour cells expressing somatostatin receptor 2 (SSTR2), were incubated with three radiopharmaceutical formulations: [^{225}Ac]Ac-crown-TATE, [^{225}Ac]Ac-DOTA-TATE, and [^{225}Ac]Ac^{3+}. Post-incubation, cells were separated from the supernatant and transferred to polypropylene sample cups with thin Mylar foil bottoms. Reference samples were prepared using the same procedure but without cells. The sample cups were positioned approximately 100 µm from the custom designed Bio-sample Alpha Detector (BAD) system, a silicon-based detector for direct alpha spectroscopy operating under ambient conditions. Decay spectra were recorded for incubated cells resuspended in media, corresponding supernatants, and reference samples. Comparative analysis of the spectral profiles was conducted to evaluate uptake and validate the method. ***Results:*** Distinct alpha spectral signatures were observed between cell samples, supernatants, and reference controls, confirming cellular uptake of the radiopharmaceuticals. Detection of ^{213}Po, a decay daughter of ^{225}Ac, in the supernatant indicates partial retention and release of decay products from the cells, offering insights into intracellular retention and radionuclide redistribution. Preliminary data support the feasibility of using the BAD system for the quantitative assessment of alpha-emitting radiopharmaceuticals in biological samples. Geant4 simulations confirmed the alignment of experimental data with theoretical models, validating the method's accuracy. ***Conclusion:*** The BAD system offers a novel, vacuum-free method for the direct detection of alpha emissions in biological samples. This approach enables quantification of cellular uptake and analysis of ^{225}Ac retention and redistribution. It offers a valuable tool for studying radionuclide behavior and microdosimetry in radiopharmaceutical research.

EPS-140

Development and Optimization of [68Ga]68Ga-DOTA-EMP-100 for Non-invasive PET Imaging and Targeted Radioligand Therapy of c-MET Overactivation in Cancer

S. Migliari[1], *C. Portal*[2], *A. Gibson*[2], *A. Gagliardi*[1], *A. Guercio*[1], *M. Scarlattei*[1], *G. Baldari*[1], *L. Ruffini*[1]; *[1]Nuclear Medicine Division, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY, [2]Edinburgh Molecular Imaging Ltd., Edinburgh, UNITED KINGDOM.*

Aim/Introduction: c-MET is a transmembrane receptor involved in various biological processes, including cell proliferation and migration, particularly during cancer invasion. Overactivation

of the HGF/c-MET signaling pathway is associated with many cancers, making its inhibition a promising therapeutic strategy. Although c-MET expression is typically assessed through immunohistochemistry on tissue samples, this technique has certain limitations. PET-CT offers the potential for in vivo mapping of c-MET-expressing lesions, enabling whole-body detection. The development of a specific c-MET radioligand for PET imaging and radioligand therapy offers a potential alternative, allowing non-invasive, real-time monitoring of target expression while simultaneously enabling a targeted treatment approach. Several radiopharmaceuticals are being developed for this purpose but are not yet used routinely in clinical practice. EMP100 is a cyclic oligopeptide linked to a DOTA chelator, exhibiting nanomolar affinity for c-MET (3.0 ± 0.5 nM) [1-2]. The aim of this project was to establish an automated radiolabelling method for the radiopharmaceutical [^{68}Ga]Ga-DOTA-EMP100. ***Materials and Methods:*** Radiosynthesis of [^{68}Ga]Ga-DOTA-EMP100 was performed using a GMP-certified ^{68}Ge/^{68}Ga generator connected to an automated synthesis module. The radiopharmaceutical production was optimized, scaling down the amount of DOTA-EMP-100 from 50 to 20 µg (50-40-30-20 µg). Synthesis efficiency and release criteria were assessed according to Ph. Eur. for all the final products evaluating radiochemical yield (RY%), radiochemical purity (RCP% = 100%-colloids-ions), presence of free gallium (by Radio-UV-HPLC) and gallium colloids (by Radio-TLC), molar activity (Am), chemical purity, pH and LAL test. Once the method was optimized, the process and the final product were validated with three consecutive syntheses whose stability was assessed over time. ***Results:*** Best results were yielded with 40 µg DOTA-EMP-100 with optimal RY% (64.93%), RCP% (100%) and molar activity (53.08 GBq/µmol). The process validation (three batches produced on three different days) confirmed optimal RY% (mean value 64.50 %) and molar activity (mean value 53.41 GBq/µmol). Finally, the stability of [^{68}Ga]Ga-DOTA-EMP100 was evaluated at room temperature over a 4-hour period, with satisfactory results regarding its appearance, pH, radiochemical purity, and sterility. ***Conclusion:*** [^{68}Ga]Ga-DOTA-EMP100 was successfully synthesised according to Ph. Eur. criteria and is now available for clinical development in PET-CT imaging. ***References:*** [1] Mittlmeier LM, et al. Eur J Nucl Med Mol Imaging. 2022 Apr;49(5):1711-1720. [2] Rusu T, et al. Development of CYP11B2 selective pyridinylbenzimidazole derivatives for pathological analysis of primary aldosteronism

Y. Yagi[1], *H. Kimura*[2], *R. Fuseda*[3], *T. Murakami*[4], *M. Omokawa*[5], *S. Kise*[6], *M. Sone*[7], *H. Yasui*[3], *N. Inagaki*[4], *H. Saji*[8];
[1]*Kyoto University of Medical Science, Nantan, JAPAN,* [2]*Agency for Health, Safety and Environment, Kyoto University, Kyoto, JAPAN,* [3]*Kyoto Pharmaceutical University, Kyoto, JAPAN,* [4]*Kyoto University Hospital, Kyoto, JAPAN,* [5]*Okayama University, Okayama, JAPAN,* [6]*Kanazawa University, Kanazawa, JAPAN,* [7]*St. Marianna University School of Medicine, Kawasaki, JAPAN,* [8]*Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, JAPAN.*

Aim/Introduction: Primary aldosteronism (PA) is a type of secondary hypertension caused by excessive production of aldosterone in the adrenal glands, accounting for 5-10% of hypertension cases. This condition is heterogeneous, with treatment options varying based on whether it is unilateral or bilateral. Unilateral PA can be effectively treated through surgery, highlighting the importance of accurate diagnosis. However, invasive procedures like adrenal vein sampling are often necessary, as non-invasive imaging techniques such as CT and MRI may not provide sufficient diagnostic information. We propose that a non-invasive nuclear medicine diagnostic approach could enhance the diagnosis of PA. To this end, we have developed a molecular probe specific to CYP11B2, which is overexpressed in patients with PA. We focused on a pyridinylbenzimidazole structure known for its selective inhibitory activity against CYP11B2 and proceeded to synthesize and evaluate its derivatives. ***Materials and Methods:*** We developed and synthesized four derivatives of pyridinylbenzimidazole (designated as PBI-1 to PBI-4). Their inhibitory effects on CYP11B2 and selectivity against CYP11B1 were assessed using V79 cells transfected with these enzymes. The synthesized derivatives were subsequently radiolabeled with either I-125 or F-18, and a biodistribution study of the radiotracers was conducted in healthy mice. Lastly, we performed in vitro autoradiography (ARG) using adrenal tissue slices from patients with PA to assess the selectivity for CYP11B2 compared to CYP11B1. ***Results:*** We obtained iodine-containing PBI-1 and PBI-2 for SPECT and fluorine-containing PBI-3 and PBI-4 for PET with relatively good yields. Inhibition assays revealed that PBI-2 and PBI-4, which are fluorochlorobenzene-containing compounds, exhibited high inhibitory activity and selectivity (IC_{50}: PBI-2 = 0.47±0.19 nM, PBI-4 = 0.25±0.05 nM; Ratio: PBI-2 = 245, PBI-4 = 625). We obtained [^{125}I]PBI-2 and [^{18}F]PBI-4. The biodistribution experiment of [^{18}F]PBI-4 showed accumulation in the adrenal glands (5.76±2.00 %ID/g at 5 min). In vitro ARG analysis using human adrenal slices demonstrated higher accumulation of radioactivity in the CYP11B2 region compared to the CYP11B1 region. This result is consistent with the findings from the cell experiments. Therefore, these results suggest that [^{18}F]PBI-4 has high selectivity for CYP11B2. ***Conclusion:*** The newly designed radioiodinated [^{18}F]PBI-4 may serve as a promising PET probe for imaging primary aldosteronism. ***References:*** ACS Medicinal Chemistry Letters 6 (5), pp 573-578, (2015)

EPS-142

La-[$^{18/19}$F]fluoride Complexes: a novel addition to the radiofluorination family.

R. Faizova[1], *S. Gruber*[2], *L. Mu*[3], *M. Schottelius*[1], *M. Behe*[4];
[1]*Lausanne University Hospital, Lausanne, SWITZERLAND,* [2]*ETH Zurich, Zurich, SWITZERLAND,* [3]*ETH Zurich, Zürich, SWITZERLAND,* [4]*Paul Scherrer Institute, Villigen, SWITZERLAND.*

Aim/Introduction: Theranostics, an approach combining diagnostic imaging and targeted therapy, has seen an explosion of research and clinical applications in recent years. With fluorine-18 being the most widely clinically used PET isotope, many groups are developing various strategies for incorporating fluorine-18 into theranostic companion tracers. Among modern ^{18}F-labeling strategies, the one-step synthesis of metal-[^{18}F]fluoride coordination species has emerged as a particularly straightforward radiofluorination method, with examples including AlF^{2+}, ScF^{2+}, GaF^{2+}, and FeF^{2+} coordination complexes. Here, we introduce a new member of the family: a series of novel La-[$^{18/19}$F]fluoride complexes, alongside studies of their stability and reactivity. ***Materials and Methods:*** A series of La-[^{19}F]fluoride coordination complexes with various macrocyclic chelators (DOTA, DOTAM, macropa, and DOTpy) was prepared, both in organic and aqueous media. The ^{19}F-fluorination of the resulting La complexes was investigated in organic and aqueous media. The reactions were monitored by ^{19}F and ^{1}H NMR spectroscopy, LC-MS, and X-ray spectroscopy. Upon verification of [^{19}F]LaF complex formation, selected complexes were further evaluated for ^{18}F-fluorination, and their stability and reactivity were assessed in vitro. Additionally, a DFT study was conducted to further elucidate the factors governing the stability and reactivity of the different La-fluoride complexes. ***Results:*** Generally, the stability in and reactivity with water of the La-chelates was found to strongly depend on the chelator used, with chelators providing more electronegative donor atoms resulting in lower stability of the corresponding La-complexes towards defluorination. The [^{19}F]LaF complexes with macropa and DOTpy were found to be particularly stable in organic solution and were isolated and fully characterized. Furthermore, for the DOTpy-complex, ^{18}F-fluorination (MeOH, 60°C, 20 min) yielded the desired [^{18}F][LaF(DOTpy)]OTf_2 in 90% radiochemical

yield (based on starting ^{18}F-fluoride). The results of the DFT study will be reported. ***Conclusion:*** In this study, we have demonstrated the synthesis of first-in-class La[$^{19/18}$F]fluoride coordination complexes with several (macrocyclic) chelators. The stability of the resulting [$^{18/19}$F]LaF complexes was found to be inversely correlated with the ligand's electron-donating properties, with less electronegative ligands resulting in more stable complexes. This work serves as a proof-of-concept and offers new possibilities for theranostic approaches beyond [La-F] chemistry. Specifically, the further development and application of this approach to ^{225}Ac-radiopharmaceuticals is currently being investigated, which may enable personalized dosimetry and therapy control of ^{225}Ac-based targeted alpha therapy on quantitative PET imaging.

EPS-143

Radiochemistry and Evaluation of Novel Selective α-Synuclein Fibrils tracers for Parkinson's Disease

N. Mortazavi Golsefidi[1], *B. Uzuegbunam*[2], *M. Luster*[1], *D. Librizzi*[1,3], *B. Hooshyar Yousefi*[1,4];
[1]*Department of Nuclear Medicine, School of Medicine, Philipps University Marburg, Marburg, GERMANY,* [2]*Department of Nuclear Medicine, Technical University of Munich, and Isotope Technologies Munich (ITM), Munich, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital OWL, Evangelisches Klinikum Bethel, Bielefeld, GERMANY,* [4]*Preclinical Imaging Core Facility, Center for Tumor Biology and Immunology (ZTI), Philipps University Marburg, Marburg, GERMANY.*

Aim/Introduction: A selective ^{18}F-labelled tracer for the detection of α-synuclein fibrils (α-syn) is crucial for early diagnosis and better understanding of Parkinson's disease (PD) and other α-synucleinopathies. Existing imaging techniques lack the specificity and sensitivity required for in vivo detection of α-syn fibrils, presenting a significant challenge worldwide. Developing selective ^{18}F-labeled positron emission tomography (PET) tracers is therefore an urgent unmet need, with the potential to revolutionize clinical diagnosis, enable precise patient stratification, and monitor therapeutic interventions. 4,4´-Disarylbisthiazoles (DABTA) have shown exceptional binding affinity to α-syn and high selectivity over β-amyloid plaques (Aβ) and tau fibrils, making them promising PET tracer candidates. These ligands were designed to be easily labeled with fluorine-18 ([^{18}F]), a radionuclide with an optimal half-life and energy profile for PET imaging. ***Materials and Methods:*** In this study, over 80 DABTAs with tailored functional groups were evaluated, and 10 lead compounds were identified for radiolabeling via ^{18}F-nucleophilic substitution using various leaving groups. The radiotracers were purified using high-performance liquid chromatography (HPLC) and comprehensively characterized through in vitro and in vivo studies. Typical preclinical evaluation and autoradiography on post-mortem human brain tissues from subjects of Multiple System Atrophy (MSA) with Glial Cytoplasmic Inclusions (GCIs), Dementia with Lewy Bodies/Parkinson's Disease (DLB/PD), Aβ- and tau-pathology, and healthy control were carried out. ***Results:*** Radiolabeling was accomplished through a one-step procedure, achieving radiochemical yields (RCYs) of 4-32% (n = 43), with a radiochemical purity of over 99% confirmed by HPLC and radio-TLC. Non-radioactive reference compounds validated the tracer identities. Notably, FS4, FS5, FS8, and FS9 exhibited significantly higher RCYs (14-32%). Post-mortem autoradiography at 0.2 MBq/mL demonstrated high-contrast binding for most of DABTAs, particularly [^{18}F]FS4, [^{18}F]FS5 and [^{18}F]FS9, in α-synuclein-rich brain regions. ***Conclusion:*** All lead DABTAs were successfully radiolabeled, with FS4, FS5, and FS9 displaying superior radiochemical yields and imaging performance. Their strong binding specificity and enhanced imaging capabilities in small animal imaging highlight their potential for translational research, including longitudinal PET/CT studies in PD animal models (will be presented in another abstract). These findings contribute to our effort in developing effective diagnostic tools for neurodegenerative diseases.

EPS-144

CADD-Guided Optimization and Synthesis of Novel CD13-Targeting PET Probes for Precision Management of Prostate Cancer

T. Liying, *Z. Ming, H. Shou;*
Xiangya Hospital, Central South University, Hunan Province, CHINA.

Aim/Introduction: Prostate cancer (PCa) ranks as the second most prevalent malignancy among men worldwide, with both incidence and mortality rates continuing to rise annually. Early and precise diagnosis and treatment are critical for improving patient prognosis. Previous research identified CD13 as a novel molecular target highly expressed in PCa, leading to the development of the targeted probe [^{18}F]AlF-CD13-L1. However, this probe exhibited limited binding affinity for CD13. Given the demonstrated efficacy of computer-aided drug design (CADD) in optimizing molecular structures for enhanced pharmacological properties, this study aims to employ CADD-based rational optimization of the precursor CD13-L1 to develop a next-generation probe with superior CD13 affinity. ***Materials and Methods:*** The CADD-optimized precursors were radiolabeled with ^{68}Ga, yielding probes [^{68}Ga]Ga-CD13-L2 and [^{68}Ga]Ga-CD13-L3. Cellular uptake studies and small-animal PET/CT imaging were performed using CD13-expressing prostate cancer cells line PC3 and corresponding xenografts. Tumor tissues were analyzed via IHC and HE staining. For therapy evaluation, CD13-L3 was labeled with ^{177}Lu, and the efficacy of [^{177}Lu]Lu-CD13-L3 was assessed in PC3 xenografts, with [^{177}Lu]Lu-CD13-L1 as a control. ***Results:*** We successfully optimized and synthesized two novel CD13-targeting precursor through CADD. The cellular uptake of [^{68}Ga]Ga-CD13-L3 in PC3 cells reached 1.99 ± 0.06%, demonstrating significantly higher accumulation compared to [^{68}Ga]Ga-CD13-L1 and [^{68}Ga]Ga-CD13-L2 (0.7 ± 0.08% and 1.19 ± 0.01%, respectively). This uptake was specifically inhibited by excess unlabeled peptide for all three probes. In PC3 xenograft models, PET imaging at 30, 60, and 90 minutes post-injection revealed superior tumor uptake of [^{68}Ga]Ga-CD13-L3 (2.04 ± 0.11 %ID/g at 90 min) versus [^{68}Ga]Ga-CD13-L1 and [^{68}Ga]Ga-CD13-L2 (0.4 ± 0.04 and 0.72 ± 0.10 %ID/g, respectively). Histopathological analysis confirmed successful tumor engraftment (HE staining) and high CD13 expression in tumor tissue (IHC). Therapeutic evaluation demonstrated that [^{177}Lu]Lu-CD13-L3 significantly inhibited tumor growth ($P < 0.005$) and extended survival compared to both saline controls and [^{177}Lu]Lu-CD13-L1 treatment groups. ***Conclusion:*** We have successfully optimized CD13-targeting precursors and synthesized novel PET probes with enhanced binding affinity. These advancements are anticipated to fully unlock the clinical potential of CD13 in prostate cancer (PCa) applications, ultimately advancing precision diagnosis and targeted therapy for PCa.

EPS-145

Developing covalent radiotracers for detection of neurodegenerative proteinpathies

P. Liu[1], *Z. Liu*[1,2];
[1]*Changping Labrotary, Beijing, CHINA,* [2]*Peking University, Beijing, CHINA.*

Aim/Introduction: To address the critical unmet challenge of developing PET radiotracers for low-abundance pathological aggregates in neurodegenerative diseases, we aimed to harness covalent radiotracers, a novel theranostic strategy, to overcome limitations in target engagement and signal-to-noise ratios.[1] These aggregates include Non-Alzheimer's tauopathies (e.g., progressive supranuclear palsy (PSP), corticobasal degeneration (CBD)), α-Synuclein in Parkinson's disease (PD), TDP-43 inclusions

in frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS). ***Materials and Methods:*** Building on the covalent radiotracer paradigm pioneered by Liu et al.[1], we employed computer-aided drug design (CADD) to develop irreversible covalent probes targeting tau protein. A covalent screening assay was developed to evaluate synthesized compounds for pathological tau aggregates using autoradiography with human postmortem brain tissue slices. Lead covalent molecules were further characterized for binding affinity (K_d) and kinetics across tauopathy subtypes, as well as selectivity against off-target tissues (e.g., amyloid-laden AD cortex and α-synuclein-rich PD midbrain). Pharmacokinetic profiles of the top candidate were assessed in healthy rats via dynamic PET imaging and ex vivo biodistribution studies to quantify brain uptake, clearance rates, and off-target retention. ***Results:*** The covalent tau probes demonstrated high specificity for pathological aggregates in human postmortem brain tissues, with autoradiography revealing preferential binding to tau lesions in AD, PSP, and CBD cases. The lead compound, Tau-3, exhibited nanomolar binding affinity for non-AD-derived tau fibrils and slower dissociation kinetics compared to non-covalent reference tracers (>3-fold improvement). Selectivity profiling confirmed negligible off-target binding to amyloid-β plaques in AD cortex or α-synuclein aggregates in Parkinson's disease (PD) midbrain. In healthy rats, dynamic PET imaging demonstrated rapid blood-brain barrier penetration and efficient systemic clearance, with ex vivo biodistribution studies revealing minimal residual brain activity (<1% ID/g at 90 min). ***Conclusion:*** These results validate the potential of covalent probes for detecting sparse pathological aggregates. Clinical translation is now underway through investigator-initiated trials (IITs) to evaluate efficacy in humans. This work establishes a foundational platform for developing next-generation neurological covalent probes tailored to low-abundance aggregates, bridging the gap between preclinical validation and clinical application. The platform holds transformative potential for addressing the unmet diagnostic needs across diverse proteinopathies. ***References:*** Cui et al., Nature 2024, 630, 206

Tetrazine Ligation Meets αvß6 Integrin-Targeted PET Imaging: Radiosynthesis and Preclinical Evaluation of ^{18}F-Flutrahexin

M. Martin[1], *V. Morath*[2], *F. Reissig*[3], *U. M. Battisti*[1,4], *N. Holzleitner*[2,5], *S. Stangl*[2,5], *V. Shalgunov*[1,6], *A. T. I. Jensen*[1], *J. Notni*[3], *S. Kossatz*[2,5], *M. M. Herth*[1,4,6];
[1]*TetraKit Technologies ApS, Copenhagen, DENMARK,* [2]*Department of Nuclear Medicine, TUM University Hospital, School of Medicine and Health, Technical University Munich, Munich, GERMANY,* [3]*TRIMT GmbH, Radeberg, GERMANY,* [4]*University of Copenhagen, Department of Drug Design and Pharmacology Faculty of Health and Medical Sciences, Copenhagen, DENMARK,* [5]*Central Institute for Translational Cancer Research (TranslaTUM), School of Medicine and Health, Technical University, Munich, GERMANY,* [6]*Rigshospitalet, Department of Clinical Physiology, Nuclear Medicine & PET, Copenhagen, DENMARK.*

Aim/Introduction: The integrin αvβ6 is a transmembrane receptor that is overexpressed in various epithelial cancers. The αvβ6-targeting radioligand ^{68}Ga-Trivehexin consists of three cyclic nonapeptides attached to a central TRAP-chelator and showed highly promising tumor imaging capabilities (pre) clinically in various cancers. These include pancreatic (PDAC), lung (NSCLC), head and neck (HNSCC), papillary thyroidal Ca, parathyroid adenoma including brain metastases as well as (lung) fibrosis. Here we report the synthesis and preclinical evaluation of ^{18}F-Flutrahexin, an ^{18}F-labelled analog of ^{68}Ga-Trivehexin, comprising three nonapeptide targeting vectors, a DOTPI chelator and the trans-cyclooctene T4CO to be labelled via tetrazine ligation. ***Materials and Methods:*** The tetrazine ^{18}F-FlutraTag was synthesized from the corresponding nosyl precursor (dried ^{18}F-tetrabutylammonium fluoride, MeCN, 100 °C, 3 min). The purified ^{18}F-FlutraTag was then clicked to the T4CO-modified click precursor in the presence of gentisic acid. After acid-mediated oxidation (r.t., 30 min), ^{18}F-Flutrahexin was purified by C18-SPE, eluted with EtOH, concentrated, and diluted with PBS. The pharmacokinetic profile of ^{18}F-Flutrahexin was investigated via dynamic and static PET imaging in healthy female Sprague-Dawley rats and mice bearing αvβ6-expressing human lung adenocarcinoma xenografts (H2009), followed by organ biodistribution via gamma-counting. In vivo specificity was assessed via blocking with ^{nat}Ga-Trivehexin. Gelofusine co-injection was investigated for kidney protection. ***Results:*** ^{18}F-FlutraTag was obtained in RCY = 10-30% and RCP > 98%. After quantitative click and oxidation ^{18}F-Flutrahexin was obtained from ^{18}F-FlutraTag in RCY = 60-80%, RCP > 95% and molar activity A_m = 9-20 GBq/µmol. In healthy rats, the radiotracer showed fast clearance from blood, renal excretion and high uptake only in the kidneys, which was reduced by a factor of 3 with gelofusine (90 min p.i.: 30 vs. 9 %ID/g). In xenograft-bearing mice, PET imaging visualized H2009 xenografts with high tumor-to-background contrast. Tumor uptake reached 7% ID/g 90 min p.i., while uptake in other organs was overall low, except for the kidneys, resulting in a tumor-to-blood ratio of 3 and tumor-to-muscle ratio of 14 (90 min p.i). Specificity was demonstrated by blocking with excess ^{nat}Ga-Trivehexin, which reduced tumor uptake from 7 to 1 %ID/g. ***Conclusion:*** Overall, ^{18}F-Flutrahexin performed similar to ^{68}Ga-Trivehexin and offers a promising alternative to for high-resolution PET imaging of αvβ6-positive tumors. Furthermore, it seems feasible to expand to a theranostic approach by using tetrazines labelled with radiohalogens like iodine-131 or astatine-211 in combination with gelofusine kidney protection.

EPS-147

Synthesis and Evaluation of a High Affinity and Long-time Retention CXCR4-Targeted Probe

X. Yu, *M. Zhang, G. Li, W. Yang, J. Wang, F. Kang;*
Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi, CHINA.

Aim/Introduction: C-X-C chemokine receptor type 4 (CXCR4) is indispensable to the development of many inflammatory disorders and malignant tumors, such as multiple myeloma and non-Hodgkin lymphomas. ^{68}Ga-PentixaFor, a radioligand targeting CXCR4, exhibits a strong affinity for CXCR4 both in vivo and in vitro. However, ^{68}Ga-PentixaFor PET still has some limits. This study aimed to develop a higher affinity and long-time retention radiotracer for CXCR4-targeted imaging to improve the detection efficiency. ***Materials and Methods:*** The new precursor Pentikra was synthesized with a positively charged tripeptide linker, D-Lys-D-Arg-D-Ala, between the chelator and the targeting peptide of iodoCPCR4. The in vitro stability of ^{68}Ga-Pentikra was evaluated in both PBS and mouse serum. The partition coefficient of ^{68}Ga-Pentikra was evaluated. The cell binding and internalization studies of ^{68}Ga-Pentikra, ^{68}Ga-PentixaFor and ^{68}Ga-PentixaTher were performed in CXCR4 positive cells (CHO-hCXCR4). The affinity assay of these three tracers was performed with CHO-hCXCR4cell line. Static PET imaging studies (1h, 2h, 3h and 4h p.i.) were performed in CHO-hCXCR4 and CHO-control tumor xenograft bearing NOD-SCID mice respectively, and the 90-min dynamic imaging PET studies of the three tracers were performed with CHO-hCXCR4 tumor xenograft bearing NOD-SCID mice only. ***Results:*** ^{68}Ga-Pentikra was stable in both PBS and mouse serum for 2 h. The lipophilicity of ^{68}Ga-Pentikra were -2.88 ± 0.14, which was comparable to those of ^{68}Ga-PentixaFor and ^{68}Ga-PentixaTher. The IC_{50} of Pentikra was 21.95 ± 6.66 nM, which was significantly lower than those of PentixaFor and PentixaTher (477.8 ± 14.86

and 277.5 ± 8.75 nM). In cell studies, the total binding rate and the internalization rate of ^{68}Ga-Pentikra at 120 min was 49.3 ± 4.4% and 20.9 ± 0.92%, which was significantly higher than those of ^{68}Ga-PentixaFor and ^{68}Ga-PentixaTher. PET studies, though the hepatic of ^{68}Ga-Pentikra is high, the SUVmean of ^{68}Ga-Pentikra in CHO-hCXCR4 tumor was 4.25 ± 1.02, which was higher than those of ^{68}Ga-PentixaFor and ^{68}Ga-PentixaTher (3.95 ± 0.60 and 2.25 ± 0.73). In the dynamic PET imaging, the tumor accumulation of ^{68}Ga-Pentikra kept increasing within 90 minutes, which was similar to those of ^{68}Ga-PentixaFor and ^{68}Ga-PentixaTher. ***Conclusion:*** In this study, a novel CXCR4-targeted probe was successfully synthesized and labeled with ^{68}Ga. Due to the high affinity of ^{68}Ga-Pentikra to hCXCR4 and the enhanced cellular retention in CXCR4 overexpressed tumors, ^{68}Ga-Pentikra may have great potential in the application of CXCR4 targeted diagnosis and treatment.

EPS-148

Chelator-free gallium-68 labeling of Nanoclays for in vivo tracking

N. Liu;
The First Affilated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.

Aim/Introduction: Nanoclays are an important class of mineral-based herbal medicines that have been widely studied as nanocarriers for drug delivery owing to their large specific surface area, abundant porosity, good adsorption properties, and biocompatibility. However, the lack of comprehensive understanding of their in vivo biological fate has restricted their further clinical development and utilization. Radiolabeling of probes for positron emission tomography (PET) imaging can track the probes with high sensitivity and quantitativity. Herein, we envisioned to use chelator-free gallium-68-labeling to evaluate the radiopharmacokinetics of nanoclays. ***Materials and Methods:*** ^{68}Ga-labeled nanoclays were prepared by simple mixture. Size distribution and zeta potentials of nanoclays were analyzed on a Malvern Zetasizer. The radiolabeling yield of 68Ga was tested by Mini-Scan radio-TLC Strip Scanner. The labeling mechanisms was explored by density functional theory (DFT) calculations. The in vivo stability and biodistribution evaluations of nanoclays were verified by PET imaging after intravenous or gavage administration. ***Results:*** $^{68}Ga^{3+}$ can be radiolabeled on all these three nanoclays with relative high labeling yields upon a short reaction time of 10 min at 37 °C. And this labeling method exhibits good radiochemical purity and serum stability. DFT calculations revealed that the strong Coulomb adsorption between gallium ions and nanoclays contributed to this reliable radiolabeling. Importantly, the PET imaging after intravenous or gavage administration shows good in vivo radiostability during the observation time, confirming the tracing feasibility of nanoclays. ***Conclusion:*** This work provides a simple and stable radiolabeling method to visualize the biological fate of nanoclays in vivo, contributing to understanding of the metabolic pathway and possible biomedical applications of nanoclays. ***References:*** [1] J. Mater. Chem. B 2020, 8, 7335-7351. [2] Natl. Sci. Rev. 2022, 9, nwac119. [3] ACS Nano 2022, 16, 5036-5061.

EPS-149

Production of 64Cu with hybrid target

D. Szikra[1], *V. Forgács*[1], *M. Fodor*[2], *Z. Szücs*[2];
[1]*University of Debrecen, Division of Nuclear Medicine, Medical Imaging Department, Debrecen, HUNGARY,* [2]*Radiochemical Laboratory, HUN-REN Institute for Nuclear Research, Debrecen, HUNGARY.*

Aim/Introduction: 64Cu production on medium energy cyclotrons, equipped with solid target systems, is a well established procedure. The most widely used method is the 64Ni(p,n)64Cu reaction, starting from enriched 64Ni, electroplated onto an appropriate backing material. After irradiation, the target is transferred to a hot cell for dissolution and purification. The implementation of this production method requires the installation of a solid target system with shuttle transport and a dissolution unit in a dedicated hot cell. This requires high investment, which inhibits the broader application of 64Cu labelled tracers. Liquid targets are easier to install and use, but the achievable yields are significantly lower. Dissolution of the irradiated target material inside the target simplifies activity transfer between the cyclotron- and the hot cell and saves precious hot cell space in the cleanroom. ***Materials and Methods:*** Natural- or enriched 64Ni was electroplated onto platinum backings (22x0.5 mm) and mounted on the target holder of a hybrid target system. The targets were irradiated with 50-70 uA 12 MeV proton beam for 1-3 h. The irradiated nickel was dissolved from the backing with 2 ml 6 M HCl at room temperature by applying 3V constant voltage beween the backing and a platinum wire electrode, fixed into the dissolution chamber of the target. The dissolution could be monitored in real time with the observation of the cell current. After the drop of cell current, the target solution was transferred from the target to a collection vial via a PEEK capillary line and loaded onto an AG1X8 column on a Trasis miniAiO module. The purified 64Cu was eluted from the column with 8 ml 0.01 M HCl. ***Results:*** Up to 56,78 GBq 64Cu was produced from 200 mg 64Ni with 70 uA beam current during 3 hour irradiation. The dissolution of the target material was complete in 20 minutes. No nickel residues were remained on the backing. Recycling of the enriched target material was performed with approx. 2% loss. ***Conclusion:*** A new method was developed for the room temperature dissolution of irradiated nickel target material. Efficient 64Cu production was realized using the combination of a hybrid target and a Trasis miniAiO module.

EPS-150

Method for producing medical ^{90}Y via radionuclide generator: improving quality and efficiency

A. Baimukhanova[1,2], *G. Magomedov*[2,3], *V. Pokalchuk*[3], *E. Magomedbekov*[3], *D. Karaivanov*[2], *D. Filosofov*[2];
[1]*Institute of Nuclear Physics of the Republic of Kazakhstan, Almaty, KAZAKHSTAN,* [2]*Joint Institute for Nuclear Research, Dubna, RUSSIAN FEDERATION,* [3]*D. I. Mendeleev Russian University of Chemical Technology, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: A radionuclide generator provides a convenient way of producing radioisotopes. Generators based on long-lived parent radionuclides are commonly used to obtain medically relevant isotopes—for example, ^{68}Ge ($T_{1/2}$ = 270.93 d) → ^{68}Ga ($T_{1/2}$ = 67.71 min), ^{229}Th ($T_{1/2}$ = 7880 y) → ^{225}Ac ($T_{1/2}$ = 9.92 d), etc. However, over time, the quality of the radiopreparation tends to degrade due to increasing breakthrough of the parent radionuclide and decreasing yields of the daughter product. This issue necessitates the development of new chemical systems and generator configurations. One promising approach is the reverse scheme, which confines the parent radionuclide within a narrow zone on the column. This enhances the stability of the generator's performance over time and improves the quality of the radiopharmaceuticals produced[1]. In this work, we consider the potential for producing ^{90}Y using a ^{90}Sr ($T_1/_2$ = 28.91 y) → ^{90}Y ($T_1/_2$ = 64.05 h) radionuclide generator based on a reverse-tandem scheme. ***Materials and Methods:*** For developing the generator scheme, the distribution coefficients (K_d) of Sr(II) and Y(III) in a system containing ion-exchange resin and a mixed citric acid and ammonia acetate medium were determined in a previous study[2]. Based on these K_d values, efficient separation was achieved using Dowex 50×8 with a 0.1 M CH_3COOH / 0.5 M CH_3COONH_4 solution, where a separation factor is 13. The tandem part of the generator based on the solid extraction chomatography in hydrochloric acid media. ***Results:*** This radionuclide generator achives a ^{90}Y yield of more than 70%, which is a key indicator of its high efficiency in isolating and producing the desired isotope.

The low breakthrough of ^{90}Sr, less than $4{\cdot}10^{-3}$, further highlights the generator's effectiveness in minimizing the contamination of the final radiopharmaceutical product with the parent radionuclide. ***Conclusion:*** The alternative method for producing of ^{90}Y has been developed based on reverse-tandem scheme of the radionuclide generator. The resulting generator parameters ensure the production of high-purity 90Y, which is crucial for medical applications where precise dosimetry and minimal side effects are essential. The combination of a high yield and minimal breakthrough makes this generator particularly reliable and suitable for clinical use, offering stable and reproducible results over time. ***References:*** 1. EPS-151

Development of novel nanobody-based ^{68}Ga and ^{131}I radiotracers for detecting MUC16 expression in vivo

J. Han, *Y. He;*
Fudan University, Shanghai, CHINA.

Aim/Introduction: MUC16, a high-molecular-weight glycoprotein, is highly expressed in various tumors and is limited to epithelial cells of several tissues. It has already been proven to be a sensitive biomarker and a promising therapeutic target for cancer. However, it still lacks small molecule tools to map the target in vivo. Here, we describe the generation of nanobody-based Immuno-PET/-SPECT tracers that could precisely and rapidly monitor MUC16 expression in vivo. ***Materials and Methods:*** Nanobody was obtained via immunization of llama using a fragment close to N sites. The initial screening of nanobodies was evaluated through an enzyme-linked immunosorbent assay to get lead molecule VHH HF-07. Further, VHH was conjugated with p-SCN-Bn-NOTA to get NOTA HF-07, and the conjugate was continuously radiolabeled with ^{68}Ga to get the radiotracer [^{68}Ga]Ga-NOTA-HF-07. In radioiodination, HF-07 was radiolabeled, followed by two-step procedures with iso-[^{131}I]SGMIB to get iso-[^{131}I]I-SGMIB-HF-07. The radiochemical purity and in vitro stability were tested by radio-thin-layer chromatography and size exclusion chromatography, respectively. The binding of the tracers was validated by saturation binding assay. The capacity of the radiotracer to quantify the MUC16 expression was investigated in vivo in NCG mice bearing OVCAR-3 tumor models through small animal PET-CT and SPECT-CT scanners for ^{68}Ga and ^{131}I tracers, respectively. Finally, the tracers were evaluated by ex vivo biodistribution at 60 min post-injection. ***Results:*** HF-07 shows a high binding affinity toward MUC16 with an EC_{50} value of 1.3 nM. And it was still kept in the nanomolar range after conjugation and radiolabeling. ^{68}Ga and ^{131}I tracers were obtained at high radiochemical purity (>99%) with moderate radiochemical yields, 32 ± 11% for g [^{68}Ga]Ga-NOTA-HF-07 (n = 9, decay-corrected) and 22 ± 6% for iso-[^{131}I]I-SGMIB-HF-07 (n = 6, decay-corrected). Both ^{68}Ga and ^{131}I radiotracers were stable after 240 min incubation at room temperature. Micro PET/CT imaging of [^{68}Ga]Ga-NOTA-HF-07 demonstrated clear and efficient tumor visualization using NCG mice bearing OVCAR-3 xenografts with a high level of MUC16 expression. In micro SPECT/CT scan, iso-[^{131}I]I-SGMIB-HF-07 showed a longer half-life and still had uptake after 24hrs. In biodistribution studies, [^{68}Ga]Ga-NOTA-HF-07 displayed radioactivity accumulation of 1.95 ± 0.89 %ID/g and iso-[^{131}I]I-SGMIB-HF-07 showed 6.06 ± 0.48 %ID/g in OVCAR-3 xenografts at 60 min post-injection. ***Conclusion:*** Two novel nanobody-based probes targeting MUC16, [^{68}Ga]Ga-NOTA-HF-07 and iso-[^{131}I]I-NOTA-HF-07, have been developed. These tracers allow for the early acquisition of the target with clear image quality. The results revealed the radiotracer's great potential for further theranostic research.

EPS-152

Discovery of a novel [^{18}F]-labeled phenylalanine derivative PET tracer for preclinical tumor imaging

Y. Xie, *Y. Wang, H. Zhou, M. Hu, W. Chen;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Accurate diagnosis of glioma is challenging due to its invasive nature and blockade of the blood-brain barrier. Amino acid PET probes targeting large neutral amino acid transporter type-1 (LAT-1) can assist in the noninvasive grading and treatment monitoring. This study aims to develop a novel PET tracer [^{18}F]fluoro-methylated-phenylalanine ([^{18}F]FMP) through direct photocatalyzed ^{18}F-deoxyfluorination that could improve the ability to differentiate non-neoplastic lesions and identify tumor extent. ***Materials and Methods:*** [^{18}F]FMP was prepared through photocatalyzed azeotropic drying-free ^{18}F-deoxfluorination[1]. Cellular uptake experiment was performed in MCF7 and U87MG cells (n=3). Biodistribution studies and imaging efficacy were evaluated in rodent models (n=5). ***Results:*** [^{18}F]FMP demonstrated high radiochemical purity (>99%) and yield (28.3 ± 1.1%, n=3, non-decay corrected). As a pan-cancer probe, the micro-PET in MCF7 and U87MG tumor-bearing mice showed superior tumor uptake for [^{18}F]FMP (SUV_{max} = 6.03 ± 0.34, 2.89 ± 0.43) compared to [^{18}F]FET (SUV_{max} = 3.30 ± 0.36, 1.42 ± 0.15) with high stability. Biodistribution of U87MG tumor in mice at 15, 30, 60, and 120 minutes after intravenous administration was 10.76 ± 1.24%ID/g, 9.58 ± 1.95%ID/g, 8.44 ± 0.96%ID/g, and 9.26 ± 1.80%ID/g. Competition inhibition assays of in vitro cancer cells and in vivo micro-PET imaging suggested [^{18}F]FMP is LAT-1 specific. ***Conclusion:*** We successfully developed a novel radiotracer [^{18}F]FMP via an efficient azeotropic drying-free photolabeling method. [^{18}F]FMP retained the advantageous properties of common amino acid PET tracers while enhancing tumor uptake and tumor-to-background ratio. Preliminary studies indicated the potential of [^{18}F]FMP in clinical applications of brain tumors. ***References:*** [1] Wei Chen, Yueqi Wang, Lili Pan et al. Simplified radiolabeling process toward rapid photoredox-catalyzed aryl ^{18}F-fluorination and PET tracer development, 09 February 2025, PREPRINT (Version 1) available at Research Square [https://doi.org/10.21203/rs.3.rs-4325597/v1]

Aim/Introduction: Actinium-225 (^{225}Ac, alpha-emitter, $t_{1/2}$ = 9.9 days) and Lutetium-177 (^{177}Lu, beta-emitter, $t_{1/2}$ = 6.71 days) are two promising radioisotopes with substantial potential for a wide range of applications in radiotherapy of cancer. Gold Nanoparticles (AuNPs) functionalized with the chelator TADOTAGA are useful multifunctional carriers for these isotopes. The aim of the current study was the development and evaluation of gold nanoparticles (AuNPs) and gold nanoflowers (AuNFs) radiolabeled with ^{225}Ac and ^{177}Lu via TADOTAGA as an injectable radiopharmaceutical form of therapy for the treatment of cancer. ***Materials and Methods:*** AuNPs/AuNFs were radiolabeled with $^{225}AcCl_3$ (~80 KBq) and $^{177}LuCl_3$ (~10 MBq) using trace-free sodium acetate buffer 0.2 M (pH 5.6) followed by incubation at 75°C. Radiolabeling yield and in vitro stability were evaluated by instant thin-layer chromatography (ITLC). Stability studies were carried out in PBS and sodium acetate over 12-14 days. Cytotoxicity of both bare and radiolabeled nanostructures was assessed using

the MTT assay in U87MG and 4T1 cells over 24, 48, and 72 hours. Therapeutic efficacy of ^{225}Ac-AuNPs and ^{225}Ac-AuNFs was further investigated in a 4T1 tumor-bearing mouse model for 15 days post-administration. ***Results:*** Radiolabeling with ^{225}Ac led to >90% radiolabeling yield for both AuNPs/AuNFs maintaining ~80% stability in PBS and ~85% in sodium acetate up to 14 days post-incubation, as evaluated by TLC analysis. Additionally, radiolabeling with ^{177}Lu resulted in excellent radiolabeling yield for the AuNPs (>97%) while [^{177}Lu]Lu-AuNFs exhibited poor labeling efficiency. Bare AuNPs exhibited minimal cytotoxicity at all concentrations and timepoints examined, while bare AuNFs demonstrated significant toxicity, particularly in U87MG cells. Radiolabeled [^{225}Ac]Ac-AuNFs presented reduced cell viability in both lines (as low as 18.13% in 4T1 at 72 h), while [^{225}Ac]Ac-AuNPs appeared less toxic (minimum 74.94% viability). In addition, cells incubated with [^{177}Lu]Lu-AuNPs maintained high viability (>85%), reinforcing their safety profile. Regarding the therapeutic efficacy study, both [^{225}Ac]Ac-AuNPs/AuNFs reduced tumor growth in 4T1 models. ***Conclusion:*** AuNPs and AuNFs can be effectively radiolabeled with ^{225}Ac, leading to stable nanoconstructs, while [^{225}Ac]Ac-AuNFs demonstrated enhanced cytotoxicity in both cell lines. Both [^{225}Ac]Ac-AuNFs/AuNPs demonstrated a similar therapeutic effect after intratumoral administration in 4T1 tumor xenografts. These results warrant further in vivo investigation for targeted radionuclide therapy in tumor xenografts. ***References:*** [1] Salvanou, E.-A. et al., A Proof-of-Concept Study on the Therapeutic Potential of Au Nanoparticles Radiolabeled with the Alpha-Emitter Actinium-225, Pharmaceutics 2020, 12, 188.

EPS-154

Development of a cGMP-compliant automated synthesis of the radiotherapeutic [^{177}Lu]Lu-ABY-271: Enabling reliable radiolabelling for a first-in-human phase I study

S. Omer[1], *M. Ferrat*[1], *E. Jussing*[1], *N. Molina*[2], *T. Tegnebratt*[2], *J. Garousi*[2], *H. Alfredéen*[1], *J. Ödling*[3], *L. Bremer*[3], *H. Bönisch*[3], *S. Wood*[3], *F. Y. Frejd*[3], *M. M. Moein*[2], *T. A. Tran*[1];
[1]*Karolinska Institutet, Solna, SWEDEN,* [2]*Karolinska University Hospital, Solna, SWEDEN,* [3]*Affibody AB, Solna, SWEDEN.*

Aim/Introduction: Human Epidermal Growth Factor Receptor 2 (HER2) is overexpressed in several malignancies, including breast, ovarian, gastric and oesophageal cancers. Approximately 15-20% of breast cancer tumors express HER2, and the development of HER2-targeted theranostic radiopharmaceuticals enables a personalised "see and treat" approach, facilitating non-invasive tumor characterisation followed by targeted therapy. In this context, the Affibody® molecule [^{68}Ga]Ga-ABY-025 has been clinically evaluated as a HER2 PET imaging tracer in metastatic breast cancer [1], and ongoing for oesophageal cancers (NCT05619016) and as an image-guided selection tool for antibody drug conjugates (ADC) treatment (NCT06830382). Molecular radiotherapy with the ABY-025 derived HER2 targeted Affibody molecule [^{177}Lu]Lu-ABY-271 might provide an alternative treatment for those patients who do not respond to current ADC treatment. For clinical translation, we developed a robust manual radiolabelling protocol that was transferred to a cGMP automatic synthesis, enabling reliable and reproducible manufacturing of [^{177}Lu]Lu-ABY-271 for a first-in-human phase I study in HER2-positive breast cancer patients. ***Materials and Methods:*** Manual radiolabeling of [^{177}Lu]Lu-ABY-271 was scaled up and optimized from earlier preclinical conditions [2]. DOTA-conjugated ABY-271 (2 mg) and $^{177}LuCl_3$ (0.5 - 5 GBq) were used for radiolabelling. Reaction was performed in a sodium acetate/sodium ascorbate buffer at 65 °C for 30 minutes, in a volume of 4 mL, during gentle mixing. The crude product was purified using solid phase extraction (SPE), eluted in a final formulation buffer with ethanol. Following establishment of an optimized protocol, the labelling was transferred to a cGMP-compliant automated synthesis on Modular-Lab PharmTracer (Eckert & Ziegler). ***Results:*** During manual labelling, key parameters influencing yield and stability, including maintaining optimal pH to avoid denaturation, and incorporating sodium ascorbate to limit possible radiolysis, were established. Those conditions were then transferred to a disposable cassette-based, programmed labelling sequence. The fully automated process resulted in a ready-to-use [^{177}Lu]Lu-ABY-271 product containing an activity range of choice 0.5 - 3.3 GBq, 2-12 mg peptide in a volume of 18-22 mL; stable up to 4 days EOS (End of Synthesis), fulfilling the specified GMP standards of a sterile product with RCP > 95%. ***Conclusion:*** This study presents an optimized manual radiolabeling protocol for [^{177}Lu]Lu-ABY-271. Critical parameters impacting the yield and product stability were established and supported the translation of this protocol to GMP-compliant radiosynthesis for clinical use. ***References: References:*** 1. EPS-155

Photocatalyzed nucleophilic ^{18}F-deoxyfluorination of highly electron-rich catechol derivatives for [^{18}F]FDOPA synthesis

W. Chen, *M. Hu, Y. Wang, C. Zheng;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Despite much progress having been made in synthesizing the multifunctional clinical PET tracer [^{18}F]FDOPA in the past decades, the established strategies, particularly the preferred direct nucleophilic ^{18}F-fluorination, generally involve complex precursor synthesis and provide unsatisfactory RCYs for scale-up automatic production. Thus, a simple and automatable direct labeling approach using a stable precursor under mild conditions is still attractive for the daily production of the [^{18}F]FDOPA when the current established methods are inaccessible or not well-performed in certain centers or labs. ***Materials and Methods:*** The precursors were prepared from a simple three-step synthesis. The challenging nucleophilic ^{18}F-fluorination of the highly electron-rich catechol moiety was performed under azeotropic drying-free photolabeling conditions[1]. The automatic synthesis was tested on the Allinone radiosynthesis module. ***Results:*** More than 20 novel precursors were rapidly obtained, and the precursors were stable at room temperature for more than 2 years. The labeling RCCs (radiochemical conversions) of the key ^{18}F-labeled intermediates for the subsequent deprotection was up to 70%. The [^{18}F]FDOPA was successfully produced in more than 20% non-decay corrected RCY in 98 minutes with >99% ee and purity on a commercial automatic radiosynthesis module. ***Conclusion:*** We successfully established a novel synthetic routine for the [^{18}F]FDOPA enabled by the photocatalyzed azeotropic drying-free ^{18}F-deoxyfluorination. The readily available and stable precursor makes this transition-metal-free approach an attractive routine for daily production of [^{18}F]FDOPA with high molar activity, and it also paved the way for the nucleophilic ^{18}F-fluorination of other catechol derivatives for PET tracer development and production. ***References:*** [1] Wei Chen, Yueqi Wang, Lili Pan et al. Simplified radiolabeling process toward rapid photoredox-catalyzed aryl ^{18}F-fluorination and PET tracer development, 09 February 2025, PREPRINT (Version 1) available at Research Square [https://doi.org/10.21203/rs.3.rs-4325597/v1]

EPS-156

Routine Radiolabeling of FAP Peptide 3BP-3940 with Y-90, Lu-177, and Ac-225 for FAP-Targeted Radiopharmaceutical Therapy (FTRT): Production and Performance Data from 5 Years and 90+ Clinical Batches

L. Greifenstein, *S. Stephan, C. Mueller, C. Landvogt, R. P. Baum;*
Curanosticum MVZ GmbH, Wiesbaden, GERMANY.

Aim/Introduction: Fibroblast activation protein (FAP) is highly expressed in cancer-associated fibroblasts and represents a promising target for radiopharmaceutical therapy (FTRT). The FAP-targeting ligand 3BP-3940 was developed for theranostic applications and allows labelling with various therapeutic radionuclides. This work presents a five-year clinical routine

experience with radiolabelling 3BP-3940 using Yttrium-90 (Y-90), Lutetium-177 (Lu-177), and Actinium-225 (Ac-225), focusing on production reliability, radiochemical purity, and regulatory compliance. ***Materials and Methods:*** Radiolabelling was performed under GMP-like conditions using standard protocols optimized for each radionuclide. Over a five-year period, a total of 103 syntheses were conducted: 20 with Y-90, 56 with Lu-177, and 27 with Ac-225 for a total of more than 300 patient doses. Radiochemical purity was assessed via radio-HPLC and radio-TLC. Each production batch was evaluated for compliance with internal quality standards. Data on labelling yields, quality control results, and batch failures were systematically recorded and analysed. ***Results:*** Of the 103 productions, 101 resulted in radiopharmaceuticals meeting the predefined quality criteria for patient administration, including 15 syntheses with out-of-expectation or out-of-specification observations. Mean radiochemical purity exceeded 95% for all three radionuclides. The average synthesis time was under 60 minutes for Y-90 and Lu-177, and approximately 90 minutes for Ac-225. No production-related technical failures or contaminations occurred during the study period. Deviations in yields occurred, but mean RCY were higher than 90% for Lu-177 and Ac-225 and above 85 % for Y-90. Issues of peptide stability that were already reported for the Y-90 labelling occurred as well for the Lu-177 protocol and were solved by the addition of L-Methionine to the reaction buffer [1]. Therefore, mean RCPs of 96,7 % were increased to 98,7 % determined by radio-HPLC ***Conclusion:*** The FAP ligand 3BP-3940 can be reliably labelled with Y-90, Lu-177, and Ac-225 under routine clinical conditions, enabling flexible and effective FAP-targeted radiopharmaceutical therapy. The high success rate over five years and more than 100 total productions support the feasibility and safety of implementing FTRT with 3BP-3940 in broader clinical practice. ***References:*** [1] Greifenstein et al., iScience 26, 108541, 2023

Extravasations in Nuclear Medicine: Mechanisms, Consequences and Dosimetry

C. Sobral*, A. Rodrigues Teixeira, M. Nicod Lalonde, J. Prior, S. Medici;*
Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, SWITZERLAND.

Aim/Introduction: Radiopharmaceutical extravasation refers to the unintended leakage or administration of a radiopharmaceutical outside the injection vein, which can lead to localized accumulation in surrounding tissues rather than systemic circulation. We aimed to retrospectively analyze cases of extravasation that occurred in the department since 2019 to estimate incidence and frequency of paravenous events, as well as to evaluate side effects, specific measures implemented and dosimetry with the goal of establishing a decision-making flowchart. ***Materials and Methods:*** All reported extravasations to our critical incident reporting system from 2019 to 2024 were analyzed, focusing on variables such as the isotope used, dosimetry, need to repeat examinations or injections, manual versus automatic injection, immediate and delayed symptoms, presence of pre-existing catheters and actions taken. ***Results:*** A total of 17 extravasations were documented between 2019 and 2024, involving isotopes Ga-68 (6%), Rb-82 (12%), F-18 (53%), and Tc-99m (29%). Manual injections accounted for 35% of cases. Observed consequences included 59% experiencing partial reinjection of the radiopharmaceutical, 24% requiring repeat CT scans, 24% reporting immediate pain at the injection site and 12% exhibiting redness or swelling. No patients experienced delayed side effects and 35% had pre-existing catheters. Skin dosimetry values ranged from 0.021 Gy to 3.1 Gy.The adverse effects of extravasation depend on the radiopharmaceutical used, the volume and the activity administered. No long-term side effects were observed and no extravasation involving therapeutic radiopharmaceuticals was identified. Immediate post-extravasation interventions, such as massage, limb elevation, and application of cold compresses are recommended to prevent repeat examinations or reinjections. ***Conclusion:*** The consequences of extravasation can be minimized through prompt and proper management and established action protocols, thereby reducing associated side effects. Dosimetric evaluation may be necessary to exclude deterministic effects and facilitate proactive measures. Adecision-making flowchart has been consequently established to determine when dosimetric evaluation or additional local CT is recommended. ***References:*** Barré , E., Nguyen, M.-L., Bruel, D., Fournel, C., Hosten, B., Lao, S.,⋯ Rizzo-Padoin, N. (2013). Extravasation des médicaments radiopharmaceutiques : mesures préventives et prise en chargerecommandées par la SoFRa (Société française de radiopharmacie). TEPS-002

A Novel ^{67}Ga-Labeled CXCR4-Targeted Tracer: Radiolabeling Performance, Stability, and In Vivo Evaluation in Atherosclerotic Models

S. Chen*, M. Chen, C. Chen, C. Hsia, M. Weng, Y. Chang, W. Chen;*
National Atomic Research Institute, Taoyuan, TAIWAN.

Aim/Introduction: Current imaging tools for atherosclerosis often detect disease only after structural plaque formation or vascular occlusion. CXCR4 (C-X-C motif chemokine receptor 4) has emerged as a key inflammatory biomarker during the early stages of atherosclerosis. It is highly expressed by macrophages, T cells, and endothelial cells in the atherosclerotic plaque microenvironment. This study aims to develop and evaluate a novel ^{67}Ga-labeled CXCR4-targeted tracer (APD) for SPECT/CT imaging, with the potential to noninvasively detect early vascular inflammation and facilitate preclinical translation. ***Materials and Methods:*** APD, a cyclen-based bifunctional chelator incorporating pyridylmethylamine moieties, was synthesized for stable radiometal chelation and specific CXCR4 binding. Radiolabeling was achieved by reacting APD with [^{67}Ga]$GaCl_3$ in sodium acetate buffer (80-95 °C, 10-30 min). Radiochemical purity was assessed by radio-TLC and radio-HPLC. The stability of ^{67}Ga-APD was evaluated by storing the tracer at room temperature for 2 hours and reanalyzing by HPLC. For in vivo studies, ApoE^{-}/$^{-}$ mice fed a high-fat diet for 8 weeks received tail vein injection of ^{67}Ga-APD. SPECT/CT imaging was conducted from 0 to 2 hours post-injection, followed by quantitative image analysis. ***Results:*** Radiolabeling yield and radiochemical purity of ^{67}Ga-APD exceeded 90%, as confirmed by both ITLC and HPLC. The tracer demonstrated high stability, maintaining >90% purity at room temperature for up to 2 hours. In vivo imaging revealed increased tracer uptake in the aortic arch and abdominal vasculature of ApoE^{-}/$^{-}$ mice—regions typically associated with early vascular inflammation. ***Conclusion:*** ^{67}Ga-APD is a promising CXCR4-targeted SPECT/CT imaging agent, demonstrating excellent labeling efficiency, radiochemical stability, and preliminary in vivo uptake in vascular regions associated with inflammation, including the coronary arteries. These features support its potential for early detection of atherosclerosis and compatibility with clinical imaging workflows.

Note: APD is a proprietary compound under IP protection. ***References:*** 1.Pharm Anal Acta. 2024 Jan 5;15(1). 2. Labelled Comp Radiopharmac. 2018 May 15;61(5):438-46.

TEPS-003

Injection Method Alters Diagnostic Confidence and Quantitative Metrics in [^{18}F]Fluorocholine PET/CT for Parathyroid Adenomas

M. Rode, *H. Reilev Møller, P. Abadi, H. Juel Nissen;*
University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: Studies evaluating [^{18}F]fluorocholine PET/CT for parathyroid adenoma localisation fail to report the injection method utilized, whether it was a manual injection method (MIM) or with an automated injection system (AIS). At our department, MIM was initially used, before switching to an AIS. However, after using the AIS, the physicians began noticing retention of the radiotracer within the veins leading from the injection site, which had not been as present when previously. The aim of this study was to evaluate whether this retention had a clinical impact or was just a visual distraction. ***Materials and Methods:*** A retrospective study compared the two injection methods from two identical patient groups consisting of 60 patient each. Two physicians, blinded to injection method, would determine if retention was present in the images and whether this affected their interpretation. A diagnostic confidence score per lesion from 1(low)-3(high), was noted for the 120 patients in the original description. These scores were compared to determine, if a significant difference between the two patient groups was present. Quantitative measures were determined based on the SUVmean of the reported parathyroid adenomas along with the thyroid and salivary glands as a reference point, to calculate parathyroid/thyroid and parathyroid/salivary gland ratios. ***Results:*** There was a significant difference in presence of retention, with 36 patients in the MIM-group and 53 patients in the AIS-group, p=.0004. However, the accumulation was not determined to influence the interpretation of the images for any patient. Two patients in the MIM-group had a negative scan, compared to nine patients in the AIS-group. A significant difference of the reported diagnostic confidence scores was observed, as more lesions with a high score in the MIM-group was reported, p>.0001. Quantitative measurement revealed a significant difference in SUVmean from the reported adenomas, with 7.52 in the MIM-group and 6.17 in the AIS-group, p=.002). A significant difference was also determined when comparing the parathyroid/thyroid ratio, with 1.75 compared to 1.50 in the MIM and AIS groups, respectively, p=.013. This difference was also present when comparing the parathyroid/salivary gland ratios, with 0.75 in the MIM-group and 0.65 in the AIS-group, p=.014. ***Conclusion:*** While the retention of radiotracer did not appear to influence the evaluation of imaging visually, the difference in diagnostic confidence scores, SUVmean and both ratios could indicate an aspect of potential clinical impact. Thus, manual injection method might be the method of choice, to ensure optimal image quality.

TEPS-004

Optimizing the Use of a Single Radiopharmaceutical Production for Increased Throughput of Patients with Primary Hyperparathyroidism in[^{18}F]Fluorocholine-PET Without Compromising Image Quality

M. Matkovic[1], *F. Hedeer*[1], *A. Stenvall*[2], *J. Oddstig*[2], *U. Bitzén*[1];
[1]*Department of Clinical Physiology and Nuclear Medicine, Lund, SWEDEN,* [2]*Radiation Physics, Department of Haematology, Oncology and Radiation Physics, Skåne, SWEDEN.*

Aim/Introduction: [^{18}F]Fluorocholine-PET in primary hyperparathyroidism was introduced at our department three years ago and replaced ultrasound and parathyroid scintigraphy as conventional first line preoperative imaging modality shortly thereafter. The aim of this study was to increase the throughput of patients with hyperparathyroidism in [^{18}F]Fluorocholine-PET by efficient use of a single production of [^{18}F]Fluorocholine while preserving high image quality. ***Materials and Methods:*** The local cyclotron unit can ensure a production of 27 GBq [^{18}F]Fluorocholine per production. When [^{18}F]Fluorocholine-PET was introduced at our department patients were scanned on digital PET/CT scanners 60 minutes after an intravenous injection of 4 MBq/kg. With a 20 cm axial field of view (aFOV) and 25% overlap two bed positions were required to cover a scanning volume from the base of the scull to the diaphragm. Acquisition time was 4 minutes/bed position and for image reconstruction a block-sequential regularized expectation maximization (BSREM) algorithm with beta value 400 was applied. Using two scanners in parallel during six hours, nine patients per scanner, i.e. 18 patients in total were examined per occasion. To maximize the number of patient doses per production of [^{18}F]Fluorocholine, the amount of administered activity was adjusted. A 25% reduction in injected activity from 4 to 3 MBq/kg was compensated by a 25% increase in acquisition time from 4 to 5 minutes/bed position. Adding a newly installed digital PET/CT scanner to work in parallel, scanner capacity was increased from two to three scanners. With a 32 cm aFOV, one bed position was sufficient to cover the volume of interest. For this scanner acquisition time was 6 minutes for the single bed position and for image reconstruction a BSREM algorithm with beta value 300 was applied. These adjustments required allocated injection rooms to be increased from six to ten and technicians from eight to twelve. ***Results:*** The number of scanned patients per occasion was increased from 18 to 27, i.e. a 50 % increase per production of [^{18}F]Fluorocholine. Additional positive consequences were fewer production occasions needed to match referral inflow, increased cost effectiveness and decreased radiation exposure to patients and technicians. ***Conclusion:*** Increasing demands for a high patient throughput and availability, resource utilization and cost effectiveness in [^{18}F]Fluorocholine-PET could be met by awareness and conscious planning without compromising image quality.

TEPS-005

Clinical Utility of Lacrimal Scintigraphy in the Management of Epiphora

L. Crook, *R. Sajjan, B. Sathyamurthi, S. Muthu;*
Department of Nuclear Medicine, Manchester Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Lacrimal dacroscintigraphy is a functional imaging study performed to investigate epiphora by assessing the drainage of the nasolacrimal system, when anatomical patency is maintained. Our aim was to evaluate the effectiveness of the study and to demonstrate the level of impairment in the nasolacrimal system which could aid in the management of patients. ***Materials and Methods:*** We retrospectively identified 37 patients over a 3-year period who had undergone lacrimal scintigraphy from Sept 2022 to Jan 2025. Scans were acquired using 1 drop Tc-99m Sodium Pertechnetate into each eye (maximum of 4 MBq). Initial dynamic images, post saline wash dynamic images and postnasal blow static images were acquired using the Siemens Symbia S camera with a pin hole collimator. ***Results:*** In our study, the scan was abnormal in 35 patients (95%) and normal in 2 patients (5%). Out of 35 abnormal scans, impairment in drainage was seen bilaterally in 65% of patients and unilaterally in 35% of patients. When the level of impairment was assessed, we noticed the abnormality was predominantly at the ductal level, followed by pre-sac and preductal levels. The scan was concordant with clinical symptoms in 62% of patients and discordant in 38%. 86% of discordance was with respect to the laterality of the symptoms (either unilateral or bilateral), except in 2 symptomatic patients (14%) where the scan was normal thus excluding functional impedance. Three patients (8%) have undergone surgery, and 8 patients (21%) are

awaiting surgery. The rest of the patients were managed medically such as warm compression, trial of lid taping, lubrication, botox, punctal plugs and treatment with olopatadine drops. There were also plans for routine follow-up, including patients with discordant findings. Few patients refused surgery after treatment discussion. ***Conclusion:*** Lacrimal scintigraphy identified abnormal drainage in most patients and was also helpful in excluding functional impedance in few symptomatic patients. Furthermore, the demonstration of level of abnormality in the scan played an important role in deciding patient management. In addition, the identification of abnormality in the asymptomatic eye may help in early intervention and prevention of epiphora.

TEPS-006

How to Ensure Sustainability and Research Governance in Nuclear Medicine? A UK Single-Site Experience.

D. Ribeiro, *M. Ratola, Z. Kingsmell;*
King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: A quality management system (denominated Q-Pulse) was implemented for use of the Radiology Care Group, at King's College Hospital National Health Service (NHS) Foundation Trust, in 2022. In 2023, it started being actively used for the management and governance of research studies. This report aims to describe our department's experience in using a quality management system to ensure regulatory compliance and foster sustainable approaches in Nuclear Medicine. ***Materials and Methods:*** The "Documents" module on Q-Pulse allows for studies to be created and the relevant documents to be saved under a study placeholder. Moreover, when a clinical trial undergoes an amendment, the study placeholder can be revised and the research documentation up versioned. An audit was conducted to understand the sustainability impact of using this system, within the Nuclear Medicine department. The total number of pages for all research documentation was compared against the number of pages that are currently being printed. This metric will act as a surrogate for understanding the effect of using Q-Pulse on the environmental and economic pillars of sustainability. ***Results:*** Out of the 78 studies uploaded onto the Radiology quality management system, 33 of them required Nuclear Medicine support, with bone densitometry (DEXA) and Positron Emission Tomography (PET)-Computed Tomography (CT) being the most common modalities. Twenty out of the 33 studies had dedicated imaging manuals which were printed and kept as hard copies, in case of an informatics outage. All other study documents were kept on Q-Pulse. The total number of pages for all the research documentation (including the dedicated imaging manuals) amounted to 6266 pages, whereas the total number of pages for the imaging manuals alone corresponded to 948 pages. As physical copies are only kept for the latter, this corresponds to only 15.13% of research documents being printed. This approach leads to a decrease in solid waste (as fewer documents are printed and, when revisions are required, less paper will go to the recycling bin) and a decrease on the money spent on consumables (both paper and ink cartridges). ***Conclusion:*** Whilst imaging documentation can be stored within normal computer drives, this does not represent a safe approach to managing research documentation (amendments cannot be tracked and documents can be inadvertently deleted). Moreover, printing all documents associated with a research study represents a significant environmental and economic burden. Quality management systems represent a suitable approach for balancing research governance and sustainability.

TEPS-007

Biodistribution of BMMSC-Derived Exosomes for Alzheimer's Disease

M. Wang, *C. Ho, C. Chan, K. Cheng, H. Yu, C. Kuo, C. Yang, S. Liu;*
National Atomic Research Institute, Taoyuan, TAIWAN.

Aim/Introduction: Alzheimer's disease (AD), the leading cause of dementia, is characterized by severe memory and cognitive decline. Interestingly, AD frequently co-occurs with osteoporosis, hinting at shared underlying pathological pathways. This study aimed to compare bone quality and the biodistribution of bone marrow mesenchymal stem cell-derived exosomes (BMMSC-Exos) in the 5xFAD mouse model of Alzheimer's disease and normal B6 mice. ***Materials and Methods:*** Bone marrow mesenchymal stem cell (BMMSC)-derived exosomes were isolated using tangential flow filtration followed by fast protein liquid chromatography. For biodistribution analysis, exosomes were conjugated with p-SCN-Bn-DOTA and radiolabeled with Gallium-67 before being administered to both aged (66 weeks) 5xFAD mice and age-matched normal B6 mice. ***Results:*** Our findings demonstrated a significantly higher accumulation of Ga-67 labeled exosomes in the hip bone, sacrum, and ilium of aged (66 weeks) Alzheimer's disease mice compared to their normal counterparts. Furthermore, we observed lower bone density in these same skeletal sites of the aged Alzheimer's disease mice. ***Conclusion:*** Given the association of Alzheimer's disease with aging, we propose that elderly individuals with AD may also be susceptible to osteoporosis. The observed preferential accumulation of BMMSC-Exos in the sacrum, hip bone, and ilium of aged AD mice suggests a potential therapeutic role for BMMSC-derived exosomes in addressing bone loss often associated with advanced age and potentially exacerbated by AD.

TEPS-008

Development and validation of a 3D-printed phantom for PET texture analysis

K. Honda[1], *K. Okuda*[1], *H. Yamamoto*[2], *R. Mori*[1], *S. Hosokawa*[1], *Y. Takahashi*[1];
[1]*Guraduate School of Health Sciences, Hirosaki University, Aomori, JAPAN,* [2]*Hirosaki University Hospital, Aomori, JAPAN.*

Aim/Introduction: Texture analysis can quantify surface conditions such as roughness and smoothness and spatial variations in voxel intensity within a volume of interest (VOI) in medical images. However, a dedicated PET phantom for texture analysis has not yet been developed. Here, we created spherical components containing acrylic beads for a National Electrical Manufacturers Association (NEMA) body phantom using a 3D printer. The aim was to validate the bead-filled spherical phantom for evaluating heterogeneous ^{18}F-fluorodeoxyglucose (FDG) distribution. ***Materials and Methods:*** To simulate the heterogeneous distribution of ^{18}F-FDG, we created spherical phantoms containing acrylic beads using a fused deposition modeling 3D printer. Three sets of spherical phantoms were produced: 10-, 13-, 17-, 22-, 28-, and 37-mm spherical phantoms without beads (SP0) and with 5-mm beads (SP1); and 37-mm phantoms in which the proportion of 5- and 10-mm beads was varied (SP2). PET images were acquired using a Discovery MI PET/CT scanner (GE Healthcare, USA) after the sphere and background radioactivity concentrations were adjusted to 10.2 and 2.55 kBq/mL, respectively. We reconstructed PET data using the Q.Clear algorithm and β-values ranged from 100-600. Standardized uptake values (SUV) and texture features were calculated using LIFEx software v. 7.60 (https://www.lifexsoft.org). A VOI was drawn on the central transaxial slice of a spherical phantom image. We evaluated ^{18}F-FDG images by analyzing 22 texture features that we previously identified. ***Results:*** The mean SUV (SUV_{mean}) values of 37-mm spheres were 3.76 for SP0, 1.54 for SP1, and 1.33 - 1.69 for SP2 in the β-value of 300. The maximum SUV (SUV_{max})values were also 4.42 for SP0, 1.93 for SP1, and 1.95 -

4.08 for SP2. The highest values of SUV_{max} and SUV_{mean} were shown in SP2 filled with only 10 mm beads, while the lowest values were shown in SP2 with 20 % of 10 mm beads for SUV_{mean} and that with 60 % of them for SUV_{max}. Heterogeneous FDG distributions were detectable using 22 texture features under various levels of statistical noise by adjusting β-values. We could classify 22 texture features into two groups: 12 texture features show higher values with increasing heterogeneity, while 10 texture features show lower values. ***Conclusion:*** The developed acrylic beads phantoms could represent heterogeneous ^{18}F-FDG distributions. We selected 22 texture features that could gradually capture image heterogeneity. Spherical components containing acrylic beads might serve as a standard phantom for PET texture analysis.

TEPS-009

Implementing a safe workflow for intra-operative PET/CT imaging of surgical specimen

F. Verschure, *B. Lambert, V. Vergucht, N. Dhont, B. De Paepe, V. Piens, M. Colle, B. Gevaert, L. Meiresonne;*
Maria Middelares, Gent, BELGIUM.

Aim/Introduction: We installed a mobile PET/CT-scanner, designed to acquire high-resolution images of surgical specimens. This camera aims to assess the metabolic activity of tissue and especially its margins in the operating room. In this presentation document, we addressed various safety issues when implementing intra-operative PET/CT imaging. We developed a workflow to achieve high quality intra-operative PET/CT images while maintaining ALARA principles. ***Materials and Methods:*** Intravenous PET-tracer injection (F18-PSMA for prostate cancer patients; FDG for remaining patients; 0.8-4MBq/kg) was done 60-90min before tumour resection. After resection, the specimen was scanned in the operating room for 12min with the AURA10 PET/CT-camera (XEOS) and the specimen was sent for pathology. We developed a work flow to minimize exposure to ionizing radiation. In the first 20 procedures our workflow was tested: We conducted dose rate measurements from injection till transfer to the recovery ward. For patients with a bladder catheter, measurements close to the urinary bag with and without lead shielding were carried out. Surgeons, nurses, and anaesthesiologists were additionally monitored by an electronic dosimeter during the entire procedure. The patient had to remain in bed post-injection to limit close contact with other patients or personnel. In case of a short-lasting surgical procedure the patient was injected with the PET-tracer at the nuclear medicine department. The patient awaited surgery at the nuclear medicine department, in a controlled area. Potential contaminations of the surgical room, instruments and waste were monitored by a survey meter. The specimens were fixed in formaldehyde for 24h before processing. No additional radioprotective measures were taken concerning the specimen. Image quality allowed us to lower the administered activity from 4MBq/kg to 0.8-1MBq/kg. ***Results:*** Dose rates around the patient dropped by a factor >5 when measured at the side of the feet instead of trunk. Normalized to an injected activity of 1MBq/kg, the estimated median absorbed doses per procedure were 15.6µSv(range 0,7-140,8) and 14,1µSv(0,5-46,2) for the surgeons and instrumenting nurses. The diuresis was kept low during urological surgery, with dose rates of 14 µSv/h near the urine bag. We positioned the bag at the far side of the surgeon, with lead shielding. At the surface of the suction unit the dose rate was 3 µSv/h. Measurements with a survey meter didn't reveal contaminations of the room. There was no need to shield the surgical specimen itself. ***Conclusion:*** We developed a safe workflow to implement intra-operative PET/CT in a general hospital.

TEPS-010

Evaluation of a reduced dose 123I-Ioflupane in patients examined with SPECT for clinically uncertain parkinsonism

G. Abell[1], *S. Skauge*[1], *T. Keil*[1], *S. Øen*[1], *A. Karlberg*[1,2];
[1]*Department of Radiology and Nuclear Medicine, St. Olavs hospital, Trondheim University Hospital, Trondheim, NORWAY,* [2]*Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, Trondheim, NORWAY.*

Aim/Introduction: Dopamine transporter imaging with 123I-Ioflupane is regularly used in patients with clinically uncertain Parkinsonian Syndromes. EANM/SNMMI guideline recommends administering 110-250 MBq and acquiring > 1.5 Mcts in the SPECT images for this examination. The aim of this retrospective study was to evaluate if halving the dose of 123I-Ioflupane (from 185 MBq to 92.5 MBq) affects the reported diagnoses in these patients. ***Materials and Methods:*** Patients examined with DaTSCAN for clinically uncertain Parkinsonian Syndromes (n=631) were included in this study. SPECT-acquisitions (180 min post injection) were performed on a dual head digital SPECT/CT-system with wide energy high resolution parallel-hole collimators, 159 keV±10% energy window, 30 sec/frame, 11-15 cm rotational radius, 360° rotation and 3° angular step. The «standard-dose group» (n=340) and the «half-dose group» (n=291) were compared for discrepancies. The nuclear medicine physicians' reported diagnoses were categorized into «normal», «pathological» or «uncertain». Striatal binding ratios (SBR) for striatum (L/R), putamen (L/R) and caudatus (L/R) were assessed for quantitative analysis. A Z-test was used to compare differences in proportions between reported diagnoses in the standard-dose group and half-dose group, and the Mann-Whitney U test were applied to compare differences in SBR between patients reported as normal and pathological. An alpha level of 0.05 were used for all statistical tests. ***Results:*** The mean total detected events were 4.6±0.7 Mcts and 2.5±0.4 Mcts in the standard-dose group and the half-dose group respectively. The proportion of patients reported as normal increased significantly with half-dose compared to standard-dose (+0.10, 95%CI [0.02, 0.18], p=0.012), while the proportion of patients reported as pathological and uncertain decreased (-0.08, 95%CI [-0.16, 0.001], p=0.053 and -0.02, 95%CI [-0.07, 0,02], p=0.322, respectively). However, dose differences did not significantly impact the median SBR-values for the cerebral regions in patients reported as normal, pathological and uncertain. ***Conclusion:*** A significant larger proportion of patients was reported as normal in the half-dose group compared to the standard-dose group. However, half-dose of 123I-Ioflupane fulfills the guidelines' criteria of > 1.5 Mcts in the SPECT-images, and the SBR- values were similar between the the two dose groups, supporting halving the dose in patients examined with SPECT for clinically uncertain parkinsonism.

TEPS-011

Pharmacokinetics and Dosimetry of ^{177}Lu-DOTATATE in Patients with Advanced well-differentiated, gastroenteropancreatic neuroendocrine tumours: results from a Sub-study of the phase 3 XT-XTR008-3-01 trial

H. Zhou[1], *A. Yin*[2], *R. Wang*[1];
[1]*Chinese PLA general hospital, Beijing, CHINA,* [2]*Beijing Sinotau Intl. Pharmaceutical Technology Co., Ltd., Beijing, CHINA.*

Aim/Introduction: While receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE is well established for treatment of GEP-NETs with somatostatin receptor expression, no data in Chinese populations has been reported yet. Herein, we present the results of a sub-study focusing on the exploratory PK and Dosimetry profile of a phase 3 clinical trial on XTR008 (XT-XTR008-3-01, NCT05459844), the first generic version of 177Lu-DOTATATE developed in China. ***Materials and Methods:*** From October 25, 2022 to May 11,

2023, 10 patients with well-differentiated, locally advanced or metastatic GEP-NETs were enrolled. Patients were administered with 4 cycles of ^{177}Lu-DOTATATE (7·4 GBq /cycle, cumulative 29.6 GBq. After the first dose, whole-body planar scintigraphy (6 time points up to 7 days) and abdominal SPECT/CT (24 and 48 h) were performed. Blood and urine samples were collected to determine PK parameters. Safety and efficacy were evaluated according to NCI-CTCAE version 5.0 and RECIST 1.1. ***Results:*** 177Lu-DOTATATE reached highest in blood at 15 min after starting infusion, then decreased with the T1/2 of 37.36±16.44 hours. Cumulative urine activity was 60.38% within 16 hours. The estimated absorbed dosed for four treatment cycles to kidneys and red marrow were 18.914 ± 6.242 Gy (excluding one patient with multifocal nephrolithiasis and absorbed dose to kidneys of 77.1Gy, who had grade 2 creatinine elevation and renal impairment) and 1.199 ± 0.337 Gy, respectively. Two other patients had absorbed doses to kidneys higher than 23 Gy (25.9 Gy, 23.1 Gy), neither developed renal toxicity. The most common TRAEs were haematological toxicities, most of which were grade 1 or 2 (81/98). No significant differences in absorbed doses between patients with and without treatment-related organ-specific toxicities was observed, while the dose to spleen between patients with and without haematological TRAEs (1.058875±0.6156 and 0.77025±0.9896) and ≥grade 3 haematological TRAEs (0.5935±0.3147 and 1.1031±0.6815) showed a numerical difference, though not statistically significant. The tumour absorbed dose ranged from 0.312 to 9.78 Gy/GBq, indicating inter- and intra-patient variabilities. Three patients achieved partial response (ORR 30%), with no significant difference in tumour absorbed doses compared with no-responders (2.68±2.53 Gy/GBq vs. 2.93±1.81 Gy/GBq, p=0.44). Pearson Correlation Analysis indicated a moderate but not statistically significant correlation coefficient (r=0.016, p>0.05) between tumour absorbed dose and tumour size change. ***Conclusion:*** PRRT with ^{177}Lu-DOTATATE showed showed favourable tolerability, PK and dosimetry outcomes in Chinese patients, supporting the potential application of XTR008 in Chinese patients with well-differentiated GEP-NETs.

TEPS-012

Split renal function in living kidney donors derived from ^{99m}Tc-DTPA vs ^{99m}Tc-DMSA: a preliminary evaluation

N. Laajimi, *A. Bouzidi, S. Bourouis, F. Dupont, N. Kanaan, R. Lhommel, F. Jamar, O. Gheysens, V. Depoortere;*
Cliniques Universitaires Saint-Luc, Bruxelles, BELGIUM.

Aim/Introduction: The global shortage of deceased kidney donors has led to an increased reliance on living kidney donors. Accurate pre-transplant assessment of donor renal function of essential for determining which kidney to donate and ensuring adequate long-term function in the remaining kidney. Radioisotopic methods are commonly used for this purpose, with 51Cr-EDTA and 99mTc-DMSA being gold standards for measuring absolute glomerular filtration rate (GFR) and split renal function, respectively. At our center, both tests were routinely performed, with a great advantage that both examinations could be performed on the same day. However, 51Cr-EDTA is no longer commercially available. 99mTc-DTPA is a potential alternative, capable of measuring absolute GFR via a single-injection two-sample method, and also offering split renal function data through a short dynamic acquisition. This dual capability could eliminate the need for an additional 99mTc-DMSA scan. This preliminary study aimed to evaluate whether 99mTc-DTPA can accurately measure split renal function compared to the 99mTc-DMSA standard. ***Materials and Methods:*** Eight patients undergoing evaluation for living kidney donation were included. Split renal function was measured using three methods: conventional geometric mean 99mTc-DMSA (DMSA, reference), posterior 99mTc-DTPA (DTPA PA), and both antero-posterior and postero-anterior 99mTc-DTPA with geometric mean (DTPA GM) using a 120-180 second post-injection window. Manual regions of interest were drawn around each kidney with background correction. Three experienced technologists independently analyzed all images. Results were expressed as the absolute deviation from equal split function (50/50), using Spearman correlation and Bland-Altman plots (mean ± 1.96SD). ***Results:*** Correlation coefficients for DMSA-DTPA PA, DMSA-DTPA GM, and DTPA PA-DTPA GM were 0.37, 0.53, and 0.91, respectively. Mean differences from DMSA were -3.52 ± 9.62% for DTPA PA and -2.49 ± 6.92% for DTPA GM. DMSA had significantly lower inter-observer variability compared to DTPA. Based on DMSA, 7 of 8 patients met the 45-55% eligibility window for donation. However, only 4-5 were eligible based on DTPA GM and 2-3 based on DTPA PA. ***Conclusion:*** This preliminary study suggests that 99mTc-DTPA cannot reliably replace 99mTc-DMSA for assessing split renal function in living kidney donor evaluation. While 99mTc-DTPA is suitable for measuring absolute GFR, accurate assessment of split function is obtained with 99mTc-DMSA. Therefore, a combined approach using 99mTc-DTPA/99mTc-DMSA on different days remains necessary for accurate donor evaluation.

TEPS-013

The Impact of PET/MRI Imaging and Tumor Markers on the Diagnosis of Prostate Cancer

M. Nürnberger[1], *S. Djouraev*[2], *M. Hacker*[1], *R. Agha Mohammadi Sareshgi*[2], *S. Rasul*[1];
[1]*Universitätsklinikum AKH Wien, Wien, AUSTRIA,* [2]*FH Campus Wien, Wien, AUSTRIA.*

Aim/Introduction: Investigation of the Diagnostic Value of PSA Density and Standardized Uptake Values (SUV) in PSMA-PET Scans in Patients with Therapy-Naïve Primary Prostate Cancer and their Influence on the Recurrence Rate and Histology. ***Materials and Methods:*** For the quantitative analysis, pre-existing PET/MRI scans of 19 patients with primary prostate cancer were used and further processed. Based on the imaging datasets, prostate volume was determined, and SUVmean, SUVmax, and SUVpeak were assessed using manually delineated volumes of interest. Additionally, clinical data such as PSA levels, the presence of biochemical recurrence (BCR), and histological findings were documented. With the collected data, statistical procedures could be applied, and the results were interpreted. Using Spearman correlation tests, the correlation between PSA density and SUVs, as well as between the histopathological ISUP score, PSA density, and SUVs, was determined. The influence of prostate cancer histology on PSA density and PSMA SUV was analysed by examining the relationship between the ISUP score and clinical parameters. To identify differences in these parameters between patients with and without biochemical recurrence (BCR), the T-Test and the Mann-Whitney U-test were performed. ***Results:*** A moderate correlation between the ISUP score and PSMA SUVs of the lesion was seen, with correlation coefficients ranging from 0.521 to 0.579 and p-values below 0.05. The investigation into whether there is a correlation between PSA density and various PSMA SUVs in prostate cancer patients revealed an overall weak to very weak correlation between the parameters, with correlation coefficients ranging from 0.190 to 0.437. However, this correlation was not statistically significant (p-values > 0.05). With p-values ranging from 0.234 to 0.731 the evaluation of the impact of recurrence rates on PSA density and PSMA SUVs demonstrated no statistically significant differences between patients with and without BCR. ***Conclusion:*** The moderate correlation between the ISUP score and PSMA SUV supports the reliability of SUV, as it indicates both the presence of prostate cancer and the aggressiveness of the disease. Furthermore, the findings suggest that neither PSA density nor PSMA SUV provide insights into the risk of biochemical recurrence.

TEPS-014

Cardiac Stress Testing: Is it time for NMTs to take the lead? - St. Barts Centre

A. Tsvetanova;
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Myocardial Perfusion Scan (MPS) stress testing for Nuclear Medicine Technologists was implemented in the PET-CT service, St. Barts Hospital in January 2025. The primary aims were to support the Rb-82 service demand and optimise patient workflow and ensure staff were appropriately trained to perform a safe and efficient MPS procedure.As to provide a common standard for patients and professionals, the British Society of Nuclear Medicine (BNMS) issued training guidelines and assesment on how to achieve clinical competencies in MPS stress testing which were incorporated in our inhouse training. ***Materials and Methods:*** Staff underwent an external intensive two-day training course workshop that delivered the core and knowledge for stress testing. The inhouse training comprised a combination of both basic clinical skills and specific cardiac skillset culminating into a series of assesments of all relevant modules related to cardiac stress testing.To be deemed competent to practice, staff were required to complete a minimum of 50 vasodilator stress tests showcasing their ability to use stress technique safely and effectively and conduct them without adverse events that would require sepervision intervention, retest or unnecessary radiation exposure. A retrospective audit was them conducted to a minimum of 20 clinical cases performed by staff undergoing the training to assess patient care outcomes and experience. ***Results:*** Since implementing Cardiac Stress Testing lead by technologists, we have been able to run a continous service and accomodate 1-2 additional Rb-82 patients a day. Rb-82 MPS appointment's cancelation rate due to list delays decreased from 10.6% in 2024 to 6.8% (Jan-March 2025).Currently, we are still collecting data on staff feedback and patient's experience. However, so far, the overall feedback has been positive. Furthermore, we haven't had any reportable clinical incidents related to Rb-82 MPS Cardiac Stressing. ***Conclusion:*** Effective communication alongside with experience and skills play a vital role in cardiac stress training. It is therefore essential for technologists to adhere to strighten safety protocols to protect themselves and others from potential hazards.

TEPS-015

Analysis of Image Artifacts in TOF-PET/CT - Impact of Defective Block Detectors on Image Quality

J. Teng[1,2], *S. Djouraev*[1], *R. A. M. Sareshgi*[1], *I. Rausch*[2];
[1]*FH Campus Wien, Vienna, AUSTRIA,* [2]*Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: This study investigates the impact of defective block detectors on image quality and quantification in time-of-flight PET systems, with a focus on artifact severity and the clinical relevance of detector failures. ***Materials and Methods:*** Phantom data were acquired using a Siemens Biograph TruePoint system without time-of-flight and a Siemens Biograph mCT system with time-of-flight. Various detector failure scenarios were simulated by virtually disabling individual block detectors during image reconstruction. Image reconstruction was performed using filtered back projection and ordered subset expectation maximization, with and without time-of-flight information. To highlight the robustness of filtered back projection against artifact formation, additional simulations were conducted involving both localized bucket failures and block detector defects distributed across all detector rings. Image quality was evaluated through visual inspection and quantitative analysis of background variability and recovery coefficients. ***Results:*** The number and spatial distribution of defective detectors influenced the severity of image artifacts. [1] Reconstructions with time-of-flight showed more spatially confined artifacts, while those without time-of-flight revealed larger regions of signal loss. [2,3] Time-of-flight notably improved image quality in iterative reconstructions, while filtered back projection particularly benefited the image quality in peripheral phantom regions. Even under extended failure scenarios, filtered back projection resulted only in minor contrast reductions without the appearance of significant artifacts. The largest improvements in background variability were observed with the use of time-of-flight, decreasing from 11 percent to 5.9 percent in filtered back projection for a 90-degree defect configuration, and from 33.7 percent to 17.3 percent in iterative reconstruction for a 180-degree configuration. ***Conclusion:*** Time-of-flight PET systems demonstrate higher tolerance to detector failures compared to non-time-of-flight systems. Filtered back projection in particular shows strong robustness, even in the presence of extensive or distributed detector defects. Preliminary results from phantom studies suggest that PET systems may remain conditionally usable in clinical settings despite multiple block detector failures. Further validation using patient data is ongoing. ***References:*** [1] Elhami E, Samiee M, Demeter S, Leslie WD, Goertzen AL. TEPS-016

Using the Monte Carlo Code RayXpert to Solve Radiation Protection Issues in Six Brachytherapy Rooms

J. Hemptinne, *I. Duarte, C. Dossat, N. Chatry;*
TRAD Tests & Radiations, Labège, FRANCE.

Aim/Introduction: The project consisted in performing a radiation protection study on six brachytherapy rooms at Institut Gustave Roussy, France. The aim was to respect the French Nuclear Safety Association (ASN) requirements regarding the dose inside and outside the rooms. In this context, two main families of calculation codes can be used for this purpose: Monte Carlo codes and deterministic (point-kernel) codes. ***Materials and Methods:*** In order to achieve a radiological zoning, the Monte Carlo software RayXpert® has been used. Its 3D interface allowed to efficiently and precisely model the infrastructure considered, including the six brachytherapy rooms, and import CAD files at the STEP format in the case of complex geometries. After this step, the sources definition and mapping setup allowed to derive results on the whole structure, including dose maps and regulatory zonings. Moreover, from the results of a preliminary study of the facility design, it has been possible to determine and/or optimize the radiological design. ***Results:*** The presentation will focus, as in the context of brachytherapy, on radiation protection issues due to the effects of injected radioactive sources in patients, such as ^{18}F or ^{192}Ir. A first investigation with a deterministic approach allowed to estimate a preliminary radiological design of the facility by using the point-kernel method. This first investigation had to be extended and completed with a Monte Carlo calculation code, here RayXpert®, which enables to consider scattered radiation. Combined with dose mapping, the software allowed to identify the origin of the dose contribution in certain areas. This feature enables to recreate particle paths, and consequently orientate efficiently the radiological design of the infrastructure considered. As a result, by employing both types of calculation codes, radiological design can be optimized, unlike using only a code based on the point-kernel method, which can be too simplistic and limiting. ***Conclusion:*** Calculation codes are widely used for radiological studies, and are in continuous development. Moreover,

Monte Carlo calculation codes bring extra precision to results and, combined with an ergonomic 3D interface like in RayXpert®, can contribute to efficiently realize radiological studies. In the context of the radiation protection study of six brachytherapy rooms at the Institut Gustave Roussy, RayXpert® has been necessary to optimize the shielding. Such tool can also be used for other projects within the nuclear medicine field, such as radiation protection on isotope production facilities, equipment shielding, waste and storage management, among many others.

TEPS-017

The updated capabilities for Registered Nuclear Medicine Technologist practice in Australia

***T. Pearson**, C. Miller, A. Reinhard;*
Medical Radiation Practice Board of Australia, Melbourne, AUSTRALIA.

Aim/Introduction: The Medical Radiation Practice Board of Australia (MRPBA) professional capabilities ("Capabilities") for Nuclear Medicine Technologist (NMT) set the standard for Registration in Australia. The Capabilities need to evolve to ensure that they remain current and are updated every 3-5 years. The Capabilities are primarily used to determine: 1. Entry level requirements for Practitioners entering or re-entering the Profession. 2. Requirements for Australian programs of study to be accredited as a pathway leading to Registration with the MRPBA. The Capabilities are also used to guiding continuous professional development (CPD) activities of already Registered NMT's in Australia. In 2025 the capabilities were updated with the aim of ensuring they align to contemporary and emerging practise. ***Materials and Methods:*** In 2024 the MRPBA undertook a scan of current and emerging NMT practices in Australia and drafted an update to the existing approved Capabilities (approved in 2020). This draft was distributed for initial targeted consultation with relevant key stakeholders, including NMT Professional Bodies, radiation licencing bodies, public and private employer groups and Education providers. This feedback was considered before an open broader public consultation for all other stakeholders. A new updated Professional Capabilities for Medical Radiation Practice was then drafted and presented to the MRPBA for approval. ***Results:*** The MRPBA approved and published the new NMS professional capabilities in mid-2025. Key updates for NMT professional practice include:1. Cultural capability2. Artificial intelligence3. Theranostics4. Radiopharmacy practice5. Leadership and Stewardship in practise. ***Conclusion:*** The MRPBA Professional capabilities for NMT practice have now been implemented in Australia. The process, feedback received, changes made and final MRPBA NMT Professional capabilities for practise in Australia will be the focus of this presentation.

TEPS-018

Comparison of Two Synthesis Methods for ^{68}Ga PSMA-11

***G. Walker**, K. Allen;*
IDX Group Lake Imaging, Ballarat, AUSTRALIA.

Aim/Introduction: The introduction of a simplified, "cold kit" solution for PSMA synthesis may hold promise for faster production times, cost reduction, and ultimately improved access to PET prostate imaging services. We performed a detailed comparison of time, workflow, costs, and radiation dose for a cassette-based method against cold kit synthesis in order to accurately identify and quantify any available efficiencies. ***Materials and Methods:*** Two operators undertook multiple production runs (n=5) for each PSMA synthesis method: lyophilized "cold kit" and cassette-based. Standard manufacturers' protocol was followed, with timing of each step recorded to the nearest 5s, and radiation exposure recorded at chest level for the entire procedure. Radiation dose was averaged for each method, then extrapolated to several time points over generator lifespan to estimate an annual dose to a typical operator. Quality control procedures including TLC and HPLC were performed as required, and also timed and included in the analysis. Any effects of time delays on ultimate injectable product yield were also calculated. Details of consumable items, labour and generator costs were tabulated and compared. ***Results:*** Cold kit synthesis achieved reductions of up to 40% in production time, 65% for radiation dose, and measurable cost savings, compared to a cassette-based method. ***Conclusion:*** In this analysis, significant savings in all areas, including time, cost, and radiation exposure were demonstrated in favour of cold kit synthesis. Implications for improving global access to PSMA PET diagnostic imaging are significant.

TEPS-019

Preclinical Biodistribution Study of [^{68}Ga]Ga-FAPI-46 in a Breast Cancer Mouse Model

***H. Hassan**[1], M. F. Othman[2], W. H. B. Wan Kamal[3], N. N. Jafperi[2], S. Mohamad[3], A. S. Sued[3], S. A. Muhamad[3], H. R. Abdul Razak[4], M. H. Zakaria[5];*
[1]Centre for Diagnostic Nuclear Imaging, Serdang, Selangor, MALAYSIA, [2]Universiti Teknologi MARA, Bandar Puncak Alam, MALAYSIA, [3]Malaysian Nuclear Agency, Kajang, MALAYSIA, [4]University of Exeter, Exeter, UNITED KINGDOM, [5]Universiti Putra Malaysia, Serdang, MALAYSIA.

Aim/Introduction: Fibroblast Activation Protein (FAP) and Cancer-Associated Fibroblasts (CAFs) are critical in cancer growth and metastasis, making them valuable targets for imaging and treatment monitoring. Fibroblast Activation Protein Inhibitor (FAPI) selectively binds to FAP on cancer cells and CAFs, demonstrating high sensitivity and specificity for early cancer detection. This study investigates [^{68}Ga]Ga-FAPI-46 biodistribution in a breast cancer mouse model, addressing limited supporting evidence. ***Materials and Methods:*** MCF7 breast cancer cells were subcutaneously injected into the mammary gland of female BALB/c nude mice (18 weeks old). Tumour growth was monitored biweekly, and mice were randomized into experimental and control groups (~2-weeks post-inoculation, n=3). The experimental group received [^{68}Ga]Ga-FAPI-46 while the control group received free ^{68}Ga via tail vein injection (3.7-7.4 MBq). After 1-hour, relevant organs and tumours were dissected, weighed and analysed for radioactivity using a gamma counter to assess biodistribution. ***Results:*** In the experimental group, [^{68}Ga]Ga-FAPI-46 exhibited remarkable uptake in the intestine (9.55% ID/g), heart (5.82% ID/g) and kidneys (4.15% ID/g), indicating its affinity for high metabolism tissues. Tumours uptake averaged 0.92% ID/g, highlighting its potential for targeted imaging of FAP-expressing tumours. Uptake was lower in muscle, bone and stomach. No tumour uptake was observed in the control group, with biodistribution predominantly in the blood (29.1% ID/g), lungs (18.5% ID/g) and bones (13.4% ID/g). ***Conclusion:*** [^{68}Ga]Ga-FAPI-46 showed significant uptake in the tumours, intestine, heart and kidneys, with biodistribution patterns similar to other studies. These findings support its potential as a targeted imaging agent for FAP-expressing tumours, enhancing FAPI-PET imaging in clinical.

TEPS-020

Utility of Tc-99m HMDP SPECT with synthetic planar images and SUV ratio for the diagnosis of cardiac amyloidosis

***Y. Miyazaki**[1], M. Nogami[1,2], Y. Izawa[3], H. Hashimura[4], K. Kubo[1], A. Kusaka[1], T. Murakami[1,4];*
[1]Department of Radiology, Kobe University Hospital, Kobe, JAPAN, [2]Biomedical Imaging Research Center, University of Fukui, Fukui, JAPAN, [3]Division of Cardiovascular Medicine, Department of Internal Medicine, Kobe University Graduate School of Medicine, Kobe, JAPAN, [4]Department of Radiology, Kobe University Graduate School of Medicine, Kobe, JAPAN.

Aim/Introduction: In Technetium-99m hydroxymethylene diphosphonate (Tc-99m HMDP) imaging for cardiac amyloidosis, few studies have demonstrated the usefulness of the heart-to-contralateral (H/CL) ratio and standardised uptake value (SUV) ratio. In addition, the usefulness of synthetic planar images generated from single photon emission computed tomography (SPECT) is unclear. This study aimed to investigate whether synthetic planar images and SUV ratios correlate with conventional methods. ***Materials and Methods:*** Eleven consecutive patients who underwent Tc-99m HMDP imaging for suspected cardiac amyloidosis at our institution were enrolled. Synthetic planar images were generated from SPECT images using a commercially available scanner (Symbia Pro.specta, Siemens Healthineers). The spherical volume of interest was set in the cardiac and contralateral regions on the SPECT images, and the SUV_{mean} ratio was calculated. The visual scores (Perugini score) were assessed by two nuclear medicine physicians. The correlation and inter-observer agreement of the visual scores between the synthetic and conventional planar images were evaluated using Spearman's rank correlation efficient and Kappa coefficient. The correlation and reproducibility between the synthetic and conventional planar H/CL ratios were evaluated using Pearson's correlation coefficient ant the Bland-Altman plot. The correlation and reproducibility between the SUV_{mean} ratio and the conventional planar H/CL ratio were evaluated using Pearson's correlation coefficient and the Bland-Altman plot. Receiver operating characteristic (ROC) analysis was performed to assess the diagnostic performance of the SUV_{mean} ratio using the visual score as the reference standard. ***Results:*** The visual scores for synthetic and conventional planar images showed substantial agreement ($k = 0.80$, $p < 0.05$) and a significant correlation ($r = 0.94$, $p < 0.05$). A significant correlation was observed between the H/CL ratios of the two types of planar images ($r = 0.99$, $p < 0.05$). Additionally, good reproducibility was observed between the H/CL ratios of both images (mean difference, -0.00055, 95% CI, -0.041 to 0.040). The SUV_{mean} ratio was highly correlated with the H/CL ratio of the conventional planar images ($r = 0.98$, $p < 0.05$). The Bland-Altman analysis showed that the SUV_{mean} ratio overestimated the H/CL ratio in the high SUV region. In the ROC analysis, the SUV_{mean} ratio demonstrated diagnostic ability with 100% sensitivity and 100% specificity, with a cutoff value of 2.31. ***Conclusion:*** Tc-99m HMDP SPECT with synthetic planar imaging and SUV_{mean} ratio demonstrated equivalent performance to the conventional method, suggesting its potential as a robust method for the diagnosis of cardiac amyloidosis.

TEPS-021

First clinical results for the unique TB-PET IMAS with TOF and DOI capabilities

A. González[1], *D. Sanchez*[2], *S. Jimenez-Serrano*[1], *A. Anreus*[1], *E. Y. Ulin-Briseño*[1], *A. Gonzalez-Montoro*[1], *M. Freire*[1], *J. Alamo*[3], *J. Barbera*[3], *A. Rios*[4], *J. M. Benlloch*[1], *B. Martinez Sanchís*[5], *A. S. Canoves Llombart*[5], *I. Torres Espallardo*[5];
[1]*Consejo Superior de Investigaciónes Cientificas, CSIC-i3M, Valencia, SPAIN,* [2]*Oncovision, SA, Valencia, SPAIN,* [3]*Oncovision SA, Valencia, SPAIN,* [4]*Full Body Insight, Valencia, SPAIN,* [5]*Hospital Universitario y Politécnico La Fe, Valencia, SPAIN.*

Aim/Introduction: Total Body - Positron Emission Tomography (TB-PET) systems are very attractive given their unique feature of a long axial field view (FOV). This allows for a significantly increased in system sensitivity and, thus, to reduce the patient dose, scanning time, or a compromise between both. In this work we present the first clinical results of a unique TB-PET, named IMAS, simultaneously enabling time of flight (TOF) and impact depth of interaction (DOI) capabilities. IMAS is installed at the largest hospital in our region: La Fe hospital. ***Materials and Methods:*** IMAS is based on the novel semi-monolithic scintillator geometry. The system has 82 cm in diameter and 71 cm axial coverage, and is made of 5 rings, each measuring 10 cm in axial direction. Novel electronics permit to decrease by a factor of 4 the total number of readout channels, without almost impacting the performance. IMAS is installed together with a standard CT. IMAS has been characterized following the NEMA 2018 protocol. A clinical validation is currently undergoing with patients that are programmed for a conventional PET/CT (Philips Gemini TF), for comparison purposes. Few patients have been already scanned, first in the PET/CT and later in IMAS. Currently, attenuation correction on the IMAS was carried out co-registering the CT of the PET/CT using deformable models. ***Results:*** Pilot results of the IMAS performance have shown an unprecedented homogeneous spatial resolution across the entire FOV below 4 mm. This is obtained because of the use of accurate DOI information during the reconstruction process. The system sensitivity is around 7% for a source located at the center FOV. The system TOF has been determined to be 480 ps, but an improvement close to 350 ps is reachable after a more accurate time skew calibration.The preliminary clinical image quality seems to be superior to the conventional PET/CT. In one of the patients, in which a multi-centric lesion was observed in the axilla, this was clearly resolved with IMAS, but blurred with the PET/CT. ***Conclusion:*** TB-PET imaging shows clear sensitivity advantages over conventional PET. IMAS is a system that saves part of the cost by using an architecture including gaps. The unique feature in clinical PET scanners enabling DOI, results in a homogeneous spatial resolution better than 4 mm.Clinically, the increased sensitivity and accurate impact determination, significantly improve the diagnostic prediction when compared to conventional PET.

Assessment of Reactive Astrocytes Across the Alzheimer's Disease Spectrum and Post-Treatment of Nrf2-Targeted Therapy via ^{18}F-SMBT-1 Imaging in 3xTg-AD mice
S. Guo[1], *F. Wei*[1], *S. Liang*[1], *Y. Ma*[1], *Q. Huang*[2], *C. Fu*[3], *W. Cheng*[1], *Y. Yin*[1];
[1]*Department of Nuclear Medicine, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA,* [3]*Institute for Developmental and Regenerative Cardiovascular Medicine, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: This study aims to determine the optimal time window for modulating reactive astrocyte phenotypes in 3xTg-AD mice using (S)-(2-methylpyrid-5-yl)-6-[(3-18F-fluoro-2-hydroxy) propoxy]quinoline (^{18}F-SMBT-1), a PET tracer for imaging reactive astrocytes, and assess the therapeutic potential of reactive astrocyte phenotype modulation in Alzheimer's disease (AD). ***Materials and Methods:*** PET imaging with ^{18}F-SMBT-1 was conducted in 3xTg-AD mice at 4, 6, 10, and 12 months of age, with age-matched wild-type (WT) mice as controls. The standardized uptake value ratio (SUVR) of cortex and hippocampus was calculated using the cerebellum as the reference region by PMOD software. To modulate astrocytes phenotype, nuclear factor E2-related factor 2 (Nrf2) was specifically overexpressed in hippocampal astrocytes of 4- and 10-month-old 3xTg-AD mice using adeno-associated virus vectors. Subsequent PET imaging with ^{18}F-SMBT-1 was performed to assess astrocytes reactivity after treatment. Cognitive function was evaluated using the open field test and Morris water maze test. Western blot and immunofluorescence were used to assess pathological features of AD, including Aβ deposition, tau pathology, neuronal and synaptic loss, as well as neuroinflammatory responses. ***Results:*** In 3xTg-AD mice of different ages, increased uptake of ^{18}F-SMBT-1 was observed in the cortex and hippocampus compared to age-matched WT controls. The uptake of ^{18}F-SMBT-1 was elevated in both the cortex and hippocampus of 6-month-old 3xTg-AD mice compared to 4-month-old 3xTg-AD mice, and showed a stabilization trend with disease progression at 10 and 12 months of age. Following the modulation of reactive astrocyte phenotype via Nrf2 overexpression, decreased uptake of ^{18}F-SMBT-1 was observed in the 3xTg-AD mice. Modulation of the reactive astrocyte phenotype demonstrated therapeutic efficacy in AD, as indicated by improved cognitive function, reduced Aβ and tau pathologies, attenuated neuronal and synaptic loss, and alleviated neuroinflammation in the 3xTg-AD mice. ***Conclusion:*** PET imaging with ^{18}F-SMBT-1 represents a valuable tool for determining the optimal timing to modulate reactive astrocyte phenotypes in AD. It also facilitates the assessment of astrocyte reactivity in response to therapeutic interventions. Modulating reactive astrocyte phenotypes by overexpressing Nrf2 has shown therapeutic benefits in AD models, suggesting that Nrf2-targeted therapy may represent a promising therapeutic strategy for AD. OP-452

PARP Inhibition Alleviates Neuroinflammation in a Rat Model of Multiple Sclerosis: Insights from a PET Study

G. Li, *M. Kominia, S. Blok, C. Kwizera, I. F. Antunes, B. T. Cornelissen, E. F. J. d. Vries;*
Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Neuroinflammation, driven by activated microglia, plays a key role in CNS disorders like multiple sclerosis (MS). PARP inhibition has been suggested to help reduce neuroinflammation and protect cellular integrity. PET imaging with the TSPO ligand [^{11}C]PBR28 allows in vivo assessment of glial activation. Here, we explored the effect of PARP inhibition on neuroinflammation in vitro, and in a lysolecithin-induced MS rat model using PET. ***Materials and Methods:*** In vitro uptake of [^{11}C] PBR28 was assessed in RAW264.7 macrophage cells exposed to LPS (vehicle, 100 or 1000 ng/mL) and/or the PARP inhibitor PJ34 (0- 20 μM). MS lesions were induced in male Sprague-Dawley rats by unilateral stereotactic injection of 1% lysolecithin in saline in the corpus callosum (3 μL) and striatum (4 μL). Animals were administered either vehicle or PJ34 (20 mg/kg, i.p. every 12 h) for 48 h. A 15-min static [^{11}C]PBR28 PET scan was performed at 3 and 7 days post lesion induction. Histological analysis of brain sections stained with IBA-1 or Luxol Fast Blue was conducted to evaluate microglial activation or myelin integrity, respectively. ***Results:*** LPS stimulation (100 ng/mL) significantly increased [^{11}C]PBR28 uptake (normalized, corrected for the number of cells and tracer amount) in RAW264.7 macrophages compared to controls, in vitro (1.91 ± 0.18 vs. 1.00 ± 0.13, $p < 0.0001$). PJ34 co-treatment (1 μM) significantly reduced this uptake (1.91 ± 0.18 to 1.24 ± 0.22 , $p < 0.0001$), indicating PARP inhibition attenuated LPS-induced macrophage activation in vitro. [^{11}C]PBR28 PET imaging revealed significantly lower tracer uptake (SUV_{mean}) in MS lesions of PJ34-administered animals, compared to vehicle-treated controls on days 3 and 7 (day 3: 1.21 ± 0.01 vs. 1.75 ± 0.01, $p < 0.001$; day 7: 0.99 ± 0.01 vs. 1.29 ± 0.02, $p < 0.001$). The decrease in tracer uptake between days 3 and 7 was most pronounced in PJ34-treated animals. In contrast, contralateral brain regions showed no differences between treatment groups or time points (approximately 0.50) in all animals. Immunohistochemistry confirmed a significant reduction in IBA-1 positive microglia in PJ34- treated animals compared to vehicle controls. LFB staining revealed a smaller demyelinated area in the PJ34 group compared to controls, suggesting that PJ34 effectively attenuates demyelination. ***Conclusion:*** This study highlights the value of [^{11}C]PBR28 PET imaging as sensitive tool for monitoring neuroinflammation in vivo and demonstrates that PJ34 treatment significantly attenuates microglial activation, as detected by PET. Post-mortem analysis revealed reduced demyelination in the MS model, supporting the therapeutic potential of PARP inhibition to reduce demyelination and neuroinflammation in MS.

Aim/Introduction: Blood-brain barrier (BBB) dysfunction is increasingly linked to depression pathophysiology[1]. Changes in BBB permeability/function may affect antidepressant distribution and response variability. In this study, we used a multitracer approach for quantitative mapping of BBB permeability and functionality using PET imaging in a validated murine model of anxiety/depression. ***Materials and Methods:*** Male C57BL/6N mice (13 weeks old) received corticosterone (35 μg/L) or vehicle (water and β-cyclodextrin) in drinking water for five weeks to induce the anxiety/depression behaviour (CORT mice). MicroPET acquisitions were performed using i) [^{18}F]fluorodeoxysorbitol ([^{18}F]FDS), a marker of BBB permeability, ii) [^{11}C]metoclopramide, a substrate of the BBB efflux transporter P-glycoprotein and iii) [^{11}C]diphenhydramine, a substrate of the uptake transporter H+/antiporter. A graphical analysis was performed to estimate the uptake transfer constant k_{uptake} of [^{18}F]FDS and [^{11}C]diphenhydramine using an image-derived input function (heart blood-pool)[2], and the efflux rate $k_{E,brain}$ of [^{11}C]metoclopramide[3]. Moreover, brain-normalized SUVR images were generated to consider region-specific differences in BBB permeability/function. ***Results:*** Kinetic modelling of whole-brain PET data (n=6-7/group) revealed no significant difference in the $k_{E,brain}$ of [^{11}C]metoclopramide, or the k_{uptake} of [^{11}C] diphenhydramine in CORT mice, suggesting no detectable global changes in uptake/efflux transport function at the BBB ($p>0.05$). In comparison, a significant 1.3±0.2-fold increase in the whole-brain k_{uptake} of [^{18}F]FDS was observed ($p<0.05$), suggesting increased BBB permeability. Regional analysis revealed higher SUVR values for [^{11}C]metoclopramide in the basal forebrain septum ($p<0.01$), suggesting decreased P-gp function. For [^{11}C]diphenhydramine, significant SUVR increases were observed in the hippocampus and olfactory bulb ($p<0.05$). [^{18}F]FDS SUVRs were significantly elevated in the thalamus ($p<0.05$), hypothalamus, and basal forebrain septum (both $p<0.01$). ***Conclusion:*** Our study reveals that depressive-like behaviour in the CORT mice model is associated with subtle yet region-specific changes in BBB permeability and membrane transporter function. From a neuropharmacokinetic perspective, the limited changes in uptake/efflux transporter function are unlikely to account for global changes in the brain exposure to antidepressant drugs in CORT mice. However, region-specific changes in BBB transporter functionality and increased BBB permeability may contribute to the neurobiology of depression. From a translational neuroimaging perspective, multitracer PET imaging using complementary markers of BBB permeability and transport enables quantitative mapping of BBB dysfunctions. This may be useful to address BBB involvement in this neuropsychiatric condition. ***References:*** [1]Dudek KA et al. Proc Natl Acad Sci U S A. 2020;117(6):3326-3336. [2]Auvity S et al. OP-454

Contribution of CXCR4-Targeted PET Imaging in the Non-Invasive Evaluation of Radiation-Induced Brain Injury

J. Pei, *S. Wang, K. Zhao, X. Zhao, J. Yu, J. Liu;*
Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA.

Aim/Introduction: Radiation-induced brain injury (RIBI) is a common and dose-limiting complication of radiotherapy for central nervous system (CNS) tumors. Currently, the lack of reliable and sensitive diagnostic techniques hampers effective prevention and treatment of progressive RIBI. Through single-cell RNA sequencing (scRNA-seq), we identified radiation-responsive cell populations and revealed CXCR4 as a potential biomarker for RIBI. This study aimed to validate the accuracy of CXCR4 as a noninvasive imaging biomarker for early detection and monitoring of RIBI. ***Materials and Methods:*** A small animal radiation research platform was used to establish an RIBI mouse model via localized hippocampal irradiation. Brain tissues were harvested at two weeks post-irradiation for scRNA-seq analysis.

The diagnostic performance of an ^{18}F-labeled CXCR4-targeted tracer ([^{18}F]AlF-NOTA-QHY-04) was evaluated using PET imaging and compared with conventional FDG PET/CT. Additional MRI, dynamic/blocking studies, and histopathological validation were performed. A longitudinal study assessed the predictive value of CXCR4-targeted PET for RIBI progression. ***Results:*** 27 distinct cell subsets were identified and a comprehensive investigation demonstrated remarkable CXCR4 expression in microglia and macrophage subsets enriched in irradiated tissues. [^{18}F]AlF-NOTA-QHY-04 PET demonstrated enhanced uptake in irradiated brain regions before MRI-detectable structural changes. In contrast, [^{18}F] FDG PET exhibited reduced uptake in necrotic areas by 4 weeks post-irradiation. Furthermore, CXCR4-targeted PET imaging enabled quantification and spatial mapping of inflamed brain regions infiltrated by CXCR4-expressing cells and emerged as a robust predictor of subsequent radiation necrosis. ***Conclusion:*** This study establishes CXCR4 as a sensitive and early biomarker for RIBI, demonstrating that CXCR4-targeted PET imaging outperforms conventional FDG PET and MRI in detecting radiation-induced damage before anatomical changes occur. These findings support the potential of CXCR4 imaging for early intervention and personalized management of RIBI. ***References:*** Jinli P, Kai C, Tianxin L, Min G, Shijie W, Shengnan X, Yanluan G, Li M, Wanhu L, Bolin W et al: Early, non-invasive detection of radiation-induced lung injury using PET/CT by targeting CXCR4. Aim/Introduction: Positron Emission Tomography (PET) has particularly advantageous in the realm of brain functional imaging [1]. However, a significant limitation of regular PET scanning is the necessity for anesthesia in small animals to mitigate motion-induced artifacts in the imaging, and anesthetics inhibit brain metabolism and affect PET image accuracy [2]. To enable brain functional imaging in conscious mice, we develop an innovative mouse brain PET scanner. ***Materials and Methods:*** The scanner comprises ten detectors, each consisting of a 6×15 LYSO crystal array (1 mm pixel size) coupled to a 2×5 SiPM array (3 mm pixel size). The scanner, weighing only 55 g, provides a cylindrical field of view (FOV) of 16 mm in diameter and axial length, sufficient to cover the mouse brain. Spatial resolution and sensitivity were evaluated using a 22-Na point source. Image quality was assessed with a Derenzo phantom. FDG-PET imaging was performed on three mice (150-190 μCi), scanned under both awake and anesthetized conditions with identical activity per subject. ***Results:*** The system maintained a stable position relative to the mouse head, enabling functional imaging in the awake state. Filtered Back Projection yielded radial and axial resolutions of 0.7 mm and 1.0 mm, respectively. With six iterations of OSEM, resolution improved to 0.5 mm in both directions. Using an energy window of 261-661 keV, the system achieved 0.8% central sensitivity. Derenzo phantom imaging demonstrated moderate contrast, though 0.7 mm rods could not be fully resolved, possibly due to phantom limitations. Brain PET scans showed distinguishable uptake patterns in both awake and anesthetized mice. Notably, awake mice exhibited slightly reduced uptake, likely due to stress-induced metabolic changes. ***Conclusion:*** This brain PET system demonstrates high spatial resolution and enables functional imaging in both anesthetized and conscious mice. Despite lower sensitivity due to miniaturization constraints, it offers a novel platform for studying natural brain function. Future work will explore mechanical assistance to support imaging during active locomotion. ***References:*** [1] Kadrmas D J, Hoffman J M. Longitudinal SV2A Expression Increase and Profound Desynchronization is Accompanied by Reactive Astrogliosis and Precedes Neurodegeneration in a Mouse Model of Taupathy: A Multi-Tracer Imaging Study

Y. Li[1], *G. Palumbo*[1], *S. Lindner*[1], *F. J. Gildehaus*[1], *A. Zatcepin*[1,2], *R. Werner*[1], *M. Brendel*[1,2,3], *L. H. Kunze*[1,2];

Aim/Introduction: Tau pathological protein accumulation and neuroinflammation are the major hallmarks of tauopathies, resulting in neuronal network dysfunction. [^{18}F]UCB-H, a PET tracer targeting the synaptic vesicle protein 2A (SV2A), holds the potential to evaluate synaptic density. Therefore, we analyzed the longitudinal synaptic density alterations in tau transgenic mice by [^{18}F]UCB-H PET imaging and integrated it with terminal immunohistochemistry to provide more evidence for synaptic quantification. ***Materials and Methods:*** PS19 and C57Bl/6 mice aged 5.7 to 11.0 months underwent four consecutive [^{18}F]UCB-H PET scans to evaluate the SV2A expression. Immunohistochemistry was performed to validate the [^{18}F]UCB-H PET results. In addition, [^{18}F]F-DED PET scans and [^{18}F]GE-180 PET scans were performed at 5.7 months of age to reveal reactive astrogliosis and activated microglia, respectively. Group differences in the uptake were assessed by SUV z-scores. For [^{18}F]UCB-H PET data, a desynchronization index (DI) was calculated for each brain region and principal component analysis (PCA) was performed to assess global differences in SV2A expression synchronization between cohorts with the first principal component (PC1). Moreover, we calculated the area under the curve (AUC) of [^{18}F]UCB-H z-scores to investigate the association between synaptic density variation and reactive gliosis. ***Results:*** Between 8.4 and 10 months we observed an increase in SV2A expression (+4.3-11.5%), followed by a rapid decline towards 11 months (-10.5-23.8%) in neocortex, hippocampus CA1, brainstem, cerebellum, hypothalamus, and thalamus. Contrary, continuous longitudinal reduction of SV2A expression was shown in hippocampus CA3, entorhinal cortex, and amygdala (-12.9-21.0%). Using advanced image processing, we found a major desynchronization of SV2A expression in PS19 cohort at 10.0 months. Immunohistochemistry confirmed the reduction of SV2A expression and a significant tau accumulation in PS19 cohort at 11.0 months, which correlated with [^{18}F]UCB-H PET. [^{18}F]UCB-H variance was positively associated with baseline [^{18}F]F-DED PET in hippocampal CA1, brainstem, piriform cortex, thalamus, and cerebellum (R=0.636-0.736) but was not related to baseline [^{18}F]GE-180 PET. ***Conclusion:*** [^{18}F]UCB-H PET is a powerful method for quantifying synaptic density, dynamically reflecting synaptic differences between cohorts at various pathological stages. As the primary increase is associated with a major desynchronization, it is most likely a reflection of neuronal dysfunction and possibly hyperexcitability in response to tau accumulation, adding to the observed hypermetabolism in the earliest stages of Alzheimer's disease. Moreover, our study shows baseline reactive astrogliosis can be a predictive marker, which is closely associated with subcortical synaptic desynchronization and possibly adding to neuronal hyperexcitability via tripartite synapse.

[18F]SDM-18: A high-affinity SV2A PET tracer for spinal cord imaging

P. W. Tan[1], *T. Balayeva*[1], *N. H. Martin*[1], *Z. Chao*[2], *S. F. Nejati*[1], *T. Toyonaga*[1], *D. Holden*[1], *M. Kapinos*[1], *M. Zheng*[1], *K. Wilcox*[3], *S. Finnema*[3], *R. Carson*[1], *Y. Huang*[1], *Z. Cai*[1];
[1]*School of Medicine, Yale University, New Haven, CT, UNITED STATES OF AMERICA,* [2]*Centre for Addiction and Mental Health, University of Toronto, Toronto, ON, UNITED STATES OF AMERICA,* [3]*AbbVie R&D Discovery Research Neuroscience - Translational Imaging Dept., Chicago, IL, UNITED STATES OF AMERICA.*

Aim/Introduction: Synaptic vesicle glycoprotein 2A (SV2A) is a biomarker for synaptic density. A series of PET imaging probes, have been developed to quantify SV2A in the brain in vivo. However, it remains challenging to quantify the synaptic density in the spinal cord due to its lower SV2A expression. [1] Recently, a high-affinity SV2A PET tracer, [18F]SDM-18 was developed through structural modifications of [18F]SDM-16.[2-4] Herein, we report the PET imaging evaluation of [18F]SDM-18 for the quantification of SV2A in both the brain and spinal cord in the same nonhuman primate (NHP). ***Materials and Methods:*** [18F]SDM-18 was synthesized from commercially available starting materials and evaluated for in vitro binding affinities. Baseline and blocking scans with levetiracetam (30 mg/kg) were performed on rhesus monkeys using a NeuroEXPLORER (NX) PET scanner. Arterial blood was collected for metabolite analysis and the construction of the plasma input function. Regional time-activity curves (TACs) were analyzed using a one-tissue compartment (1TC) model to calculate the volume of distribution (V_T). Binding potential (BP_{ND}) was calculated using the non-displaceable volume of distribution (V_{ND}) determined from the blocking study. ***Results:*** SDM-18 exhibits high affinity for human SV2A (Ki = 2 nM). [18F]SDM-18 was synthesized with >99% radiochemical purity and molar activity of 188 ± 9 GBq/μmol (n = 4). It showed strong uptake in brain and spinal cord, with peak SUVs of ~12 and ~6, respectively. Spinal cord regional V_T values ranged from 15.0 to 50.0 mL/cm^3. SV2A occupancy by levetiracetam (30 mg/kg) was 83% in the brain (V_{ND} = 9.4 mL/cm^3) and 76% in the spinal cord (V_{ND} = 5.7 mL/cm^3). BP_{ND} values for [18F]SDM-18 were higher than [18F]SynVesT-1, [11C]UCB-J, and [18F]SDM-16 in the brain. Notably, cervical spinal cord BP_{ND} for [18F]SDM-18 was over 10-fold higher than that of [11C]UCB-J, highlighting its potential for spinal cord imaging. ***Conclusion:*** We have successfully synthesized [18F]SDM-18 and assessed its imaging properties in NHPs. [18F]SDM-18 has high specific binding signals and appropriate kinetics in the brain and spinal cord, supporting its translation into first-in-human studies for imaging SV2A in the spinal cord. ***References:*** Rossano. Aim/Introduction: Alpha-synuclein (αsyn) is a synaptic protein that, in pathological conditions, forms hyperphosphorylated, insoluble aggregates with high neurotoxic properties. Accumulation and propagation of αsyn aggregates in the brain drives disease progression in Parkinson's disease (PD) and multiple system atrophy (MSA). The aim of this project is the discovery of PET tracers for the visualization of αsyn aggregates in living human subjects, to be used as imaging markers in PD and other synucleinopathies, such as MSA. ***Materials and Methods:*** Compound affinity (K_i) for αsyn aggregates was measured in a miniaturized radioligand binding assay on αsyn aggregate-enriched, idiopathic PD (iPD) brain extracts; selectivity vs. tau and amyloid-beta (Aβ) aggregates, and monoamine-oxidase (MAO) enzymes was investigated using Alzheimer's disease (AD) brain homogenates and microsomes expressing recombinant human MAO. Autoradiography (ARG) and micro-ARG experiments with [3H]-labeled compounds were used to confirm binding to αsyn and measure the affinity (K_D) and the B_{max}. PET studies with [18F]-labeled compounds were performed in anesthetized transgenic (TG) mice expressing aggregated hA53T-αsyn (line-M83) and healthy non-human primates (NHPs). In NHP, the total volume of distribution (V_T) was estimated using and the Logan graphical method with metabolite corrected plasma input function for ROIs defined on a subject specific MRI using a brain atlas. ***Results:*** Up to now, ~900 compounds have entered the project's screening cascade. The most advanced compound, A-2, had a K_i of 41 nM for iPD brain extracts and low affinity for common off targets (K_i=901 nM for Aβ and K_i>4740 nM for tau, MAO-A and MAO-B). Micro-ARG and ARG experiments confirmed that [3H]-A-2 binds specifically to αsyn in brain samples from TG mice, MSA and iPD subjects, with K_D values of 39 nM in the TG mouse medulla, 29 nM in the MSA cerebellar white matter and 24-117 nM in the iPD grey matter. Specific saturable binding was also detected in normal human grey matter. PET studies in NHPs with [18F]-A-2 showed high brain penetration and homogeneous distribution across regions (V_T=3.9±0.23) with rapid washout kinetics. ***Conclusion:*** Compound [18F]A-2 has in-vitro and in-vivo properties suggesting a potential as an αsyn PET tracer for MSA subjects. Despite the in-vitro evidence of specific binding to αsyn aggregates in iPD, the lower predicted in-vivo binding potential (BP_{ND}) and the limited differentiation from normal brain samples advise caution in considering [18F]A-2 for potential use as an αsyn PET tracer in iPD. Further optmization of the K_D and/or B_{max} is warranted.

Aim/Introduction: To optimize a specific 18F-labeled PET tracer based on diarylbisthiazole ([18F]FS9) with excellent binding affinity to α-synuclein fibrils (α-syn), exceptional selectivity over β-amyloid plaques (Aβ) and tau fibrils. It shall exhibit favorable brain uptake, pharmacokinetics, and be evaluated in vitro, by in

vivo longitudinal PET studies, and post-mortem patient-brain and animal models of Parkinson's disease (PD), compared with [^{18}F]FS3. ***Materials and Methods:*** Using an in-silico approach, [^{18}F]FS9 was optimized from [^{18}F]FS3 by synthesizing several leads with promising preclinical results, including enhanced binding affinity and selectivity to α-syn, biodistribution, metabolite analyses, lipophilicity, pharmacokinetics (PK), and Blood-Brain-Barrier permeability. Postmortem autoradiography on human brains with α-synucleinopathies, alongside PET imaging in mouse models, confirmed tracer efficacy. [^{18}F]FS9 was radiolabeled, purified, and applied to a longitudinal study of dynamic 90-minute PET/CT scans, conducted 3-6 months post intrastriatal injection of mouse α-synuclein preformed fibrils (PFF). PFF mice (n≥3) were compared with monomeric α-synuclein-injected control mice (ctrl, n≥3). Preclinical results for PFF and control mice brains were also compared with [^{18}F]FS3 in E46K transgenic and control rats, with ex vivo immunohistochemical (IHC) confirmation. ***Results:*** [^{18}F]FS9 demonstrated a higher binding affinity to α-syn (Ki 2 nM) and >100-fold selectivity over Aβ plaques and neurofibrillary tangles (NFT) than [^{18}F]FS3 (Ki 3.7 nM, logD= 3.4). It showed suitable lipophilicity (logD= 2.8) and favorable PK. In patient brains, [^{18}F]FS9 selectively bound α-synucleinopathies, showing no binding in healthy controls, confirmed by IHC. Compared to [^{18}F]FS3, [^{18}F]FS9 had higher brain uptake (>7% ID/g at 5 min p.i.), rapid washout, and remarkable stability (brain t1/2 >8 hours). Longitudinal PET in PFF mice showed SUV values between 2.0-3.9, with distribution values significantly higher in the PFF brain (1.8-2.7 ml/cm^3 in the left striatum) versus control mice brains (0.8 ml/cm^3). ***Conclusion:*** This work represents a significant advancement in the development of optimized PET tracers, offering groundbreaking potential for accurately detecting and quantifying α-synuclein aggregates, thus paving the way for improved diagnostic and therapeutic strategies in α-synucleinopathies. The rational optimization of [^{18}F]FS3 to [^{18}F]FS9 through an in-silico approach resulted in a highly specific and effective tracer for detecting and quantifying α-synuclein aggregates. [^{18}F]FS9's excellent binding properties and imaging performance establish its further role for clinical investigations in patients with α-synucleinopathies. ***References:*** Uzuegbunam,...Hooshyar Yousefi et al. Bone2Report: Automated Bone Scintigraphy Reporting with Clinically-Inspired Vision-Language Reasoning

X. Wu[1,2], *X. Xie*[1,2], *S. Huang*[3], *H. Zheng*[1,2], *N. Zhang*[1,2], *D. Liang*[1,2], *Y. Liang*[3,4], *Z. Hu*[1,2];
[1]*Research Center for Medical AI, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA,* [2]*Key Laboratory of Biomedical Imaging Science and System, Chinese Academy of Sciences, State Key Laboratory of Biomedical Imaging Science and System, Shenzhen 518055, Shenzhen, CHINA,* [3]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen, CHINA,* [4]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.*

Aim/Introduction: Bone scintigraphy is a widely used imaging modality for detecting skeletal metastases and metabolic abnormalities, playing a crucial role in oncology and metabolic bone disease assessment. Automating the reporting process for bone scans holds substantial clinical value, as it can reduce radiologists' workload and improve report consistency. However, automated report generation for this modality remains underexplored due to blurred image structures, small and dispersed lesions, and limited paired datasets. This work presents Bone2Report(B2Rep), the first framework for automated bone scan reporting, enabling clinically informed multimodal generation and offering a promising pipeline and a foundation for future research. ***Materials and Methods:*** Inspired by the clinical diagnostic and reporting workflow, we propose B2Rep, a multimodal automated bone scan reporting framework. B2Rep mimics physicians' diagnostic process by integrating: (1) a disease-related visual feature extractor that focuses on small-scale abnormalities, and (2) an associative memory-enhanced language module that aligns long-range image-text semantics. Trained on 2,043 image-report pairs, B2Rep generates structured, accurate, and clinically coherent reports. The dataset contains 2,043 clinical bone scans, each consisting of anterior and posterior whole-body images along with corresponding reports. Images were extracted from DICOM format, normalized, and standardized. Reports were processed through lexical analysis and semantic categorization to construct structured image-text pairs. ***Results:*** Evaluation was conducted using standard metrics, including Bilingual Evaluation Understudy(BLEU), Recall-Oriented Understudy for Gisting Evaluation-Longest Common Subsequence(ROUGE-L), and Consensus-based Image Description Evaluation(CIDEr). Training was performed on four NVIDIA RTX 5880 GPUs, and beam search decoding was employed to improve text fluency. B2Rep achieved a BLEU-4 score of 0.204 and a CIDEr score of 0.448, outperforming CT2Rep and CvT2DistilGPT2 (Table 2). The model effectively captured subtle visual cues and generated reports with strong structural and semantic alignment. However, we found some generated reports only contained partial descriptions (Table 1), potentially due to the retrospective reasoning behavior of large language models.[1] ***Conclusion:*** This work presents the first systematic framework for automated bone scan reporting. B2Rep demonstrates the feasibility of clinically informed multimodal generation in nuclear medicine, offering a promising pipeline and a foundation for future research. ***References:*** [1] Ameisen E, Lindsey J, Pearce A, Gurnee W, Turner NL, et al. Deep Multimodal Visual Question Answering System for Prognostication of PSMA-RPT Outcomes Using PSMA-directed Imaging and Clinical Data

M. Kassar[1], *J. Hu*[2], *I. Rauscher*[1], *C. V. Gomes*[2], *T. Wendler*[3], *S. Ziegler*[4], *A. Afshar-Oromieh*[2], *A. Rominger*[2], *N. Navab*[1], *M. Eiber*[1], *K. Shi*[2], *R. Seifert*[2];
[1]*Technische Universität München, München, GERMANY,* [2]*University Hospital Bern, Bern, SWITZERLAND,* [3]*University Hospital Augsburg, Augsburg, GERMANY,* [4]*LMU University Hospital, München, GERMANY.*

Aim/Introduction: The emergence of large language models (LLMs) presents new opportunities for interactive clinical support, though integrating LLMs with imaging-based AI remains a challenge. While vision-language models (VLMs) have been introduced, their synergy for prognostic support is still limited. This study proposes a deep multimodal visual question answering (VQA) approach to integrate imaging data with interactive querying for clinical decision support. As a proof-of-concept, we predict overall survival (OS) using post-therapeutic SPECT from the first two treatment cycles and compare performance with corresponding pre- and post-therapy PSMA-PET scans. ***Materials and Methods:*** We retrospectively analyzed data from 64 mCRPC patients who received more than two cycles of ^{177}Lu-PSMA-I&T and

had baseline ^{68}Ga-PSMA-11 PET/CT. Median OS was 16 months (95% CI:13-24), ranging from 2 to 107 months, with 40% surviving beyond 24 months. A VQA deep learning model was developed to prognosticate 24-month OS by integrating two post-therapy PSMA-SPECT scans via 3D encoders, early biochemical response through PSA levels, and clinical question text via RadBERT[1], a domain-specific pretrained language model. To assess the impact of input modalities, different combinations of PET, SPECT, and PSA data were used during training. The dataset was split 80/20 for training and testing. To enable efficient adaptation and reduce overfitting, Low-Rank Adaptation (LoRA) [2] was used for parameter-efficient fine-tuning of the RadBERT encoder. To preserve the multimodal data's spatial and temporal structure, we applied 3D positional embeddings to image tokens for post-cycle SPECT volumes[3] and standard 1D encodings to text tokens, following the original transformer design[4]. ***Results:*** The best prognostic performance was achieved by combining first- and second-cycle SPECT images with PSA values, yielding 81.82% accuracy (95% CI: 0.54-1.0) and F1 score of 0.82 (95% CI:0.40-1.0) for predicting 24-month OS. Comparable performance was observed with first- and third-cycle PET with PSA. Slightly lower performance was obtained using only first-cycle PET, SPECT, and PSA, with 72.73% accuracy (95% CI:0.45-0.91) and F1 score of 0.73 (95% CI:0.22-1.0). ***Conclusion:*** Our preliminary findings suggest that the developed a deep multimodal VQA approach is feasible for investigating the prognostication of 24-month OS in patients undergoing PSMA-RPT. For this, post-therapeutic SPECT imaging of the first two treatment cycles and corresponding PSA values had best accuracy. However, external validation in additional patient cohorts is needed to confirm these findings. ***References:*** [1] A. Yan et al., Radiol AI 4(4):e210258, 2022. [2] J. Integrated PET/CT Multimodal Automated Report Generation for Lung Cancer Diagnosis

X. Xie[1,2], *H. Wang*[1,2], *E. Liu*[3], *N. Zhang*[1,2], *H. Zheng*[1,2], *D. Liang*[1,2], *X. Yao*[4,5], *S. Cong*[4,5], *L. Jiang*[3], *Z. Hu*[1,2];
[1]*Research Center for Medical AI, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China, Shenzhen, CHINA,* [2]*Key Laboratory of Biomedical Imaging Science and System, Chinese Academy of Sciences, State Key Laboratory of Biomedical Imaging Science and System, Shenzhen, China, Shenzhen, CHINA,* [3]*PET Center, Department of Nuclear Medicine, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China, Guangzhou, CHINA,* [4]*College of Intelligent Science and Engineering, Harbin Engineering University, Harbin 150001, China, Harbin, CHINA,* [5]*Qingdao Innovation and Development Center, Harbin Engineering University, Qingdao, 266000, China, Qingdao, CHINA.*

Aim/Introduction: Automated medical report generation significantly alleviates radiologists' workload and addresses healthcare resource scarcity, with successful applications already established in CT and X-ray domains. However, its implementation in PET imaging remains underexplored due to the modality's inherent limitations in structural delineation and relatively lower spatial resolution.This study establishes the first PET/CT-based multimodal report generation achieving promising clinically automated reporting in lung cancer. ***Materials and Methods:*** In this work, we propose a novel multimodal report generation framework that simultaneously analyzing PET metabolic maps and CT anatomical data, emulating radiologists' diagnostic workflows. Our model introduces two key innovations: 1) A dual-branch adapter architecture that synergizes CT's high-resolution structural mapping and PET's metabolic quantification, with shared transformer parameters facilitating cross-modality attention fusion while maintaining distinct feature hierarchies. 2) a contrastive learning mechanism that aligns metabolic abnormalities with anatomical structures in a shared subspace.The framework processes paired PET/CT scans through coordinated feature extractors that analyze metabolic patterns (PET) and structural details (CT), then fuses these insights through cross-modality reasoning to generate diagnostic reports mimicking radiologists' PET/CT interpretation workflows. We developed a multimodal dataset comprising 600 pathologically confirmed lung cancer cases, augmented to include 1,238 whole-body [18F] FDG PET images, 1,179 CT scans (effective dose ≤1.0 mSv), and 1,830 structured diagnostic reports. ***Results:*** Report generation quality was assessed using natural language processing (NLP) metrics: Bilingual Evaluation Understudy(BLEU), Recall-Oriented Understudy for Gisting Evaluation(ROUGE), Consensus-based Image Description Evaluation(CIDEr), while clinical efficacy (CE) was evaluated through a three-tier classification system: i) lesion malignancy (malignant/benign/indeterminate), ii) metabolic grading (elevated/normal),iii)anatomical localisation (precise/adjacent/erroneous). Proposed multimodal framework demonstrated superior report generation ability due to metabolic-anatomical integration. NLP metrics significantly outperformed conventional baselines (ΔBLEU1=+34%, ΔBLEU4=+57%, ΔROUGE=+66%, ΔCIDEr=+93%). Clinical validation showed: 1) 10.1±3.2% absolute error reduction in sublobar anatomical localisation; 2) 89.7% accuracy in metabolic identification; 3) malignant progression prediction achieved F1-score=0.48 (precision=0.47, recall=0.48) for differentiating aggressive vs indolent tumour subtypes; The method demonstrates promising performance even in ultra-low-dose scenarios (0.9 vs 5.0 mSv), showcasing significant potential. ***Conclusion:*** This study establishes the first PET/CT-based multimodal report generation framework achieving automated reporting in lung cancer. The approach enables radiation-sparing precision diagnostics through synergistic metabolic-anatomical analysis, demonstrating significant potential for clinical translation. To our knowledge, this represents the first multimodal framework specifically designed for PET report generation, establishing a new paradigm for metabolic imaging interpretation.

Aim/Introduction: Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous disease, with approximately 40% of patients experiencing primary treatment failure (PTF) following standard R-CHOP therapy, leading to poor prognosis. The existing risk assessment index, International Prognostic Index (IPI), is limited in

capturing tumor biological heterogeneity, hindering accurate high-risk identification. Therefore, the effective identification of high-risk DLBCL patients for PTF prior to standard R-CHOP treatment is crucial for accurate risk stratification, facilitating individualized treatment plans that enhance prognosis and optimize treatment outcomes. ***Materials and Methods:*** In this study, we developed, validated, and tested a deep learning-based model, LymRadar, for PTF prediction in DLBCL using a large multi-center dataset comprising ^{18}F-FDG PET/CT scans, IPI scores, and other relevant clinical metadata from 1,049 patients across four independent medical centers (n=522, 293, 154 and 80, respectively), with one used for model development and internal testing, and the remaining three for independent external evaluation. To develop LymRadar, a contrastive-learning-enhanced dual-stream 3D ResNet-18 with multi-scale feature fusion module and multi-modality contrastive learning module was used to extract prognostic representations from unannotated pre-treatment whole-body ^{18}F-FDG PET and the corresponding CT images. The deep imaging-derived prediction score was then integrated with the IPI using a logistic regression model to improve outcome prediction. Grad-CAM was applied to generate importance maps of the involvement sites based on LymRadar. ***Results:*** The multi-modality LymRadar model demonstrated robust and consistent performance in predicting primary treatment failure (PTF), achieving average area under the receiver operating characteristic curve (AUC) values ranging from 0.85 to 0.89 across four independent testinig cohorts. These results markedly outperformed models based on single modalities, including PET alone (AUC: 0.81-0.82), CT alone (AUC: 0.70-0.71), and the IPI score alone (AUC: 0.71-0.81). Beyond its predictive accuracy, LymRadar also exhibited strong prognostic relevance. When patients were stratified into high- and low-risk groups based on the model-derived risk probabilities, significant differences in both progression-free survival (PFS) and overall survival (OS) were observed across all cohorts (log-rank test, $P < 0.05$), highlighting the potential of LymRadar as a clinically actionable tool for individualized risk assessment in DLBCL. Additionally, the involvement sites importance mapping could prioritize lesions with higher malignancy and drug resistance with Precision-Recall AUC (PRAUC) of 0.92. ***Conclusion:*** These results demonstrate that the LymRadar model can accurately identify high-risk patients with primary treatment failure and provide involvement sites importance mapping for guiding clinicians in developing refined treatment strategies and biopsy site selection.

OP-464

Large-Scale Analysis of Melanoma Recurrence-Free Survival and Predictors Using AI-Driven Data Extraction from non-English Clinical Reports

C. Hinge*, C. N. Ladefoged, F. L. Andersen, K. Korsholm;*
Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Large-scale retrospective analysis of cancer outcomes, like melanoma recurrence, often requires manual analysis of free-text clinical reports, making such studies difficult at scale. Open-weight Large Language Models (LLMs), deployable offline, offer a potential data-private solution for automated analysis. However, their reliability on non-English nuclear medicine text, requires validation. This work performs the first ever such evaluation, and second, applies an LLM to extract structured data from PET/CT melanoma reports to enable a large-scale analysis of melanoma recurrence-free survival. ***Materials and Methods:*** Study 1 (PET/CT LLM Validation): Three open-weight LLMs (Llama3 70b, Gemma3 27b, Mistral 24b) were evaluated using 852 Danish PET/CT reports - each containing an indication, description, and conclusion section. For each report, the LLM was given the indication and description sections and asked to select the correct conclusion section among five presented options: the report's original conclusion, and four incorrect conclusions randomly sampled from other reports. Study 2 (Melanoma Recurrence Analysis): For each patient, Llama3 70b was given the content of all said patient's PET/CT reports and asked to identify key data (treatment/recurrence/follow-up dates and primary melanoma location). This was done for 1442 melanoma patients (N=4061 reports from Sept 2019 to Sept 2024). Recurrence-free survival (RFS) within 3 years was analyzed using Kaplan-Meier and Cox Proportional Hazards (Cox PH) models, assessing predictors (sex, age, location). ***Results:*** PET/CT LLM Validation: High conclusion classification accuracy was achieved: Llama 3 70b (96.2%), Mistral 24b (94.8%), Gemma 27b (94.7%). An error analysis of Llama 3 70b (32 mistakes total) revealed only 7 instances (0.8% of all cases) where the predicted conclusion was significantly different from the original conclusion. Melanoma Recurrence Analysis: The LLM identified 879 melanoma patients (61%) containing sufficient information for complete data extraction. A multivariable Cox PH analysis on the extracted survival data identified significant predictors of 3-year recurrence: increasing age (HR per year=1.026, $p<0.0005$) and primary melanoma location head/neck (HR=1.444, $p=0.003$). Male sex was significant univariably (HR=1.471) but not multivariably ($p=0.061$) after adjusting for age and location. ***Conclusion:*** Open-weight LLMs demonstrate good performance for complex clinical text analysis as shown by the clinically significant errors (<1%) on classifying Danish PET/CT reports. The subsequent application of the best LLM enabled scalable data extraction for a large retrospective melanoma study (N=879), which showed older age and primary melanoma location as significant 3-year recurrence risk factors. This LLM-driven methodology holds promise for efficient large retrospective analyses of PET/CT studies.

Device-independent Artificial Intelligence Approach for Fast Bone Scintigraphy

V. Menezes[1]*, A. A. S. Oliveira*[1]*, A. J. S. Filho*[1]*, A. F. Morais*[1]*, M. E. Flamini*[1]*, F. A. Mourato*[1]*, T. I. Ren*[2]*, A. Vigário*[3]*, C. Queiroz*[4]*, M. Machado*[5]*;*
[1]Hospital das Clínicas da UFPE, Recife, BRAZIL, [2]Univerisade Federal de Pernambuco, Recife, BRAZIL, [3]ND Núcleo Diagnóstico Maringá, Maringá, BRAZIL, [4]Hospital Universitário Professor Alberto Antunes, Maceió, BRAZIL, [5]Hospital Universitário Professor Edgard Santos - HUPES, Salvador, BRAZIL.

Aim/Introduction: Whole-body bone scintigraphy is essential in oncology diagnostics but involves radiation exposure and long acquisition times. Deep learning (DL) approaches such as U-Net and diffusion-based models have demonstrated effectiveness in enhancing image quality under reduced-dose conditions. However, their clinical adoption is limited due to poor generalizability across different imaging systems. This study introduces a vendor-agnostic adaptive U-Net architecture enhanced with adaptive diffusion layers designed to significantly reduce acquisition time and radiation dose without compromising diagnostic quality. ***Materials and Methods:*** A total of 3,635 retrospective whole-body bone scintigraphy images from four scanner models across five hospitals were included. Images underwent Poisson and Monte Carlo subsampling to simulate reduced count levels (10%, 30%, 50%, 70%) and were normalized to [0,1]. The dataset was split into training (90%), validation (5%), and test (5%) sets. The proposed adaptive U-Net employed a trainable diffusion layer with depthwise convolutions optimized via Adam (learning rate=1×10^{-3}, batch size=1). Data augmentation and weighted sampling balanced the heterogeneous dataset. Image quality metrics included Structural Similarity Index (SSIM), Peak Signal-to-Noise Ratio (PSNR), and Learned Perceptual Image Patch Similarity (LPIPS). Clinical validation was conducted prospectively by three nuclear medicine physicians on 60 additional images using a five-point Likert scale. ***Results:*** The proposed adaptive

model significantly improved image quality compared to noisy counterparts at 50% count reduction: global mean PSNR (39.0 vs. 28.0 dB), SSIM (0.97 vs. 0.87), and LPIPS (0.04 vs. 0.07) (all p<0.01). Clinical assessments demonstrated that DL processing restored image quality (Likert score: 4.4 ± 0.7) comparable to standard acquisition (4.5 ± 0.5) and superior to accelerated acquisitions without DL (3.4 ± 0.7). No diagnostic misinterpretations occurred with DL-processed images. Vendor-agnostic generalizability was validated across different scanner models, including those absent from training data. ***Conclusion:*** An adaptive U-Net architecture with trainable diffusion layers effectively halves whole-body bone scintigraphy acquisition time while maintaining diagnostic image quality. Its vendor-agnostic nature facilitates widespread clinical deployment without scanner-specific retraining, significantly enhancing clinical workflow efficiency and patient comfort. ***References:*** Anand A., et al. Aim/Introduction: Structured and clinically accurate PET/CT report generation remains a time-intensive task requiring expert integration of complex lesion characteristics and anatomical context. Manual reporting is often prone to inter-observer variability and delays, particularly in oncologic imaging with high lesion burden. While recent advances in artificial intelligence (AI) have enabled automated image analysis, the application of large language models (LLMs) to nuclear medicine reporting is still in its infancy. ***Materials and Methods:*** We developed a fully automated pipeline for PET/CT report generation that integrates deep learning-based lesion and organ segmentation with a Qwen LLM fine-tuned via Low-Rank Adaptation (LoRA). Co-registered PET/CT scans undergo lesion segmentation on PET and anatomical segmentation on CT using a previously validated nnUNet-based model. Quantitative imaging biomarkers—including SUVmax, metabolic tumor volume (MTV), total lesion glycolysis (TLG), and anatomical location—are extracted into structured lesion summaries. These summaries are embedded into a prompt template and passed to the fine-tuned Qwen LLM to generate comprehensive clinical reports. The pipeline was trained and evaluated on a multi-center dataset of 1,308 patients, including 905 with lymphoma and 403 with head and neck cancer, all with paired PET/CT scans and corresponding clinical reports. ***Results:*** The segmentation model achieved a Dice coefficient of 0.82 for PET-based lesions and 0.89 for CT-based organ structures. The generated reports reached a BLEU score of 0.79 and a ROUGE-L score of 0.87 when compared with reference reports. Clinical accuracy, as evaluated by board-certified nuclear medicine physicians, was 92.4%. Agreement between AI-generated and physician-authored reports showed a Cohen's kappa of 0.82, indicating substantial concordance. ***Conclusion:*** This study presents a robust and efficient framework for automated PET/CT report generation, leveraging lesion-aware image segmentation and a LoRA-fine-tuned large language model. The pipeline demonstrated good agreement with expert reports and has the potential to support standardized reporting, reduce interpretation time, and assist in managing larger imaging workloads in oncology settings.

Q Amyloid: building an open-access platform for automated amyloid-beta quantification

F. Piva[1], *B. Marin*[1], *C. Da Villa*[1], *L. Maccioni*[1], *M. Moretto*[1,2], *L. Lorenzini*[3], *M. Veronese*[1];
[1]*Department of Information Engineering, University of Padova, Padova, ITALY,* [2]*Department of Neuroimaging, King's College London, London, UNITED KINGDOM,* [3]*Department of Radiology and Nuclear Medicine, Vrije Universiteit Amsterdam, Amsterdam UMC location VUmc, Amsterdam, NETHERLANDS.*

Aim/Introduction: The deposition of amyloid-beta (Aβ) plaques is one of the earliest neuropathological hallmarks of Alzheimer's disease (AD). Positron Emission Tomography (PET) is commonly adopted for in vivo Aβ detection. However, an accurate, efficient, and automated PET-based pipeline to detect brain Aβ accumulation is still missing. This project aims to develop Q Amyloid, an open-access platform for the automated quantification of brain Aβ burden. ***Materials and Methods:*** The Q Amyloid platform quantifies Aβ load using the Centiloid (CL) scale [1]. Structural Magnetic Resonance Imaging (T1-MRI) and PET data from the GAAIN website were adopted in the development of the algorithm. Specifically, PET scans of ^{11}C-PiB, ^{18}F-Florbetaben, ^{18}F-Florbetapir, and ^{18}F-Flutemetamol radiotracers were included to ensure compatibility of the platform with the most commonly used Aβ-PET radiotracers. MRI and PET scans preprocessing was included in the pipeline, following the standard method proposed by Klunk and colleagues [1]. Since poor co-registration quality can impact quantification accuracy, an automated quality control was incorporated to assess the co-registration outcome. Individual Standardised Uptake Value ratios (SUVr) were finally computed and converted to CL [1]. The pipeline was initially evaluated on the GAAIN dataset to replicate the results reported on the website. Then, it was applied and validated to unseen T1-MRI and Aβ-PET scans on impaired and unimpaired individuals pooled from different public and private datasets. ***Results:*** Validation of Q Amyloid pipeline using the standard ^{11}C-PiB dataset downloaded from GAAIN demonstrated that mean SUVr values were within 2% of the published SUVR data for both AD and young control (YC) ($^{PiB}SUVR_{QAmyloid}$: AD = 2.057 ± 0.193, YC = 1.018 ± 0.046; $^{PiB}SUVR_{GAAIN}$: AD = 2.076 ± 0.201, YC = 1.010 ± 0.046). Furthermore, the pipeline showed an excellent correlation with published Centiloid data ($CL_{QAmyloid} = 0.997 \times CL_{GAAIN} + 0.152$; $R^2 > 0.99$). ***Conclusion:*** Once operational, receiving subject-specific T1-MRI and PET scans as input, the platform will generate a report detailing the amyloidosis status. Q Amyloid will serve as a valuable tool in clinical trials, offering quantitative biomarkers to support early AD diagnosis and supporting the development of new Aβ-targeting therapies. This project is supported by the cascading grant "Q Amyloid - Quantitative Amyloid Imaging" under PNRR ECS00000017 "THE-Tuscany Health Ecosystem," Spoke 6: "Precision Medicine & Personalised Healthcare" funded by the NextGeneration EU programme. ***References:*** [1] Klunk, William E., et al. "The Centiloid Project: standardizing quantitative amyloid plaque estimation by PET." Alzheimer's & dementia (2015.)

Improving the referral process to bone scintigraphy by multi-modal detection of at-risk populations for cardiac amyloidosis using machine learning

C. Spielvogel[1], *D. Kersting*[2], *D. Haberl*[1], *J. Yu*[1], *J. Hennenberg*[1], *K. Kluge*[1], *J. Ning*[1], *K. Kumpf*[1], *M. Koefler*[1], *F. Hofer*[1], *T. Traub-Weidinger*[1], *C. Hengstenberg*[1], *M. Hacker*[1], *R. Calabretta*[1], *C. Nitsche*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*University of Duisburg-Essen, Essen, GERMANY.*

Aim/Introduction: Cardiac amyloidosis (CA) is a progressive, underdiagnosed disease characterized by amyloid deposition in cardiac tissue. Early diagnosis is crucial, as novel disease-modifying therapies are most effective in the initial disease stages. However, overlapping symptoms with other cardiac conditions often delay diagnosis. While bone scintigraphy with bone-avid tracers is a reliable tool for confirming CA, timely identification of at-risk patients for referral remains challenging. We propose a multimodal machine learning (ML) approach that integrates clinical routine imaging and non-imaging parameters to support early identification of patients with suspected CA and guide referrals for confirmatory scintigraphy. ***Materials and Methods:*** We retrospectively analyzed all patients undergoing bone scintigraphy for any indication at the Vienna General Hospital between 2010 and 2023 (n = 11,616). Patients scanned before July 2020 were used for model training and cross-validation (n = 9,170) and those after for independent validation (n = 2,446). A total of 65 routinely available pre-scan parameters from electronic health records, including echocardiography, cardiac MRI (CMR), laboratory data, demographics, and comorbidities, were used as predictors. Missing values were retained to reflect real-world clinical settings. Model performance was assessed via 10-fold cross-validation and independent validation. Prognostic value was evaluated using Cox regression for heart failure-associated hospitalization and overall mortality. Additionally, we conducted a trait-wide association study (TWAS) to identify individual predictors of CA. ***Results:*** Of 11,616 patients, 279 (2.3%) showed CA-suggestive uptake. TWAS identified key markers associated with CA, including carpal tunnel syndrome, extracellular volume on CMR, interventricular septum thickness, left ventricular diameter, diastolic function, and blood urea nitrogen (all $p < 0.0001$). In independent validation, the ML model accurately detected high-grade CA (Perugini ≥2) with AUC 0.91, sensitivity 0.82, and specificity 0.84. For any uptake (Perugini ≥1), performance remained strong (AUC 0.89, sensitivity 0.85, specificity 0.71). Notably, the model identified 63% of high-uptake cases that were not suspected by cardiologists in clinical routine. Performance was consistent across subgroups, including patients with comorbidities that may mask CA (AUC > 0.84). All models were significantly associated with heart failure hospitalization and mortality (HR range 1.78-9.08, $p < 0.0001$). ***Conclusion:*** The developed approach reliably identifies patients at risk for CA and may be integrated into hospital information systems to prompt early referral for confirmatory diagnostics. By flagging overlooked cases, this tool has the potential to improve early diagnosis and patient outcomes. A user-friendly web app is available for immediate clinical use and validation.

Clinical Translation of ^{68}Ga-aGPC3-scFv ImmunoPET for Precision Diagnosis and Staging of Newly Diagnosed Hepatocellular Carcinoma

M. Li[1], *W. Hu*[1], *X. Zhang*[1], *X. Cai*[2], *D. Jiang*[1], *X. Lan*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology ; Hubei Key Laboratory of Molecular Imaging, Wuhan 430022, China, Wuhan, CHINA,* [2]*Department of Hepatobiliary Surgery, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related death worldwide. Glypican-3 (GPC3) is a cell surface receptor overexpressed in most HCCs but not by normal or cirrhotic liver tissue, thus providing a unique target for molecular diagnostics. Herein, we have developed a GPC3-specific radiotracer, ^{68}Ga-aGPC3-scFv, and present a prospective, investigator-initiated trial to explore the clinical value of ^{68}Ga-aGPC3-scFv PET/MRI in treatment-naïve patients with hepatic lesions, comparing to conventional imaging methods . ***Materials and Methods:*** ^{68}Ga-aGPC3-scFv was synthesized by radiolabeling NOTA-conjugated scFv with ^{68}Ga (radiolabeling yield >85%, purity >99%). In this translational study, 36 patients with known or suspected HCC who underwent ^{68}Ga-aGPC3-scFv PET/MRI were enrolled prospectively. Among them, 35 patients underwent paired ^{68}Ga-aGPC3-scFv and contrast-enhanced-MRI (CE-MRI). Histopathologic examination and ≥6-month clinical-imaging follow-up served as the reference standard. Two blinded nuclear medicine physicians assessed images to determine lesion detection rates and Barcelona Clinic Liver Cancer (BCLC) staging. Diagnostic performance metrics (sensitivity, specificity, accuracy) and BCLC staging accuracy were assessed against gold standard. ***Results:*** In this study, with a mean age of 62 years (range, 35-77 years), 30 were male and 6 were female. All participants tolerated ^{68}Ga-aGPC3-scFv well, with no adverse events reported during injection or the 4-hour follow-up period. ^{68}Ga-aGPC3-scFv demonstrated favorable pharmacokinetics with rapid blood clearance (blood pool SUVmean decreased by 55% from 0.5 h to 2.5 h). The probe successfully detected HCC lesions and provided high imaging contrast. The tumor-to-liver ratio (TLR) demonstrated high and progressively increasing contrast at dual time points, with median values of 6.48 (range: 1.69-25.78) and 10.09 (range: 2.20-39.85), respectively. Diagnoses were confirmed via pathology (from biopsy or surgery samples) in 32 patients and via imaging and/or clinical follow-up in the remaining 4 patients. ^{68}Ga-aGPC3-scFv PET/MRI demonstrated superior diagnostic performance for detecting primary tumors over enhanced-MRI, sensitivity (90.63% [28/31] vs. 86.67% [26/30]), specificity (>99.99% [5/5] vs. 20% [1/5]) and accuracy (91.67% [33/36] vs. 77.14% [27/35]). Notably, 68Ga-aGPC3-scFv achieved 100% concordance (36/36) with gold-standard BCLC staging and rectifying CE-MRI overstaging in 6 cases (16.7%). ***Conclusion:*** ^{68}Ga-aGPC3-scFv immunoPET enables high-contrast, precise HCC diagnosis and BCLC staging, surpassing conventional modalities. Its exceptional specificity and ability to refine clinical staging highlight its potential to optimize therapeutic decision-making in newly diagnosed HCC patients.

[68Ga]Ga-FAPI-46 PET/CT Enhances Preoperative Assessment of Peritoneal Metastases - Updated Interim Analysis of prospective FAPeCa trial

A. Arçay Öztürk, *G. Liberale, L. Polastro, A. Veron Sanchez, A. Deleu, P. Kristanto, Z. Wimana, L. Taraji, P. Flamen;*
Institut Jules Bordet, Hôpital Universitaire de Bruxelles (H.U.B), Université Libre de Bruxelles (UL), Brussels, BELGIUM.

Aim/Introduction: Standard imaging modalities; CT, MRI, and FDG PET/CT face challenges in accurate preoperative staging of peritoneal metastases (PM) and often underestimate PM extent, leading to unexpected non-resectable disease during surgery. Preliminary reports suggest [68Ga]Ga-FAPI PET/CT, targeting fibroblast activation protein, may offer superior sensitivity for PM detection. This study evaluates [68Ga]Ga-FAPI-46 PET/CT as a preoperative imaging tool for peritoneal carcinomatosis by correlating [68Ga]Ga-FAPI-46 PET/CT findings with surgerical outcomes and standard imaging modalities in colorectal and ovarian cancer. ***Materials and Methods:*** In this ongoing prospective study (NCT06061874), eligible patients with confirmed/suspected PM undergo [68Ga]Ga-FAPI-46 PET/CT, [18F]FDG PET/CT, and abdominopelvic MRI within four weeks before scheduled cytoreductive surgery (CRS) and/or diagnostic laparoscopy (DL). Patients receiving neoadjuvant chemotherapy (NAC) are scanned pre- and post-NAC. Target enrollment is 80 patients. The extent of PM was determined by the peritoneal cancer index (PCI) scoring system. Intraclass correlation coefficient (ICC) was used to assess the concordance between the PCI determined based on [68Ga]Ga-FAPI-46 PET/CT (FAPI-PCI), [18F]FDG PET/CT (FDG-PCI), MRI (MRI-PCI) and the PCI found during surgery (S-PCI). ***Results:*** Fourty-one patients (30 ovarian, 11 colorectal cancer; mean age 61.7) were analyzed. The mean PCI score at surgery (n=48; 38 based on CRS, 10 based on DL) was 15.6±9.4. The mean FAPI-PCI score (n=48, 13.4±9) was significantly higher than the mean MRI-PCI (n=45, 9±7.3, p<0.001) and FDG-PCI (n=46, 7.2±8.8, p<0.001). FAPI-PCI correlated very well with surgical PCI (ICC 0.83, 95% CI: 0.68-0.91). ICC between S-PCI and FAPI-PCI was substantially higher than that between S-PCI and MRI-PCI (ICC 0.49, 95% CI: 0.02-0.75) and S-PCI and FDG-PCI (ICC 0.41, 95% CI: -0.03-0.69). Using PCI≤20 as the resectability threshold, ROC analysis (area under the curve, AUC) showed excellent accuracy with FAPI PET (AUC:0.92), outperforming MRI (0.81) and FDG PET (0.74) in predicting operability. Quantitative parameters, SUVmax (maximum standardized uptake value), TBR (target-to-background ratio) and PTV (total peritoneal tumour volumes) of [68Ga]Ga-FAPI-46 PET/CT for the PM lesions were significantly higher than those of [18F]FDG PET/CT (mean SUVmax: 11.5±6.7 vs. 7.4±8,p<0.001; mean TBR: 9±5.7 vs. 3.7±4.1,p<0.001; mean PTV: 129.1±271.4 ml vs. 80.5±248.3 ml,p<0.001, Wilcoxon signed-rank test). ***Conclusion:*** This expanded interim analysis validates the utility of [68Ga]Ga-FAPI-46 PET/CT in the preoperative PM assessment. It correlates very well with surgical findings, outperforming standard imaging modalities MRI and [18F]FDG PET/CT. Combined with its superior accuracy in predicting resectability, these findings establish FAPI PET/CT as a highly promising preoperative imaging modality for peritoneal carcinomatosis.

OP-471

The Analysis of Biodistribution and Tumor Uptake of [18F] AlF-FAPI-74 in Patients with Soft Tissue Sarcoma and Gastro-Intestinal Tumors compared with [18F]FDG in a prospective, exploratory study

E. Novruzov[1], *F. L. Giesel*[1], *E. Mamlins*[1], *T. Watabe*[2], *J. Cardinale*[1], *Y. Mori*[1], *N. Schupps*[1], *C. Pinto*[3], *C. Soza-Ried*[4], *R. Fernandez*[5], *H. Amaral*[4], *V. Kramer*[4], *L. Badinez*[6];

Aim/Introduction: The roll-out of FAP imaging with small-molecule PET tracers marks one of the major breakthroughs in nuclear medicine. The majority of current evidence, however, has been generated by 68Ga-labelled FAPI tracers, a reliance that presents serious economical and logistic challenges to the oncological community. [18F]AlF-FAPI-74, a recently introduced radiotracer, emerges as a promising candidate to overcome those limitations of 68Ga-labelling. This single-center, prospective, head-to-head analysis aimed to investigate the biodistribution and tumor uptake pattern of [18F]AlF-FAPI-74 in comparison to [18F] FDG imaging in patients with sarcoma and GI-tumors. ***Materials and Methods:*** A total of 19 patients (15 males and 4 females) were enrolled in this prospective study with a head-to-head analysis of [18F]AlF-FAPI-74 and [18F]FDG PET/CT imaging between May 2021 and January 2024. The mean injected activity for [18F] AlF-FAPI-74 and [18F]FDG PET/CT was 239 MBq (± 57) and 209 MBq (± 74) and the mean uptake time was 72 min (± 10) and 73 min (± 17), respectively. All patients had histologically proven malignancies of pancreatic adenocarcinoma (PDAC) in 8 patients, soft tissue sarcoma (STS) in 6 patients, colorectal carcinoma (CRC) in 4 patients and gastric carcinoma in 1 patient. The indications for the conduct of PET/CT scans were completion of primary staging, re-staging in suspected recurrency or therapy response monitoring. ***Results:*** [18F]AlF-FAPI-74 demonstrated superior lesion detectability compared to [18F]FDG, identifying a greater number of both primary and metastatic lesions for tumor entities in total, but also for GI-tumors separately. The detection rate of primary lesions in patients with STS was comparable for both tracers, albeit [18F]AlF-FAPI-74 imaging outperformed [18F]FDG regarding metastatic lesions. Our SUV-metrics analysis revealed more favorable results for the detection of primary lesions with [18F]FAPI-74 imaging (e.g. SUV_{max} ± SD, 6.41 ± 2.8 vs. 9.79 ± 4.2), whereas only the TBR in relation to blood pool appeared to be statistically significant (3.15 vs. 5.08; p: 0,03). We observed a similar tendency in the analysis of SUV-metrics (e.g. SUV_{max} ± SD, 6.18 ± 2.7 vs. 7.42 ± 2.8) in metastatic lesions as well. ***Conclusion:*** Our study confirms that [18F]AlF-FAPI-74 outperformed [18F]FDG, particularly in the detection of metastatic lesions. Therefore, we consider [18F]AlF-FAPI-74 currently to be one of the most promising FAPI candidates for widespread use. Given the advantages of 18F-labelled FAPIs, future research should focus on designing prospective trials with larger cohorts to determine its diagnostic potential and clinical impact.

OP-472

Role of 68Ga-FAPI-46 PET/CT in the evaluation gastrointestinal tract tumors: comparison with 18F-FDG PET/CT

M. Komarova[1], *A. Pronin*[1], *V. Sinitsyn*[2], *E. Davydova*[1], *A. Martinovich*[1], *I. Nazarenko*[1], *V. Solomyany*[1];
[1]*N.N. Blokhin National Medical Research Center of Oncology, Moscow, RUSSIAN FEDERATION,* [2]*Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: the purpose of the study was to evaluate the role of 68Ga-FAPI-46 PET/CT for staging and restaging of gastrointestinal tract tumors and to compare the results with 18F-FDG PET/CT. ***Materials and Methods:*** The study included 52 patients diagnosed with esophageal (10 patients), gastric (39 patients) and colorectal (3 patients) cancers who underwent 68Ga-FAPI and 18F-FDG PET/CT. The time interval between the performed studies was limited to 3-7 days. The tracer uptakes, quantified by maximum standardized uptake value (SUVmax) and target-to-background ratio (TBR) were compared for paired positive lesions between both modalities using Mann-Whitney test. The diagnostic accuracy (sensitivity (Se), specificity (Sp), and accuracy (Ac)) of the 68Ga-FAPI compared with 18F-FDG PET/CT within each clinical case and in the diagnosis of each tumor

lesions were also calculated. ***Results:*** Based on visual assessment, 68Ga-FAPI detected more metastatic lesions than ^{18}F-FDG PET/CT, especially in lymph nodes and peritoneum involvement (total 167 vs 78, respectively). There were no significant differences between SUVmax values in local tumor and metastatic lymph nodes in 68Ga-FAPI and ^{18}F-FDG PET/CT (p>0.05). However, SUVmax in metastases to other organs (mainly peritoneum) and TBR values in primary tumor, positive lymph nodes and metastases to other organs were significantly higher in 68Ga-FAPI-46 PET/CT than in ^{18}F-FDG PET/CT (p<0,05). In patients with histologically proven signet ring cell carcinoma and mucinous tumor, SUVmax and TBR values were significantly higher with 68Ga-FAPI than with ^{18}F-FDG PET/CT (p<0.001). Diagnostic accuracy was higher with 68Ga-FAPI than ^{18}F-FDG PET/CT on a per-patient basis (Se, Sp and Ac were 97.73%, 87.5% and 96.15% vs. 86.05%, 83.33% and 85.71%, respectively) and per-region basis (Se, Sp and Ac were 93.55%, 92.16% and 93.06% vs. 62.35%, 77.97% and 68.75%, respectively). ***Conclusion:*** 68Ga-FAPI PET-CT is a very promising tool for evaluation of patients with gastrointestinal tract tumors, more accurate than ^{18}F-FDG PET-CT and could be recommended as a method of choice for staging and restaging in order to plan the most appropriate therapy.

OP-473

Diagnostic accuracy of 68Ga-FAPI-46 PET/CT vs.^{18}F-FDG PET/CT in patients with liver tumors

M. Komarova[1], *A. Pronin*[1], *A. Martinovich*[1], *O. Ryzhova*[1], *V. Solomyany*[1], *I. Amosova*[1], *V. Sinitsyn*[2];
[1]*N.N. Blokhin National Medical Research Center of Oncology, Moscow, RUSSIAN FEDERATION,* [2]*Lomonosov Moscow State University, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: To compare the diagnostic accuracy of 68Ga-FAPI-46 PET/CT and ^{18}F-FDG PET/CT in patients with liver tumor. ***Materials and Methods:*** 15 patients (mean age 57,5 y.o, 7male/8 female) diagnosed with liver cancer who underwent 68Ga-FAPI and ^{18}F-FDG PET/CT between 7 days were included in the study. 4 patients (pts) were examined to detect progression of the underlying disease (had the previous treatment). The all liver lesions had morphological verification (11 pts had cholangiocarcinoma G1-3, 2 pts. - hepatocellular carcinoma, 1-intraductal papillary tumor of the bile duct and 1 pts - calcifying nested stromal-epithelial tumor). Uptake intensity (SUVmax) and target-to-background ratio (TBR) of the primary liver tumor and lymph nodes metastasis were compared between two imaging modalities. Sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and accuracy (Ac) were calculated for each modality on a per-region basis. ***Results:*** 14 pts were found primary tumor and 3 pts of them had metastases in regional lymph nodes or lung. There was a better contrast with 68Ga-FAPI, with SUVmax of the liver tumors of 14,9 [8,94-23,48] compared with SUVmax of 7,81 [3,55-10,21] of the liver tumors with ^{18}F-FDG (p=0,02). The TBR of primary tumor were higher in 68Ga-FAPI compared with ^{18}F-FDG - 10,56[4,15-16,46] vs. 2,5[1,17-3,67] respectively, p=0,0014. For detection of primary liver tumor and metastasis on region based level Se, Sp, PPV, NPV and Ac of Ga-68 FAPI PET/CT were higher than F18-FDG PET/CT (97,3%, 71,43 %, 90,00%, 90,91% and 90,20% vs. 78,38%, 57,14%, 82,86%,50,00% and 72,55 %, respectively). ***Conclusion:*** 68Ga-FAPI PET-CT is a very promising tool for evaluation of patients with liver tumor because more accurate than ^{18}F-FDG PET-CT. The high level of FAPI uptake in the primary hepatic lesions is indicate the potential of FAP-targeted radionuclide therapy.

OP-474

Dynamic [68Ga]Ga-FAPI-46 LAFOV PET/CT in pancreatic cancer- preliminary results

M. Krarup[1], *R. Aleksyniene*[1], *C. P. Hansen*[2], *J. Madsen*[1], *F. L. Andersen*[1], *K. Korsholm*[1], *J. M. Hall*[1], *I. Chen*[3], *B. M. Fischer*[4], *A. Loft*[1];
[1]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK,* [2]*Department of Surgery, Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK,* [3]*Department of Oncology, Herlev Hospital, Herlev, DENMARK,* [4]*Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: [^{68}Ga]Ga-FAPI-46 long axial field of view (LAFOV) PET/CT has the potential to improve diagnostic imaging for pancreatic cancer patients. The ongoing clinical trial "BEFAST-study" investigates the diagnostic sensitivity of [^{68}Ga]Ga-FAPI-46 LAFOV PET/CT for preoperative staging in pancreatic cancer (CTIS: 2023-503632-41-01). This report presents a preliminary analysis of 10 dynamic [^{68}Ga]Ga-FAPI-46 LAFOV PET/CTs, exploring changes in tracer-uptake over time in both primary tumor and surrounding tissues. ***Materials and Methods:*** Patients referred for curative surgery with pathologically verified or suspected pancreatic cancer were prospectively included in the study. The participants underwent a 65 min dynamic [^{68}Ga]Ga-FAPI-46 PET/CT on a LAFOV scanner prior to surgery. A low-dose CT (ref mAs 7.0) was used for attenuation correction. Patients received an injection of 1.5-2.0 MBq/kg of [^{68}Ga]Ga-FAPI-46. Static images were reconstructed with 5 min duration at 5,10,15,20,25 and 60 minutes(min) after scan initiation. A volume of interest (VOI) was drawn with visual adaption in the primary tumor using a threshold of 40% of the SUV_{max}. SUV_{max} and SUV_{mean} were obtained from the tumor VOI. VOIs (diameter 3cm) were placed in healthy liver and muscle tissue to assess background SUV_{mean}. Tumor-to-background ratio (TBR) was calculated by dividing the primary tumor SUV_{max} by the liver tissue SUV_{mean}. Friedmans test and the Wilcoxon signed-rank test were used to evaluate changes in SUV and TBR across the timepoints. ***Results:*** Ten patients were included in this preliminary analysis. Postsurgical pathology confirmed pancreatic ductal adenocarcinoma in 8 patients, intraductal papillary mucious neoplasia (IPNM) in 1 patient and non-specified adenocarcinoma in 1 patient. Tumor SUV_{max} and SUV_{mean} peaked between 15-20min and were lowest after 60min. No significant differences were observed in tumor SUV_{mean} or SUV_{max} across the timepoints. The patient with IPNM exhibited the lowest tumor SUV-values. Significant differences were observed in liver SUV_{mean}, muscle SUV_{mean} and TBR across the time-points. Liver SUV_{mean} was significantly higher in early timepoints (5-15min), whereas muscle SUV_{mean} peaked between 15-30min compared to other timepoints. TBR was significantly lower from 5-10min compared to later time points. Highest mean TBR-values were observed after 25-30min. ***Conclusion:*** This preliminary analysis showed no significant changes in tumor SUV across the timepoints, and the highest mean TBR at 25-30min, supporting [^{68}Ga]Ga-FAPI-46 PET/CT acquisitioning at earlier timepoints. Lowest tumor SUV-values were observed in the IPMN-case, which aligns with previous findings, suggesting potential for discriminating malignant and benign pancreatic lesions with [^{68}Ga]Ga-FAPI-46 LAFOV PET/CT.

OP-476

The Role of [^{68}Ga]Ga-FAPi PET/CT in Evaluating Treatment Response in Gastrointestinal System Malignancies

G. Beydagi[1], *K. Akcay*[1], *A. Gormez*[2], *L. Kabasakal*[1], *N. Alan-Selcuk*[1];
[1]*Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Yeditepe University, Department of Radiology, Istanbul, TÜRKIYE.*

Aim/Introduction: This study aims to investigate the potential efficacy of [^{68}Ga]Ga-FAPi PET/CT in evaluating treatment response in gastrointestinal system malignancies. ***Materials and Methods:***

Patients with histopathologically confirmed gastrointestinal malignancies who were prospectively enrolled for treatment response assessment between November 2020 and January 2025 were included in the study. All imaging studies were interpreted by consensus among three experienced nuclear medicine specialists. The maximum standardized uptake values (SUVmax), total tumor volumes, and total lesion FAP expression values were recorded. Patients' serum tumor marker levels (such as carcinoembryonic antigen [CEA] and CA 19-9) were also recorded. Imaging-based treatment responses were separately evaluated according to PERCIST criteria on [^{68}Ga]Ga-FAPi PET/CT and RECIST criteria on CT scans. ***Results:*** A total of 100 [^{68}Ga]Ga-FAPi PET/CT scans were performed in 50 patients (mean age: 61.62 ± 12.95) who were referred for treatment response assessment, including both pre- and post-treatment imaging. Among the patients included in the study, 70% were diagnosed with gastric cancer, 14% with colorectal cancer, 8% with pancreatic cancer, 4% with appendiceal cancer, 2% with hepatocellular carcinoma (HCC), and 2% with cholangiocellular carcinoma. Primary tumor lesions were present in 62% of patients, lymph node metastases in 24%, visceral metastases in 10%, peritoneal metastases in 76%, and bone metastases in 14%. A strong correlation was observed between tumor volumes measured by [^{68}Ga]Ga-FAPi PET/CT and serum tumor markers. The area under the curve (AUC) for ΔTumor Volume was 0.875. A statistically significant and near-perfect agreement was observed between [^{68}Ga]Ga-FAPi PERCIST and CT-based RECIST criteria (Kappa = 0.833, $p < 0.05$). Moderate agreement was observed in primary tumor sites (Kappa = 0.526, $p < 0.05$) and bone metastases (Kappa = 0.657, $p < 0.05$), while near-perfect agreement was noted in lymph node metastases (Kappa = 1, $p < 0.05$), peritoneal metastases (Kappa = 0.815, $p < 0.05$), and visceral metastases (Kappa = 1, $p < 0.05$). According to Kaplan-Meier analysis, treatment responses assessed by [^{68}Ga]Ga-FAPi PET/CT were predictive of overall survival ($p = 0.02$). According to PERCIST criteria on [^{68}Ga]Ga-FAPi PET/CT images, median overall survival was 7.6 months in patients with progressive disease and 19.8 months in those with stable disease, while the median overall survival was not reached in patients with partial or complete response. ***Conclusion:*** Our findings suggest that [^{68}Ga]Ga-FAPi PET/CT may be an effective alternative for treatment monitoring and follow-up in gastrointestinal malignancies, especially in tumors with low FDG avidity.

OP-477

A Clinical-Radiomics Integrated Model Based on Baseline ^{18}F-FDG PET/CT Predicts Survival Outcomes in Hepatocellular Carcinoma Patients Receiving PD-1 Inhibitor Combined with Lenvatinib as Preoperative Conversion Therapy

J. Zhang[1], *G. Wang*[2], *J. Cui*[1], *C. Li*[1], *Y. Han*[1], *Y. Pan*[1], *B. Xu*[1];
[1]*Department of Nuclear Medicine, The First Medical Center of Chinese PLA General Hospital, Beijing, CHINA,* [2]*Nuclear Medicine Department, Beijing Friendship Hospital, Affiliated to Capital Medical University, Beijing, CHINA.*

Aim/Introduction: Preoperative conversion therapy strategies, such as Lenvatinib combined with programmed cell death protein 1 (PD-1) inhibitors, significantly improve surgical resectability in hepatocellular carcinoma (HCC). However, heterogeneous patient outcomes limit clinical benefits. This study aims to construct a combined predictive model integrating baseline ^{18}F-FDG PET/CT radiomics features and clinical parameters to precisely evaluate overall survival (OS) and progression-free survival (PFS), providing imaging-based biological evidence for personalized therapeutic decision-making. ***Materials and Methods:*** We retrospectively enrolled 90 HCC patients treated with Lenvatinib plus PD-1 inhibitors as preoperative conversion therapy. Baseline ^{18}F-FDG PET/CT images and clinical data were collected. LifeX software was used to delineate tumor regions of interest (ROIs) at an 80% SUVmax threshold, extracting radiomics features including morphological, textural, and metabolic heterogeneity. Minimum redundancy and maximum relevance (mRMR) and LASSO regression were applied for feature selection. A multivariate Cox proportional hazards model combining radiomics signatures and clinical variables was developed. ***Results:*** The clinical-radiomics integrated model demonstrated superior performance in both OS and PFS prediction. For OS, the model incorporated radiomics features, albumin (ALB), major pathological response (MPR), and radiotherapy, achieving C-indices of 0.905 (95% CI: 0.866-0.943) in training and 0.814 (95% CI: 0.713-0.915) in validation cohorts, with significant improvement over clinical-only models. High-risk patients showed markedly reduced median OS (training HR=14.141, 95% CI: 3.464-57.732; validation HR=3.969, 95% CI: 0.846-18.626). For PFS, the model integrated radiomics features with surgery, transarterial chemoembolization (TACE), and radiotherapy, yielding C-indices of 0.842 (95% CI: 0.774-0.910) and 0.857 (95% CI: 0.800-0.914) in training and validation cohorts, respectively. Stable HRs (training HR=8.385, 95% CI: 1.691-41.570; validation HR=6.796, 95% CI: 1.741-26.525) confirmed robust generalizability for short-term prognosis. ***Conclusion:*** This clinical-radiomics integrated model, by quantifying tumor metabolic heterogeneity, enables noninvasive prediction of OS and PFS in HCC patients undergoing PD-1 inhibitor plus Lenvatinib conversion therapy. It provides a critical tool for risk stratification and personalized preoperative treatment optimization. Multicenter prospective studies are warranted to validate its clinical translation and elucidate underlying biological mechanisms.

OP-478

Evaluation of the Performance of [^{18}F]fluorocholine PET/CT for the Preoperative Localization of Parathyroid Adenoma in Patients with Primary Hyperparathyroidism and Negative [^{99m}Tc]Tc-MIBI SPECT/CT: Our experience

E. Pérez de los Ríos*, O. Ajuria Illarramendi, A. Martínez Lorca, T. Navarro Martínez, P. Azpeitia Hernández, M. Gutiérrez Guerrero, U. Vera Schmülling, I. Hernández Pérez, P. Paredes Rodríguez, M. Ottino, M. Orduña Díez;*
Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: To determine the utility of [^{18}F]fluorocholine PET/CT for the preoperative localization of parathyroid adenoma in patients with primary hyperparathyroidism and negative [^{99m}Tc]Tc-MIBI SPECT/CT, and to evaluate the diagnostic performance of this test at our center. ***Materials and Methods:*** A retrospective and descriptive study including patients with primary hyperparathyroidism (PHPT) meeting surgical criteria, who underwent an [^{18}F]fluorocholine PET/CT study between 2020 and 2024 at our center for preoperative localization of parathyroid adenoma. Data collected: age, sex, parathyroid hormone (PTH) levels, [^{99m}Tc]Tc-MIBI SPECT/CT, surgical intervention, and pathology results for operated cases. Exclusion criteria: positive [^{99m}Tc]Tc-MIBI SPECT/CT, and patients who previously underwent parathyroid surgery. The gold standard was the pathological analysis of the lesion. ***Results:*** A total of 139 patients were included (mean age 61.75 years; 67.6% female). Mean PTH levels were 119.33 ng/mL in women and 118.25 ng/mL in men. [^{18}F] fluorocholine PET/CT detected 78 positive and 61 negative cases.

Surgery was performed in 41% of the PHPT patients (57/139). 64% (50/78) with positive [^{18}F]fluorocholine PET/CT results, and 11.47% (7/61) with negative [^{18}F]fluorocholine PET/CT results underwent surgery. Of the positive [^{18}F]fluorocholine PET/CT cases, 35% (28/78) are pending surgery or declined surgery, and 11.47% (7/61) of the negative [^{18}F]fluorocholine PET/CT cases underwent surgery due to elevated PTH levels and suspicion of other pathologies. Pathological analysis confirmed parathyroid adenoma in 92% (46/50) of the operated patients with positive [^{18}F] fluorocholine PET/CT, 4 false positives (FP). 0% (0/7) of operated patients with negative [^{18}F]fluorocholine PET/CT, 7 true negatives (TN). The results yielded a sensitivity (Se) of 100%, a specificity (Sp) of 63%, a positive predictive value (PPV) of 90%, and a negative predictive value (NPV) of 100%. ***Conclusion:*** [^{18}F]fluorocholine PET/CT is a highly useful technique for the localization of parathyroid adenomas, which facilitates surgical intervention due to its excellent diagnostic performance.

OP-479

Development of a set of predictors for a machine learning model that will be able to predict ^{18}F-fluorocholine PET/CT findings in patients with primary hyperparathyroidism based on a medical record

N. Pantic[1], *B. Radovic*[1,2], *L. Grujicic*[1], *M. Kotur*[1], *K. Petrovic*[1], *J. Malicevic Crevar*[1], *J. Zivanovic*[1], *A. Novkovic*[1], *O. Radivojevic*[1], *A. Ivanovski*[1], *A. Jovanovic*[1], *M. Veljkovic*[1,3], *I. Grozdic Milojevic*[1,3], *D. Sobic Saranovic*[1,3], *V. Artiko*[1,3], *S. Odalovic*[1,3];
[1]*Center for Nuclear Medicine with PET, University Clinical Center of Serbia, Belgrade, SERBIA,* [2]*Faculty of Medicine, University of Pristina with temporary headquarters in Kosovska Mitrovica, Kosovska Mitrovica, SERBIA,* [3]*Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.*

Aim/Introduction: Partial-body [^{18}F]fluorocholine (FCH) positron emission tomography and computed tomography (PET/CT) might substitute cervical ultrasonography and [^{99m}Tc]Tc-methoxy isobutyl isonitrile (MIBI) single-photon emission computed tomography and computed tomography (SPECT/CT) in the evaluation of patients with primary hyperparathyroidism, such that imaging can be developed into an FCH PET/CT-based one-stop-shop localization strategy. In line with this, a recent meta-analysis demonstrated the superior performance of FCH PET/CT in both patient-based and lesion-based analyses. However, FCH PET/CT is currently more expensive than MIBI SPECT/CT (1). We are conducting a prospective study of patients with primary hyperparathyroidism, with the goal of detecting potential predictors of FCH PET/CT positivity. ***Materials and Methods:*** A three-dimensional PET scan and a low-dose non-enhanced CT scan were acquired from the cranial base to the apex of the heart 45 minutes after the injection of 192.57+/-40.89 MBq of FCH. After the exclusion of the patients with inconclusive FCH PET/CT findings, a total of 86 patients were enrolled in the study. ***Results:*** The difference between the total calcium blood level median of patients who are positive on FCH PET/CT examination (2.35-4.05 mmol/l; median 2.75 mmol/l) and the total calcium blood level median of patients who are negative on FCH PET/CT examination (2.19-3.25 mmol/l; median 2.53 mmol/l) is statistically significant (p=0.028), with the specificity of 82% and sensitivity of 57% for the cut-off value of 2.63 mmol/l. Meanwhile, the difference between means, medians, and proportions for PTH, vitamin D, ionized calcium, and phosphate blood levels, as well as history of nephro- or urolithiasis and pathologic fractures, is not statistically significant (p>0.05). ***Conclusion:*** Serum total calcium concentration is the only variable among laboratory and clinical parameters that has shown a correlation with FCH PET/CT findings so far. The goal is to reach a high enough number of patients so that a machine learning model that will be able to predict FCH PET/CT findings before the examination itself can be formulated and so that only those in need of the procedure go through one. In that case, the method will be utilized only for a localization of the overactive parathyroid gland, and costs will drastically reduce since the selection of patients will be the most accurate possible. ***References:*** 1. van Mossel S, Saing S, Appelman-Dijkstra N, Quak E, Schepers A, et al. Cost-effectiveness of one-stop-shop [18F] Fluorocholine PET/CT to localise parathyroid adenomas in patients suffering from primary hyperparathyroidism. Protocol Optimization in 3T PET/MRI for Primary Hyperparathyroidism: Comparative Analysis of MRI Sequences and [18F]Fluorocholine Uptake.

V. Carrero-Vásquez, *A. Villamayor Hernández, J. Díaz-Moreno, M. Cortés Romera, B. Hervás-Sanz, M. Zamorano-Rivas, A. Bagan-Trejo, C. Martínez-Ramos, M. Pudis, I. Sanchez-Rodriguez;*
Nuclear Medicine, Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: [18F]Fluorocholine PET/MRI has emerged as a promising second-line tool for localizing hyperfunctioning parathyroid glands in primary hyperparathyroidism (PHPT), especially in cases with inconclusive conventional imaging. However, the need for multiple MRI sequences in this setting is debated. This study aims to determine the minimal MRI sequence set required without compromising diagnostic accuracy, analyze adenoma signal characteristics, explore the relationship between MRI signal intensity and PET uptake (SUVmax), and assess PET/MRI concordance. ***Materials and Methods:*** We retrospectively included 47 patients with PHPT and negative or inconclusive ultrasound and/or 99mTc-sestamibi SPECT/CT. All underwent 3T [18F]fluorocholine PET/MRI, including axial T1-Dixon, T2-TSE, and coronal T2-STIR sequences. Lesions were evaluated for signal intensity (hypo-, iso-, or hyperintense) and detection in each MRI sequence. PET uptake was measured using SUVmax. Diagnostic performance was assessed descriptively. Kruskal-Wallis tests were used to analyze the association between signal intensity and SUVmax. Histopathological confirmation was available in 12 patients. ***Results:*** All 47 patients had PET-positive lesions, with 100% concordance with MRI detection in at least one sequence. Detection rates were 82.6% for T1, 87.2% for T2-TSE, and 85.1% for T2-STIR. Hyperintensity was more frequently observed in T2-TSE (78.7%) and T2-STIR (80.9%) than in T1 (4.3%). Mean SUVmax was 6.6 (T1-detected), 6.4 (T2-TSE), and 6.5 (STIR). SUVmax significantly correlated with signal intensity across all sequences ($p < 0.01$). Among histologically confirmed lesions, all showed hyperintensity on T2/STIR and 91.6% had SUVmax > 4. Comparative analysis between T2-TSE and STIR revealed near-identical diagnostic performance, suggesting one sequence—preferably T2-TSE—could be omitted to streamline acquisition. ***Conclusion:*** The study confirms that a simplified MRI protocol using T1 and STIR provides robust diagnostic accuracy for detecting hyperfunctioning parathyroid adenomas. T2-STIR offers similar or superior lesion conspicuity compared to T2-TSE, with fewer artifacts, supporting its selection when reducing sequence count. The strong correlation between MRI signal intensity and SUVmax highlights the functional-anatomical relationship captured by PET/MRI. Histopathological concordance further supports the imaging findings. This optimized PET/MRI protocol could enhance clinical workflow by reducing scan time and improving patient tolerance without compromising diagnostic confidence. Larger prospective studies are warranted to validate these findings and support wider implementation.

OP-481

Clinical application and semiquantitative analysis of ^{18}F-FCH PET/CT in the pre-surgical localization of primary hyperparathyroidism.

E. Campaña Díaz[1], *P. García-Talavera San Miguel*[1], *F. Gómez-Caminero López*[1], *J. Álvarez Pérez*[1], *C. Montes Fuentes*[1], *J. Badell Martínez*[1], *E. Martin Gallardo*[2], *S. Rama Alonso*[1], *A. Peñaherrera Cepeda*[1], *J. Villanueva Curto*[1], *F. Caltagirone*[1], *B. Santos García*[1], *M. Tamayo Alonso*[1], *M. Martín Gómez*[1];

Aim/Introduction: To evaluate the diagnostic performance of the technique to distinguish between pathological parathyroid gland, lymph node, and thyroid nodule. To propose cut-off points

for uptake values to differentiate these structures and study their behavior in the PET/CT imaging technique. ***Materials and Methods:*** We included 74 patients (59 females; 60.11±12.82 years) in whom ^{18}F-FCH PET/CT was performed for pre-surgical localization of PHPT. Standard ^{18}F-FCH images were acquired 5 and 60 minutes after 185 MBq intravenous administration. Delayed images were assessed semiquantitatively by means of calculation of SUVmax and SUVpeak of pathological parathyroid (P-SUVmax, P-SUVpeak), thyroid gland SUVpeak (T-SUVpeak), mediastinum SUVpeak (M-SUVpeak), lymph nodes (N-SUVmax, N-SUVmean) and thyroid nodules (NT-SUVmax, NT-SUVmean). SUV ratios were calculated with thyroid and mediastinum. The diagnostic performance of the ^{18}F-FCH PET/CT to discriminate pathological parathyroid gland vs lymph node and thyroid nodule was evaluated by analysis of the receiver operating characteristic (ROC) curve analyzing P-SUVmax vs N-SUVmax, P-SUVpeak/M-SUVpeak vs N-SUVpeak/M-SUVpeak, P-SUVmax/T-SUVpeak vs NT-SUVmax/T-SUVpeak in the delayed images. ***Results:*** During surgery the pathological gland was located in 72 cases (66 solitary adenomas, 5 double adenomas, 1 hyperplasia). The histological results of the other 2 patients were papillary thyroid carcinoma and oncocytic thyroid adenoma, which were 2 false positives for ^{18}F-FCH PET/CT. PET/CT had 2 false negatives in the analysis per patient. The ROC curves showed a cut-off of 2.72 for P-SUVmax vs N-SUVmax (S=82%, E=69%, AUC=0.8), 3.34 for P-SUVpeak/M-SUVpeak vs N-SUVpeak/M-SUVpeak (S=69%, E=85%, AUC=0.8), and 1.66 for P-SUVmax/T-SUVpeak vs NT-SUVmax/T-SUVpeak (S=65%, E=87%, AUC=0.8). ***Conclusion:*** The semiquantitative analysis in ^{18}F-FCH PET/CT is a useful and complementary support for the visual analysis in the pre-surgical localization of primary hyperparathyroidism.

OP-482

Incremental benefit of integrated 18-fluorocholine PET and 4DCT in preoperative parathyroid adenoma localization over either modality alone

D. Malik, *D. Thakrani, J. Gupta, M. Koley, N. Rana, A. Uppal, P. Thakral, I. B. Sen;*
Fortis Memorial research institute (FMRI), Gurugram, INDIA.

Aim/Introduction: Unilateral minimally invasive parathyroidectomy is the favoured surgical technique for treating parathyroid adenomas which needs accurate preoperative localization of the adenomas. Both 18F-Choline(18F-CH) PET and 4D-CT show good sensitivity for diagnosis and localization of parathyroid adenoma /hyperplasia pre-operatively. We aim to determine the incremental value of combined 18F-CH PET and 4D-CT over either modality alone. ***Materials and Methods:*** This was a prospective single centre study of 63 patients with clinically suspected primary hyperparathyroidism (hypercalcemia with hypophosphatemia and elevated PTH levels), who had a negative or a discordant 99mTc- Sestamibi scan and/or neck ultrasound and were planned for surgical exploration. The exclusion criteria included pregnant or lactating females, age<18, hypocalcemic, hyperparathyroidism,contrast allergy and deranged renal function. 63 patients underwent integrated 18F-CH PET CT and 4DCT, out of which 49 patients were found positive either by 18F-CH PET or 4DCT or both and subsequently underwent surgery. The other 14 patients were excluded as both 18F-CH PET and 4DCT were negative and patients were, therefore, not taken up for surgery. Sensitivity, positive predictive value and diagnostic accuracy were calculated as per lesion analysis for integrated 18F-CH PET and 4DCT and for each of these modalities separately. The post-operative histopathology was considered as the gold standard. ***Results:*** Of the 49 patients, 40 were positive on both modalities (concordant positive), while 9 had discordant results (6 4DCT negative patients were positive on FCH PET, and 3 FCH PET negative patients were positive on 4DCT). On the post-operative histopathology, 3/40 concordant positive patients tested negative while rest of the 37 tested positive for an adenoma. 5 / 6 "FCH positive-4D CT negative" patients tested positive for an adenoma and 1/6 turned out be negative while all of the 3 patients negative on FCH PET and positive on 4D CT turned out to be positive on post-operative histopathology. The highest sensitivity (100%) and diagnostic accuracy (93.8 %) for adenoma detection was recorded with the integrated 18FCH PET/4DCT. FCH-PET alone demonstrates higher sensitivity (93% vs 89%) and accuracy (87% vs 85%) than 4DCT alone. ***Conclusion:*** Integrated modality 18F-CH PET /4DCT demonstrates higher diagnostic accuracy in the pre -operative detection and localization of parathyroid adenoma than either modality used alone.

OP-483

[^{18}F]Fluorocholine PET/CT in the Diagnosis of Hyperparathyroidism: Comparison with Other Preoperative Localization Methods and correlation with biochemical markers

N. Calviño, *A. García-Burillo, D. Sanchez-Artuñedo, A. Palomar-Muñoz, R. Vilallonga-Puy, M. Diez Castro, M. Rubio Alvarez, J. Echeverri-Díaz, M. Marusso Fizzani, Ó. Hernandez Cristancho, L. Marconi Porcel, L. Nunes Lemos, C. Gámez-Cenzano;*
Vall d´Hebron Hospital Universitari, Vall d´Hebron Barcelona Hospital Campus, Passeig Vall d´Hebron 119-129, Barcelona, SPAIN.

Aim/Introduction: To evaluate the diagnostic performance of [18F] fluorocholine PET/CT in patients with hyperparathyroidism (HPT), compare it with neck ultrasound (US) and [99mTc]Tc-MIBI SPECT/CT, and analyze correlations with histopathological findings and biochemical markers (PTH and calcium). ***Materials and Methods:*** This retrospective study included a cohort of 126 patients with HPT who were referred for [18F]fluorocholine PET/CT at our center between 2022-2023. Only those who had undergone surgery by the time of the study were included in the analysis. For these patients, preoperative localization imaging results, serum PTH and calcium levels, and histopathological findings were collected. For each imaging modality, a true positive was defined as histology confirmation of an abnormal parathyroid gland (hyperplasia or adenoma) corresponding to the same side of the neck as indicated on imaging. ***Results:*** Among 126 patients that underwent [18F] fluorocholine PET/CT, 50 patients (38 women [76%], mean age 61.3 years [28-80]) were surgically treated. All patients had at least two preoperative localization studies, US, [99mTc]Tc-MIBI and/or [18F]fluorocholine PET/CT. The [18F]fluorocholine PET/CT was positive in 49 patients and negative in 1 patient (US positive); US was performed in all except two patients, both of these had positive PET/CT and [99mTc]Tc-MIBI. [99mTc]Tc-MIBI SPECT/CT was performed in 40 patients of whom 14 showed positive results. Sixty-eight glands were removed: 2 patients had 4 glands, 4 patients had 3 glands and 5 had 2 glands removed. One patient had no identifiable parathyroid tissue in the submitted samples. Histopathology revealed 37 adenomas, 19 hyperplasias and 11 glands with no morphological abnormalities. The sensitivity of [18F]fluorocholine PET/CT for the localizing hyperfunctioning parathyroid tissue was 84%, being higher than the other imaging tests (US 41% and [99mTc]Tc-MIBI 45%). Sensitivity was higher for detecting adenomas (89%) than hyperplasia (73%). Analysis of PTH, total calcium, and SUVmax values showed no significant correlations between variables. However, when comparing calcium levels with histological subtypes using the Kruskal-Wallis test, a statistically significant difference was observed (p=0.047): patients with adenomas had a median calcium level of 10.9mg/dL, compared to 10.2mg/dL in those with hyperplasia. ***Conclusion:*** Our results demonstrate that [18F]fluorocholine PET/CT has superior diagnostic accuracy in preoperative localization of hyperfunctioning parathyroid glands compared to conventional imaging such as US and [99mTc]Tc-MIBI SPECT/CT. Sensitivity was higher for detecting adenomas than hyperplasia. It can

significantly improve surgical planning, particularly when prior imaging is inconclusive. Additionally, serum calcium levels may provide complementary diagnostic value in distinguishing between adenoma and hyperplasia.

OP-484

Real-World Diagnostic Performance of 99mTc-SestaMIBI Scintigraphy and Fluorocholine PET/CT in Primary Hyperparathyroidism: A Comparative Analysis from Two Italian Centers

I. Gotuzzo[1], *F. Garrou*[1], *L. Airò Farulla*[2], *S. Vadalà*[3], *F. Lattuada*[1], *F. Del Gaudio*[1], *E. Bressan*[3], *M. Carrara*[1], *A. Rossini*[4], *S. Ippolito*[4], *S. Cassibba*[4], *C. Rossetti*[2], *P. A. Erba*[3];
[1]*Nuclear Medicine Unit - ASST Papa Giovanni XXIII Hospital, Bergamo, ITALY,* [2]*Nuclear Medicine Unit - ASST Grande Ospedale Metropolitano Niguarda, Milano, ITALY,* [3]*School of Medicine and Surgery, University of Milano-Bicocca, Milano, ITALY,* [4]*Endocrinology Unit - ASST Papa Giovanni XXIII Hospital, Bergamo, ITALY.*

Aim/Introduction: Primary hyperparathyroidism (PHPT) is a prevalent endocrine disorder typically managed through surgical resection of hyperfunctioning parathyroid glands. While fluorocholine (FCH) PET/CT has demonstrated superior sensitivity—particularly in detecting multiple hyperfunctioning glands—Italian reimbursement policies still mandate initial imaging with 99mTc-SestaMIBI scintigraphy, with FCH PET/CT reserved for equivocal or negative cases. ***Materials and Methods:*** A retrospective analysis of 193 PHPT patients (148 women, 45 men; mean age 64.4 ± 10.2 years) referred between January 2023 and April 2025 to two hospitals (ASST Papa Giovanni XXIII, Bergamo; ASST Grande Ospedale Metropolitano Niguarda, Milan) was conducted. Data were extracted from electronic medical records. Patients underwent clinical evaluation, laboratory testing, and neck ultrasonography prior to imaging. ***Results:*** ^{99m}Tc-SestaMIBI scintigraphy (dual time planar and SPECT/CT imaging protocol) was performed as first imaging test in all patients, resulting positive in 113/193 patients (59%) with a detection rate of 80% (90/113) for parathyroid adenoma. In the positive group US identified a suspected adenoma in 45% (51/113), while it was negative or non-specific in the remaining 34.5%. Mean PTH was 154.7 ± 67.7 pg/ml (medium 126, range 106-232); hypercalcemia was present in 27% of the cases and hyperphosphatemia/hypercalciuria in 6%. In the 80 patients with a negative/equivocal ^{99m}Tc-SestaMIBI scintigraphy, [^{18}F]FCH PET/CT images were acquired 45 minutes from radiopharmaceutical administration using a Biograph mCT scanner. Images were positive in 77/80 (96.2%), with detection rates of 83% (64/77) for adenoma and 17% (13/77) for hyperplasia. In this positive group, US suspected adenoma in 56.3% while multiple nodules were observed in 13.7%. Negative/non-specific findings were observed in 30%. Mean PTH value was 226.6 ± 330.8 pg/ml (medium 137,5, range 47-2000); hypercalcemia was present in 32%, hyperphosphatemia in 12.5%, hypercalciuria in 13.7%Statistical Analysis: the Mann-Whitney U and Fisher's Exact tests revealed no significant differences in demographic or ultrasonographic features between groups. The only statistically significant variable was serum PTH, which was lower in the PET-positive group. ***Conclusion:*** [^{18}F]FCH PET/CT demonstrated excellent detection performance even in cases with relatively lower PTH levels compared to ^{99m}Tc-SestaMIBI scintigraphy. These findings suggest that serum PTH may be useful in guiding the selection of first-line imaging, challenging current reimbursement-driven diagnostic pathways in Italy. For effective healthcare resource allocation, a comprehensive definition of clinical and biochemical predictors of 99mTc-SestaMIBI positivity should be established through large-scale studies, enabling evidence-based stratification of patients and reducing reliance on fluorocholine PET/CT as second-line modality, thus preventing redundant imaging and optimizing diagnostic pathways.

Impact of critical appraisal of parathyroid SPECT-CT requests: an opportunity to improve efficacy and safety.

I. Lopez Villar[1], *M. Vinuesa Sebastian*[2], *J. Alonso Farto*[3], *R. Jover Díaz*[1], *D. Tamayo Carabaño*[1], *J. Diaz Melguizo*[4], *G. Torralbo Caballero*[5], *A. Planas Roca*[6], *F. Sebastian Valles*[7], *J. Muñoz de Nova*[8];
[1]*Department of Nuclear Medicine, La Princesa University Hospital, Madrid, SPAIN,* [2]*Clinical Quality Coordinator, La Princesa University Hospital, Madrid, SPAIN,* [3]*Department of Nuclear Medicine, Gregorio Marañón University Hospital, Madrid, SPAIN,* [4]*Medical Director, La Princesa University Hospital, Madrid, SPAIN,* [5]*Medical Director, La Princesa University Hospital, Madrid, SPAIN,* [6]*Associate Medical Director, La Princesa University Hospital, Madrid, SPAIN,* [7]*Department of Endocrinology, La Princesa University Hospital, Madrid, SPAIN,* [8]*Department of Surgery, La Princesa University Hospital, Madrid, SPAIN.*

Aim/Introduction: The only curative treatment for primary hyperparathyroidism (PHPT) is surgery. Nuclear medicine techniques are the main tool to localize the pathological glands in patients with a confirmed diagnosis and indication for surgery, allowing in many cases the use of focused minimally invasive parathyroidectomies. However, on many occasions, these tests are requested with the aim of confirming a doubtful diagnosis or in patients with no surgical indication, increasing the costs of the system and exposing patients to an unnecessary source of radiation. The "Do Not Do" recommendations from the Spanish Society of Nuclear Medicine and Molecular Imaging advise against parathyroid SPECT-CT, in patients without a biochemical diagnosis of hyperparathyroidism or those not eligible for surgery.Aim: To evaluate the efficacy of a critical review program of parathyroid SPECT-CT requests in patients with PHPT to confirm a proper indication: confirmed diagnosis in a patient who is a candidate for surgery. ***Materials and Methods:*** Prospective observational study in which consecutive SPECT-CT requests between October 2024 and March 2025 were included. All requests were evaluated jointly with an endocrine surgeon with expertise in hyperparathyroidism. The correct indication as well as the outcome of the test were analyzed. The results were compared with historical control of requests made between January 2024 and September 2024, before starting the new protocol.The study was validated by the Hospital Appropriateness Committee. ***Results:*** A total of 71 parathyroid SPECT-CT requests were analyzed during the study period, and 41 of them (57.7%) were denied due to inadequate indication. Of the 30 tests performed, 22 were positive (73,3%), localizing pathological parathyroids. The average delay until the test was performed was 29 days (cost-opportunity improvement). In the previous period, 105 SPECT-CT scans were performed. In the review it was considered that 70 of them (66.7%) did not meet the criteria to indicate the test. The rate of positive tests was 24,7%. The mean delay in this period was 61 days. The extension of the new strategy to an annual period would mean saving 42.340 euros for our institution. ***Conclusion:*** A detailed analysis of the correct indication for parathyroid localization tests allows detection of a high rate of incorrectly indicated tests. Not performing these tests means an improvement in the management of the services provided by the Nuclear Medicine Department, significant economic savings (cost-opportunity improvement) and the avoidance of unnecessary exposure of patients to radiation (improved safety).

OP-486

Preoperative Localization in Primary Hyperparathyroidism with Combined 4DCT-MIBI SPECT/CT

K. Y. Li[1], *S. K. Wu*[1], *C. Tang*[1], *H. K. Wong*[1], *H. M. Leung*[2], *W. H. Luk*[1]; [1]*Department of Interventional and Diagnostic Radiology, Kowloon West Cluster Hospitals, Hong Kong, HONG KONG,* [2]*Faculty of Medicine, The University of Hong Kong, Hong Kong, HONG KONG.*

Aim/Introduction: Primary hyperparathyroidism (PHPT) requires precise preoperative localization for minimally invasive parathyroidectomy. This study evaluates the efficacy of combined four-dimensional computed tomography (4DCT) and technetium-99m sestamibi single-photon emission computed tomography/computed tomography (MIBI SPECT/CT) at our center over five years. ***Materials and Methods:*** We conducted a retrospective search for patients with biochemically proven PHPT who underwent combined 4DCT-MIBI SPECT/CT from October 2018 to September 2023. Images were reviewed by two radiologists for lesion presence and location. Enhancement patterns of the parathyroid lesions were classified in relation to the thyroid. Data was analyzed for sensitivity, interobserver agreement and statistical difference between modalities. Demographic and histopathological results were also retrieved. ***Results:*** Of 122 parathyroid lesions, 4 were intrathyroidal and 1 was ectopic. One parathyroid carcinoma was found, with others being either adenoma or hyperplasia. There was one false positive case of thymoma in the anterior mediastinum. Combined 4DCT-MIBI SPECT/CT achieved 87.7% sensitivity (95% CI 81.9%-93.5%), outperforming 4DCT (77.0%, 95% CI 69.6%-84.5%) and MIBI scan (71.3%, 95% CI 63.3%-79.3%) alone. Interobserver agreement was near-perfect (kappa: 0.91-0.98). On 4DCT, 48% of lesions showed Type A enhancement, 47% Type B, and 5% Type C. ***Conclusion:*** The combined 4DCT-MIBI SPECT/CT protocol offers high sensitivity and excellent inter-observer reliability for pre-operative lesion localization in patients with PHPT, outperforming standalone 4DCT or MIBI studies. These findings underscore the potential of this integrated imaging approach to enhance targeted surgical treatment and patient outcomes.

Two-step pretargeted radioimmunotherapy of GPA33-expressing colorectal cancer with optimized self-assembling and disassembling bispecific fusion protein tetramer (SmartCC)

Z. Qiao*, Y. Yang, Q. Liu, Y. Liu, T. Hu, C. Wei, T. Xu; SmartNuclide Biotech, Suzhou, CHINA.*

Aim/Introduction: We developed a bispecific fusion protein for two-step pretargeted radioimmunotherapy (PRIT) to enhance the therapeutic index (TI). This innovative construct incorporates three key components, including a tumor-targeting domain, (ii) a lanthanide metal (Ln)-DOTA binding domain, and (iii) a novel tetramerization domain derived from human. The self-assembly and disassembly of this bispecific fusion protein are mediated by our proprietary tetramerization domain library, designated as SmartCC. The resulting tetramer exhibits strong tumor-binding avidity while achieving rapid blood clearance upon dissociation into small monomers (<70 kDa). Importantly, the SmartCC platform demonstrates the ability to modulate protein pharmacokinetics, thereby amplifying the biological effects of radiation dose delivery to tumors and significantly widening the therapeutic window. In this present study, we evaluated the SmartCC platform's potential for PRIT applications using GPA33-expressing colorectoal cancer as a model system. ***Materials and Methods:*** A library of SmartCCs capable of modulating the pharmacokinetic properties of tumor-targeting antibodies was established and used for in vivo screening to identify GPA33-SmartCCs exhibiting the favorable TI. Protein was intravenously administrated to LS174T tumor-bearing mice, followed by the injection of a ^{177}Lu-DOTA-Bn. Pretargeted in vivo and ex vivo biodistribution studies were performed to determine the appropriate tetramerization domain to form bispecific fusion protein tetramers for the PRIT in terms of therapeutic index (TI). Tumor growth inhibition studies were conducted by monitoring the tumor size by using 2 doses of PRIT. ***Results:*** The pretargeted in vivo biodistribution studies showed that selected bispecific fusion protein (SNA028) had favorable biodistribution properties including high tumor uptake and low blood and kidney toxicity, which is consistent with the ex vivo biodistribution properties. The tumor uptake was of 49.12 ± 2.98 %ID/g and 26.15 ± 3.42 %ID/g at 24 h and 120 h postinjection, respectively. Tumor showed the highest absorbed dose of 457.26 cGy/MBq, followed by kidney of 24.08 cCy/MBq (TI = 19) and blood of 6.44 cCy/MBq (TI=71). SNA028-PRIT resulted in LS174T tumor growth inhibition without significantly altering the weight up to 26 days. ***Conclusion:*** SNA028-PRIT showed favorable ex vivo biodistribution properties in terms of high tumor uptake and low kidney and blood toxicity. In addition, SNA028-PRIT enabled control of tumor growth without significantly altering body weight. These promising data with 177Lu prompts us to study SNA028-based PRIT strategy with α-emitters in the future.

A Hapten-Based Background-Free Reporter System for Longitudinal PET Imaging of CAR-T Cells

B. Wang[1], *W. Niu*[2], *Y. Zhang*[2], *J. Li*[1], *H. Wu*[1], *Z. Xiao*[1], *P. Lei*[2], *Y. He*[1];
[1]*Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA,* [2]*Department of Immunology, School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, Wuhan, CHINA.*

Aim/Introduction: CAR-T cell therapy faces challenges in solid tumors, such as infiltration barriers, immunosuppressive microenvironments, and off-target effects. Thus, assessing CAR-T cell infiltration, persistence, and distribution is critical for improving efficacy and safety. Reporter gene-based PET/CT imaging allows real-time tracking of CAR-T cells. We developed a novel hapten-based reporter gene (anti-HSG-scFv) and engineered two CAR-T variants: HSG-FAP CAR-T (HF CAR-T) and FAP-T2A-HSG CAR-T (FTH CAR-T). Using [^{68}Ga]Ga-IMP-288 PET/CT, we successfully tracked both CAR-T types in vivo. ***Materials and Methods:*** This study designed two FAP-targeting CAR-T cells with distinct reporter gene expression structures. We first validated HF CAR-T and FTH CAR-T cells for expression, activation, cytotoxicity and cytokine secretion. Their antitumor effects were then evaluated in hFAP-HT1080 xenografts. Additionally, we extensively validated the specific binding between two CAR-T cells and IMP-288, and quantitatively assessed [^{68}Ga]Ga-IMP-288 PET/CT imaging capability in vitro and in vivo. Finally, we employed [^{68}Ga]Ga-IMP-288 PET/CT to track the biodistribution of infused CAR-T cells, monitor their dynamic tumor infiltration patterns, and comparatively evaluate therapeutic efficacy. ***Results:*** The reporter gene did not affect the activation, cytotoxicity, or cytokine secretion of HF CAR-T and FTH CAR-T cells. [^{68}Ga]Ga-IMP-288 PET/CT imaging successfully tracked both types of CAR-T cells in vitro and in vivo: For HF CAR-T cells, the detection sensitivity was 50 cells/mm^3 in vitro and 100 cells/mm^3 in vivo, while for FTH CAR-T cells, the detection sensitivity was 250 cells/mm^3 in vitro and 100 cells/mm^3 in vivo. Longitudinal sequential imaging demonstrated that tumors in the HF CAR-T and FTH CAR-T groups began to show significant localized radioactive accumulation on day 3, with radioactive uptake in the HF CAR-T group slightly higher than that in the FTH CAR-T group (ID%/g: 1.484 ± 0.124 vs 1.223 ± 0.051, $p < 0.05$), whereas no such accumulation was detected in the other three groups. On day 7 and day 14, radioactive uptake within the tumor in the HF CAR-T and FTH CAR-T groups remained consistently high, with a notable expansion in the accumulation area. [^{68}Ga]Ga-IMP-288 PET/CT could specifically track both HF CAR-T and FTH CAR-T cells infiltrating the tumor, with both cell types exhibiting significant therapeutic efficacy. ***Conclusion:*** Our study demonstrated that [^{68}Ga]Ga-IMP-288 PET/CT successfully achieved in vivo tracking of HF CAR-T and FTH CAR-T cells, and the two CAR-T cells demonstrated excellent therapeutic efficacy. The [^{68}Ga]Ga-IMP-288/anti-HSG-scFv pairing, as a novel reporter gene imaging system, shows significant potential for clinical translation.

EPS-159

First clinical experience with the bicyclic peptide radiotracer [^{68}Ga]Ga-BCY25286 for PET/CT imaging of MT1-MMP in lung, urothelial and head and neck cancer

A. Eder[1,2], *C. Wielenberg*[1], *M. A. Omrane*[1,2], *C. A. Jilg*[1], *C. F. Waller*[1], *M. Mix*[1], *C. Schell*[1], *B. Passlick*[1], *M. Eder*[1,2], *P. T. Meyer*[1,2], *M. T. Freitag*[1,2];
[1]*University Medical Center, Freiburg, GERMANY,* [2]*German Cancer Consortium, Freiburg, GERMANY.*

Aim/Introduction: Membrane type 1 matrix metalloproteinase (MT1-MMP) is overexpressed in various solid tumors and associated with poor prognosis. Despite its established role in tumor progression and its potential as a theranostic target, clinical translation of MT1-MMP-targeted radiopharmaceuticals has not been previously reported. This study presents the first clincical experience with [^{68}Ga]Ga-BCY25286, a bicyclic peptide-based PET radiotracer, for imaging of MT1-MMP expression in patients with lung, urothelial, and head and neck cancer. ***Materials and Methods:*** Seven patients (lung cancer: n=3; urothelial carcinoma: n=3, head and neck CUP: n=1) underwent [^{68}Ga]Ga-BCY25286 PET/CT imaging (MT1-PET/CT). Four patients had prior [^{18}F]FDG-PET/CT within a maximum interval of 16 days. MT1-PET/CT scans were performed 15, 30, 45 and 60 min after intravenous injection of [^{68}Ga]Ga-BCY25286 (mean activity: 203 MBq) (ethical approval #25-1019-S1). Standardized uptake value (SUVs) was determined for all lesions and organs of interest (liver, blood pool, kidneys). In selected patients histopathological confirmation and MT1-MMP immunohistochemistry were performed and correlated with imaging findings. ***Results:*** In 6 out of 7 patients, tumors and/or metastatic lesions demonstrated increased [^{68}Ga]Ga-BCY25286 uptake compared to the local background. Mean (± SD) SUV_{max} values at 60 minutes after injection was 7.4 ± 3.8 g/mL for primary tumors, 4.6 ± 1.7 g/mL for lymph node metastases, and 5.5 ± 2.4 g/mL for organ metastases. Kinetic analysis revealed rapid tracer accumulation in tumors, with optimal tumor-to-background ratios achieved within 60 minutes after injection. Physiological tracer distribution was characterized by persistent vascular activity (SUV_{mean}: 1.9 ± 0.3 g/mL at 60 min), high renal uptake reflecting renal excretion (SUV_{mean}: 9.4 ± 2.0 g/mL) and low hepatic uptake (SUV_{mean}: 1.5 ± 0.2 g/mL). Compared to [^{18}F]FDG-PET/CT, [^{68}Ga]Ga-BCY25286-PET/CT yielded a comparable lesion visualization in two patients, although [^{18}F]FDG-PET/CT showed higher SUV_{max} (13.9 g/mL vs. 6.7 g/mL). In one patient, lymph nodes that were false-positive on [^{18}F]FDG-PET/CT exhibited markedly lower SUV_{max} on [^{68}Ga]Ga-BCY25286-PET/CT (8.4 ± 1.9 g/mL vs. 3.2 ± 0.3 g/mL). In the patient with histologically confirmed lung cancer, [^{68}Ga]Ga-BCY25286-PET/CT showed no relevant tracer uptake, despite high uptake on [^{18}F]FDG-PET/CT. In cases with histological validation, PET-positive lesions demonstrated membranous and/or stromal MT1-MMP expression. ***Conclusion:*** This first clinical series of [^{68}Ga]Ga-BCY25286 imaging in cancer patients demonstrates the feasibility of visualizing MT1-MMP-expressing primary tumors and metastatic lesions. These initial results support further investigation of this radiotracer as a diagnostic tool for tumor characterization in MT1-MMP-positive cancers, potentially facilitating personalized treatment strategies and improved patient management.

EPS-160

Multi-Organ Metabolic Profiling with ^{18}F-FDG PET/CT Predicts Pathological Response to Neoadjuvant Immunochemotherapy in Resectable NSCLC

J. Li, *Q. Ma, Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Neoadjuvant Immunochemotherapy has revolutionized resectable non-small cell lung cancer (rNSCLC) management, yet 30-50% of patients experience suboptimal pathological responses while facing immune-related toxicities. Current post-treatment biomarkers delay risk stratification, and baseline predictors for major pathological response (MPR) integrating systemic tumor-host metabolic interactions remain unexplored. This study aims to develop and validate a machine learning-powered nomogram combining multi-organ PET metabolic metrics to predicts pathological response to neoadjuvant immunochemotherapy in rNSCLC. ***Materials and Methods:*** This retrospective cohort included rNSCLC patients who underwent baseline ^{18}F-FDG PET/CT prior to neoadjuvant immunochemotherapy at Xiangya Hospital from April 2020 to April 2024. Patients were randomly stratified into training (70%) and validation (30%) cohorts. Using deep learning-based automated segmentation, we quantified metabolic parameters (SUV_{mean}, SUV_{max}, SUV_{peak}, MTV, TLG) for primary tumors and nine key organs. Feature selection employed a tripartite approach: univariate analysis, LASSO regression, and random forest optimization. The final multivariable model was translated into a clinically interpretable nomogram, with validation assessing discrimination,

calibration, and clinical utility. ***Results:*** Among 115 patients (MPR rate: 63.5%, n=73), five metabolic parameters emerged as predictive biomarkers for MPR: Spleen_SUV_{mean}, Colon_SUV_{peak}, Spine_TLG, Lesion_TLG, and Spleen-to-Liver SUV_{max} ratio. The nomogram demonstrated consistent performance across cohorts (training AUC=0.78 [95%CI 0.67-0.88]; validation AUC=0.78 [0.62-0.94]), with robust calibration and clinical net benefit on decision curve analysis. Compared to tumor-only parameters, the multi-organ model showed enhanced specificity (100% vs 92%) and positive predictive value (100% vs 90%) in the validation set, maintaining 76% overall accuracy. ***Conclusion:*** This first-reported multi-organ metabolic nomogram noninvasively predicts MPR in rNSCLC patients receiving neoadjuvant immunochemotherapy, outperforming conventional tumor-centric approaches. By quantifying systemic host-tumor metabolic crosstalk, this tool could guide personalized therapeutic decisions while mitigating treatment-related risks, representing a paradigm shift towards precision immuno-oncology management.

EPS-162

Prognostic Value of Preoperative [^{18}F]FDG PET/CT in Malignant Pleural Mesothelioma: Correlation with Surgical Resectability and Survival Outcomes

J. Hong, *K. Kimura, V. Ludwig, A. Salavati, A. Nguyen, L. Theus, A. Holzgreve, M. Allen-Auerbach, J. Czernin, R. B. Cameron, J. Calais; University of California, Los Angeles (UCLA), Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Malignant pleural mesothelioma (MPM) carries a poor prognosis. However, appropriate patient selection for surgery can lead to some survival benefit. Thus, accurate preoperative assessment is crucial. [^{18}F]fluorodeoxyglucose positron emission tomography/computed tomography ([^{18}F]FDG PET/CT) provides information that may aid this selection. The aim of this study was to evaluate how preoperative [^{18}F]FDG PET/CT is associated with tumour resectability and prognosis in MPM patients undergoing surgical resection. ***Materials and Methods:*** This was a single-centre retrospective study of patients who underwent [^{18}F]FDG PET/CT prior to surgery, identified from the institution's MPM database (n = 428) since 1998. Eligible patients had histologically confirmed MPM, curative-intent surgery, and available preoperative in-house [^{18}F]FDG PET/CT. Exclusion criteria included scans performed >6 months before surgery, or unavailable follow-up. PET/CT scans were reviewed by a blinded evaluator. Tumour lesions were quantified using the PERCIST 1.0 criteria: derived metabolic tumour volume (MTV), maximum standardized uptake value (SUV_{max}), mean SUV (SUV_{mean}), and total lesion glycolysis (TLG = MTV × SUV_{mean}). Clinical progression-free survival (PFS), defined as time from PET/CT to progression or death, and overall survival (OS) were calculated. Statistical analysis included Spearman's correlation, Kaplan-Meier analysis, and Cox regression. ***Results:*** Forty-nine patients were included: median age 70 years (interquartile range [IQR]: 64-75), 31 (63%) had epithelioid, 18 patients (37%) biphasic MPM. The median resected specimen weight during surgery was 678 g (IQR: 476-1010). Median MTV, SUV_{max}, SUV_{mean}, and TLG were 52.9 mL (IQR: 13.0-298.1), 9.7 (IQR: 7.4-14.7), 5.1 (IQR: 4.3-6.3), and 331.6 (IQR: 56.8-1836.8), respectively. MTV and TLG showed strong positive correlations with the resected specimen weight ($\rho = 0.69$ and 0.68, respectively; both $p < 0.001$). Median follow-up was 18.2 months (95% CI: 14.8-not reached [NR]). PFS and OS were significantly shorter in the high-MTV vs. the low-MTV group (hazard ratio [HR] = 3.53, 95% confidence interval [CI]: 1.69-7.40, $p < 0.001$ for PFS; HR = 3.71, 95% CI: 1.54-8.99, $p < 0.001$ for OS). The median PFS was 8.5 months (95% CI: 4.8-11.2) in the high-MTV and 21.6 months (95% CI: 10.1-NR) in the low-MTV. At 2 years, the PFS rate was 6% (95% CI: 1-37) in the high-MTV and 37% (95% CI: 19-73) in the low-MTV. ***Conclusion:*** MTV derived from [^{18}F]FDG PET/CT was strongly correlated with the resected specimen weight and was a significant prognosticator in MPM patients undergoing surgery. These findings underscore the utility of PET/CT in preoperative risk stratification and surgical decision-making.

EPS-163

Preliminary Clinical Studyon the Safety and Antitumor Activity of^{177}Lu-Catelase in Soft Tissue Sarcoma

X. Guo, *Z. Tan, J. Liu, H. Zhu, J. Liu, Z. Yang; Beijing Cancer Hospital, Beijing, CHINA.*

Aim/Introduction: Local radioisotope injection represents a promising approach to localized radiotherapy; however, challenges such as poor retention within tumors and tumor hypoxia have limited its effectiveness. Here, we have developed a hydrogel preparation for intratumoral radiotherapy, containing catalase (CAT) labeled with the therapeutic radioisotope ^{177}Lu (^{177}Lu-CAT/ALG) and sodium alginate (ALG). Preclinical studies demonstrated prolonged tumor hypoxia relief, enhanced tumor retention, and significant antitumor efficacy. This phase 1 clinical trial evaluates the safety and efficacy of ^{177}Lu-CAT/ALG in patients with soft tissue sarcoma (STS). ***Materials and Methods:*** Eligible patients with locally advanced STS were recruited. Baseline metabolic and volumetric assessments were performed using ^{18}F-FDG PET/MR imaging. The intratumoral injection dose was calculated using OLINDA 2.0 Sphere Model. Intra-tumoral injections of ^{177}Lu-CAT/ALG were performed every 8 weeks, guided by ultrasound or direct visualization by experienced clinicians. Participants underwent single-photon emission computed tomography (SPECT) imaging at 2, 24, 96, and 168 h post-injection to assess tumor retention. Efficacy was evaluated every 8 weeks through ^{18}F-FDG PET/MR. The primary endpoints included tumor retention of ^{177}Lu-CAT/ALG and safety (graded per CTCAE v5.0). Secondary endpoints included objective response rate (ORR), progression-free survival (PFS), and overall survival (OS), evaluated per PERCIST criteria. ***Results:*** Seven patients with locally advanced STS were enrolled and provided informed consent (see Table). The median primary tumor size was 8.5 cm. Retention analysis indicated that at least 60% of the administered ^{177}Lu-CAT/ALG remained within tumors across all patients at 168 h. The most common adverse events (AEs) were grade 1-2 decreases in white blood cell count (4/7 patients). One patient experienced a grade 4 adverse event (thrombopenia). The best observed response was stable disease in two patients, with disease control durations of 16.53 and 12.8 months, respectively. As of the data cut-off, one patient remains on treatment. Pathological analysis from a post-injection tumor specimen of one patient—who exhibited an increase in tumor volume on PET/MR imaging one month post-injection—revealed 70% tumor bed necrosis after radical resection of the primary tumor. ***Conclusion:*** ^{177}Lu-CAT/ALG demonstrated a favorable safety profile and potential antitumor activity in patients with locally advanced STS. These findings suggest that ^{177}Lu-CAT/ALG could serve as an effective treatment for locally advanced STS and warrant further investigation in larger trials. ***References:*** 1. Chao Y, Xu L, Liang C, et. Combined local immunostimulatory radioisotope therapy and systemic immune checkpoint blockade imparts potent antitumour responses. Nat Biomed Eng. 2018 Aug;2(8):611-621.

EPS-164

Superior performance of ^{68}Ga-Pentixafor PET/CT on detecting lymphoma lesions: comparison with ^{18}F-FDG PET/CT

H. Liu, *Y. Wang, Z. Xiao, Y. Huang, Y. He; Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.*

Aim/Introduction: ^{18}F-FDG PET/CT for the evaluation of lymphoma, especially indolent lymphoma, exists some limitations.

The C-X-C motif chemokine receptor 4 (CXCR4) overexpressed in hematological tumors, has been used as a promising target for lymphoma PET imaging. Thus, we designed the study to evaluate the diagnostic performance of ^{68}Ga-Pentixafor, a CXCR4-targeting probe, PET/CT for lymphoma, compared with ^{18}F-FDG PET/CT. ***Materials and Methods:*** 36 untreated or recurrent participants with different lymphoma subtypes (8 marginal zone lymphoma, 7 diffuse large B-cell lymphoma, 7 follicular lymphoma, 3 mantle cell lymphoma, 2 Burkitt lymphoma and 9 other lymphoma subtypes) were prospectively recruited and underwent ^{68}Ga-Pentixafor and ^{18}F-FDG PET/CT in a week. Positive lesions were defined as focal uptake above background. And semiquantitative metrics on both scans were compared for paired positive lesion. ***Results:*** Totally 513 lymphoma lesions (412 nodal and 101 extranodal) were identified. ^{68}Ga-Pentixafor PET/CT found 441 lesions (86.0%; 357 nodal and 84 extranodal), whereas ^{18}F-FDG PET/CT detected 407 (79.3%; 319 nodal and 88 extranodal) ($p<0.05$). Among lesions, 335/513 (65.3%) were interpreted positive on both scans. Additionally, 106 ^{68}Ga-Pentixafor-positive/^{18}F-FDG-negative lesions and 72 ^{68}Ga-Pentixafor-negative/^{18}F-FDG-positive lesions were identified. Paired positive lesions on both scans consistently exhibited significantly higher median maximum/peak standardized uptake values (SUVmax/SUVpeak), target-to-blood ratio (TBR) and target-to-liver ratio (TLR) on ^{68}Ga-Pentixafor PET/CT vs. ^{18}F-FDG PET/CT: SUVmax, 6.06 (range, 1.39-24.65) vs. 5.24 (range, 1.12-37.29); SUVpeak, 3.71 (range, 0.71-21.58) vs. 3.23(range, 0.64-29.46); TBR, 3.26 (range, 0.78-22.23) vs. 2.92 (range, 0.67-22.08); TLR, 4.38 (range, 1.00-26.17) vs. 2.34 (range, 0.57-17.47) (all $p<0.05$). ***Conclusion:*** Compared to ^{18}F-FDG PET/CT, ^{68}Ga-Pentixafor PET/CT was superior in detecting lymphoma lesions of most lymphoma subtypes. Semiquantitative analysis uniformly revealed higher values on ^{68}Ga-Pentixafor PET/CT, suggesting that ^{68}Ga-Pentixafor PET/CT might become an alternative to ^{18}F-FDG PET/CT in most lymphoma subtypes.

EPS-165

Head-to-head comparison of mpMRI, PSMA and GRPR PET/CT for local staging of primary prostate cancer: results from a prospective, single-arm, phase II multimodal imaging trial

Y. Li, *Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Optimal therapeutic options of primary prostate cancer (PCa) rely on the accurate assessment of the local extent and localization. Advanced imaging plays a crucial role in initial evaluation, with enhanced sensitivity leading to stage migration. Prostate-specific membrane antigen (PSMA) and gastrin-releasing peptide receptors (GRPR) represent the promising PCa imaging targets. The feasibility of GRPR PET/CT in local staging has been underexplored, nor compared with multiparametric MRI (mpMRI), PSMA, or their combined use. We report an exploratory analysis from a prospective trial, comparing the efficacy in identifying PCa local stage. ***Materials and Methods:*** Intermediate-/high-risk PCa who underwent mpMRI, PSMA and GRPR PET/CT before radical prostatectomy (RP) were included. Each modality was interpreted by two independent readers. Histopathology from RP served as the gold standard. Imaging T staging was assessed and summarized, in addition to bilateral intraprostatic disease (BID), extraprostatic extension (EPE) and seminal vesicle invasion (SVI). The index lesion was defined as the most clinically significant lesion (highest stage, SUV or PI-RADS). PET/CT + mpMRI findings were obtained by combining the two. ***Results:*** Eighty-one treatment-naïve PCa were included. Prostate adenocarcinomas (ACs) were found in 81 (100%) cases from RP, while 10 (12%) admixed with unconventional pathological patterns. PSMA PET/CT showed greater accuracy in local staging than GRPR PET/CT (56% vs. 36%, P=0.011), but was not superior to mpMRI (56% vs. 41% P=0.073); however, PSMA PET/CT was superior to both modalities in the pure AC subgroup (58%, vs. 39% and 34%, P=0.029 and 0.005). PSMA PET/CT was superior to mpMRI for BID identification (72%, vs. 54%, P=0.024), and superior to GRPR PET/CT for SVI identification (93%, vs. 85%, P=0.039). PSMA PET/CT + mpMRI demonstrated superior accuracy to mpMRI alone (60% vs. 41%, P=0.002). GRPR PET/CT + mpMRI was superior to GRPR PET/CT alone (49% vs. 36%, P=0.035). Using PET/CT + mpMRI detected more index lesions (93% and 89% vs. 77% P<0.001 and P=0.002) and identified BID in higher accuracies (74% and 67% vs. 54%, P=0.002 and 0.041) compared to mpMRI alone. ***Conclusion:*** For local staging intermediate-/high-risk PCa, PSMA PET/CT exhibited the highest accuracy among the three modalities, with statistical superiority in pure AC cases. This advantage primarily stems from better identification of BID, followed by index lesions and SVI. Combining PET/CT + mpMRI enhances the accuracy compared to mpMRI alone, allowing for capturing index lesions and BID, which may be significant for targeted biopsy guidance and local treatment planning.

EPS-166

Benfo-Oxythiamine as a Radiosensitizer in PSMA-Targeted Radioligand Therapy for Treatment-Refractory Prostate Cancer - Analysis of Clinical Outcome Data

C. Kramer, *R. P. Baum;*
Curanosticum Wiesbaden-Frankfurt MVZ GmbH, Wiesbaden, GERMANY.

Aim/Introduction: Recently, we reported a patient with metastatic castration-resistant prostate cancer (mCRPC) who exhibited an extraordinary response when the thiamine antagonist benfo-oxythiamine (B-OT) was added to prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (PRLT) ('B-OT PRLT') [Ref 1]. To further support the hypothesis that B-OT may help overcome radiation resistance in mCRPC patients unresponsive to conventional PRLT with Lutetium-177 or Actinium-255, we conducted a retrospective analysis of a larger patient cohort. ***Materials and Methods:*** 19 patient records contained complete data after the first B-OT PRLT cycle, and 12 had comprehensive follow-up data for all treatment cycles. B-OT was administered in six different dosing regimens (ranging from 15-90 mg orally per cycle, either constant or escalating). The mean activities of ^{177}Lu- and ^{225}Ac-labeled PSMA-I&T used were consistent with those applied in standard PRLT. Complete follow-up included both serological prostate-specific antigen (PSA) assessments and imaging response evaluations using PET/CT or SPECT/CT. Treatment responses were defined as a change from progressive disease (PD) to either stable disease (SD), mixed response (MR), partial remission (PR), or complete remission (CR). ***Results:*** Prior to receiving their first cycle of B-OT PRLT, patients had undergone a median of 3 (range: 0-10) cycles of PRLT (with Lutetium-177, or TANDEM therapy using Lutetium-177 in combination with Actinium-225). Baseline tumor status before B-OT PRLT was: PD in 15/19 patients, MR in 1, and PR in 3; no patients presented with SD. After one cycle of B-OT PRLT, 6 out of 15 patients with PD showed both serological response (PSA decline up to 73%) and response by molecular imaging criteria (THERCIST), while another 6 patients with PD demonstrated imaging-based response. Six patients had no status change (PD to PD (3/6), MR to MR (1/6), PR to PR (2/6)), and the condition of one patient deteriorated (PR to PD). Notably, two patients who had previously been resistant to alpha-emitter therapy (with Actinium-225) responded to the combination of B-OT with ^{177}Lu-PSMA-I&T. Across subsequent treatment cycles, B-OT continued to be well tolerated and appeared to enhance PRLT efficacy. ***Conclusion:*** These retrospective data further support that the addition of B-OT to PRLT is well tolerated and may enhance treatment response in heavily pre-treated mCRPC

patients who are progressing under beta- and alpha-emitting PSMA-directed therapies. ***References:*** 1. Kramer CS, Zhang J, Baum RP (2024), Front. Med. 11: 1462234.

EPS-167

Comparison of [^{68}Ga]Ga-DOTA-FAPI-04and [^{18}F]FDG PET/CT in the Evaluation of Ovarian Cancer

J. Wang, *Y. Li, H. Pang;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: 2-deoxy-2-[^{18}F]fluoro-D-glucose ([^{18}F]FDG) PET/CT still has some limitations in the evaluation of ovarian cancer, such as false positives caused by inflammation and physiological uptake, and false negatives caused by mucinous and low-grade tumors. Fibroblast activation protein (FAP) is highly expressed in cancer-associated fibroblasts (CAFs) in more than 90% of epithelial tumors. This study aims to compare the value of [^{68}Ga]Ga-DOTA-fibroblast activation protein inhibitor (FAPI)-04 and [^{18}F]FDG PET/CT in the evaluation of primary and metastatic tumors of ovarian cancer and to analyze the correlation between the radioactive uptake and the size of the lesion. ***Materials and Methods:*** We retrospectively analyzed patients with suspected or confirmed ovarian cancer who completed [^{18}F]FDG and [^{68}Ga]Ga-DOTA-FAPI-04 PET/CT in our hospital from December 2021 to December 2024. Lesions confirmed by histopathologic diagnosis or clinical imaging and follow-up were included. The uptake of radioactive tracers and the values of two techniques were evaluated and compared. ***Results:*** 516 lesions in 80 patients were included. Compared with FDG PET/CT, FAPI-04 PET/CT had a higher specificity, PPV and accuracy in diagnosing primary tumors (71.4%, 90.5% and 92.3% vs. 28.6%, 79.2% and 80.8%), and a higher diagnostic value for peritoneal metastases of ovarian cancer [AUC: 0.834, 95% CI: 0.740-0.929, P < 0.001; vs. AUC: 0.628, 95% CI: 0.530-0.726, P = 0.018; P = 0.003]. Both of them had high sensitivity, specificity, PPV and accuracy in diagnosing lymph node metastases of ovarian cancer (98.4%, 100.0%, 100.0% and 98.6% vs. 96.1%, 93.8%, 99.2% and 95.8%). There was no significant difference in the SUV_{max} and SUV_{mean} in primary tumors, lymph node and peritoneal metastases of ovarian cancer between two techniques. The long diameter of the lesion was positively correlated with the SUV_{max} (P < 0.001) and SUV_{mean} (P < 0.001) from FAPI-04 PET/CT, and the cutoff values of the long diameter of the ovarian cancer lesion when predicting $SUV_{max} \geq 1$, $SUV_{max} \geq 2.5$, and $SUV_{max} \geq 5$ were 4.5 mm, 8.5 mm, and 14.5 mm, respectively. ***Conclusion:*** For ovarian cancer, [^{68}Ga]Ga-DOTA-FAPI-04 PET/CT had an advantage over [^{18}F]FDG PET/CT in diagnosing peritoneal metastases, both techniques had a high value in diagnosing lymph node metastases. [^{68}Ga]Ga-DOTA-FAPI-04 PET/CT had greater diagnostic value for primary or metastatic lesions of ovarian cancer larger than or equal to 4.5mm.

EPS-168

Dual-Tracer FAPI and FDG PET/CT Enhances Prediction of Pathological Response and Survival in Neoadjuvant Immunochemoradiotherapy for Esophageal Squamous Cell Carcinoma

J. Dai[1], *H. WANG*[2], *R. Tian*[2];
[1]*West China Hospital, Chengdu, CHINA,* [2]*West China Hospital, Sichuan University, Chengdu, CHINA.*

Aim/Introduction: This study evaluated the predictive utility of serial FAPI and FDG PET/CT imaging for pathological response and prognosis in patients with locally advanced esophageal squamous cell carcinoma (LA-ESCC) receiving neoadjuvant concurrent chemoradiotherapy with or without PD-1 blockade (Tislelizumab). ***Materials and Methods:*** Forty-nine patients with LA-ESCC were prospectively enrolled and divided into two groups: Group A (n=35, tislelizumab + chemoradiotherapy) and Group B (n=14, chemoradiotherapy alone). All patients underwent pre- and post-treatment FAPI and FDG PET/CT scans. Two calibration methods of PET (body weight and lean body weight) and two volume-of-interest (VOI) thresholds (41% and 50% of the SUVmax) were applied were used to generate imaging parameters, including intensity-based, volume-based, distribution-based parameters, TLG and their change ratio over the treatment. Clinical and imaging parameters were analyzed for their association with pathological tumor regression grade (TRG) and progression-free survival (PFS). TRG = 0 was considered as well-responders and TRG = 1 ~ 3 was defined as poor-responders. Statistical methods included univariate Logistic regression, Cox regression, receiver operating characteristic (ROC) curve analysis, and Kaplan-Meier survival estimates. ***Results:*** Well-respond was observed in 29 of 49 patients (59.2%), whereas poor-respond persisted in 20 patients (40.8%) after neoadjuvant treatment. Pretreatment FAPI PET parameters, including tumor volume (maximum 3D diameter: AUC = 0.78) and intensity distribution (kurtosis: AUC = 0.75), significantly predicted TRG. A combined model integrating volume and distribution parameters improved predictive accuracy (AUC = 0.84, sensitivity = 75%, specificity = 86.21%). Post-treatment FDG PET parameters, TRG and yp T and N stage significantly predict PFS. While Group A demonstrated a higher well-respond rate than Group B (65.7% vs. 42.86%), this difference lacked statistical significance (p=0.14). Higher baseline BMI was associated with improved pathological response. ***Conclusion:*** FAPI PET excels in preoperative prediction of pathological response, whereas FDG PET better forecasts long-term prognosis. Combined imaging biomarkers may optimize personalized treatment strategies for LA-ESCC. While our findings highlight the complementary roles of FAPI and FDG PET/CT, the relatively small cohort and limited follow-up duration necessitate validation in larger, multi-center studies. Future research should also explore the spatial heterogeneity of FAPI and FDG uptake in residual tumors to refine prognostic models.

EPS-169

Comparison of [^{99m}Tc]Tc-FAPI SPECT/CT and [^{18}F]FDG PET/CT as Predictive Biomarkers for Immunotherapy Response in Gastrointestinal Cancer

Y. Zhang, *W. Chen;*
Department of Nuclear Medicine, Fuzhou University Affiliated Provincial Hospital, Fuzhou, CHINA.

Aim/Introduction: To explore the diagnostic performance of [^{99m}Tc]Tc-FAPI SPECT/CT for gastrointestinal cancer, compared to [^{18}F]FDG PET/CT. ***Materials and Methods:*** In this analysis of a prospective trial, consecutively recruited patients from a single center with pathologically confirmed gastrointestinal cancer were prospectively enrolled from September 2022 to June 2024 and underwent paired [^{99m}Tc]Tc-FAPI and [^{18}F]FDG PET/CT examinations at intervals of more than 1 day and within 7 days of each other.The activity of tracer accumulation in lesions was assessed by maximum standardized uptake value (SUVmax) and TBR (lesions SUVmax/ascending aorta SUVmean). Histopathologic and clinical follow-up results were used as reference standards for final diagnoses. ***Results:*** Seventy-eight patients (46 men; median age, 58.8 ± 14.5 years) were evaluated. Compared with the TBR for [^{18}F]FDG uptake, TBR for [^{99m}Tc]Tc-FAPI uptake was higher in primary tumor(4.6±2.0 vs. 3.4±1.7; P=0.001) ,peritoneal spread (1.3 [1.1, 7.3] vs. 1.1 [1.1, 1.1]; P=0.001) and liver metastases(2.5 [1.1, 8.5] vs. 1.1 [1.1, 3.4]; P=0.031). For diagnostic accuracy in a total of 253 lesions in 78 patients, compared with [^{18}F]FDG PET/CT, [^{99m}Tc]Tc-FAPI SPECT/CT demonstrated a higher sensitivity (100% [15 of 15 lesions] vs. 20% [3 of 15]; P< 0.001), accuracy (100% [48 of 48 lesions] vs. 75% [36 of 48]; P< 0.001), and negative predictive value (100% [33 of 33 lesions] vs. 69% [36 of 48 lesions]; P=0 .001) in detecting peritoneal spread, and a higher sensitivity (85% [17 of 20 lesions] vs. 50% [10 of 20]; P=0.041) in detecting liver metastases. Patients with metastatic gastrointestinal carcinomas

negative on the [^{99m}Tc]Tc-FAPI scan showed improved clinical prognosis after immunotherapy (P<0.006). TBR-FDG/TBR-FAPI was the main predictor of better prognosis post-immunotherapy ([stable disease,SD]+[partial response,PR]), with an optimal cut-off of 3.82. ***Conclusion:*** [^{99m}Tc]Tc-FAPI SPECT/CT can better evaluate peritoneal spread and liver metastases in gastrointestinal cancer. Furthermore,TBR-FDG/TBR-FAPI is a valuable imaging parameter for monitoring immunotherapy responses.

EPS-170

Preoperative Noninvasive ^{18}F-FDG PET/CT-Based Nomogram For Predicting HER2 Expression in Gastric Adenocarcinoma

S. Yang, *X. Shao, X. Zhang;*
Department of Nuclear Medicine, the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: Human epidermal growth factor receptor 2 (HER2) overexpression represents a pivotal molecular aberration in gastric adenocarcinoma, critically determining eligibility for targeted therapies. Current gold-standard methods employ immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH) to evaluate HER2 protein expression and gene amplification, respectively. However, their invasive nature precludes real-time monitoring of HER2 dynamics during treatment, hindering therapeutic optimization. This study establishes and validates an ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT)-based nomogram which integrates metabolic parameters and clinical covariates to non-invasively predict HER2 status and enable therapeutic personalization. ***Materials and Methods:*** This retrospective study included 231 gastric adenocarcinoma patients who underwent preoperative ^{18}F-FDG PET/CT. Clinical data were systematically retrieved, and primary tumor metabolic parameters—maximum standardized uptake value (SUVmax), mean SUV (SUVmean), metabolic tumor volume (MTV), and total lesion glycolysis (TLG)—were quantified using a fixed SUV≥2.5 threshold. Univariate and multivariate analyses were employed to identify independent predictors of HER2 expression status. A nomogram was subsequently developed and validated through assessments of discriminatory capacity (area under the receiver operating characteristic [ROC] curve, AUC), calibration accuracy (Brier score), and clinical net benefit (decision curve analysis across threshold probabilities). ***Results:*** PET metabolic thresholds (SUVmax=19.22, SUVmean=4.85) were established through ROC analysis. Univariate regression (P < 0.1) identified potential predictors of HER2 expression: SUVmax (P = 0.006), SUVmean (P = 0.021), tumor location (P = 0.009), lymph node metastasis (P = 0.061), and tumor differentiation grade (P = 0.051). Subsequent multivariate logistic regression confirmed tumor location (odds ratio [OR] = 0.285, P = 0.004), differentiation grade (OR = 2.613, P = 0.029), and SUVmax (OR = 4.494, P = 0.002) as independent predictors. The constructed nomogram demonstrated robust discriminatory capacity (concordance statistic [C-statistic] = 0.715), maintained stability on bootstrap validation (C-statistic = 0.695). Model calibration was satisfactory (Brier = 0.102), while decision curve analysis confirmed superior net clinical benefit compared to default strategies. ***Conclusion:*** The PET/CT-based nomogram shows significant potential for non-invasive HER2 detection in gastric adenocarcinoma, and can serve as a novel substitute for invasive testing.

EPS-171

Trop2-Targeted PET/CT for Diagnosis and Patient Stratification in Breast Cancer Toward Trop2-Directed Antibody-Drug Conjugate Therapy

L. Zhao, *H. Chen;*
The First Affiliated Hospital of Xiamen University, Xiamen, CHINA.

Aim/Introduction: Trop2-targeted antibody-drug conjugates (ADCs) have demonstrated promising efficacy and have been approved in patients with HR+HER2- and triple-negative breast cancer (TNBC). However, not all patients within these subtypes benefit equally from such treatment, highlighting the urgent need for developing effective tools for patient selection and stratification. ***Materials and Methods:*** This study enrolled patients with newly diagnosed or previously treated breast cancer at the First Affiliated Hospital of Xiamen University between November 2023 and December 2024. All patients underwent paired ^{18}F-FDG PET/CT and ^{68}Ga-MY6349 PET/CT imaging for tumor staging or recurrence/metastases detection. SUVmax derived from the two PET/CT modalities and pathological results were recorded to evaluate the tumor uptake pattern and lesion detectability of the two imaging modalities. ***Results:*** A total of 61 patients were prospectively enrolled, including 7 true-negative and 54 true-positive cases. Among the 562 true-positive lesions, ^{68}Ga-MY6349 uptake (SUVmax) was significantly associated with breast cancer subtypes (P<0.001, Kruskal-Wallis H=34.9). SUVmax values were highest in HR+/HER2- [7.2 (4.4-9.4)], followed by TNBC [5.2 (3.8-6.4)], HER2+ [4.8 (1.7-7.4)], and HR+/HER2+ [3.3 (2.1-8.1)]. In HR+/HER2- subtypes, ^{68}Ga-MY6349 demonstrated significantly higher uptake compared to ^{18}F-FDG [7.2 (4.4-9.4) vs. 3.6 (2.3-5.5), P<0.001]. Specifically, the uptake of ^{68}Ga-MY6349 in lymph node metastases and distant metastatic lesions was significantly higher than ^{18}F-FDG (lymph nodes: 6.6 [4.0-10.2] vs. 2.8 [1.9-4.6], P < 0.001; distant metastases: 7.9 [5.7-9.4] vs. 4.1 [2.4-6.2], P < 0.001). In 27 patients with HR+/HER2- subtypes, ^{18}F-FDG PET/CT detected 139/208 lesions (missing 2 primary, 40 visceral and bone metastases, and 27 lymph node metastases), while ^{68}Ga-MY6349 PET/CT detected 202/208 lesions (missing 1 visceral and bone metastasis and 5 lymph node metastases). Interestingly, among 215 lesions in 16 TNBC patients, ^{18}F-FDG PET/CT detected 206 metastatic lesions (missing 9 lymph node metastases), whereas ^{68}Ga-MY6349 PET/CT detected all lesions. For HER2+ (7 patients with 74 lesions) and HR+/HER2+ (4 patients with 65 lesions) subtypes, the two tracers exhibited comparable lesion detectability. ***Conclusion:*** ^{68}Ga-MY6349 PET/CT demonstrated superior uptake and greater lesion detectability compared to ^{18}F-FDG PET/CT in patients with HR+/HER2- breast cancer. The high uptake of ^{68}Ga-MY6349 in HR+/HER2- and TNBC lesions may partially explain the favorable clinical outcomes observed with Trop2-targeted ADCs in these subtypes, suggesting its potential role for patient selection and stratification for Trop2-targeted therapies. However, the observed heterogeneity in uptake warrants further investigation to clarify its applications across different patient populations.

EPS-172

The prognostic value of PET/MR in children with hepatoblastoma

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To investigate the prognostic significance of ^{18}F-FDG PET/MR metabolic parameters and clinicopathological factors in pretreatment pediatric hepatoblastoma (HB). ***Materials and Methods:*** A retrospective analysis was conducted on 98 children with newly diagnosed hepatoblastoma who underwent ^{18}F-FDG PET/MR imaging. Univariate and multivariate Cox regression analyses were performed to evaluate the association between clinicopathological variables (e.g., histology, serum alpha-fetoprotein [AFP], tumor size) and metabolic indices, including maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG), for predicting relapse-free survival (RFS) and overall survival (OS). ***Results:*** During a median follow-up of 36 months, relapse occurred in 42 patients (42.85%). Univariate analysis identified AFP level (P=0.001), histology (P=0.008), tumor size (P=0.012), MTV (P=0.004), and TLG (P=0.006) as significant predictors of RFS and

OS. Multivariate analysis demonstrated that TLG (RFS: P=0.015; OS: P=0.019) and AFP (RFS: P=0.022; OS: P=0.028) were independent prognostic factors for both endpoints, while MTV retained significance for OS (P=0.035). ***Conclusion:*** Pretreatment ^{18}F-FDG PET/MR provides valuable prognostic information in pediatric hepatoblastoma. Elevated TLG, higher AFP stage, and higher MTV are strongly associated with increased risk of recurrence and mortality, highlighting their utility in risk stratification and therapeutic planning.

EPS-173

Head-to-head Comparison of [^{18}F]MFBG and [^{18}F]FDG PET in Neuroblastoma

P. Wang[1], *S. Yu*[1], *J. Mao*[2], *X. Su*[1];
[1]*The First Affiliated Hospital Zhejiang University School of Medicine, Hangzhou, CHINA,* [2]*The Children's Hospital Zhejiang University School of Medicine, Hangzhou, CHINA.*

Aim/Introduction: To compare the diagnostic performance of [^{18}F]MFBG PET (PET/CT or PET/MR) with [^{18}F]FDG PET/CT in patients with neuroblastoma, particularly in post-treatment evaluation settings where lesion detectability is often challenging. ***Materials and Methods:*** In this prospective study, 42 neuroblastoma patients (median age: 5 years) underwent paired [^{18}F]MFBG and [^{18}F]FDG PET imaging. PET scans were acquired 60-90 minutes after intravenous administration of 2-3 MBq/kg of either tracer within one week. Lesion quantification included Curie scores for bone lesions and lesion counts for soft tissue involvement. ***Results:*** Among 42 patients, 32 had active disease while 10 were confirmed disease-free through multidisciplinary clinical assessment and 3-6 months of follow-up. These 10 patients showed negative findings on both [^{18}F]MFBG and [^{18}F]FDG PET.Of the 32 patients with active disease, 6 were newly diagnosed, all showing concordant results on both tracers with 100% sensitivity for primary and metastatic lesion detection. In the remaining 26 patients received treatment (6 with suspected recurrence, 4 refractory cases, 2 under survival follow-up, and 14 undergoing end-of-treatment evaluation), [^{18}F]MFBG demonstrated markedly higher sensitivity (25/26, 96.2%) than [^{18}F]FDG (10/26, 38.5%) based on patient-level analysis. Notably, [^{18}F]FDG missed most bone lesions, often producing false-negative results even in clinically active disease. Only one hepatic metastasis was missed by [^{18}F]MFBG due to physiological liver uptake.In patients with bone-only involvement (n=21), [^{18}F]MFBG yielded a total Curie score of 214 (mean: 10.2), significantly higher than [^{18}F]FDG's score of 30 (mean: 1.4) ($P < 0.0001$). In patients with soft-tissue-only involvement (n=5), [^{18}F]MFBG identified 9 lesions across 4 patients, whereas [^{18}F]FDG detected only 4 lesions in 2 patients. ***Conclusion:*** [^{18}F]MFBG PET imaging significantly outperformed [^{18}F]FDG in evaluating residual or recurrent disease in NB patients after treatment. While both tracers are reliable for initial diagnosis, [^{18}F]MFBG provides superior accuracy during post-treatment surveillance, supporting its clinical value in guiding NB management.

EPS-174

A Predictive Model Based on Lymph Node-to-Primary Tumor SUV Ratio Accurately Classifies Neck Nodal Malignancy Risk and Guides Neck Dissection in Head and Neck Squamous Cell Carcinoma Patients

S. Chan[1], *S. Chi*[2];
[1]*Hualien Tzu Chi Hospital, Hualien, TAIWAN,* [2]*Tzu Chi University, Hualien, TAIWAN.*

Aim/Introduction: Accurate detection of cervical lymph node metastasis in head and neck cancer patients is crucial for determining whether to perform neck dissection. This study investigates the predictive value of [18F]fluorodeoxyglucose positron emission tomography/computed tomography ([^{18}F]FDG PET/CT) parameters in determining the pathological status of neck lymph nodes in patients with head and neck cancer (HNC). ***Materials and Methods:*** This retrospective study included patients with stage M0 HNC who underwent surgery as definitive treatment. All patients received [^{18}F]FDG PET/CT prior to treatment. The diagnostic performance in detecting neck lymph node metastases was assessed using pathological results as the gold standard. Clinical and imaging predictors associated with neck nodal metastases were analyzed using univariate and multivariate analyses. The area under the curve (AUC) was calculated to evaluate predictive capacity. ***Results:*** A total of 168 HNC patients were included. Visual interpretation of [^{18}F]FDG PET/CT demonstrated moderate sensitivity (84.8%) and specificity (75.0%), but a suboptimal positive predictive value (65.7%) for detecting nodal metastasis. Univariate analysis identified several significant predictors of metastases including tumor site, T classification, maximum standardized uptake value (SUVmax), lymph node-to-primary tumor SUVmax ratio, and total lesion glycolysis. Multivariate logistic regression analysis revealed lymph node SUVmax ($p = 0.049$, AUC=0.849) and lymph node-to-primary tumor SUVmax ratio ($p = 0.004$, AUC=0.848) as independent predictors for neck nodal metastasis. A scoring system was developed based on these independent predictors. Among patients with a score of 2 (n = 53), the likelihood of nodal metastasis was 86.8%, while those with a score of 0 (n = 88) had an 88.6% likelihood of no metastasis. Notably, among patients showing cervical lymph node metastasis on contrast-enhanced CT images, 20% were classified as score 0 and subsequently confirmed to have no lymph node metastasis by pathological examination. ***Conclusion:*** This research demonstrates that a predictive model based on the lymph node-to-primary tumor SUV ratio outperforms traditional visual interpretation in assessing cervical lymph node metastasis. It has the potential to reduce unnecessary neck dissections caused by false-positive findings on CT in patients with head and neck cancer. Compared to other complex PET-derived parameters, the SUV ratio offers greater inter-scanner and inter-observer consistency, resulting in a more reproducible and clinically applicable predictive model.

EPS-175

A Novel Prognostic Scoring System Integrating [^{18}F]PFPN PET Metrics and Clinical Parameters for Mucosal Melanoma Survival Stratification

Z. Lin[1,2], *C. Tang*[1,2], *Y. Feng*[1,3,4], *W. Ruan*[1,3,4], *F. Hu*[1,3,4], *Y. Gai*[1,3,4], *X. Zhang*[1,3,4], *X. Lan*[1,3,4];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*First School of Clinical Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [3]*Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [4]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: Mucosal melanoma, a rare and aggressive malignancy with heterogeneous outcomes, lacks robust prognostic tools. While [^{18}F]FDG PET has limitations in specificity, [^{18}F]PFPN, a melanin-targeted tracer, offers enhanced lesion detection and metabolic quantification. This study aimed to develop a prognostic scoring system combining [^{18}F]PFPN PET-derived biomarkers and clinical factors to optimize risk stratification. ***Materials and Methods:*** In this retrospective study, 50 primary mucosal melanoma patients (mean age 60.5±8.8 years) underwent [^{18}F]PFPN PET imaging (2021-2024). Whole-body melanotic tumor volume (WBMTV), clinical staging, age, treatment regimens, and anatomical subtypes were analyzed. Cox regression and stepwise modeling identified independent prognostic factors for overall survival (OS). A simplified scoring system was derived, validated against clinical staging, and stratified into risk groups. ***Results:*** Multivariate analysis revealed whole-body melanotic tumor volume (WBMTV, HR=1.003, $p<0.01$), advanced stage (HR=4.366, $p<0.01$), age ≥60 (HR=1.171, $p<0.01$), absence of immunotherapy (HR=0.17, $p<0.05$), and non-head&neck/vulvar subtypes as key OS predictors. The scoring model (C-index=0.85)

outperformed clinical staging (C-index=0.76). Risk stratification demonstrated marked survival disparities: Group 1 (0-19 points) had 100% 1-year survival, while Group 3 (30-50 points) exhibited a 74.59% 1-year and 0% 3-year survival. WBMTV thresholds (<1.52 vs. ≥1.52 cm^3) and stage-specific scores effectively differentiated outcomes (p<0.001). ***Conclusion:*** Integrating [^{18}F]PFPN PET metrics with clinical variables enables precise prognostic stratification in mucosal melanoma. This automated scoring system facilitates rapid risk assessment, guiding personalized therapeutic strategies. Further validation in multi-center cohorts is warranted to confirm its clinical utility.

EPS-176

Comparison of [18F]AlF-NOTA-FAPI-04 PET/CT and [^{18}F] FDG PET/CT for diagnosing lymph node metastasis in malignant tumors

W. Zhou, *J. Dai, K. Zheng, X. Peng, Y. Zhang, C. Jiang, J. Yang, H. Ye;*
The Affiliated Cancer Hospital of Xiangya School of Medicine/ Hunan Cancer Hospital, Changsha, CHINA.

Aim/Introduction: This study compared the diagnostic performance, semi-quantitative analysis, and staging accuracy of [^{18}F]AlF-NOTA-FAPI-04 and [^{18}F]FDG PET/CT in detecting lymph node metastases. ***Materials and Methods:*** This single-center retrospective study included 41 patients with suspected lymph node metastases who received both [^{18}F]FDG and [^{18}F]AlF-NOTA-FAPI-04 PET/CT. The study compared metastatic lymph node detection, semi-quantitative values, and N staging accuracy. Subgroup analyses were performed for lymph nodes with short-axis diameters (SAD) ≥10 mm and <10 mm. ***Results:*** 41 patients with 126 nodes were include. [^{18}F]AlF-NOTA-FAPI-04 outperformed [^{18}F]FDG in the detection of metastatic lymph nodes, achieving higher accuracy in both patient-based (92.7% vs. 70.7%, p=0.004) and node-based analyses (91.3% vs. 60.3%, p<0.001). In semi-quantitative analysis, the maximum standardized uptake value and target-to-background ratio of [^{18}F]AlF-NOTA-FAPI-04 were higher than those of [^{18}F]FDG in metastatic lymph nodes (all p < 0.001). Both tracers distinguished metastatic from benign nodes with SAD ≥ 10 mm (p<0.05). [^{18}F]AlF-NOTA-FAPI-04 PET/CT could distinguish between benign and metastatic lymph nodes with SAD < 10mm (p<0.001), whereas [^{18}F]FDG PET/CT could not (p >0.05). [^{18}F]AlF-NOTA-FAPI-04 also provided more accurate N staging assessments (87.8% vs. 65.9%, p = 0.006). ***Conclusion:*** [^{18}F]AlF-NOTA-FAPI-04 PET/CT demonstrated superior diagnostic performance, semi-quantitative capability, and N staging accuracy compared to [^{18}F] FDG PET/CT, particularly for small metastatic lymph nodes (SAD < 10 mm), offering enhanced guidance for tumor staging.

EPS-177

Complementary role of ^{11}C-acetate to ^{68}Ga-FAPI-46 in tumor imaging with negative/indeterminate ^{18}F-FDG findings

I. Ho[1,2], *S. Chen*[2], *Y. Wong*[2], *K. Wu*[2], *S. Cheung*[2], *Y. Yip*[2], *K. Cheng*[2], *J. Kung*[1], *C. Ho*[2];
[1]*Queen Elizabeth Hospital, Hong Kong, HONG KONG,* [2]*Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

Aim/Introduction: ^{11}C-acetate is a metabolic tracer partially complementary to ^{18}F-FDG in PET imaging. ^{68}Ga-FAPI is a receptor tracer to evaluate abnormal dysmoplastic reactions caused by stromal cancer associated fibroblasts (CAF). Much of the published data worldwide have compared the diagnostic performance of ^{68}Ga-FAPI with ^{18}F-FDG, putting emphasis on its superior advantage over conventionally ^{18}F-FDG non-avid or minimally-avid entities, such as mucinous neoplasm, signet-ring clear-cell carcinoma, renal cell carcinoma (RCC) and certain hepatobiliary tumors. In this single-center prospective study, we aimed to compare ^{11}C-acetate with ^{68}Ga-FAPI-46 for the evaluation of various tumors that were non-avid/indeterminate by ^{18}F-FDG PET/CT. ***Materials and Methods:*** During Jan-2022 to Dec-2024, we recruited 55 patients (M:38, F:17; age range:34-85 years, mean=61.2±13.3 years) having clinical suspicion of malignancy but with negative/indeterminate ^{18}F-FDG PET/CT. They all underwent ^{68}Ga-FAPI-46 and ^{11}C-acetate PET/CT separately within 1 week and subsequently had histopathology for final diagnosis. FAPI or ^{11}C-acetate-avid lesions were automatically drawn by MIMContouring software and SUV_{max} of the index lesion/patient was recorded. PET/CT diagnostic criteria of ^{11}C-acetate were based on the degree and uptake pattern with reference to our prior published studies. ***Results:*** Histopathology diagnosed 34/55 patients with malignant tumors and 21/55 with benign lesions. FAPI-46 PET/CT showed prominent expression (SUV_{max}=9.3±4.8, range:3.8-20.4) in 22/34 (sensitivity=64.7%) malignant entities: intrahepatic cholangiocarcinoma (small-duct and Klatskin, n=7); poorly-differentiated hepatocellular carcinoma (PDHCC, n=5); liver metastases (n=5, from cholangiocarcinoma, PD neuroendocrine tumor, gallbladder clear-cell adenocarcinoma, leiomyosarcoma); sarcoma (n=2); tonsillar SCC (n=2); hemangioendothelioma (n=1). However, FAPI-46 PET/CT was false negative in 12/34 patients with malignancy: well-differentiated HCC (n=7); RCC clear-cell subtype (n=2); multiple myeloma (n=2); liver secondary from colon (n=1). Of these 12/34 malignancies missed by FAPI-46, ^{11}C-acetate PET/CT was positive in 11/12 (SUV_{max}=12.4±6.9). Taken together, the sensitivity could be increased from 64.7% by FAPI-46 alone to 97% (33/34, P<0.01) by both. Among the 21 benign entities in liver (n=14), enlarged lymph node (n=4), kidney (n=2) and lung (n=1), FAPI-46 PET/CT showed little to no tracer uptake (SUV_{max}=1.2±0.8, range:0.6-3.0) in 19/21 (specificity=90.5%). Two FP cases with markedly FAPI-avid liver masses (SUV_{max}=11.5&6.4) were confirmed hepatic confluent fibrosis (HCF), despite being negative on ^{11}C-acetate PET/CT. ***Conclusion:*** ^{68}Ga-FAPI-46 PET/CT has an important role for detection of suspected tumor entities that are non-avid/indeterminate by ^{18}F-FDG. However, ^{11}C-acetate PET/CT remains an important metabolic tracer partially complementary to either ^{18}F-FDG or ^{68}Ga-FAPI-46, and could not be replaced by ^{68}Ga-FAPI in tumor evaluation.

CT-free attenuation correction for cardiac-dedicated CZT SPECT: update of the CASCTEC study
***M. Hesse**, F. Dupont, N. Laajimi, A. Oulad Bouchetta, R. Lhommel, V. Roelants;*
Cliniques Universitaires Saint-Luc, Brussels, BELGIUM.

Aim/Introduction: While attenuation-correction (AC) improves the diagnostic accuracy of myocardial perfusion scintigraphy (MPS) for detecting coronary artery diseases (CAD), most clinical cardiac-dedicated CZT cameras are still marketed without a CT. The CASCTEC clinical study aims at developing an approach to generate attenuation maps for pinhole CZT cameras, from emission scans only. This work presents an update of the study results obtained with more patients and after optimization of the attenuation map generation. ***Materials and Methods:*** Fifty patients (34 male; BMI: 27±5 kg/m2) referred for MPS were enrolled in the single-center prospective CASCTEC study. Two-day stress/rest MPS SPECT was performed on a pinhole CZT camera. A standard of care (SOC) 5-minute acquisition was immediately followed by an additional 5-minute acquisition after retracting the detectors without moving the patient. Subsequently all patients underwent SPECT/CT imaging to be used as reference. The acquisition with retracted detectors allowed to delineate the patient body contour, and together with the SOC acquisition, enabled the segmentation of soft and lung tissues to produce an attenuation map. Non-corrected (NC) and AC images were compared together and to the NC and AC SPECT/CT images using the AHA 17-segment model polar maps. Stress and rest summed scores for the different reconstructed images were calculated automatically (Quantitative Perfusion SPECT software) and visually by an experienced physician. ***Results:*** CASCTEC-AC stress and rest perfusion images showed a more homogeneous tracer distribution compared to NC images. All perfusion defects observed on the SPECT/CT-AC images were also visible on CASCTEC-AC images. The mean stress and rest AC summed scores were 13.4±5.1 for CASCTEC vs 14.5±5.6 for SPECT/CT (p=0.25) using the automatic scoring, and 11.3±5.3 for CASCTEC vs 12.6±5.5 for SPECT/CT (p=0.10) with the visual analysis. When focusing especially on the inferior segments, the AC-NC score differences were -2.5±2.1 for CASCTEC vs -3.1±2.0 for SPECT/CT (p=0.09) using the automatic scoring, and -2.9±2.1 for CASCTEC vs -3.2±2.5 for SPECT/CT (p=0.45) with the visual analysis. No significant change of the perfusion was observed on the CASCTEC-AC images in the other segments less affected by the attenuation. ***Conclusion:*** These results show that the CT-free patient-specific attenuation map enhances NC perfusion in the inferior wall similarly to CT-based AC images from a SPECT/CT. CASCTEC-AC summed scores are in good agreement with CT-AC ones, both for automatic and visual scoring. This CT-free method might so enhance the diagnostic accuracy of current cardiac pinhole CZT systems for detecting obstructive CAD.

OP-497
Multimodal Approaches to Coronary Arteries: Myocardial Perfusion Imaging, Coronary CT Angiography, Calcium Score, MESA Risk Score and Coronary Age
***A. Dursun**[1], N. A. Dizdar[1], Y. Aktürk[2], F. Başyiğit[3], E. Tatcı[4], Ö. Özmen[4];*
[1]Ankara Etlik City Hospital, Nuclear Medicine Clinic, Ankara, TÜRKIYE, [2]Ankara Etlik City Hospital, Radiology Clinic, Ankara, TÜRKIYE, [3]Ankara Etlik City Hospital, Cardiology Clinic, Ankara, TÜRKIYE, [4]Health Sciences University, Ankara Etlik City Hospital, Nuclear Medicine Clinic, Ankara, TÜRKIYE.

Aim/Introduction: Multi-Ethnic Study of Atherosclerosis (MESA) is a scoring system used to calculate 10-year Coronary Heart Disease(CHD) risk and coronary age. Coronary CT Angiography (CCTA) imaging can be used to calculate severity of coronary artery stenosis (CAD-RADS) and calcific plaque burden coronary artery calcium score (CACS) of patients. In our study, patients'Tc99m-MIBI myocardial perfusion imaging (MPI) findings, CAD-RADS, calcium score, MESA risk scores and coronary artery ages were evaluated. ***Materials and Methods:*** Between November 2022 and January 2025, 12.423 patients who underwent MPI at our hospital were screened. Among them, 132 patients (aged 45-85) were included in study. Using "MESA Risk Score and Coronary Age Calculator", 10-year CHD risk, coronary artery age and chronological age difference (Delta Age) of all patients were determined. According to CCTA findings, stenosis with 0-49% were classified as normal-mild; 50-69% as moderate, and ≥70% as severe stenosis. MPI findings were grouped by summed difference scores (SDS) as <2, 2-4, and >4. ***Results:*** Patients with SDS >4 had significantly higher coronary age, delta age, CACS, and MESA risk scores compared to other groups (p<0.001) (Table-1). EF was significantly higher in patients with SDS score <2 than those with score >4 (p=0.026). In CCTA images of normal-mild stenosis group, both CACS and MESA risk scores with CACS were lower than in other groups (p<0.001 and p<0.001, respectively) (Table-2). In group, coronary artery age and delta age were lower than in those with severe stenosis (p<0.001 and p<0.004, respectively). Myocardial ischemia percentage was higher in severe stenosis than in other groups (p<0.05). In logistic regression analysis, strong relationship was found between the severity of coronary artery stenosis detected in CCTA and ischemia percentage in MPS (p<0.001) (Table-3).SDS was <2 in 7/16 patients with severe stenosis on CCTA and only one patient in this group underwent revascularization. The other patients in this group (n=9) with SDS score >4 underwent revascularization. Two patients with normal-mild stenosis on CCTA and SDS>4 on MPI underwent revascularization due to >70% stenosis on coronary angiography. ***Conclusion:*** Many studies revealed that anatomical degree of coronary artery stenosis may not correlate with its physiological reflection. According to our findings, MPI provides valuable prognostic information beyond anatomical stenosis, correlates with MESA scores, and helps guide treatment decisions, especially in moderate coronary artery stenosis, by reflecting hemodynamic impact and potentially reducing unnecessary interventions. ***References:*** Sirajuddin A, et al.Ischemic Heart Disease: Noninvasive Imaging TechniquesandFindings. Radiographics. 2021 Jul-Aug;41(4):990-1021. doi: 10.1148/rg.2021200125.

OP-498
Diagnostic value of pericoronary fat attenuation index (FAI) in predicting abnormal myocardial perfusion in INOCA patients: a comparative study of CCTA and CZT-SPECT
***H. Zhang**[1], F. Caobelli[2], K. Shi[2], R. Ji[1], M. Fei[3], F. Yu[1];*
[1]Tongji University School of Medicine,shanghai Tenth People's Hospital, Shanghai, CHINA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [3]Tongji university School of Medicine, Shanghai Pulmonary Hospital, Shanghai, CHINA.

Aim/Introduction: Although coronary inflammation has been established as a critical factor in obstructive coronary heart disease, it remains unclear whether a class of Non-invasive imaging inflammatory biomarkers, exemplified by the fat attenuation index (FAI), can detecting a high-risk subset of INOCA patients with myocardial ischemia. ***Materials and Methods:*** 191 consecutive patients with symptoms suggestive for myocardial ischemia were prospectively evaluated. All patients were referred for CZT-SPECT MPI and CCTA in one week. INOCA was defined as the presence of symptoms suggestive for myocardial ischemia, including angina pectoris associated with ischaemic ECG (electrocardiogram) changes and/or abnormal myocardial perfusion imaging (MPI), without detectable stenosis or luminal stenosis <50% on CCTA. Patients were divided into two groups according to CZT-SPECT MPI ***results:*** Ischemia (SSS>4 and SDS>2) and non-Ischemia group. ***Results:*** This study included 112 INOCA patients [mean age 64.52±11.14 years, 43.8% male]. Among them, 28/112 (25.0%) had abnormal MPI. LCX-FFR (0.93±0.07 vs 0.95±0.03, p=0.04) were significantly lower in Ischemia group. LAD-FFR and RCA-FFR were not different between groups. LAD-FAI (-85.21±8.10 vs -90.80±7.51, p=0.001), LCX-FAI (-78.38±8.30 vs -84.35±7.97, p=0.001) and RCA-FAI (-88.13±8.91 vs -93.60±9.87, p=0.01) were significantly high in Ischemia group.A moderate correlation of Stress LVEF with FAI was founded for both LAD-FAI (r=-0.26, p=0.006) and LCX-FAI (r=-0.35, p<0.001). Similarly, moderate correlation of Rest LVEF with FAI was also founded for both LAD-FAI (r=-0.22, p=0.02) and LCX-FAI (r=-0.20, p=0.04). Accordingly, the efficacy of FAI in diagnosing ischemia was LAD-FAI >-94.9 (AUC 0.67, 95% CI 0.57-0.76, p=0.003, sensitivity 92.9%, specificity 34.5%), LCX>-78.3(AUC 0.68, 95% CI 0.58-0.76, p=0.002, sensitivity 53.6%, specificity 79.8%) and RCA>-97.23(AUC 0.64, 95% CI 0.55-0.73, p=0.01, sensitivity 92.4%, specificity 39.3%). Nevertheless, the Delong test suggested that there was no significant difference in the efficacy of the three indices in the diagnosis of ischemia (LAD-FAI vs LCX-FAI, p=0.83; LCX-FAI vs RCA FAI, p=0.52; LAD-FAI vs RCA-FAI, p=0.63). In Univariate Logistic regression analysis, LAD-FAI (OR 1.10, 95%CI 1.03-1.17, p=0.002), LCX-FAI (OR 1.09, 95%CI 1.03-1.16, p=0.002) and RCA-FAI (OR 1.06, 95%CI 1.01-1.11, p=0.01) were significant predictors of ischemia. In multivariable Logistic regression analysis, SSS (OR 17.82, 95%CI 4.55-69.84, p<0.001), Rest EF (OR 1.34, 95%CI 1.04-1.72, p=0.02), LAD-FAI (OR 1.22, 95%CI 1.04-1.42, p=0.01) were independent predictors of ischemia in INOCA patients. ***Conclusion:*** Abnormal FAI has been confirmed to be associated with myocardial ischemia in INOCA patients, providing a foundation for the future development of individualized treatments targeting inflammation or microvascular dysfunction.

Assessment of myocardial perfusion Sestamibi CZT-SPECT reconstructed using deep-learning-based virtual attenuation correction maps with correlation to results from Rubidium-PET and coronary angiography

T. Sprauel[1], *L. Imbert*[1,2], *K. Doyeux*[3], *M. Perrin*[1], *M. Claudin*[1], *V. Roch*[1], *M. Doyen*[2], *N. Roth*[4], *Y. Lamash*[4], *R. Chequer*[3,5], *F. Rouzet*[3,5], *F. Hyafil*[6,7], *P. Marie*[1,2];
[1]*Université de Lorraine, Department of Nuclear Medicine and Nancyclotep Imaging Platform, CHRU Nancy, Nancy, FRANCE,* [2]*Université de Lorraine, IADI, INSERM U1254, Nancy, FRANCE,* [3]*Department of Nuclear Medicine, Bichat university Hospital, Assistance Publique-Hopitaux de Paris (AP-HP), Paris, FRANCE,* [4]*Spectrum Dynamics Medical, Caesarea, ISRAEL,* [5]*Université Paris Cité, INSERM U 1148, Paris, FRANCE,* [6]*Department of Nuclear Medicine, DMU IMAGINA, European Hospital Georges-Pompidou, Assistance Publique-Hopitaux de Paris (AP-HP), Paris, FRANCE,* [7]*INSERM U 970, University Paris-City, Paris, FRANCE.*

Aim/Introduction: Attenuation artifacts may affect the analysis of myocardial perfusion imaging recorded with single-photon emission computed tomography (SPECT), especially in the right coronary artery (RCA) territory and with semi-conductor (CZT)-cameras. This study evaluates the results provided by stress [^{99m}Tc] sestamibi CZT-SPECT when reconstructed using a deep-learning-based attenuation correction (DLAC) algorithm, with correlation to [^{82}Rb]rubidium-PET (Rb-PET) and coronary angiography results. ***Materials and Methods:*** We compared stress-rest [^{99m}Tc]sestamibi CZT-SPECT reconstructed without (i.e., standard (SD-SPECT)) and with DLAC maps obtained using an algorithm developed from another study population (DLAC-SPECT) in 84 patients at risk of attenuation artifacts (overweight individuals and women), with no previous history of coronary artery disease (CAD) and who also had stress-rest Rb-PET with CT-based attenuation correction, and when indicated, coronary angiography. ***Results:*** Normal segmental uptake values at stress, estimated in a low CAD-risk group of 74 patients, were homogeneous between the three coronary territories with DLAC-SPECT (for the RCA: 81.2±7.1 %, left anterior descending (LAD): 82.5±8.3 %, and left circumflex (LCx): 81.9±7.0 % territories) and Rb-PET (76.5±8.9%, 77.7±8.5%, 78.1±8.6%, respectively), but exhibited a 10% drop in the RCA territory compared to LAD and LCx territories with SD-SPECT (69.1±8.2 % vs. 78.2±8.2 % and 79.5±8.6 %, respectively, both p<0.001). In the RCA territory, the absolute difference between the normal rest and stress segmental uptakes was particularly high with SD-SPECT (5.13±4.04 %) and higher than with DLAC-SPECT (4.21±3.24 %, p<0.001) and Rb-PET (3.92±3.08 %, both p<0.001).Reversible stress perfusion defects, identified through standard quantitative criteria (< 70% segmental stress uptake and ≥ 10% rest-minus-stress difference) (i) had equivalent per-patient detection rates with SD-SPECT (15.5%), DLAC-SPECT (16.7%) and Rb-PET (17.9%) and (ii) were a significant predictor of coronary stenosis with DLAC-SPECT (p=0.003) and Rb-PET (p=0.021) but not with SD-SPECT (p=0.17) in a sub-group where a stenosis was documented in 11 out of 42 analyzed coronary territories. ***Conclusion:*** When reconstructed with deep-learning-based attenuation correction maps, perfusion, [^{99m}Tc]sestamibi CZT-SPECT images exhibit a high diagnostic potential with properties approaching those achieved by Rubidium-PET and enhancing the identification of reversible stress perfusion defects -i.e., more homogeneous repartition of the normal stress uptake and lower ranges of normal stress-to-rest uptake fluctuations.

Diagnostic Validation of a Novel Deep Learning Attenuation Correction Software for Stress MPI using a Dedicated CZT Cardiac Camera. A comparison with Fractional Flow Reserve acquired during Invasive Coronary Angiography in Patients with Suspected CAD

A. Manrique[1], *M. Esnault*[1], *R. Baavour*[2], *N. Coudrais*[1], *N. Roth*[2], *D. Agostini*[1];
[1]*CHU de Caen, Caen, FRANCE,* [2]*Spectrum Dynamics, Cesarea, ISRAEL.*

Aim/Introduction: To validate a novel deep learning attenuation correction (DLAC) software for stress myocardial perfusion imaging (MPI) using a dedicated CZT camera by comparing with Fractional Flow Reserve (FFR) in patients suspected with CAD from the Waterday trial (EJNMMI 2018). ***Materials and Methods:*** Retrospective assessment of 27 patients (18 males [66%], age 66.9, BMI 29±7) with no history of cardiac disease undergoing MPI from November 2014 to November 2016, followed by ICA and FFR within one month after MPI. FFR less than 0.8 was defined as abnormal. The MPI was performed on a dedicated CZT cardiac camera (D-SPECT) on supine position with a one-day protocol. We compared regadenoson stress 99mTc sestamibi CZT-SPECT reconstructed without (NC) and with DLAC, an algorithm based on a computational neural network (CNN) with U-Net architecture. Short axis images were converted to polar maps using the Cedars Sinai Cardiac Suite and normal databases supplied by

the vendor (TruCorr, Spectrum Dynamics). All SPECT images were reconstructed in a standard way recommended by the manufacturer with a specific iterative reconstruction algorithm. The severity and extent of perfusion abnormality were expressed as total perfusion deficit (TPD). Stress TPD ≥ 6% myocardium was considered abnormal.The receiver-operating-characteristic (ROC) curve analysis was performed to evaluate the ability of the quantification to predict an abnormal FFR less than 0.8. ROC curves were created using a step of 0.1% for the TPD values, and the differences between ROC curve areas (NC vs DLAC) were compared. ***Results:*** The diagnostic accuracy of global TPD on stress MPI NC images was 74%, sensitivity 73%, specificity 75%, PPV 67%, NPV 80% and AUC 0.74 for TPD ≥ 6% normal limit. Using DLAC images the diagnostic accuracy of global TPD was 81%, sensitivity 82%, specificity 81%, PPV 75%, NPV 87% and AUC 0.89 for TPD ≥ 4% normal limit. The diagnostic accuracy of global Extent on stress MPI NC images was 70%, sensitivity 73%, specificity 69%, PPV 62%, NPV 79% and AUC 0.73 for Extent ≥ 7% normal limit. Using DLAC images the diagnostic accuracy of global Extent was 89%, sensitivity 82%, specificity 94%, PPV 90%, NPV 88% and AUC 0.92 for Extent ≥ 5% normal limit. ***Conclusion:*** Using the CZT D-SPECT camera with novel DLAC software improves quantitative accuracy of the stress MPI images for TPD and Extent measurements compared to invasive FFR in patients suspected with CAD.

Aim/Introduction: While PET/CT remains the standard for quantification of absolute myocardial blood flow (MBF) and coronary flow reserve (CFR), its clinical use is limited by cost and availability. Dynamic acquisition with dedicated cardiac SPECT systems has shown promise in addressing these issues, albeit with further research yet needed. This study aims to evaluate CFR using a novel multi-pinhole collimator on a Triple-NaI-detector SPECT/CT system [(1)] and correlate CFR data with the clinical pretest probability of coronary artery disease (CAD). Keywords: Coronary artery disease, Multi-pinhole collimator, Myocardial flow imaging, Coronary flow reserve, Myocardial blood flow ***Materials and Methods:*** Eleven patients (median age: 62) with known or suspected CAD underwent one-day stress-rest 99mTc-MIBI SPECT/CT imaging using a multi-pinhole collimator system on a Triple-NaI-detector. Dynamic flow imaging followed rest and Regadenoson-induced stress phases. Images were reconstructed with a Monte Carlo-based algorithm for multi-pinhole projections. MBF and CFR were quantified using a dedicated software suite and compared with pretest CAD probability scores to assess diagnostic value. ***Results:*** No patient showed significant obstructive CAD (≥70% stenosis) on angiography. CFR showed a moderate, though not statistically significant, positive correlation with CAD risk scores, $r(7) = 0.62$, $p = 0.077$, suggesting a potential physiological link between non-invasive flow data and baseline cardiovascular risk. Measured flow values were lower than those reported using other dedicated cardiac SPECT systems. [(2)] ***Conclusion:*** The multi-pinhole collimator on the Triple-NaI-detector SPECT/CT system yields reliable flow measurements that align with CAD risk scores, even in the absence of angiographic stenosis. This technique shows promise for early detection of microvascular dysfunction and may offer a cost-effective alternative to PET or other specialized SPECT systems. Further studies are needed to define diagnostic flow thresholds.

The fesibility of CZT-SPECT in the assessment of coronary microvascular dysfunction (CMD) in INOCA patients: a comparative study with Coronary Agnio-IMR

H. Zhang[1], *F. Caobelli*[2], *K. Shi*[2], *F. Yu*[3], *K. Wang*[1], *M. Fei*[4];
[1]*Tongji University School of Medicine, Shanghai Tenth People's Hospital, Shanghai, CHINA,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bren, SWITZERLAND,* [3]*Tongji University School of Medicine, Shanghai Tenth people's Hospital, Shanghai, CHINA,* [4]*Tongji University School of Medicine, Shanghai Pulmonary Hospital, Shanghai, CHINA.*

Aim/Introduction: Although our previous study[1] demonstrated the strong prognostic value of CZT-SPECT derived Stress myocardial blood flow (sMBF) and coronary flow reserve (CFR) in ischemia with Non-obstructive coronary artery disease (INOCA) patients, its value and Optimal cut-off value in the diagnosis of coronary microvascular dysfunction (CMD) is still unclear. ***Materials and Methods:*** We prospectively recruited 56 INOCA patients referred to nuclear medicine from cardiovascular medicine, each of whom underwent CZT SPECT imaging and coronary angiography derived index of microcirculatory resistance (IMR_{angio}) within one week. Dynamic data were reconstructed, and MBF was quantified using net retention model. CMD were defined as IMR_{angio}>25U. Receiver operating characteristic (ROC) curves and Youden's index were used to calculate the best cut-off values of sMBF and CFR for the prediction of CMD. ***Results:*** Based on the IMR_{angio} results, CMD was present in 42 (75.0%) patients. Regional IMR_{angio} was significantly higher (LAD: 38.8±15.5 vs 22.8±5.8, p<0.001; LCX: 39.9±13.7 vs 23.5±6.3, p<0.001; RCA: 29.8±9.0 vs 17.2±5.6, p<0.001) and CFR (LAD: 2.87±0.86 vs 3.71±0.69, p=0.002; LCX:2.83±0.98 vs 3.96±1.45, p=0.002; RCA:2.90±1.10 vs 3.87±0.73, p=0.003) significantly lower in the CMD group. Global IMRangio (36.7±8.1 vs 21.1±3.4, p<0.001) was significantly higher, sMBF (3.8±1.2 vs 4.5±0.9, p=0.04) and MFR (3.0±0.9 vs 3.9±0.8, p=0.001) significantly lower in the CMD group. A moderate correlation with IMR_{angio} was founded for both global sMBF (r=-0.43, p=0.001) and CFR (r=-0.32, p=0.02). Accordingly, the efficacy of sMBF and CFR in diagnosing CMD was sMBF<3.77(AUC 0.68, 95% CI 0.55-0.80, p=0.02, sensitivity 52.4%, specificity 92.9%, PPV 39.4%, NPV 95.7%, accuracy 62.5%), CFR<2.94(AUC 0.80, 95% CI 0.68-0.90, p<0.001, sensitivity 64.3%, specificity100%, PPV 48.3%, NPV 100%, accuracy 73.2%). Nevertheless, the Delong test suggested that there was no significant difference in the efficacy of the two parameters in the diagnosis of CMD (95% CI -0.06-0.30, p=0.19). ***Conclusion:*** The results suggest that regional and global sMBF and CFR can serve as valuable diagnostic indicators for INOCA patients with CMD, providing novel criteria for early prevention and intervention strategies.

OP-503

A new parameter - increasing ratio derived from SPECT: validation by PET- myocardial flow reserve

A. Inoue, *M. Nagao, A. Yamamoto, A. Sakai, R. Nakao, M. Watanabe, J. Yamaguchi, S. Sakai;*
Tokyo Women's Medical University Hospital, Tokyo, JAPAN.

Aim/Introduction: Myocardial flow reserve (MFR) obtained from ^{13}N-ammonia PET is valuable for predicting the prognosis of patients with various heart diseases. Myocardial perfusion SPECT has a lower blood flow tracking ability for myocardial accumulation than ^{13}N-ammonia PET, and there are false negatives due to balanced ischemia in patients with multiple coronary artery lesions, so its diagnostic accuracy is inferior to that of ^{13}N-ammonia PET. The increase ratio (IR), a new parameter in ^{99m}Tc-sestamibi SPECT, is an indicator of the relative increase in blood flow during stress compared to rest, and the concept is similar to that of PET-MFR. We investigated the relationship between IR and PET-MFR as well as their clinical significance. ***Materials and Methods:*** Patients who underwent ^{13}N-ammonia PET and ^{99m}Tc-sestamibi SPECT within one year of each other were enrolled. Using adenosine-stress and resting images of ^{99m}Tc-sestamibi SPECT, the stress image count was divided by the resting image count, and IR was calculated. We investigated the correlation between IR and PET-MFR and validated the optimal IR cutoff value for detecting PET-MFR<1.6(in our facility, previous research has shown that a PET-MFR <1.6 is a sensitive cutoff value for detecting poor prognosis) by receiver-operating-characteristic (ROC) analysis. And the mean IR and MFR values were compared between patients with and without multiple coronary artery lesions. ***Results:*** 33 patients (28 males, mean age 65.7±12.9) were analyzed. IR was significantly lower than PET-MFR (mean IR, 1.198; mean PET-MFR, 1.910; p<0.0001) and positively correlated with PET-MFR (Pearson r=0.3567; p<0.01). ROC analysis indicated that the optimal IR cutoff value for detecting PET-MFR<1.6 was 1.06, yielding an area under the curve (AUC) of 0.683, with 50% sensitivity and 83% specificity. By combining summed stress score with IR, the detectability of PET-MFR<1.6 improved the AUC of 0.798 with 83% sensitivity, and 70% specificity. The IR of the group with multiple coronary artery lesions was 1.04 ± 0.32 and that of the group with single-vessel lesions or no significant stenosis was 1.30 ± 0.27. Hence, the IR of the group with multiple coronary artery lesions was significantly lower than that with a single-vessel lesion or nonsignificant stenosis (p=0.0199). ***Conclusion:*** IR was positively correlated with PET-MFR. This suggests that IR may be useful for detecting patients with a low MFR in facilities that don't perform ^{13}N-ammonia PET.

Aim/Introduction: [^{123}I]CC1 is a novel cancer therapy combining Auger electron-emitting radionuclide ^{123}I with a PARP inhibitor. It

targets the DNA damage repair protein PARP in cancer cells, causing DNA damage and cell death. Moreover, [^{123}I]CC1 shows remarkable radiotoxicity against PARP-expressing cancer cells while sparing healthy tissue [1]. This study examines its radiobiological effects and synergy with chemotherapy as radiosensitizers. ***Materials and Methods:*** PSN1 and U87MG cells were exposed to [^{123}I]CC1 (100 kBq) for 1 h at 37°C. Cell cycle analysis was performed up to 10 days by flow cytometry. Western blot, staining for DNA damage response and cell stress markers, was performed up to 16 days post-exposure. Clonogenic survival assays were conducted in PSN1 cells exposed to [^{123}I]CC1 (100 kBq) or vehicle control, for 1 h at 37°C followed by washing and exposure to one of 166 FDA-approved chemotherapy agents. These agents target diverse cancer growth and survival mechanisms, including microtubule and kinase inhibitors, alkylating agents, antimetabolites and therapies targeting specific molecular pathways or repair mechanisms. ***Results:*** An initial wave of DNA damage and replication stress showed an early rise in DNA damage and cell cycle arrest markers, accompanied by increased replication stress markers. A second wave of DNA damage and cellular stress followed, potentially triggered by replication stress. An early G2 decline correlated with p21 upregulation, suggesting involvement in cycle arrest. Despite CDK4 accumulation, no G1/S arrest occurred, indicating that low-dose radioactivity may not fully induce G1 arrest but contributes to replication stress and genomic instability. Later, G1 depletion and G2 accumulation were consistent with a second wave of replication stress and p21 upregulation. These findings highlight the impact of low-dose [^{123}I]CC1 on cellular mechanisms inducing alterations in DNA damage repair, apoptosis, senescence, replication stress, and autophagy. Combination clonogenic assays tested 102 chemotherapy agents for radiosensitization, excluding those with antagonistic interactions. The top-performing synergistic drugs targeted multiple pathways, indicating that [^{123}I]CC1 modulates cellular responses through various mechanisms. Future studies will explore combinations with the most radiosensitizing potential. This screening identifies promising combinations and key pathways for further exploration of the biological response to [^{123}I]CC1. ***Conclusion:*** [^{123}I]CC1 modulates a multitude of cell cycle and impacts key cellular mechanisms. Its combination with radiosensitising chemotherapy agents holds promise for optimizing personalised radiotherapy. ***References:*** [1] C. Chan (2023) [^{123}I]CC1: A PARP-Targeting, Auger Electron-Emitting Radiopharmaceutical for Radionuclide Therapy of Cancer. Journal of Nuclear Medicine.

Synergistic Anti-Tumour Effects of ^{225}Ac-DOTA-Girentuximab Combined with DNA Damage Response Inhibitors in CAIX-Positive Renal Cancer

Z. Cao[1,2,3], *C. Wichmann*[1,2,3], *A. Ivashkevich*[4], *A. Zimmermann*[5], *C. Sirrenberg*[5], *H. Dahmen*[5], *L. Osellame*[1,2], *N. Guo*[1], *F. Scott*[1,2], *M. Wheatcroft*[4], *A. Scott*[1,2,3];
[1]*Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,* [2]*School of Cancer Medicine, La Trobe University, Bundoora, AUSTRALIA,* [3]*Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA,* [4]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [5]*Merck Healthcare KGaA, Darmstadt, GERMANY.*

Aim/Introduction: Radiopharmaceutical therapies achieve anti-cancer effects primarily by inducing abundant DNA double-strand breaks (DSBs) in target cells. However, these lesions can be repaired through DNA damage response (DDR) mechanisms, leading to disease recurrence and therapeutic resistance. Previous studies demonstrated that combining DDR inhibitors (DDRis) with ^{177}Lu-based radiopharmaceuticals enhances therapeutic efficacy and cancer cures in preclinical models (1,2). Given the higher linear energy transfer (LET) of alpha particles, which induces more extensive DSBs, this study aims to evaluate the anti-tumour efficacy of combining DDRis with ^{225}Ac-DOTA-girentuximab, targeting CAIX-expressing SK-RC-52 renal cancer cells. ***Materials and Methods:*** Girentuximab was conjugated with DOTA (1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid) and radiolabelled with ^{225}Ac. Clonogenic assays were performed to determine half-maximal inhibitory concentration (IC50) and evaluate the combination effects of ^{225}Ac-DOTA-girentuximab with two DDRis: lartesertib (ATM inhibitor) and peposertib (DNA-PK inhibitor). Synergy analyses were conducted, and combination index (CI) was calculated. In vivo therapeutic efficacy was assessed in SK-RC-52 xenograft model using a subeffective dose (5 kBq/mouse) of ^{225}Ac-DOTA-girentuximab. To explore underlying mechanisms, DDR-related molecular markers were analysed at multiple time points following treatment of SK-RC-52 cells with ^{225}Ac-DOTA-girentuximab in vitro. ***Results:*** Both peposertib and lartesertib reduced the IC50 of ^{225}Ac-DOTA-girentxuimab in SK-RC-52 cells. Synergy analysis indicated an additive effect with lartesertib (CI = 0.985), while a synergistic effect was observed with peposertib (CI = 0.760). Strikingly, in vivo studies demonstrated enhanced anti-tumour effects and improved tumour cures for both combinations, achieving complete responses in 2 out of 6 mice for both combinations. Molecular analysis showed time- and dose-dependent activation of DDR pathways following ^{225}Ac-DOTA-girentuximab treatment. High-dose exposure predominantly activated the non-homologous end joining (NHEJ) pathway targeted by peposertib, whereas lower doses stimulated the homologous recombination (HR) pathway targeted by lartesertib. ***Conclusion:*** The combination of ^{225}Ac-DOTA-girentuximab and DDR inhibitors demonstrated superior efficacy compared to monotherapies. Although in vitro synergy was only observed with peposertib, both combinations achieved synergistic anti-tumour effects in vivo, leading to improved tumour control and extended survival. These findings support further investigation of DDR inhibitors as combination partners for alpha-emitting radiopharmaceutical therapies. ***References:*** 1. Johnstone CN, Osellame LD, Cao Z, et al. Radiation Induced Senescence Limits Radiopharmaceutical Therapy Efficacy in Murine Models of GU Cancers

M. Lindsey, *M. Bio Idrissou, H. Comas-Rojas, A. Adeniyi, A. Pinchuk, L. Lambert-Lepesevich, N. Clemons, E. Santos, O. Kwon, G. Iyer, B. Bednarz, R. Hernandez;*
University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Senescence, a state of stable cellular arrest, can hinder radiotherapy efficacy and is associated with radioresistance, chronic inflammation, recurrence, and metastasis. Senotherapeutics, which selectively eliminate senescent cells (SNCs), have emerged as potential radiotherapy adjuvants. We present our initial findings and rationale for using senotherapeutics to augment radiopharmaceutical therapy (RPT) response in models of GU cancers (senoRPT). ***Materials and Methods:*** For PC3PIP (metastatic prostate cancer) and SKRC52 (clear cell renal cell carcinoma) cells treated with EBRT/^{177}Lu/^{225}Ac (6&10Gy), flow cytometry gating for morphology (FSC^{high}/ SSC^{high}) and SNC markers (SA-β-gal^{high}/p21^{high}/p16^{high}) provided estimates of senescent fraction (SF). Senescence-associated changes in gene expression were investigated by RNAseq in PC3PIP cells treated with ^{177}Lu (3Gy) and ^{225}Ac (0.3&1Gy). For both cell lines, cellular vitality and IC_{50} were determined via PrestoBlue following

combination treatment with EBRT/^{177}Lu/^{225}Ac (0-30Gy) and the BCL-family inhibitor ABT263 (0-3µM). In therapeutic studies, tumor selective ^{177}Lu-based agents were administered to male athymic nude mice implanted with PC3PIP or SKRC52 xenografts either alone or in combination with daily oral ABT263 (50mg/kg). Tumor growth and animal health were followed for 120d. SF was estimated from the delayed doubling time of senoRPT-treated tumors. Longitudinal SPECT/CT imaging was used to determine the agent biodistribution and estimate absorbed dose to the tumors and normal tissue. The clearance of SNCs by ABT263 was confirmed by fluorescence microscopy. ***Results:*** Flow cytometry revealed dose-dependent increases to SF, from ~10% untreated to ~60% with 10Gy. This was corroborated by RNAseq, revealing ≥125 senescence-associated genes significantly ($p<0.05$) upregulated across all treatments, with the 3Gy ^{177}Lu group showing the highest frequency (191 genes) and the 1Gy ^{225}Ac group having the largest mean differential expression. Synergistic combination of EBRT/^{177}Lu/^{225}Ac and ABT263 resulted in significant ($p<0.001$) reduction in vitality for both cell lines compared to radiation or ABT263 alone. In vivo, mice receiving senoRPT demonstrated marked tumor regression over RPT alone ($p<0.02$) or other controls ($p<0.01$). SF estimates suggest SNCs compose ~10-40% of the remaining tumor volume following non-curative RPT. Notably, senoRPT was well tolerated and demonstrated superior long-term survival, having been the only treatment arm to achieve complete responses. ***Conclusion:*** These preliminary findings underscore the relevance of the largely overlooked senescent phenotype on the efficacy of RPT and underscores the potential of senotherapeutics to expand RPT cure rates in GU cancers. This work exposes untapped areas for continued research related to the radiobiology of RPT-induced senescence and continued exploration of the senoRPT technique.

Targeted Radionuclide Therapy of Prostate Cancer using a ^{177}Lu- and ^{47}Sc-labeled Gastrin-Releasing Peptide Receptor Antagonist. Evaluation as Monotherapy and in Combination with Everolimus

N. Kumar[1], *A. Bilinska*[1], *E. Menéndez*[1], *T. Läppchen*[1], *E. S. Moon*[2], *M. Zoltowska*[3], *D. Pawlak*[3], *I. Cieszykowska*[3], *R. Mikolajczak*[3], *F. Rösch*[2], *A. Rominger*[1], *E. Gourni*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Chemistry-TRIGA site, Johannes Gutenberg University of Mainz, Mainz, GERMANY,* [3]*Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.*

Aim/Introduction: The gastrin-releasing peptide receptor (GRPR) promotes prostate cancer progression by activating pathways such as MAPK and PI3K/AKT. Radiolabeled GRPR antagonists show promise for treating GRPR-positive tumors. Everolimus, an mTOR inhibitor, may enhance these therapies by acting as a radiosensitizer. This study evaluates the effects of ^{177}Lu- and ^{47}Sc-labeled GRPR antagonists, alone and combined with everolimus, on tumor growth and survival in PC3-mice. ***Materials and Methods:*** The GRPR antagonist (AAZTA^5-Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH_2: LF1) was radiolabeled with lutetium-177 and scandium-47. The radiotherapeutic efficacy of [^{47}Sc]Sc-LF1 and [^{177}Lu]Lu-LF1 was investigated in PC3-mice. In the monotherapy study, a fractionated regimen consisted of six doses, was administered. Two cohorts of mice were used: one cohort received a total activity of approximately 40 MBq (equivalent to 1200 pmol), and the second received approximately 80 MBq (equivalent to 2400 pmol). In the ^{177}Lu-based combination, PC3-mice treated with 40 MBq of [^{177}Lu]Lu-LF1 alone or everolimus daily (5 mg/kg) for 72 h, followed by 40 MBq of [^{177}Lu]Lu-LF1. For the ^{47}Sc-based combination, mice were treated at days 1, 3 and 5 with 3 doses of [^{47}Sc]Sc-LF1 (total 30 MBq) alone or everolimus (5 mg/kg) with [^{47}Sc]Sc-LF1 (total 30 MBq) at the same days. Control groups received either ^{nat}Sc/ ^{nat}Lu-LF1 (400 pmol), PBS or everolimus (5 mg/kg). ***Results:*** Monotherapy with [^{47}Sc]Sc/[^{177}Lu]Lu-LF1 at the highest administered activities (80 MBq, 2400 pmol) significantly inhibited tumor growth compared to both the lower administered activities (40 MBq, 1200 pmol) and the control groups. Tumor volume reduction was more pronounced in the [^{177}Lu]Lu-LF1 group than in the [^{47}Sc]Sc-LF1 group. In the combination therapy, the combined treatment of everolimus and [^{47}Sc]Sc/[^{177}Lu]Lu-LF1 demonstrated the most significant tumor growth inhibition. Tumor regression was observed in all animals receiving combination therapy. Tumors in the untreated groups exhibited rapid progression. In terms of survival rate, the monotherapy group of [^{177}Lu]Lu-LF1 (2400pmol) showed significantly extended survival compared to all other groups (median survival: 50 days), followed by the [^{47}Sc]Sc-LF1 (2400pmol) (median survival: 32 days). The median survival for [^{47}Sc]Sc/[^{177}Lu]Lu-LF1 (1200pmol) groups was comparable to the control groups (median survival: 19, 16 and 18 days, respectively). In combination therapy, the median survival was 26 days for everolimus, 40 and 38 days for everolimus along with [^{47}Sc]Sc-/[^{177}Lu]Lu-LF1, respectively. ***Conclusion:*** Fractionated therapeutic regimens of radionuclide therapy, as well as its combination with mTOR inhibitors, like everolimus, represent a rational and innovative approach to improve prostate cancer treatment outcomes. ***References:*** This work is a PRISMAP contribution.

OP-519

Combining CD44v6-Targeted Radionuclide Therapy with Chemotherapy for Treatment of Pancreatic Ductal Adenocarcinoma

A. Gustafsson[1], *H. Svedberg*[1], *S. S. Rinne*[1], *A. Lundgren Mortensen*[1,2], *M. Nestor*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Karolinska Institutet, Stockholm, SWEDEN.*

Aim/Introduction: Pancreatic ductal adenocarcinoma (PDAC) is among the deadliest malignancies, owing to its rapid progression, resistance to available therapies, and poor prognosis. The cell surface marker CD44v6 is frequently overexpressed in PDAC, making it a promising target for targeted radionuclide therapy (TRT), capable of addressing metastatic disease and potentially enabling surgical intervention. This study evaluated the therapeutic potential of [^{177}Lu]Lu-DOTA-AKIR001, a full-length human IgG antibody targeting CD44v6 and currently in Phase I trials for multiple CD44v6-positive solid tumors. Additionally, the study explored potential benefits from combining [^{177}Lu]Lu-DOTA-AKIR001 with standard chemotherapeutics. ***Materials and Methods:*** Radiochemical stability of [^{177}Lu]Lu-DOTA-AKIR001 was evaluated in PBS, mouse serum, and EDTA using ITLC. CD44v6 expression, radioligand uptake, and sensitivity to the chemotherapeutic agents paclitaxel and gemcitabine were assessed across a panel of PDAC cell lines. In vivo tumor targeting and therapeutic efficacy were investigated in immunodeficient BALB/c nu/nu mice bearing subcutaneous human PDAC xenografts. To assess therapeutic outcomes, mice received [^{177}Lu]Lu-DOTA-AKIR001 (4 or 12 MBq), paclitaxel, gemcitabine, or a combination of 4 MBq [^{177}Lu]Lu-DOTA-AKIR001 with either chemotherapeutic agent. Haematologic toxicity was monitored via serial blood sampling. ***Results:*** Radiochemical yield consistently exceeded 95% and [^{177}Lu]Lu-DOTA-AKIR001 remained stable for at least 48 hours (>95%). CD44v6 expression was observed in three out of four tested cell lines, to which AKIR001 bound with target-specific, picomolar affinity. All cell lines showed at least partial sensitivity to both paclitaxel and gemcitabine. At 96 hours p.i., tumour uptake in vivoexceeded 100% injected activity per gram (%IA/g) tissue. An activity-dose-dependent inhibition of tumour growth was observed, with the greatest anti-tumour activity noted in the 12 MBq group. A trend favouring combination therapy over 4 MBq [^{177}Lu]Lu-DOTA-AKIR001 monotherapy was observed. Contrary to the in vitro results, chemotherapy alone had no significant

impact on tumour growth or median survival. Mild and transient hematologic toxicity was observed across all treatment groups, most pronounced in the high-activity treatment group followed by the combination treatments. Weight loss was observed only in gemcitabine-treated animals. ***Conclusion:*** [^{177}Lu]Lu-AKIR001 demonstrated high stability, selective tumour targeting, and promising anti-tumour activity in our preclinical PDAC model. Combination with chemotherapy, particularly paclitaxel, showed potential to enhance treatment outcome at lower activity levels without increased toxicity. Thus, [^{177}Lu]Lu-AKIR001 may represent a feasible treatment option for PDAC in the future, though further optimization of dosing and combination regimens is warranted to maximize its therapeutic potential.

OP-520

New combination therapies to improve [^{177}Lu]Lu-PSMA treatment in prostate cancer cells.

F. Amoroso[1,2], *E. O'Neill*[2], *L. Hernandez Cano*[1], *B. T. Cornelissen*[1,2]; *[1]Dept. of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, NETHERLANDS, [2]Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Most patients with locally advanced prostate cancer (PCa) are treated with surgery or radiotherapy with curative intent. Although the treatments can extend survival, delayed diagnosis as well as development of therapy resistance can result in cases where the metastatic disease becomes incurable. Despite the clinical development for PCa theranostics of several radiolabelled [^{177}Lu]Lu-PSMA, all undergoing clinical trials for treating metastatic Castrate Resistant PCa (mCRPC), little we know about the radiobiological effects of ^{177}Lu. Moreover, regardless of some highly promising results from the VISION Study (NTC03511664), only a subset of mCRPC patients responds to the treatment and only 10% showed a complete response (1). For these reasons, we evaluated whether combining [^{177}Lu]Lu-PSMA with other compounds would improve the radiobiological effects of this radioligand therapy. ***Materials and Methods:*** While performing a big scale screening for combination therapies on a PCa cell line (22Rv1) in vitro, we identified Tosedostat (CHR-2797) among several compounds that significantly reduced clonogenicity and showed super-additivity when combined with [^{177}Lu]Lu-PSMA. Tosidostat is an aminopeptidase inhibitor with anti-proliferative, anti-angiogenic, and pro-apoptotic activity through disruption of protein synthesis and the cell cycle (2). To further analyse the (radio)biology involved, we performed Western blot analysis and immunofluorescence staining in 22Rv1 cells treated with [^{177}Lu]Lu-PSMA in combination with Tosedostat (at the IC50 concentration of 60 nM) over a period of 10 days. ***Results:*** We observed a consistent overexpression of ɤH2AX, indicating the formation of double stranded breaks (DSBs) as consequence of the combination, compared to both monotherapies. We also described pro-apoptotic pathways activated in response to this combination over 10 days, when PARP1 and caspase 3 are cleaved. We finally identified 3 aminopeptidases that could play as drivers of the phenotypic changes we observed with this combination. ***Conclusion:*** Tosedostat (CHR-2797) is currently in phase II clinical trials for the treatment of blood-related cancers. Here we show that combining [^{177}Lu]Lu-PSMA with Tosedostat in PCa cells can improve the efficacy of this radioligand therapy. This represents a big step forward towards the development of new targeted and more effective treatments for PCa patients. ***References:*** (1) Novartis. Phase III VISION study. 2021. (2) Alan F. List, Leukemia Research (2012).

OP-521

Combining CAIX-targeted radionuclide therapy with immune checkpoint inhibitors: which inhibitor and when?

S. Kleinendorst[1], *E. Oosterwijk*[1], *M. Konijnenberg*[1], *S. Wenker*[1], *K. Twumasi-Boateng*[2], *M. Wheatcroft*[2], *S. Heskamp*[1]; *[1]RadboudUMC, Nijmegen, NETHERLANDS, [2]Telix Pharmaceuticals Limited, Melbourne, AUSTRALIA.*

Aim/Introduction: The carbonic anhydrase IX (CAIX)-targeting antibody [^{177}Lu]Lu-DOTA-hG250 represents a novel therapeutic approach for targeted radionuclide therapy (TRT) in advanced clear cell renal cell carcinoma (ccRCC). Preclinical studies have demonstrated the promising potential of combining CAIX-TRT with immune checkpoint inhibitors (ICI). This study explores how the type of ICI and timing of administration influence the therapeutic efficacy of CAIX-TRT/ICI combinations. ***Materials and Methods:*** Balb/C mice bearing subcutaneous Renca-hCAIX tumors were randomized into groups of 10 mice to receive intravenous saline or 4 MBq [^{177}Lu]Lu-DOTA-hG250 on day 0. Animals were subsequently treated with saline, aPD-1, aCTLA-4, or dual-ICI (aPD-1 + aCTLA-4) every three days starting from day 1 (concurrent timing). In a second experiment, aPD-1 or aCTLA-4 were administered beginning on day 7 post-TRT (sequential timing), and outcomes were compared to concurrent administration. Tumor growth was monitored, and results were quantified as the area under the tumor growth curve normalized for lifetime (median nAUC [interquartile range]). Survival and complete responses (CRs) were assessed. ***Results:*** The combination of CAIX-TRT with dual-ICI significantly reduced tumor growth compared to untreated controls (nAUC=50.3 [17.8–264.4] vs 521.9 [424.5–689.0] mm^3 (untreated), $p<0.01$) and resulted in the longest survival benefit, including 8 CRs. TRT/aPD1 showed partial tumor regression in some animals, but high variability was observed between mice (nAUC=164.6 [52.5–698.8] mm^3, $p>0.05$) with 4 CRs. In contrast, TRT/aCTLA4 failed to demonstrate significant therapeutic benefit (nAUC=311.9 [183.9–574.8] mm^3, $p>0.05$). Comparing concurrent and sequential schedules, no statistically significant differences in efficacy were observed for either TRT/aPD-1 or TRT/aCTLA-4 combinations (nAUC=149.9 [96.6-376.7] vs 278.0 [99.3 - 690.0] mm^3, $p>0.05$, and nAUC=415.5 [305.3-562.1] vs 417.0 [313.4-546.4] mm^3, $p>0.05$). However, there was a trend towards better survival after concurrent administration within the aPD-1 combination arm (6 survivors/3 CRs versus 3 survivors/2 CRs). ***Conclusion:*** These findings underscore the therapeutic potential of CAIX-TRT combined with ICIs, particularly dual-ICI, for advanced ccRCC treatment. They emphasize the importance of carefully selecting the ICI type to maximize therapeutic efficacy and provide a foundation for future clinical trial designs using optimized treatment parameters.

Fractionated versus single-dose PSMA-targeted radioligand therapy as adjuvant therapy in a murine model for oral squamous cell carcinoma treated with immune checkpoint inhibitors

M. Henrotte[1,2,3], *D. Creytens*[1,2,3], *F. De Vos*[2], *B. Descamps*[2,3], *L. Devisscher*[2,3], *G. Holtappels*[2], *W. J. A. Huvenne*[1,2,3], *K. Kersemans*[1,3], *A. Meskens*[2,3], *S. Neyt*[2,3], *S. Rottey*[1,2,3], *M. Saerens*[1,2,3], *C. Vanhove*[2,3], *T. Vermassen*[1,2,3], *J. M. Debacker*[2,4,5]; *[1]Ghent University Hospital, Ghent, BELGIUM, [2]Ghent University, Ghent, BELGIUM, [3]Cancer Research Institute Ghent (CRIG), Ghent, BELGIUM, [4]Vrije Universiteit Brussel (VUB), Molecular Imaging and Therapy Research Group (MITH), Brussels, BELGIUM, [5]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, BELGIUM.*

Aim/Introduction: Immune checkpoint inhibition (ICI) is a cornerstone in the management of relapsed or metastatic head and neck squamous cell carcinoma (R/M HNSCC). However, response rates and survival remain limited, warranting novel therapies. One approach is targeting prostate-specific membrane antigen (PSMA), which is expressed on the endothelium of tumour-associated neovasculature in oral squamous cell carcinoma (OSCC). We assessed the effects of fractionated (FX) versus single-dose (SD) PSMA-targeted radioligand therapy (TRT) in monotherapy and combined with ICI, using a syngeneic, orthotopic, immunocompetent murine OSCC model. ***Materials and Methods:*** OSCC tumours were induced by injecting 7.5 × 10^5 MOC1 cells into the anterior lateral tongue of 55 adult male C57BL/6J mice. On day 12, mice were randomised to different treatment protocols: (a) 100 MBq [^{177}Lu]Lu-PSMA-I&T IV on day 12 (SD-TRT, n = 8); (b) 4 × 25 MBq [^{177}Lu]Lu-PSMA-I&T IV (Q1W), starting on day 12 (FX-TRT, n = 8); (c) 8 doses of anti-murine PD-1 IP BIW, starting on day 12 (ICI; n = 11); (d) SD-TRT + ICI (n = 10); (e) FX-TRT + ICI (n = 10); or (f) untreated controls (n = 8). Tumour volumes were measured twice a week. Animals were sacrificed at humane endpoint or arbitrarily on day 90. Tumour volumes (absolute and relative to day 12), complete response (CR) rate, and overall survival (OS) were compared across treatment groups. Tumours exhibiting intrinsic immune escape phenotypes were excluded. ***Results:*** Median OS was 41 (control), 48.5 (SD-TRT), 54 (FX-TRT), 61.5 (ICI), 73.5 (SD-TRT + ICI) and > 90 days (FX-TRT + ICI). CR rates were 0% (control, SD-TRT), 25% (FX-TRT), 20% (ICI), 37.5% (SD-TRT + ICI) and 62.5% (FX-TRT + ICI). Combined therapies achieved greater tumour growth suppression and volume reduction compared to monotherapies. Notably, FX-TRT + ICI achieved tumour volumes significantly lower compared to ICI alone, from treatment week 2 through 1 week after the final dose (p = 0.004-0.030). ***Conclusion:*** This is the first study to compare single-dose and fractionated PSMA-TRT in an immunocompetent OSCC model treated with ICI. Combined therapy with fractionated PSMA-TRT significantly enhanced therapeutic efficacy, yielding greater response and survival rates, and improving tumour growth control compared to ICI alone. These results support the clinical translation of fractionated PSMA-TRT as therapeutic adjunct in patients with R/M HNSCC, where currently ICI monotherapy is standard of care. Further investigations are warranted to better understand the immunogenic and radiobiological mechanisms underlying these findings.

OP-523

PD-1 blockade enhances therapeutic effects of ^{177}Lu-DOTA-M5A in colorectal cancer CEA-transgenic mice

T. Mohajershojai[1], *E. Bengtsson*[1], *I. Vallin*[2], *D. Spangler*[2], *M. Melssen*[2], *P. J. Yazaki*[3], *M. Nestor*[2];
[1]*Karolinska Institute, Stockholm, SWEDEN,* [2]*Uppsala University, Uppsala, SWEDEN,* [3]*Beckman Research Institute, Duarte, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Radioimmunotherapy (RIT) has emerged as a promising strategy for treating metastatic solid tumors by delivering targeted radiation through the coupling of radionuclides with tumor-specific antibodies, thereby minimizing damage to healthy tissues. Carcinoembryonic antigen (CEA) is a well-established target in CEA-expressing malignancies, such as colorectal cancer (CRC), making it an attractive candidate for RIT. Increasing evidence suggests that RIT can potentiate anti-tumor immune responses, and combining RIT with immune checkpoint inhibitors (ICIs), such as anti-PD-1 antibodies, may further amplify therapeutic efficacy. This study aimed to evaluate, for the first time, the in vivo therapeutic effects of CEA-targeted RIT using the novel humanized anti-CEA antibody hT84.66-M5A conjugated to ^{177}Lu (^{177}Lu-DOTA-M5A), both as a monotherapy and in combination with PD-1 blockade. ***Materials and Methods:*** Radioconjugate uptake and efficacy were assessed in vitro using the MC38-CEA1 colorectal cancer spheroid model, and in vivo in CEA-transgenic mice bearing CEA-expressing tumors. Biodistribution and SPECT/CT imaging confirmed tumor-specific accumulation of the radioconjugate. In vitro studies demonstrated a dose-dependent cytotoxic effect of ^{177}Lu-DOTA-M5A. ***Results:*** In vivo, both ^{177}Lu-DOTA-M5A and PD-1 blockade monotherapies reduced tumor growth, with the combination therapy yielding the most pronounced and significant tumor growth inhibition (average daily growth: -6%) compared to PD-1 blockade (+7%), ^{177}Lu-DOTA-M5A (+7.9%), and untreated controls (+13.5%). Median survival was extended by 31% with PD-1 blockade and 52% with ^{177}Lu-DOTA-M5A; notably, the median survival in the combination group was not reached during the study period. Importantly, neither the monotherapies nor the combination therapy induced bone marrow toxicity. Furthermore, ^{177}Lu-DOTA-M5A modestly modulated the tumor immune microenvironment, increasing the presence of cytotoxic and helper T cells. In the combination-treated group, there was a notable shift toward pro-inflammatory macrophages, indicating an enhanced anti-tumor immune response. ***Conclusion:*** These findings support the therapeutic potential of ^{177}Lu-DOTA-M5A in CRC and underscore the added benefit of combining RIT with immune checkpoint inhibition. Further in vivo studies are warranted to validate these results and explore the clinical applicability of this combinatorial approach.

Decision support for early treatment adaptation, a case study for NSCLC: RTEP7-IFCT 14.02

Z. Mesbah[1,2,3], *R. Modzelewski*[1,3], *P. Le Roux*[1], *G. Zalcman*[4,5], *P. Giraud*[6], *P. Vera*[1,7], *S. Thureau*[1,7];
[1]*Henri Becquerel Cancer Center, Rouen, FRANCE,* [2]*Siemens Healthineers, Courbevoie, FRANCE,* [3]*AIMS-QuantIF, Rouen, FRANCE,* [4]*Bichat Claude Bernard Hospital, Paris, FRANCE,* [5]*Francophone Intergroup of Thoracic Oncology, Paris, FRANCE,* [6]*European Hospital Georges Pompidou, Paris, FRANCE,* [7]*AIMS-QuantIF, Paris, FRANCE.*

Aim/Introduction: The RTEP7 study is a phase II-III study originally designed to prove the efficiency and safety of dose escalation, up to 74 Gy (boost), during the external radiotherapy (RT) treatment, based on 18F-FDG-PET/CT imaging after 42 Gy of treatment (PET/CT 2). The goal of our study is to detect patients which could benefit from a RT boost from the start of the treatment. ***Materials and Methods:*** Our study focuses on 67 of the 138 patients which benefited from adaptive treatment based on the analysis by a physician of PET/CT 2. We evaluate the potential lesion radiomics as well as that of healthy organs omics (organomics). Thoracic organ groups are defined as follows: lungs, heart, aorta, trachea, oesophagus, spinal cord and thoracic vertebrae. The organs composing these groups are contoured using the TotalSegmentator tool. We extract 214 features (107 on PET and 107 on CT) for lesions and for each of the thoracic organ groups. We select the features most correlated to the target value, using Spearman's correlation coefficient, then fit a Machine Learning (ML) model on these features. A 6 folds cross validation (CV) was performed: 5 folds used to train the model and 1 fold kept as internal validation. Best performances were attained using a SVM model. We score the radiomics and organomics models

on the full CV as well as for each patient, to obtain accuracy score and a contigency matrix. Finally we perform a McNemar statistical test to assess the significance of potential performance differences between models. ***Results:*** Patients classification using the radiomics model yielded a balanced accuracy of 60.15%, sensitivity of 59.29%, a specificity of 61.01% and AUC of 62.52%. Using the organomics model, we improve performance greatly: a balanced accuracy of 76.25%, sensitivity of 79.02%, a specificity of 73.49% and AUC of 79.04%. The McNemar test yielded a p-value of 0.009, meaning the performances of radiomics and organomics models are significantly different. ***Conclusion:*** We demonstrated a significant (p=0.009) improvement in performance when using organomics over radiomics as input to a ML model, for the task of predicting treatment adaptation using pre-treatment PET/CT scan. The organomics-based model reached an accuracy of 76.25% in the task of predicting wether a patient will need a RT boost or not.

OP-525

Systemic Metabolic Signatures of Lung Cancer: A Machine Learning Approach Using Whole-Body Dynamic [^{18}F]FDG-PET

S. Castaneda Vega[1,2], *V. Agrawal*[3,2], *M. Weissinger*[1,4], *M. Stettler*[2], *V. Groos*[5], *A. Assmann*[5], *S. von Beschwitz*[1], *B. Pichler*[2,6], *S. Bauer*[7,8], *C. la Fougère*[1,9,10];
[1]*Departmenf of Nuclear Medicine and Clinical Molecular Imaging, Tübingen, GERMANY,* [2]*Werner Siemens Imaging Center, Tübingen, GERMANY,* [3]*Max Planck Institute for Intelligent Systems, Tübingen, GERMANY,* [4]*Department of Diagnostic and Interventional Radiology, Tübingen, GERMANY,* [5]*University of Tübingen, Tübingen, GERMANY,* [6]*iFIT-Cluster of Excellence, Tüebingen, GERMANY,* [7]*Helmholtz AI, München, GERMANY,* [8]*Technical University, München, GERMANY,* [9]*iFIT-Cluster of Excellence, Tübingen, GERMANY,* [10]*German Cancer Consortium (DKTK), Tübingen, GERMANY.*

Aim/Introduction: [^{18}F]FDG-PET/CT is widely used for lung cancer diagnosis and staging, yet typically relies on static imaging. Whole-body dynamic [^{18}F]FDG-PET, which captures tracer kinetics across time and organs, remains underutilized due to data complexity. However, its potential to reveal systemic physiological responses to malignancy is of increasing interest. This study investigates whether glucose metabolism in extra-tumoral organs—reflecting a tumor-organ axis—can be used to predict malignancy in pulmonary lesions using machine learning (ML). ***Materials and Methods:*** Thirty-four patients with indeterminate lung lesions underwent whole-body dynamic [^{18}F]FDG-PET/CT (0-80 min, Biograph™ mCT, Siemens). Lesions were classified as malignant or benign based on histopathology. Patlak modeling was used to generate parametric maps. Volumes of interest were drawn on the spleen, liver, bone marrow, and skeletal muscle, from which SUVmax, SUVmean, SUVpeak, and slope values were extracted. These features were used to train ML classifiers, and Shapley values were calculated to interpret feature importance. ***Results:*** The ML models achieved classification accuracies of up to 97% using only organ-level features. High TNM-stage tumors showed pronounced bone marrow activation, whereas benign lesions exhibited relatively elevated metabolic activity in the spleen. Interestingly, low-TNM malignancies displayed spleen metabolic slopes slightly higher than in high-TNM cases. Normalization of spleen values to liver uptake revealed that benign lesions retained a higher spleen metabolic rate compared to malignant cases. These subtle yet distinct patterns across distant organs reflect a measurable tumor-organ axis and provide classifiable signatures of malignancy. ***Conclusion:*** Whole-body dynamic PET imaging combined with machine learning can reveal systemic metabolic signatures associated with lung cancer. Differences in spleen and bone marrow activity, particularly when normalized to liver uptake, reflect disease burden and progression. These findings demonstrate the diagnostic potential of analyzing extra-tumoral organ metabolism and support a shift toward system-wide, non-invasive biomarkers for cancer detection and monitoring. ***References:*** Feng T, et al. J Nucl Med. 2021;62(5):738-744.

Transfer Learning and External Validation of a ResNet-Based Deep Learning Model for Deauville Score Classification with [18F]FDG-PET-CT: A Retrospective Analysis

M. Dubrocq[1], *A. Mezher*[1], *T. Guiot*[2], *A. Gjukaj*[1], *O. Debeir*[3], *P. Flamen*[2], *E. Woff*[2];
[1]*Université Libre de Bruxelles, Brussels, BELGIUM,* [2]*Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (H.U.B), Institut Jules Bordet, Department of Nuclear Medicine, Brussels, BELGIUM,* [3]*Université libre de Bruxelles (ULB), Ecole polytechnique de Bruxelles, Brussels, BELGIUM.*

Aim/Introduction: To evaluate the feasibility of a deep learning model for automatically classifying post-treatment [^{18}F]FDG-PET maximum intensity projection (MIP) images of lymphoma patients as negative (Deauville scores 1-3) or positive (scores 4-5). ***Materials and Methods:*** This retrospective study included 1602 [^{18}F]FDG-PET-CT scans from 882 adult patients with biopsy-confirmed FDG-avid lymphoma, acquired between 2015 and 2025 at the Institut Jules Bordet (Brussels, Belgium). All patients were diagnosed according to Lugano guidelines and underwent [^{18}F]FDG-PET-CT imaging for baseline and post-treatment follow-up.A previously published ResNet34-based model, the Lymphoma Artificial Reader System (LARS, Häggström et al.), was first externally validated on our test set. Secondly, the same architecture was retrained from scratch with our local data. Finally, a fine-tuning of the pretrained LARS model on our cohort was performed. Inputs of the models consisted of coronal and sagittal MIP images derived from SUV-converted PET scans. Patient-wise stratified splitting was employed in allocating 80% of cases for the training set and 20% for the test set. Model optimization was performed using binary cross-entropy loss with hyperparameters selected based on the area under the receiver operating characteristic curve (AUC). ***Results:*** External validation of LARS achieved an AUC of 0.915 (95% CI: 0.857-0.963), accuracy of 0.886 (0.848-0.924), sensitivity of 0.816 (0.700-0.917), and specificity of 0.900 (0.861-0.938).The locally retrained model showed decreased sensitivity 0.765 (0.634-0.871) despite a comparable AUC (0.900, 0.842-0.948) and specificity 0.929 (0.898-0.959).Fine-tuning the pretrained LARS model significantly improved performance, yielding the highest AUC (0.932, 0.884-0.971), sensitivity (0.878, 0.783-0.960), and robust specificity (0.908, 0.871-0.942). ***Conclusion:*** This study confirms the feasibility of using deep learning for automated Deauville-based classification of post-treatment [^{18}F]FDG-PET scans in lymphoma. The externally validated LARS model generalized well to an independent clinical dataset, achieving high AUC and accuracy. Retraining the same architecture (ResNet34) on a local dataset reproduced the approach but resulted in lower sensitivity. Fine-tuning the pretrained model on local data led to significantly improved performance, with the highest AUC and sensitivity across all configurations. These results demonstrate the transferability of this classification task across institutions and highlight the added value of transfer learning in adapting existing models to new clinical settings. Fine-tuned AI models may serve as reliable and scalable toolsfor treatment response assessment in molecular imaging, and their strong performance provides a compelling basis for further exploration toward multicenter generalization.

Performance of an automatic tool for breast cancer staging with [^{18}F]FDG PET/CT

C. Constantino[1,2], *C. Oliveira*[1], *F. P. Oliveira*[1], *S. Vinga*[2], *D. C. Costa*[1];
[1]*Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*INESC-ID, Instituto Superior Tecnico, University of Lisbon, Lisbon, PORTUGAL.*

Aim/Introduction: Whole-body [^{18}F]FDG PET/CT imaging is widely used to guide treatment decisions in breast cancer staging. In this study, we evaluate the potential of an AI-based tool to automatically localize key tumor regions with paramount importance for breast cancer staging using [^{18}F]FDG PET/CT. ***Materials and Methods:*** 263 histologically confirmed breast cancer patients (female, 54±11 y.o.) with staging [^{18}F]FDG PET/CT scans were retrospectively included. Images were acquired on Philips Gemini TF 16 (N=99) or Digital Vereos (N=164). [^{18}F]FDG avid lesions were identified by an experienced nuclear medicine physician and stratified according to their location: primary tumor (pT), axillary lymph nodes (ALN), extra-axillary loco-regional nodes (internal mammary and/or supraclavicular lymph nodes), and distant metastases (dM). Lesions were semi-automatically segmented with an adaptive Bayesian classifier [1]. All 263 patients had pT, 188 with ALN, 33 with extra-ALN, and 50 with dM. A two-channel (PET and CT) 3D U-Net based on the state-of-the-art nnU-Net framework [2] was used to train a four-class deep-learning-based model. The train/test set selection ensured adequate representativity of the four classes in both sets. In the test, there were pT in 60, ALN in 35, extra-ALN in 5, and dM in 14. To evaluate model performance, sensitivity and specificity to identify and classify the four key tumor regions were calculated. Furthermore, the SUV_{max} automatically retrieved from each class was compared with the physician-based ground truth, and the absolute agreement was assessed with the intraclass correlation coefficient (ICC). ***Results:*** In total, 1416 lesions were identified by the physician. In the test set (N=60 scans), there were 90 pT lesions, 71 ALN, 10 extra-ALN, and 220 dM). The AI-based tool was able to localize primary tumors with 100% sensitivity. For the identification and classification of ALN, extra-ALN, and dM, the sensitivity and specificity were 97% and 67%, 60% and 100%, and 72% and 94%, respectively. ICC for SUVmax between physician ground-truth and AI-based segmentation for the pT, ALN, extra-ALN, and dM were 0.98, 1.00, 0.65, and 0.98, respectively, showing good to perfect agreement. ***Conclusion:*** The developed AI-based tool has the potential to automatically map breast cancer involvement, using the location of four key tumor regions highly important for the staging. This aids breast cancer treatment decision-making. Ongoing work is expected to demonstrate improved results by increasing data training with higher numbers of regional lesions involvement. ***References:*** [1] Constantino et al, doi:10.1007/s10278-023-00823-y; [2] Isensee et al., doi:10.1038/s41592-020-01008-z

AI-based Prediction of Myocardium Viability Using [^{82}Rb] PET/CT

A. Chevalley[1,2], *G. Bonnet*[2], *M. Amirian*[1,2], *V. Andrearczyk*[1,2], *S. Bors*[2], *R. Klein*[3], *R. DeKemp*[4], *E. Moulton*[5], *J. O. Prior*[2], *M. Jreige*[2], *C. H. Kamani*[2], *A. Depeursinge*[1,2];
[1]*Institute of Informatics, HES-SO Valais-Wallis, Sierre, SWITZERLAND,* [2]*Department of Nuclear Medicine and Molecular Imaging, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, SWITZERLAND,* [3]*Division of Nuclear Medicine and Molecular Imaging, University of Ottawa, Ottawa, ON, CANADA,* [4]*Division of Cardiology, University of Ottawa Heart Institute,, Ottawa, ON, CANADA,* [5]*Jubilant DraxImage Inc., Kirkland, QC, CANADA.*

Aim/Introduction: Myocardial viability assessment is crucial to determine the potential need for revascularisation after myocardial infarction (MI). While [^{18}F]FDG combined with [^{82}Rb] myocardial perfusion imaging is the gold standard, this study aims to detect non-viable tissues using only [^{82}Rb] PET and artificial intelligence (AI). ***Materials and Methods:*** The cohort was retrospectively composed of MI patients who underwent clinically indicated [^{82}Rb] and [^{18}F]FDG at our institution. For ground truth, we computed the viability score by normalizing the FDG uptake map to the regions with normal [^{82}Rb], defined as ≥ 60% maximum. Viability score bellow 50 % defined non-viable regions. We propose two approaches to infer viability from Rubidium alone: the regression (Reg) approach predicts the viability score, while the classification (Cl) approach detects non-viable tissues. We compared two models for both methods, support vector models ($SVM_{Reg/Cl}$) using 93 radiomic features extracted from the segment uptake rate K_1 and a convolutional neural network ($CNN_{Reg/Cl}$) using myocardial blood flow segment. Only the best modality for each model is reported. For classification models, the static [^{82}Rb] segment value is added to help differentiate normal from abnormal. The metrics reported are positive predictive value (PPV), true positive/negative rate (TPR/TNR). For the regression approach, the predicted score is binarized using the 50% threshold for classification. Analysis was performed at the segmental level using the 17-segment American Society of Nuclear Cardiology model, excluding the apex. Training used five stratified folds, allowing us to compute the 95% confidence intervals assuming a Student-t distribution. ***Results:*** The study includes 34 patients (29 male; mean age 70 ± 9 years), resulting in 544 segments. As normal segments are trivial to classify, evaluation is conducted on the 114 abnormal segments. For regression, CNN_{Reg} predicts the viability score with a mean absolute error (MAE) of 8.52[6.50,10.54], and achieves a PPV, TPR and TNR of 0.75[0.45,1.00], 0.80[0.63,0.98] and 0.89[0.77, 1.00]. Therefore, CNN_{Reg} slightly outperforms its classification counterpart CNN_{Cl}, which shows PPV, TPR and TNR of 0.74[0.53,0.94], 0.78[0.57,0.99] and 0.86[0.73, 1.00]. Radiomics-based models are slightly worst, SVM_{Reg} with an MAE of 9.04[7.19,10.90], PPV, TPR and TNR of 0.68[0.42,0.94], 0.62[0.30,0.95] and 0.85[0.72, 0.98] and SVM_{Cl} (PPV, TPR and TNR of 0.68[0.44,0.91], 0.87[0.70,1.00] and 0.80[0.62,0.97]). ***Conclusion:*** AI may help predict segmental myocardial viability after an infarction using rest [^{82}Rb] PET alone and remove the costs and radiation associated with the use of [^{18}F]FDG.

OP-529

Integration of Spatial Analysis and Deep Learning for Enhanced Tumour Classification in Total-Body PET/CT Imaging: A Preliminary Study

D. Han[1], *S. Wail*[2];
[1]*Telix Pharmaceuticals, Sydney, AUSTRALIA,* [2]*Telix Pharmaceuticals, Melbourne, AUSTRALIA.*

Aim/Introduction: This study aims to improve tumour classification of total-body ^{68}GaPSMA11 PET/CT scans by integrating lesion segmentation, quantitative spatial analysis with machine-learning. The objective is to differentiate tumour types, including bone, lymphatic, liver, and prostate, while establishing criteria that may support future evaluation of cancer progression based on anatomical spread and established staging systems (TNM, miTNM, PROMISE). The focus of our efforts is on quantitative spatial analysis. ***Materials and Methods:*** 297 image sets from total-body ^{68}GaPSMA11 PET/CT scans were used for training, 3771 tumours were identified throughout the dataset. The binary tumour segmentations of the 297 PET/CT scans were generated using an internally developed nn-UNet-based segmentation algorithm. CT scans were further processed to accurately delineate major organs by a state-of-the-art total-body segmentation algorithm (TotalSegmentator). From the PET and CT segmented images, spatial relationships between tumours and organs were quantified. Key features were derived: tumour centroid coordinates and volumes; organ centroid coordinates and volumes; minimal distance between tumour and organ surfaces; distance between

the centroids of tumour and each organ; and volume of overlap when present. These relational metrics provided a robust data foundation to characterise the anatomical context of tumours. Two complementary machine learning models were developed: both a convolutional neural network (CNN) that and a graph neural network (GNN) were developed that incorporates the extracted spatial relationships in a network-based framework. Both models were trained to classify tumour types into pre-defined categories, facilitating comparisons between approaches. ***Results:*** Preliminary experiments with a validation dataset indicate that both CNN and GNN models achieved promising classification performance, yielding an overall 90% accuracy for both test and validation datasets, with bone class > 98%, lymph class > 85%, prostate > 85% and liver > 90%.The inclusion of spatial relational features improved the overall discrimination of tumour types. Furthermore, the generation of detailed classification criteria per tumour segment not only enhanced model accuracy but also provided a framework for future applications in monitoring cancer progression. ***Conclusion:*** The presented workflow establishes a novel framework for tumour classification by combining advanced organ segmentation, quantitative relational feature extraction, and dual-modality machine-learning. This integrated approach not only offers enhanced accuracy in distinguishing tumour types but also lays the groundwork for future prognostic applications in clinical oncology. Further validation with larger datasets is planned to refine the methodology and explore its potential in informing treatment planning and dynamic cancer staging.

Wasserstein Distance as a Metric for Molecular Connectivity Analysis in Amyotrophic Lateral Sclerosis

C. Tang[1], *J. De Vocht*[2,3], *K. Van Laere*[1,4], *P. Van Damme*[2,3], *M. Koole*[1];
[1]Nuclear Medicine and Molecular Imaging, Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Laboratory for Neurobiology (VIB-KU Leuven), Department of Neurosciences, KU Leuven, Leuven, BELGIUM, [3]Neurology, University Hospitals Leuven, Leuven, BELGIUM, [4]Department of Nuclear Medicine, University Hospitals UZ Leuven, Leuven, BELGIUM.

Aim/Introduction: Molecular imaging is increasingly important in investigating brain connectivity, advancing our understanding of the brain connectome (1). However, evaluating molecular connectivity at the individual level using static ^{18}F-FDG PET is challenging due to the absence of temporal information. This limitation calls for alternative approaches to conventional functional connectivity methods, which rely on correlations of time series. In this study, we introduce a novel approach based on the Wasserstein distance (WD), a concept from optimal transport theory (2). Unlike previous approaches that depend on Kullback-Leibler divergence similarity estimation (KLSE) (3), WD does not require the estimation of probability density functions (PDFs), while it can effectively measure distances between regions with minimal or no spatial overlap, avoiding the issue of infinite values. We compared the classification performance of WD- and KLSE-based methods in distinguishing healthy controls (HC), persons with Amyotrophic Lateral Sclerosis (pwALS), and persons with ALS-mimicking diseases (Mimics). ***Materials and Methods:*** Our dataset included ^{18}F-FDG PET scans from 36 HC (55.0±13.0 years, 19F/17M), 167 pwALS (63.9±11.1 years, 64F/103M), and 25 Mimics (62.4±8.0 years, 8F/17M). All PET images were spatially normalized to MNI space, and regional data were extracted using an atlas of 53 brain regions. Regional adjacency matrices were computed using either WD or KLSE between region pairs and then transformed into similarity matrices via an exponential function. These similarity matrices served as input for Support Vector Machine (SVM) classification, alongside an image-based SVM classifier for comparison. We evaluated the performance of each SVM approach using 10-fold cross-validation repeated 10 times, with statistical comparison via paired t-tests. ***Results:*** In the classification of pwALS versus HC, the image-based SVM achieved an accuracy of 0.84±0.01. WD-based and KLSE-based SVM classifications yielded accuracies of 0.86±0.00 ($p<0.05$) and 0.83±0.01 ($p>0.05$), respectively. For distinguishing pwALS from Mimics, the image-based SVM reached an accuracy of 0.52±0.02, while the WD- and KLSE-based methods achieved 0.58±0.02 ($p<0.05$) and 0.56±0.02 ($p<0.05$), respectively. ***Conclusion:*** SVM classification using WD- and KLSE-based adjacency matrices showed performance comparable to voxel-based methods, demonstrating their ability to capture disease-relevant patterns while reducing data dimensionality. Among the two, WD emerges as a more suitable metric for discrete PET data, offering a continuous and intuitive measure of regional distances without requiring PDF estimation. Future work will explore clustering of individual adjacency matrices to identify disease-specific brain network patterns. ***References:*** 1. A. Sala et al., 2023. 2. G. Peyré, M. Cuturi, 2019. 3. Detecting The Epileptogenic Zone Using Attention U-Net Model in FDG PET Images: Integration of Deep Learning Techniques to PET Imaging

M. Bodur[1], *L. Uslu-Besli*[1], *O. E. Sahin*[1], *K. Saglam*[1], *A. Sarikas*[2], *O. Demir*[2], *C. Ozkara*[3], *H. B. Sayman*[1];
[1]Isanbul University-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Marmara University, Department of Computer Engineering, Istanbul, TÜRKIYE, [3]Isanbul University-Cerrahpasa, Department of Neurology, Istanbul, TÜRKIYE.

Aim/Introduction: This study aims to develop a deep learning technique to detect epileptogenic zone using interictal FDG PET images in epilepsy patients. ***Materials and Methods:*** Interictal F-18 FDG PET images of 20 drug-resistant epilepsy patients were evaluated and hypometabolic areas that were in accordance with the epileptogenic zones were manually contoured by experienced nuclear medicine specialists. The Attention U-Net architecture, known for its effectiveness particularly in biomedical image analysis, has been employed[1]. The rationale behind choosing this architecture for nuclear medicine image analysis is to leverage the superior spatial localization capability of the classical U-Net structure in conjunction with the ability of attention mechanisms to emphasize signals specific to lesion regions. The image data was randomly divided into training (80%), validation (10%), and testing (10%) sets for model learning, verification, and performance evaluation, respectively. All PET images were standardized to a size of 384x384 pixels to suit the model's input requirements. The training of the Attention U-Net model was performed by minimizing a linear combination of the binary cross-entropy loss function, commonly used for pixel-level classification, and the Dice loss function, which optimizes regional similarity. The Adam optimization algorithm, known for its adaptive learning rate, was used for weight updates, and the entire training process was conducted for 100 epochs with a mini-batch size of 4. ***Results:*** The trained Attention U-Net model demonstrated a high accuracy of 96% in segmenting the extent of hypometabolic areas on FDG PET images included. However, the F1-score was calculated to be relatively lower at 65%, likely due to the imbalance in the number of pixels between the lesion and normal tissue. Visual inspection of the obtained segmentation masks revealed that the model exhibited pixel-level uncertainties and irregularities in the boundary regions of the lesions at certain locations. ***Conclusion:*** This preliminary study on a limited dataset indicates that Attention U-Net is a promising architecture for automated epilepsy lesion segmentation, achieving high accuracy in overall localization. However, the lower F1-score suggests a need for improved performance, especially for small or irregular lesions. Future work should assess generalization on larger,

diverse datasets and compare architectures, also exploring post-processing and alternative loss functions for better segmentation quality. ***References:*** [1]Al Qurri A, Almekkawy M. Improved UNet with Attention for Medical Image Segmentation. Sensors (Basel). 2023 Oct 20;23(20):8589. doi: 10.3390/s23208589. PMID: 37896682; PMCID: PMC10611347.

OP-532

Stratified Evaluation of Deep Learning Models by Age and Cognition Level for Amyloid Positivity Prediction in [^{18}F]FDG PET

S. Seo[1], *M. So*[1], *S. Lee*[1], *Y. Yoon*[1], *D. Seo*[1], *D. Kim*[2], *H. Han*[2], *S. Kang*[1], *D. Kim*[3], *M. Yun*[1];
[1]*Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Yonsei University, Seoul, KOREA, REPUBLIC OF,* [3]*Hallym University College of Medicine, Anyang, KOREA, REPUBLIC OF.*

Aim/Introduction: Deep learning (DL)-based analysis of [^{18}F] fluorodeoxyglucose ([^{18}F]FDG) PET has emerged as a promising and cost-effective approach for predicting amyloid positivity, a key biomarker in Alzheimer's disease (AD). However, substantial variability in classification accuracy has been observed across studies, potentially reflecting differences in model design and subject demographics. This study aimed to evaluate the performance of multiple deep learning models for amyloid positivity prediction from [^{18}F]FDG PET and to examine how accuracy varies by age and cognitive impairment severity. ***Materials and Methods:*** We retrospectively analyzed 2,671 in-house [^{18}F]FDG PET scans (795 amyloid-positive, 1,876 amyloid-negative), with amyloid positivity confirmed by expert visual assessment of amyloid PET images obtained within approximately one year of [^{18}F]FDG PET scans. Four DL architectures—ResNet, Swin Transformer (SwinT), Vision Graph Neural Network (ViG), and ConvNeXt—were trained to classify amyloid status. The dataset was partitioned into training (n=2002), validation (n=350), and test sets (n=319). Model performance was evaluated using accuracy and Area Under the Receiver Operating Characteristic Curve (AUROC), stratified by age (≤60, 60-70, 70-80, ≥80 years) and cognitive impairment severity based on MMSE z-scores (> -1.5, -2.5 to -1.5, < -2.5). To evaluate the consistency of predictions across four DL architectures, Fleiss' kappa was calculated. ***Results:*** Overall test-set accuracies were 78.1% (ResNet), 76.8% (SwinT), 73.7% (ViG), and 73.0% (ConvNeXt), with AUROCs of 0.836, 0.839, 0.814, and 0.818, respectively. Stratified by age, model accuracy consistently declined with increasing age: highest accuracy was observed in patients aged ≤60 (accuracy: 95.6±1.73%, AUROC: 0.983±0.01), progressively decreasing for age groups 60-70 (accuracy: 83.3±1.05%, AUROC: 0.908±0.02), 70-80 (accuracy: 70.4±3.71%, AUROC: 0.752±0.02), and ≥80 (accuracy: 62.3±5.83%, AUROC: 0.702±0.04). This declining trend was consistently observed across individual models, except for SwinT between the 70-80 and ≥80 age groups. Stratified by cognitive impairment, models exhibited improved AUROCs with greater impairment severity: MMSE z-score > -1.5 (accuracy: 78.2±1.87%, AUROC: 0.728±0.03), -2.5 to -1.5 (accuracy: 67.9±5.25%, AUROC: 0.790±0.02), and < -2.5 (accuracy: 74.5±5.25%, AUROC: 0.834±0.05). Fleiss' kappa across the four DL models was 0.48, indicating the observed classification trends reflect consistent model behavior rather than random effects. ***Conclusion:*** The accuracy of DL-based amyloid positivity prediction using [^{18}F]FDG PET significantly varies with patient age and cognitive impairment, which might reflect age-related brain metabolic differences and disease severity-related neurodegenerative patterns. These findings underscore the necessity of explicitly considering demographic and clinical characteristics when assessing and reporting DL model performance in neurodegenerative diseases.

Validation of the collapsed-cone superposition for whole-body patient-specific dosimetry in [177Lu]Lu-PSMA-617 radionuclide therapy

A. Terro[1], *S. Perret*[1], *A. Dumouchel*[1,2], *D. Tonnelet*[2], *A. Edet-Sanson*[1,2], *P. Vera*[1,2], *P. Decazes*[1,2], *A. Dieudonné*[1,2];
[1]*QuantIF-AIMS, Rouen University, Rouen, FRANCE,* [2]*Nuclear Medicine Department, Henri Becquerel Center, Rouen, FRANCE.*

Aim/Introduction: [177Lu]Lu-PSMA-617 therapy has emerged as a promising treatment option for patients with metastatic castration-resistant prostate cancer (mCRPC). Accurate dosimetry in radiopharmaceutical therapy offers a promising approach to optimize the balance between treatment efficacy and toxicity. The development of personalized dosimetry through whole-body single photon emission computed tomography and computed tomography (SPECT/CT) imaging is made possible with the advent of 360° CZT gamma cameras. SimpleDose [1] is an automated whole-body dosimetry software that employs the collapsed cone superposition (CCS) approach [2,3]. This study aims to validate the CCS approach for whole-body dosimetry in [177Lu]Lu-PSMA-617 therapy by comparing it with Monte Carlo (MC) simulations at the organ, lesion, and voxel levels. ***Materials and Methods:*** Thirty mCRPC patients were imaged after the infusion of [177Lu]Lu-PSMA-617 on a VERITON-CT 200 (Spectrum Dynamics®, Caesarea, Israel). Dose rate maps (mGy/h) were generated from single SPECT/CT scans with a sampling of 2.46 x 2.46 x 2.46 mm^3. The CCS approach takes into account tissue densities using dose-point kernels adjusted to those densities. Organ and lesion delineation were automated using the nnU-Net V2 neural network. Reference MC simulations were conducted using GATE 10 for 10^8 events. The comparison between CCS and MC was performed at the organ, lesion, and voxel levels. ***Results:*** The organ wise comparison between CCS and MC showed a median (IQR) absolute percentage error of 3.92 (2.22), 1.11 (0.66), 0.78 (0.72), 3.13 (1.38), 4.76 (4.00), 2.74 (2.92), 3.06 (2.76), 3.10 (1.22) for bone marrow, kidneys, liver, lungs, pancreas, salivary glands, spleen and lesions, respectively, with no significant organ-level differences ($p > 0.70$). Voxel-level errors were mostly < 2%. CCS had a median computation time of 24.5 seconds, compared to 6.8 hours for MC on a computer with an Intel Xeon 20 x 3.70 GHz CPU. ***Conclusion:*** CCS approach showed strong agreement with MC, offering improved computational efficiency and clinical potential for whole-body dosimetry in [177Lu]Lu-PSMA-617 therapy. ***References:*** 1. The tumour sink effect on healthy tissues dosimetry in ^{177}Lu-PSMA-I&T radiopharmaceutical therapy

A. Zamanian[1], *F. A. Buteau*[2], *G. April*[2], *F. Arsenault*[2], *A. Beaulieu*[2], *F. Pouliot*[3], *J. M. Beauregard*[1];
[1]*Department of Radiology and Nuclear Medicine, Université Laval, Quebec City, QC, CANADA,* [2]*Department of Medical Imaging, CHU de Québec - Université Laval, Quebec City, QC, CANADA,* [3]*Urology Division, Department of Surgery, Université Laval, Quebec City, QC, CANADA.*

Aim/Introduction: The biodistribution of therapeutic PSMA-targeting radiopharmaceutical may be affected by the tumour sink effect, a phenomenon by which the radiopharmaceutical's sequestration into lesions leads to a reduction in absorbed doses (ADs) to healthy tissues. This study aimed to investigate the tumour sink effect, and secondarily the impact of body size and renal function, on dosimetry in patients receiving ^{177}Lu-PSMA-I&T. ***Materials and Methods:*** Twenty-six mCRPC patients underwent quantitative SPECT/CT from neck to pelvis approximately 48 hours after injection of around 7.4 GBq ^{177}Lu-PSMA-I&T. Activity concentration (Bq/mL) was sampled using 2 or 3 cm spherical VOIs over healthy tissues (kidneys, spleen, liver, and proximal aorta), and specific ADs (Gy/GBq) were estimated via Hänscheid's single-time-point method. Whole-body tumour burden was delineated using an SUV threshold of three times the liver SUV_{mean}, excluding physiological uptake. Total lesion fraction (TLF) was defined as total lesion activity divided by body weight (g), expressed as percentage. Participants were stratified into three TLF groups: small <10%, moderate 10-25%, and large ≥25%. Estimated glomerular filtration rate (eGFR) and body surface area (BSA) were other evaluated predictive variables, as well as the combination of the three: BSA•eGFR/[1-TLF]. * indicates p<0.05, **p<0.01, and ***p<0.001. ***Results:*** The median TLF was 5.8% (range: 0.6-55.6%). Consistent with literature, the median specific ADs (range) for the kidney, spleen, liver and blood were 0.81 (0.24-2.17), 0.047 (0.007-0.154), 0.034 (0.016-0.120), and 0.007 (0.001-0.015) Gy/GBq, respectively. Kidney specific AD was inversely correlated with TLF (r=-0.49*), BSA (r=-0.35), eGFR (r=-0.51**), and BSA•eGFR/[1-TLF] (r=-0.67***). Similar trends were observed for the spleen (r=-0.68***, -0.46*, -0.41*, and -0.84***, respectively) and the liver (r=-0.42*, -0.31, -0.33, and -0.46**, respectively). For the blood, the correlations with predictive factors were more variable (r=0.22, -0.32, -0.54**, and -0.08, respectively). Patients with a large TLF (n=4) showed a significantly lower mean renal specific AD compared to those with a small TLF (n=15): 0.54 vs. 1.01 Gy/GBq(*). Corresponding mean spleen specific ADs were 0.01 vs. 0.07 Gy/GBq(**). ***Conclusion:*** Patients with a large tumour burden, larger body habitus, and/or good renal function tend to receive lower specific ADs to healthy tissues and are therefore likely to be undertreated with a fixed-activity regime. Dosimetry-based personalisation of PSMA radiopharmaceutical therapy could allow a safe escalation of administered activity in many, offering the prospect of improved outcomes, particularly for patients with extensive disease who are the most in need of therapeutic benefit.

OP-536

Prognostic value of ^{68}Ga-PSMA PET radiomics in metastatic castration-resistant prostate cancer treated with ^{177}Lu-PSMA radioligant therapy

L. Edouard[1], *L. Ferrer*[2], *L. Papillon*[2], *Y. Godbert*[1], *M. Meyer*[1], *V. Préga-Renaud*[1], *C. Subreville*[3], *N. Anizan*[4], *M. Cabart*[5], *D. Teyssonneau*[5], *G. Roubaud*[5], *T. Colin*[2], *P. Schwartz*[1];
[1]*Nuclear Medicine Department, Institut Bergonié, Bordeaux, FRANCE,* [2]*Sophia Genetics, Pessac, FRANCE,* [3]*Department of Pharmacy, Institut Bergonié, Bordeaux, FRANCE,* [4]*Department of Physics, Institut Bergonié, Bordeaux, FRANCE,* [5]*Oncology Department, Institut Bergonié, Bordeaux, FRANCE.*

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) remains incurable despite recent therapeutic advances. ^{177}Lu-PSMA radioligand therapy (RLT) shows clinical benefits in selected patients. However, approximately 30% of patients do not respond to ^{177}Lu-PSMA RLT. There is a lack of strong pre-therapeutic predictive biomarkers. Radiomics, by extracting quantitative imaging features, offers a novel approach to predict clinical outcomes beyond standard visual interpretation. We evaluated the prognostic value of pretherapeutic ^{68}Ga-PSMA PET radiomic features for overall survival (OS) in patients with mCRPC treated with ^{177}Lu-PSMA RLT. ***Materials and Methods:*** This retrospective monocentric study included 102 mCRPC patients treated with ^{177}Lu-PSMA between January 2022 and March 2024. Five lesions per patient were segmented on their pretherapeutic ^{68}Ga-PSMA PET/CT. Radiomic features were extracted following IBSI guidelines. Associations with OS were evaluated using Cox proportional hazard models. A multimodal machine learning (ML) model integrating clinical, genomic, biochemical, and imaging features (including radiomics) was developed to predict OS. ***Results:*** Median OS of the total cohort was 11.2 months. Intralesional homogeneity characterised by 2nd order radiomic feature "Normalised Inverse Difference Moment" was associated with shorter OS (p=0.025). Among clinical parameters, ECOG ≥2, liver metastases, and high tumor burden (≥20 metastases or superbone scan) were significantly correlated with poor OS (p<0.05).The best-performing ML model achieved a 12-month AUC of 0.778 by combining 22 clinical, biochemical, genomic, and radiomic features. The model leveraging PET data alone achieved strong performance, with an AUC comparable to the clinical model (0.715 vs 0.766). ***Conclusion:*** Radiomic features extracted from ^{68}Ga-PSMA PET/CT, particularly intralesional homogeneity, provide independent prognostic information for OS in mCRPC patients undergoing ^{177}Lu-PSMA RLT. Their integration into a multimodal ML model improves prediction performance, supporting their potential role in personalized treatment strategies.

OP-537

Early Progression Prediction with RECIP 1.0 on Routine Post-Therapy ^{177}Lu-PSMA SPECT/CT

M. Kassas[1], *L. Devriendt*[2], *T. Guiot*[3], *M. Manley*[1], *C. Marin*[3], *R. Danieli*[3], *L. Taraji*[1], *I. Karfis*[1], *E. Woff*[1], *P. Flamen*[1], *C. Artigas*[1];
[1]*Institut Jules Bordet, Hôpital Universitaire de Bruxelles, Université Libre de Bruxelles, Nuclear Medicine Department, Brussels, BELGIUM,* [2]*Faculté de Médecine, Université Libre de Bruxelles, Brussels, BELGIUM,* [3]*Institut Jules Bordet, Hôpital Universitaire de Bruxelles, Université Libre de Bruxelles, Medical Physics Department, Brussels, BELGIUM.*

Aim/Introduction: To assess the prognostic value of early response assessment through applying the Response Evaluation Criteria in PSMA PET/CT (RECIP1.0) on the 24hr post-therapy SPECT/CT images of the second cycle of ^{177}Lu-PSMA radioligand therapy (RLT). ***Materials and Methods:*** A retrospective analysis was conducted on 136 patients with metastatic castration resistant prostate cancer (mCRPC) treated with ≥2 cycles of ^{177}Lu-PSMA-I&T, with evaluable 24hr post-therapy SPECT/CT scans obtained after cycle 1 (C1) and cycle 2 (C2). Automated segmentation with LesionID Pro from MIM Software was used to quantify total tumor volume (TTV). Relative changes in TTV and detection of new lesions (NLs) at C2 post-therapy SPECT/CT scans were used to classify patients into two categories according to RECIP1.0: a) progressive disease (RECIP-PD), with an increase in TTV≥20% and the appearance of NLs; and b) non-progressive disease (RECIP-non-PD) otherwise. Association of these criteria with progression free survival (PFS) and overall survival (OS) was performed using univariate and multivariate Cox regression and plotted on Kaplan-Meier curves. ***Results:*** After a median follow-up of 23 months, 123/136 patients (90%) experienced disease progression and 90 (66%) passed away.

Median PFS was 6.4 months (95%CI 5.5-7.4); median OS was 16.6 months (95%CI 12.7-20.5). RECIP-PD patients (n=16/136) exhibited significantly reduced PFS (median PFS: 3.6 vs 7.0 months, HR=3.6 95%CI[2.1-6.2] p<0.001) and OS (median OS: 7.4 vs 17.5 months; HR=3.1 95%CI[1.6-5.8], p<0.001) compared to RECIP-non-PD. TTV increase ≥20% at C2 (n=23/136) was significantly associated with shorter PFS (median PFS 3.3 vs 7.1 months, HR=3.5, 95%CI[2.2-5.6], p<0.001) and OS (median OS 10.2 vs 17.5 months, HR=1.8, 95%CI[1.1-3.1], p=0.023) compared to those without. NLs at C2 (n=28/136) were significantly associated with shorter PFS (4.4 vs 7.3 months, HR=2.6, 95%CI[1.7-4.0], p<0.001) and OS (7.7 vs 18.0 months, HR=2.3 95%CI[1.4-3.8], p=0.002) compared to those without. Harrell's C-index showed that RECIP-PD had the highest and most consistent predictive power for both endpoints (PFS: 0.80; OS: 0.78), compared to TTV increase≥20% (PFS: 0.81; OS: 0.68) or NLs (PFS: 0.72; OS: 0.74) alone. ***Conclusion:*** These results suggest that applying RECIP1.0 to post-therapy SPECT/CT imaging provides a practical, cost-effective method for early identification of patients unlikely to benefit from continued ^{177}Lu-PSMA-RLT. This may enable a rapid shift of therapeutic plan (i.e. alpha-emitting RLT, chemotherapy) and increase the cost-effectiveness of RLT. Although TTV increase and NL appearance were also independently associated with poorer outcomes, RECIP-PD categorization had the most consistent prognostic value for both PFS and OS.

OP-538

Comparison of PET Response Criteria in mCRPC Patients Treated with [^{177}Lu]PSMA

T. Telli[1], *V. Grünwald*[2], *B. Hadaschik*[3], *C. Kesch*[3], *L. Umutlu*[4], *K. Herrmann*[1], *W. P. Fendler*[1];
[1]*Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY,* [2]*Department of Urology, University Hospital Essen, Essen, Germany, Essen, GERMANY,* [3]*Department of Urology, University Hospital Essen, Essen, GERMANY,* [4]*Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY.*

Aim/Introduction: In this study we aimed to compare various imaging-based response criteria in men with metastatic castration-resistant prostate cancer (mCRPC) treated with [^{177}Lu]PSMA radioligand therapy. ***Materials and Methods:*** This retrospective study included 84 patients who received a median of 4 [^{177}Lu]PSMA cycles (IQR 2-5; median 24.3 GBq, IQR 14.9-32.9 GBq) at the University Hospital Essen between March 2019 and May 2022. Response assessments were conducted using multiple criteria comparing baseline and 6-8 weeks post-second cycle scans: Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, the adapted Prostate Cancer Working Group Criteria (aPCWG), Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST), the PSMA PET Progression (PPP), the Response Evaluation Criteria in PSMA-Imaging 1.0 (RECIP) (based on qPSMA and SUV≥4 thresholds), and visual RECIP. Responses were categorized as progressive disease (PD) or non-PD. The primary endpoint was the prognostic significance of these response criteria for overall survival, evaluated via Cox regression analysis. Harrell`s C-index was used for concordance of different imaging-based criteria and survival. ***Results:*** A total of 34 (40.5%) patients had non-measurable disease according to RECIST 1.1. Twenty (40%), 43 (51.2%), 44 (52.4%), 47 (56.0%), 35 (41.7%), 37 (44.0%), and 31 (36.9%) of patients had PD according to RECIST 1.1, aPCWG, PERCIST, PPP, RECIP qPSMA, RECIP SUV≥4, and visual RECIP respectively. PD patients had a significantly higher risk of death compared to non-PD patients according to RECIST 1.1 (HR = 5.0; 95%CI, 2.5-10.0; p < 0.001), PERCIST (HR = 2.9; 95%CI, 1.8-4.8; p < 0.001), aPCWG (HR = 3.6; 95%CI, 2.1-6.0; p < 0.001), PPP (HR = 3.9; 95%CI, 2.3-6.6; p < 0.001), RECIP qPSMA (HR = 2.7; 95%CI, 1.6-4.4; p < 0.001), RECIP SUV≥4 (HR = 2.2; 95%CI, 1.6-3.6; p < 0.001) and visual RECIP (HR = 3.5; 95%CI, 2.1-6.0; p < 0.001). Higher C-indices were observed for PPP: 0.68 (95%CI, 0.58-0.77), and aPCWG: 0.67 (95%CI, 0.57-0.77) in comparison to PERCIST: 0.65 (95%CI, 0.54-0.75), visual RECIP: 0.63 (95%CI, 0.52-0.73), RECIP qPSMA: 0.62 (95%CI, 0.51-0.74) and, RECIP SUV≥4: 0.62 (95%CI, 0.50-0.73). ***Conclusion:*** Under [^{177}Lu]PSMA the presence of progressive disease, as indicated by any of the evaluated criteria, has been observed to be consistently associated with a significantly elevated risk of death. Among the evaluated methods, PSMA PET Progression (PPP) demonstrated the highest prognostic performance. These findings lend support to the clinical value of standardised imaging criteria, particularly PPP, for the early response assessment under [^{177}Lu]PSMA.

OP-539

SPECT to PET image translation with a conditional Generative Adversarial Network (GAN) improves assessment of ^{177}Lu-PSMA post therapy scans

T. Otani*, F. Moradi, H. Song, G. Davidzon, A. Iagaru;*
Stanford Healthcare, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Direct comparison between SPECT/CT after ^{177}Lu-PSMA treatment and PSMA PET could be challenging due to differences in image quality and visual appearance. We used a conditional GAN (Pix2Pix) to transformed SPECT into PET-quality images (synthetic PET). ***Materials and Methods:*** 97 prostate cancer patients treated with ^{177}Lu-PSMA therapy were divided into training sets (n = 72) and test sets (n = 25). For model training, the input data consisted of SPECT images acquired at the time of the first 177Lu-PSMA treatment cycle, and the ground truth data comprised PSMA PET/CT images obtained prior to the first treatment. In the test set, SPECT/CT images acquired after the first and last cycles of Lu-PSMA therapy were converted into synthetic PET images by the trained model. Therapeutic response to ^{177}Lu-PSMA therapy was assessed using the Response Evaluation Criteria in PSMA Imaging (RECIP), based on synthetic PET images versus the original SPECT images. The results derived from the two imaging modalities were then compared. The treatment response assessment based on post-therapy PSMA PET/CT was used as the gold standard. The ^{177}Lu-PSMA-617-positive total tumor volume (Lu-TTV) and lesion count for each modality were quantified using the Segment Lesion workflow (MIM Software Inc., Cleveland, OH). ***Results:*** Treatment response assessment was concordant between SPECT and synthetic PET in 22 of 25 cases, with discrepancies observed in the remaining three. In all three discordant cases, the response classification based on synthetic PET was consistent with that derived from PSMA PET/CT. Specifically, two of the discordant cases were classified as complete response (CR) on SPECT but as partial response (PR) on synthetic PET. In the third case, the response was assessed as stable disease (SD) on SPECT and as PR on synthetic PET. The total tumor volume (Lu-TTV) derived from SPECT was significantly higher than that from synthetic PET in both the first and last treatment cycles (p = 0.033 and p = 0.136, respectively). Furthermore, the number of lesions detected on SPECT was significantly lower than that detected on synthetic PET for both the first and last cycles (p = 0.014 and p = 0.015, respectively). ***Conclusion:*** This study demonstrates that synthetic PET from post-therapy SPECT using the pix2pix model added value for the assessment of treatment response following 177Lu-PSMA therapy. ***References:*** 1) European Journal of Nuclear Medicine and Molecular Imaging. 2024: 1-10.2) Radiology. 2023; 308(1):e22148

OP-540

Post-Therapy Planar ^{177}Lu-PSMA Imaging: Lesion-to-Parotid Ratio Predicts Early PSA Response

H. Pekedis*, E. M. Kaya, A. S. Yilmaz, G. Yilmaz, B. Esen Akkaş;*
Basaksehir Çam ve Sakura City Hospital Nuclear Medicine Department, Istanbul, TÜRKIYE.

Aim/Introduction: To determine whether the lesion-to-parotid activity ratio (L/P), derived from routine day-1 post-therapy planar whole-body scans, can predict early biochemical response to [^{177}Lu]PSMA radioligand therapy in men with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Twenty nine consecutive mCRPC patients treated with [^{177}Lu]PSMA between January 2021 and December 2024 were retrospectively

reviewed. Anterior and posterior planar images obtained 24 h after the first treatment cycle were analysed. Circular 2-cm regions of interest were placed over metastatic bone foci; geometric-mean counts defined the lesion value (L). The mean counts of bilateral parotid glands provided the reference value (P); L/P = L ÷ P. Baseline and week-8 PSA levels were recorded. A ≥ 50 % decrease in PSA at week 8 defined responders; < 50 % defined non-responders. Group differences were assessed with the Mann-Whitney U test, and the discriminative performance of L/P was evaluated with receiver operating characteristic (ROC) curve analysis. ***Results:*** Median age was 71 years (IQR; 65-77). Fifteen patients (52 %) were responders. Responders had a significantly lower median L/P than non-responders—0.89 (IQR; 0.49-1.66) vs 4.49 (IQR; 1.09-9.81); p = 0.018. An L/P cut-off of 1.93 predicted PSA response with 73 % sensitivity, 86 % specificity, and an area under the ROC curve of 0.757 (95 % CI, 0.568-0.946). ***Conclusion:*** The post-therapy planar lesion-to-parotid (L/P) ratio is a simple and reproducible imaging-derived metric that may predict early biochemical response to ^{177}Lu-PSMA therapy in mCRPC. Early PSA decline can guide timely treatment decisions, avoid ineffective therapies, and improve patient stratification. Given its potential prognostic relevance, prospective multicentre validation is warranted.

OP-541

Balancing efficacy and nephrotoxicity in Lu-177 PSMA I&T therapy: clinical and imaging determinants of significant eGFR decline, an Asian cohort

D. Lim[1], *C. Tang*[1], *W. Chua*[1], *A. Tong*[1], *A. Wong*[2], *Y. Khor*[1], *W. Tham*[1], *W. Lam*[1], *S. Thang*[1];
[1]*Singapore General Hospital, Department of Nuclear Medicine and Molecular Imaging, Singapore, SINGAPORE,* [2]*National University Cancer Institute, Singapore, SINGAPORE.*

Aim/Introduction: There is emerging evidence for nephrotoxicity in patients undergoing PSMA Radioligand therapy (PRLT). Decline in renal function precludes the completion of therapy thus limiting efficacy. We aim to describe the incidence of nephrotoxicity and identify contributing clinical factors and imaging biomarkers. ***Materials and Methods:*** We recruited 60 patients treated with Lu-177 PSMA I&T between 2018 and 2024. All patients had requisite Ga-68 PSMA PET/CT and SPECT/CT studies 1 day after PRLT. Significant decline in eGFR/nephrotoxicity was defined as more than 30% in baseline. Clinical parameters collected for each patient included Gleason Score and treatment history (including immunotherapy, Radium-223, and radiotherapy involving the flank region). Clinical renal risk factors collected included: metabolic diseases, obstructive uropathy, urinary tract infections and proteinuria. Imaging biomarkers included total renal volumes and lengths. These were segmented and measured by Nuclear Medicine Physicians/Radiologists on the pre-therapy PSMA PET/CT and subsequent SPECT/CTs. All patients were dichotomized based on eGFR decline (≥30% vs <30%). Group comparisons were performed using the Mann-Whitney U test, and logistic regression was used to identify factors associated with significant eGFR decline. ***Results:*** Out of 60 patients (median age 75), 46 (76.7%) patients received 4 or more cycles of PRLT with a median cumulative administered activity of 768mCi. 41 patients (85%) had only G0 or G1 (CTCAE v5.0) renal impairment before PRLT. 29 (48.3%) had more than 30% decline in eGFR after PRLT. The median duration to significant decline in renal function was 411 days. Comparison between ≥30% vs <30% eGFR decline revealed statistically significant differences in the collected variables (p<0.05). Patients with significant nephrotoxicity had lower baseline eGFR; steeper GFR slopes; a higher number of renal risk factors; lower total renal volumes after the 2nd and 3rd cycles; and a greater difference in renal volume after the 3rd cycle vs baseline. Logistic regression analysis identified the following variables associated with significant nephrotoxicity (p<0.05): the number of renal risk factors; eGFR at 3 months post-PRLT; change in eGFR after the 3rd cycle from baseline; GFR slope; total renal volume after 2nd cycle and the rate of change in renal volume after the 3rd cycle vs baseline. ***Conclusion:*** Decline in renal function during PRLT is gradual, giving physicians adequate reaction time to prevent nephrotoxicity. By earlier identifying factors and measureables via our study, physicians can better select patients and identify strategies during PRLT to mitigate nephrotoxicity.

18F-FET PET : a potential new tool for localizing ACTH-producing pituitary adenomas in patients with newly diagnosed Cushing's disease

L. Al Mansour*, C. Merino, S. Solomon, S. Chaib, C. Sergeant, M. Janier, E. Jouanneau, G. Raverot, A. Flaus;*
Hospices Civils de Lyon, Lyon, FRANCE.

Aim/Introduction: Cushing's disease (CD) is associated with significant morbidity and increased mortality. Pituitary MRI remains the primary imaging modality for localizing adenomas but remains inconclusive or doubtful in up to 30% of cases. Inaccurate identification of the surgical target increases the risk of postoperative pituitary insufficiency or incomplete tumor resection. This study evaluates the potential of [18F] fluoroethyltyrosine positron emission tomography/computed tomography ([18F]FET PET/CT) for localizing ACTH-producing pituitary adenomas in patients with newly diagnosed CD. ***Materials and Methods:*** In this retrospective analysis, inclusion criteria were biochemically confirmed CD and either a pituitary microadenoma or inconclusive MRI with available [^{18}F]FET PET/CT imaging. PET scans were obtained 20-40 minutes after intravenous injection of 200 MBq of [18F]FET. Images were assessed by one experienced nuclear medicine physician. Maximum tumor-to-background ratios (TBRmax) were calculated by comparing the maximal standardized uptake values (SUVmax) of pituitary adenomas to mean standardized uptake values (SUVmean) of the right frontal and temporal lobes. Numeric values are expressed as median (interquartile range). ***Results:*** Eighteen patients (85% female; median age 50 [30-57.8] years) were evaluated between 11/2023 and 02/2025. Inferior Petrosal Sinus Sampling (IPSS) confirmed the diagnosis of central Cushing in 6 patients. MRI results were positive in 7, negative in 4, doubtful in 7 patients. [18F] FET PET/CT showed clear focal uptake in 12 cases and doubtful uptake in 6 cases, with a median TBRmax was 2.1 [1.7-2.3]. Nine patients underwent transsphenoidal surgery. In 8/9 cases, PET findings were concordant with histopathology. Among these, MRI were positive in 4, negative in 2, doubtful in 2 patients. PET uptake was clear in 8 cases and doubtful in one case, which had a positive MRI. PET uptake was concordant with MRI (positive or doubtful) in 6/6 cases. Postoperative remission was achieved in 7/9 patients. In the remaining surgical case, MRI was negative, and PET showed doubtful uptake contralateral to the surgery IPSS-guided target. Pathology was negative, and remission was not achieved. Of the 6 patients pending surgery, PET/MRI results were concordant in 3 and discordant in 3, including one with a negative MRI. Surgery was declined in three patients. ***Conclusion:*** [^{18}F]FET PET/CT appears to be a valuable complementary tool for localizing ACTH-producing pituitary adenomas in patients with Cushing's disease, particularly when MRI findings are inconclusive or doubtful. Its

high concordance with surgical pathology suggests that it may improve preoperative targeting and potentially enhance surgical outcomes.

OP-543

Diagnostic Value of FDG PET/CT Quantitative Parameters in Differentiating Adrenal Masses: Our Clinical Experience

G. Deniz[1], *E. Isik*[1], *D. Arslan*[1], *S. Erturk*[2], *D. Has Simsek*[1], *Y. Sanli*[1];
[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Istanbul University,I stanbul Faculty of Medicine, Department of Radiology, Istanbul, TÜRKIYE.*

Aim/Introduction: Differentiating adrenal lesions on F-18 FDG PET/CT remains a diagnostic challenge. In addition to visual assessment, the use of quantitative PET/CT parameters enhances diagnostic accuracy. This study aimed to evaluate the contribution of quantitative parameters in distinguishing benign from malignant adrenal lesions. ***Materials and Methods:*** In this retrospective study, we analyzed 569 patients who underwent FDG PET/CT between 2011 and 2024. A total of 165 patients with 192 lesions, confirmed by follow-up MRI or histopathology, were included. Parameters assessed included lesion size, laterality, SUVmax, metabolic tumor volume (MTV), total lesion glycolysis (TLG), and Hounsfield units (HU). For metabolic parameters, three-dimensional regions of interest (ROIs) were delineated. Group comparisons were performed using Kruskal-Wallis and Mann-Whitney U tests. ROC analysis was applied to determine optimal diagnostic thresholds. ***Results:*** The cohort included 165 patients (mean age: 59 ± 15 years; 75 males, 90 females), with 27 presenting bilateral lesions. Based on pathology and MRI results, six subgroups (G1-6) were defined. Mean values for PET/CT and CT-derived parameters were calculated for each group. Of the 165 patients, 84 had adenomas (G1), 10 had pheochromocytomas (G2), 37 had adrenocortical carcinomas or metastases (G3), 8 had hyperplasia (G4), 5 had myelolipomas (G5), and 21 had other lesions (G6). Mean PET/CT and CT parameters per group are shown in Table 1. According to ROC analysis, the SUVmax cut-off values were: ≤4.10 for Group 1 (sensitivity 84.2%, specificity 70.4%) and >5.47 for Group 3 (sensitivity 88.4%, specificity 87.9%) (p<0.001). The MTV cut-off values were: ≥33.37 for Group 3 (sensitivity 74.4%, specificity 82.6%). TLG cut-off values were: ≤93.10 for Group 1 (sensitivity 85.1%, specificity 70.2%) (p<0.001) and >93.10 for Group 3 (sensitivity 83.7%, specificity 83.2%)(p<0.001). The HU cut-off value for Group 5 was found to be ≤-17.95 (sensitivity 100%, specificity 95.7%)(Table 2). Lesion-based analysis showed statistically significant differences between Group 1 and Group 3 across all parameters (p<0.001). Although SUVmax did not significantly differ between Group 2 and Group 3 (p=0.063), volumetric parameters—MTV (p=0.009) and TLG (p=0.007)—were significantly higher in Group 3 (Table 3). ***Conclusion:*** Quantitative FDG PET/CT parameters, especially the volumetric metrics, offer valuable diagnostic insight into adrenal lesion characterization. The combination of MTV and TLG with SUVmax enhances lesion characterization, informs biopsy planning, and may help avoid unnecessary interventions. Furthermore, these parameters aid not only in distinguishing benign from malignant lesions but also in differentiating pheochromocytomas from malignant adrenal tumors.

OP-544

^{68}Ga-Pentixafor PET/CT versus Adrenal Venous Sampling for Surgical Decision-Making in Primary Aldosteronism

W. Zhengjie*, Z. Xiaoyang, L. Junyang, L. Jia, Z. Rui, L. Mengdan, P. Hua;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: Primary aldosteronism (PA) is the most common cause of secondary hypertension, with unilateral disease often requiring adrenalectomy for cure. While adrenal venous sampling (AVS) remains the gold standard for lateralization, its invasiveness and technical complexity limit widespread use. CXCR4-directed PET imaging has emerged as a promising, non-invasive alternative. This study aimed to evaluate the clinical utility of ^{68}Ga-Pentixafor PET/CT versus AVS in guiding surgical decision-making for PA and to identify key factors influencing the diagnostic performance of CXCR4 imaging. ***Materials and Methods:*** This study prospectively enrolled 155 patients who met the clinical diagnostic criteria for PA, all of whom underwent ^{68}Ga-pentixafor PET imaging. According to Primary Aldosteronism Surgical Outcome (PASO) criteria, outcomes were assessed at 6-month follow-up. The primary endpoints were clinical and biochemical remission rates at 6 months post-surgery. Postoperative KCNJ5 genetic testing was performed. Secondary analysis focused on the differences between patients with KCNJ5 mutations and wild-type group, and between CXCR4-positive and CXCR4-negative patients. ***Results:*** Of the 115 patients who completed the 6-month follow-up, adrenalectomy was performed in 66 cases under AVS guidance and in 49 cases based on CXCR4 PET/CT findings. Clinical complete remission rates were 57.6% in the AVS group and 67.3% in the CXCR4 PET group, while biochemical complete remission rates were 93.9% and 89.8%, respectively. Among the 115 patients, 99 cases were CXCR4-positive, yielding a positivity rate of 86.1% (99/115). CXCR4-positive patients exhibited significantly higher clinical (63.4% vs. 33.3%) and biochemical remission rates (88.8% vs. 81.0%,) compared to CXCR4-negative patients. Notably, all patients with KCNJ5 mutations (100%) were CXCR4-positive, whereas wild-type patients had a false-negative rate of 42.6%. Among CXCR4-positive patients, tumor size did not differ significantly between KCNJ5 mutant and wild-type groups (13.0 ± 2.0 mm vs. 11.8 ± 2.5 mm, P=0.467), but SUV_{max} was significantly higher in the mutant group (13.1 ± 3.9 vs. 8 ± 2.75, P<0.001). Additionally, in wild-type patients, CXCR4-positive tumor size were significantly larger than CXCR4-negative ones (13.44 ± 4.84 vs. 9.38 ± 2.42, P=0.01). ***Conclusion:*** ^{68}Ga-Pentixafor PET/CT demonstrates clinical value comparable to AVS in PA surgical management, particularly for KCNJ5 mutant patients, serving as a non-invasive alternative. CXCR4 negativity is primarily influenced by smaller tumor size and is associated with significantly lower clinical benefit compared to CXCR4-positive cases.

Aim/Introduction: The difficulty in the diagnosis and treatment of PA lies in the subtype diagnosis and screening out patients with unilateral primary aldosteronism (UPA) who are more suitable for surgery. Our purpose is to develop and validate a clinical-radiomics model based on ^{68}Ga-Pentixafor PET/CT for differentiating UPA from bilateral primary aldosteronism (BPA). ***Materials and Methods:*** This multicenter retrospective study included 379 patients with PA (Center 1 = 288; Center 2 = 91), all of whom underwent dual-time-window (10 min and 40 min) ^{68}Ga-Pentixafor PET/CT. Patients from Center 1 (169 UPA; 99 BPA) were randomly divided into training (70%) and testing (30%) groups, while patients from Center 2 (61 UPA; 30 BPA) served as an independent external validation group. Radiomics features were extracted using LIFEx software. Feature selection and model construction were performed using least absolute shrinkage and selection operator (LASSO) regression and logical regression. Model performance was assessed using receiver operating characteristic (ROC) curves analysis. Clinical

utility of the models was evaluated by calibration curves and decision curve analysis (DCA). ***Results:*** Diagnostic efficiency in 10 min PET_40 min PET_CT model was higher than10 min PET_CT model and 40 min PET_CT model. A total of 5 radiomics features based on dual-time ^{68}Ga-Pentixafor PET/CT and 3 clinical features were selected to construct the clinical-radiomics model. This model showed superior diagnostic performance in the training, testing, and validation groups, with areas under the curve (AUCs) of 0.810 (95% CI: 0.748-0.872), 0.770 (95% CI: 0.659-0.881) and 0.874 (95% CI: 0.794-0.954), respectively. In the training cohort, the clinical-radiomics model significantly outperformed both the clinical-only model (0.810 vs. 0.766, P<0.001) and the PET/CT-feature-only model (0.810 vs. 0.779, P=0.039), while there was no significant differences in the testing group (both P > 0.05). In the validation group, it showed a statistically improvement over the clinical model (0.874 vs. 0.745, P=0.003), but not over the PET/CT-feature model (0.874 vs. 0.845, P=0.227). DCA indicated that the clinical-radiomics model offered higher net benefit and greater clinical value. ***Conclusion:*** The clinical-radiomics model based on ^{68}Ga-Pentixafor PET/CT enables more accurate subtyping of PA, potentially guiding personalized treatment strategies.

Evaluation of Al^{18}F-NOTA-Pentixafor PET/CT in Subtyping and Surgical Guidance in Primary Aldosteronism Patients: A Prospective Phase II Study

X. Yan[1], *G. Zheng*[2], *M. Liu*[1], *Y. Zhang*[1], *Y. Xie*[1], *L. Huo*[1];
[1]*Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA,* [2]*Department of Urology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, CHINA.*

Aim/Introduction: Primary aldosteronism (PA) subtyping is essential for guiding treatment.Current diagnostic methods remain limitations, and PET imaging targeting CXCR4, which strongly correlated with aldosterone synthase (CYP11B2) expression, offered a promising alternation. This prospective study evaluated the diagnostic performance of Al^{18}F-NOTA-Pentixafor PET/CT for PA subtyping. ***Materials and Methods:*** This prospective study enrolled 125 PA patients with CT-confirmed adrenal nodules/nodular hyperplasia who underwent Al18F-NOTA-Pentixafor PET/CT, with subsequent surgical (targeting PET-identified functional lesions) or medical management guided by imaging findings. Two blinded nuclear medicine specialists independently performed visual interpretation. Semiquantitative parameters including lesion SUVmax, lesion-to-adrenal ratio (LAR), and lesion-to-liver ratio (LLR) were analyzed. Final diagnosis were established combining histopathology (surgical cases), AVS results, and 6-month follow-up, with diagnostic performance assessed by calculating sensitivity, specificity, positive predictive value(PPV) and negative predictive value (NPV). ***Results:*** A total of 125 PA patients with adrenal nodule were evaluated. Reference standard confirmed 95 APA and 30 non-APA (PAH or NFA) cases. Visual interpretation of Al^{18}F-NOTA-Pentixafor PET/CT demonstrated 100% (95% CI: 88.7-100%) sensitivity and 97.9% specificity (95% CI: 92.7-99.6%), achieving PPV of 100% (95% CI: 96.0-100%) and NPV of 93.8% (95% CI: 79.9-98.9%). Quantitative analysis demonstrated robust diagnostic performance across all parameters: LLR showed optimal cutoff of 7.44 with AUC 0.87 (95%CI 0.802-0.937), sensitivity 70.2%, specificity 87.1%, PPV 94.3%; SUVmax achieved cutoff 6.8 with AUC 0.901 (95%CI 0.844-0.958), sensitivity 87.2%, specificity 80.6%, PPV 93.2%; while LAR demonstrated cutoff 2.4 with AUC 0.861 (95%CI 0.791-0.931), sensitivity 88.3%, specificity 64.5%, and PPV 88.3%. ***Conclusion:*** Al^{18}F-NOTA-Pentixafor PET/CT demonstrates promising diagnostic accuracy for PA subtyping.

OP-547

The value of chemokine receptor type 4 targeted PET imaging in treatment management for primary aldosteronism compared to adrenal venous sampling

N. Lu*, Z. Xiao, D. Xing, D. Zeng, Y. He;*
Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.

Aim/Introduction: Primary aldosteronism (PA) is the most common cause for secondary hypertension, and lateralized forms of PA are recommended resection for treatment purpose. We aimed to assess the value of ^{68}Ga-Pentixafor PET imaging targeting chemokine receptor type 4 (CXCR4) in treatment management for PA, compared to adrenal venous sampling (AVS), the current gold standard for PA lateralization. ***Materials and Methods:*** We prospectively recruited 70 PA patients (36 males and 34 females, 49±12 years old). All patients underwent PET/CT imaging of adrenal region 30 min after injection of ^{68}Ga-Pentixafor, and AVS was performed in 53 patients. The SUVmax of adrenal lesions were measured, and the ratio of bilateral adrenal SUVmax (lateralization index, LI) was used to determine the dominant side. Lateralized patients determined by PET/CT or AVS underwent adrenalectomy, with a 12-month follow-up. Postoperative outcomes were evaluated using the Primary Aldosteronism Surgical Outcome (PASO) definitions for biochemical success, including cured, improvement, and no improvement. The threshold of LI for PA lateralization was determined by receiver operating characteristic (ROC) analysis. The correlations of PET/CT, as well as AVS outcomes, with postoperative outcomes were then analyzed. ***Results:*** Except 7 cases of idiopathic hyperaldosteronism (IHA) determined by AVS, 63 patients with a dominant side underwent an adrenalectomy. Based on clinical characteristics, pathology, and follow-up data, 50 lateralized PA patients showed 100.0% of postoperative benefit, including 39 cases of aldosterone-producing adenoma (APA), and 11 cases of unilateral adrenal hyperplasia (UAH). Thirteen non-lateralized patients, including 11 cases of nonfunctional adenoma (NFA) surrounded by multiple aldosterone-producing micronodules (MAPMs), and 2 cases of IHA, showed no improvements after surgery. The area under the ROC curve of LI for PA lateralization was 0.77 (95%CI, 0.64-0.91; P < 0.05), and the optimal cut-off level of LI=1.59 was associated with a sensitivity of 63%, a specificity of 100%, and a maximized Youden's index. PET/CT successfully lateralized all 39 cases of APA, and 18% (2/11) of UAH cases. All IHA patients exhibited non-lateralized forms on PET/CT. However, 54% (6/11) of NFAs were lateralized by PET/CT. Lateralization based on PET/CT significantly correlated with surgical outcomes during follow-up (χ2=17.38, P < 0.001). There was no significant difference in postoperative outcomes between PET/CT and AVS lateralization (χ2=2.99, P=0.224). ***Conclusion:*** ^{68}Ga-Pentixafor PET imaging showed comparable value with AVS for guiding PA treatment and predicting prognosis. However, for some UAH patients with bilateral similar tracer uptake, AVS should be a supplementary method.

OP-548

Organ-Specific Alterations in Physiological FDG Uptake in Diabetic Patients: A Retrospective PET/CT Study Using Japanese Cancer Screening Cohort

H. Wakabayashi[1], *Z. Chen*[1], *S. Gutschmayer*[2], *D. Ferrara*[2], *M. Pires*[2], *S. Takeda*[3], *J. Taki*[3], *S. Kinuya*[1], *L. Shiyam Sundar*[2,4], *T. Beyer*[2];
[1]*Kanazawa University, Kanazawa, JAPAN,* [2]*Quantitative Imaging Medical Physics (QIMP) Team, Medical University of Vienna, Vienna, AUSTRIA,* [3]*PET Center, Kanazawa Advanced Medical Center, Kanazawa, JAPAN,* [4]*DIGIT-X Lab, Department of Radiology, LMU Munich, Munich, GERMANY.*

Aim/Introduction: FDG-PET/CT is well established in oncology and selected non-oncologic indications, but its use for evaluating systemic metabolic disorders such as diabetes remains limited. With its ability to quantify glucose metabolism and tissue density across organs, FDG-PET/CT provides a powerful tool for characterizing systemic metabolic phenotypes. This study aimed to assess organ-specific alterations in FDG uptake and CT density

associated with diabetes and to characterize systemic metabolic profiles in a non-cancer population. ***Materials and Methods:*** A total of 501 individuals who underwent FDG-PET/CT for cancer screening were retrospectively analyzed. Among them, 46 (9%) had confirmed diabetes (F/M = 3/43, 53±12 years, range: 40-75), and 455 (91%) were non-diabetic controls (F/M = 147/308, 54±8 years, range: 22-89). Automated organ segmentation was performed on the CT images using MOOSE [1]. Quantitative measures included mean CT Hounsfield Units (HU) and PET standardized uptake value (SUV) in the bone marrow, liver, brain, muscle, subcutaneous fat, visceral fat, spleen, and thyroid. A second-degree polynomial regression analysis evaluated age-related correlations with HU and SUV. Group differences were assessed using a t-test and percentage differences, with statistical significance set at $p < 0.05$. ***Results:*** In diabetic subjects, CT density and SUV were markedly reduced in bone marrow (-6%, 158±32 vs. 148±31; -12%, 1.7±0.3 vs 1.5±0.3, respectively). Brain SUV was also reduced (-24%, 6.7±1.0 vs. 5.1±1.0) compared to non-diabetic individuals, while muscle SUV increased (+6%, 0.62±0.07 vs. 0.67±0.06). The liver of diabetic subjects showed lower HU (-8%, 52±0.4 vs. 48±1.3) but higher SUV (+4%, 2.22±0.01 vs. 2.33±0.04). Subcutaneous fat showed increased CT density (+3%, -96±0.4 vs. -93±1.3) and SUV (+17%, 0.36±0.06 vs. 0.43±0.07), while visceral fat had elevated SUV (+11%, 0.70±0.14 vs. 0.78±0.21) without CT changes. SUV of the thyroid was unaffected, while diabetic subjects presented lower CT density (-6%, 81±15 vs. 76±14). Age-related increases in SUV were more pronounced in diabetics, particularly in the bone marrow (R^2 = 0.26 vs. 0.10) and subcutaneous fat (R^2 = 0.26 vs. 0.02), suggesting altered metabolic aging. ***Conclusion:*** Diabetes induces distinct organ-level changes in tissue density and glucose metabolism detectable by whole-body FDG-PET/CT. The observed patterns—decreased uptake in the bone marrow and brain, and increased uptake in the muscle, liver, and adipose tissues—likely reflect impaired glucose utilization, insulin resistance, and inflammation. FDG-PET/CT reveals a phenomic signature of diabetes. ***References:*** [1] Shiyam Sundar LK, et al. Fully automated, semantic segmentation of whole-body ^{18}F-FDG PET/CT images based on data-centric artificial intelligence. JNM 2022;63:1941-48.

Detection of pancreatic β-cells in individuals with type 1 and type 2 diabetes and obesity, via the PET tracer [68Ga] Ga-NODAGA-Exendin-4

S. Migliari[1], *M. Scarlattei[1], A. Gagliardi[1], A. Guercio[1], G. Baldari[1], R. Aldigeri[2], V. Spigoni[2], F. Fantuzzi[2], G. Cinquegrani[2], E. Balestreri[2], A. Dei Cas[2], R. Bonadonna[2], L. Ruffini[1];*
[1]Nuclear Medicine Division, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY, [2]Laboratory of Endocrinology, Diabetes and Metabolic Disease, Department of Medicine and Surgery, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY.

Aim/Introduction: GLP-1R is a molecular imaging target to quantify in vivo pancreatic β-cell mass (i.e. the product of β-cell density times pancreas volume), aiding in diabetes research and treatment monitoring. Throughout 2020-2022, we developed and validated an automated radiosynthesis of [^{68}Ga]Ga-NODAGA-exendin-4 (68Ga-Ex4) with high molar activity (A_m) [1-2], and optimized a PET-CT scan method to assess its pancreatic uptake, aiming to distinguish GLP-1R expression in type 1-2 diabetes (T1D;T2D) and obesity (OB). ***Materials and Methods:*** The synthesis of 68Ga-Ex4 was performed using an automated module connected to a GMP-certified 68Ge/68Ga generator, following our validated procedure. Immediately after i.v. tracer injection, dynamic images were acquired over 20' on the pancreatic region and static images at 45'-60'. Quantitative analysis measured SUVmax-SUVmean using spherical volumes of interest on the whole pancreas. OU2 selected patients and quantified their β-cell function (data not shown). ***Results:*** 68Ga-Ex4 (mean dose 119.17±22.5MBq) was injected in 8 T1D (51±11yrs, HbA1c% 7.45±1, BMI 26.6±3.2kg/m^2), 10 early T2D (59±12yrs, HbA1c% 6.8±1.1, BMI 29.9±6.0kg/m2) and 10 OB subjects (age 46±10yrs; HbA1c% 5.42±0.5; BMI 38.7±6.9kg/m^2). Mean RCP%, RCY% and A_m of 68Ga-Ex4 were 97.7%, 52.5% and 244.3 GBq/μmol; injected peptide amount wasc3.0±0.01ug. SUVs of the whole pancreas were: $SUVmean_{60}$ 2.0±0.86 (T1D), 3.6±1.2 (T2D), 3.8±1.1 (OB); $SUVmean_{20}$ 3.41±0.85 (T1D), 4.7±1.4 (T2D), 4.86±0.73 (OB); $SUVmax_{60}$ 3.4±0.96 (T1D), 4.8±1.2 (T2D), 5.9±1.5 (OB); $SUVmax_{20}$ 4.7±1.3 (T1D), 6±1.7 (T2D), 7.3±1.1 (OB). SUVmean and SUVmax resulted significantly lower in T1D than in OB at all time points ($p<0.05$), while no significant differences were found between T2D and OB pancreatic SUVs at any time point. SUVmean was higher in T2D compared to T1D at 20 and 60 min ($p<0.05$). ***Conclusion:*** 68Ga-Ex4, synthesized with high molar activity, ensured stability and minimal peptide doses, avoiding side effects during PET-CT. SUV_{60} resulted in a strong and repeatable marker of β-cells density. As a result, 68Ga-Ex4 facilitates the safe and non-invasive assessment of pancreatic β-cell mass. Due to these results, a new experimental study began in November 2024 to evaluate the association between metabotypes of (poly)phenolic dietary compounds and β-cell mass and function. ***References:*** [1] Migliari S, et al. 2022, Curr Radiopharm., 15(1):63-75. Triple-Tracer Imaging in Metastatic High-Grade Neuroendocrine Neoplasms: A Preliminary Observational Study

P. HJ[1], *K. G. Kallur[2], S. S P[1], D. Kumar[3], P. Wadhwa[3];*
[1]Aster Hospital, Banglore, INDIA, [2]HCG Cancer Center, Banglore, INDIA, [3]United Imaging Healthcare, Delhi, INDIA.

Aim/Introduction: High-grade neuroendocrine neoplasms (NENs) are a biologically heterogeneous group of tumors with variable expression of somatostatin receptors (SSTRs), glycolytic activity, and tumor-associated stroma. This study investigates the uptake patterns of three PET tracers—[^68Ga]Ga-DOTANOC, [^18F]FDG, and [^68Ga]Ga-FAPI—in patients with metastatic high-grade NENs to assess inter- and intra-lesional tracer heterogeneity. ***Materials and Methods:*** Thirteen patients (9 males, 4 females; mean age: 58.6 ± 10.2 years) with histologically confirmed metastatic high-grade NENs underwent PET/CT imaging with [^68Ga]Ga-DOTANOC, [^18F]FDG, and [^68Ga]Ga-FAPI within a 7-day interval. Visual and semi-quantitative analyses (SUVmax) were performed for each tracer across representative metastatic sites including liver, lymph nodes, and bones. ***Results:*** A total of 92 metastatic lesions were analyzed (liver: 32, lymph nodes: 24, bones: 36). Liver lesions: [^18F]FDG detected the most lesions (n=29; mean SUVmax: 18.6 ± 5.3), followed by [^68Ga]Ga-FAPI (n=15; SUVmax: 9.1 ± 3.0), and [^68Ga]Ga-DOTANOC (n=12; SUVmax: 7.8 ± 2.6).Skeletal metastases: [^68Ga]Ga-FAPI identified the most lesions (n=33), with higher uptake (mean SUVmax: 12.3 ± 3.5) than [^18F]FDG (n=22; SUVmax: 8.7 ± 2.9) and DOTANOC (n=14; SUVmax: 3.9 ± 1.6).Lymph nodes: Displayed mixed uptake: FDG detected 21 lesions (SUVmax: 11.2 ± 3.4), FAPI 15 lesions (SUVmax: 7.4 ± 2.5), and DOTANOC 11 lesions (SUVmax: 5.8 ± 2.1). Multiple lesions demonstrated uptake on all three tracers, underscoring the complex biology of high-grade NENs—characterized by active metabolism, SSTR expression, and fibrotic stroma. Notably, 23% of bone lesions were exclusively FAPI-avid and not visualized on FDG or DOTANOC PET. ***Conclusion:*** Triple-tracer PET imaging in metastatic high-grade NENs reveals significant lesion-specific heterogeneity. [^18F]FDG demonstrated the highest sensitivity and uptake in liver metastases, while [^68Ga]Ga-FAPI emerged as the second-best tracer in the liver and the most sensitive in bone metastases. These results highlight the value of multi-tracer imaging for comprehensive disease characterization and support the consideration of Lu-177 DOTATATE + FAPI cocktail therapy in selected cases. Further prospective studies with histopathological correlation are warranted. ***References:*** Cuthbertson DJ, Shankland R, Srirajaskanthan R. Diagnosis and management of neuroendocrine tumours. [1]*McGill University Healthcare Center, Montréal, QC, CANADA,* [2]*McGill University, Montréal, QC, CANADA,* [3]*Jewish General Hospital, Montréal, QC, CANADA,* [4]*François Mitterrand University Hospital, Dijon, FRANCE,* [5]*Université Bourgogne Franche-Comté, Dijon, FRANCE,* [6]*University Medical Center Groningen, Groningen, NETHERLANDS,* [7]*University of Groningen, Groningen, NETHERLANDS,* [8]*Hôpital du Sacré-Cœur de Montréal, Montréal, QC, CANADA,* [9]*Université de Montréal, Montréal, QC, CANADA,* [10]*University of Sherbrooke, Montréal, QC, CANADA,* [11]*Centre hospitalier de l'Université de Sherbrooke, Sherbrooke, QC, CANADA.*

Aim/Introduction: Giant cell arteritis (GCA) is the most common form of vasculitis. Diagnosis is challenging and mainly relies on temporal artery biopsy (TAB) and/or Doppler ultrasound (DUS). Although PET/CT is the test of choice in patients with suspected large vessel (LV)-GCA, it was previously limited for cranial artery GCA (C-GCA) detection, primarily due to the small size of these arteries. Digital PET/CT devices have significantly improved PET resolution and allow accurate imaging of smaller cranial arteries. Results of an international prospective cross-sectional comparative study of digital FDG PET/CT and DUS in patients with suspected GCA are presented. ***Materials and Methods:*** Patients aged ≥50 years with suspected GCA were prospectively enrolled in 5 centers across Canada, France, and the Netherlands. Exclusion criteria included corticosteroid therapy >3 days prior to FDG PET/CT or prior history of vasculitis. FDG PET/CT scans were interpreted independently by two blinded readers using visual grading scales as presented in the joint EANM/SNMMI guidelines; in case of disagreement, a third blinded reader adjudicated. Final clinical diagnosis at 6 months served as the reference standard. ***Results:*** Of 104 enrolled subjects, 9 were excluded as they did not undergo DUS. Ninety-five subjects (56 women, 39 men; mean age: 72 years; mean CRP: 66.1 mg/L) were included in the analysis with mean follow-up of 27 months (range 6-74). GCA was diagnosed in 45/95 (47.4%) patients. Of these, FDG PET/CT correctly identified 37 cases: 15 had isolated C-GCA, 7 had isolated LV-GCA, and 15 had both. Sensitivity of FDG PET/CT increased from 48.9% (95%CI: 33.7-64.2%) when assessing large vessels alone to 82.2% (95%CI: 68.0-92.0%) with the addition of cranial vessel evaluation, while specificity remained unchanged at 98.0% (95%CI: 89.4-100.0%). DUS demonstrated sensitivity 68.9% (95%CI: 53.4-81.8%) and specificity 92.0% (95%CI: 80.8-97.8%). Bayesian modeling estimated that, compared with DUS, FDG PET/CT incorporating C-GCA assessment increased sensitivity for GCA diagnosis by 12.8% (95%CrI: -4.7 to 29.9%) and specificity by 5.6% (95%CrI: -3.2 to 15.6%), with respective posterior probabilities of 92% and 90% of FDG PET/CT outperforming DUS. Inter-observer agreement for FDG PET/CT interpretation was near-perfect for both C-GCA (κ=0.928) and LV-GCA (κ=0.915). ***Conclusion:*** Digital FDG PET/CT demonstrates high diagnostic accuracy and excellent inter-observer reliability in identifying C-GCA, supporting its potential role as a first-line modality in the evaluation of suspected GCA.

OP-552

FDG PET-CT in suspected giant cell arteritis: visual analysis has superior diagnostic accuracy compared to semiquantitative image analysis. The VASCAI study.

F. Caobelli, *R. Friedli, N. Gözlügöl, S. Bucher, P. Seitz, F. Lötscher, M. Gilgen, P. Stähli, F. Helfenstein, Y. Döring, G. Hamvas, M. Schindelwolf, A. Rominger, B. Maurer, L. Christ, L. Seitz; Inselspital Bern, Bern, SWITZERLAND.*

Aim/Introduction: Giant cell arteritis (GCA) often affects the aorta and large vessels. ^{18}F-FDG PET/CT is a recommended diagnostic tool to visualize vascular inflammation, with high sensitivity (~80-90%) and specificity (~90-98%) [1,2]. Interpretation can be either visual (grading arterial uptake relative to liver uptake on a 0-3 scale) or semiquantitative (SUVs and target-to-background ratios). This study compared the diagnostic performance of these methods in a large patients' cohort with suspected new-onset GCA. ***Materials and Methods:*** We retrospectively included treatment-naïve patients (≥50 year-old) undergoing standardized FDG-PET/CT for suspected GCA. PET scans were re-read by two nuclear medicine physicians, blind to clinical data and diagnosis. Thirty-three arterial segments were graded visually (0= no uptake; 1= below liver; 2= equal to liver; 3= above liver). Scans were deemed positive on a per-patient basis if any segment had grade ≥2 (or =3 for stricter criteria). Subsequently, SUVmax, SUVmean, and SUVpeak were measured in all segments, and ratios to liver and blood-pool uptake were calculated. Best thresholds were calculated for the diagnosis of GCA. Final GCA diagnosis was determined independently after clinical workup and follow-up (≥3-6 months). Diagnostic metrics (sensitivity, specificity, PPV, NPV, LR±) were calculated. ***Results:*** We included 163 patients, 39 of whom (24%) had confirmed GCA. Visual analysis (score ≥2) showed high sensitivity (80.0%) and specificity (83.0%), with 82% accuracy, PPV 60%, NPV 93%, LR+ 4.7, LR- 0.25. Using visual score 3 as separator, specificity increased to 96% at expenses of lower sensitivity (59%), with diagnostic accuracy 87%, PPV 82%, NPV 88%, LR+ 14.63, LR- 0.43. Semiquantitative methods performed less well. The most accurate among semiquantitative parameters was the ratio arterial SUVmax/Liver SUVmean (Youden's Index 1.11), with very high sensitivity (94%) but poor specificity (35%), accuracy 49%, PPV 32%, NPV 97%, LR+ 1.49, LR- 0.07. No quantitative threshold matched the sensitivity and specificity combination achieved by visual interpretation. ***Conclusion:*** In newly suspected, untreated GCA patients, FDG-PET/CT with expert visual interpretation using a standardized 0-3 grading scale outperformed semiquantitative methods. Visual analysis offered high specificity (at expenses of slightly lower sensitivity) and better overall diagnostic performance. These findings support the use of expert visual reading as the primary interpretive method, with quantitative metrics serving as a useful complement. ***References:*** [1] Knappe L, et al Eur J Nucl Med Mol Imaging. 2023 Nov;50(13):3890-3896. doi: 10.1007/s00259-023-06423-w. [^{18}F]FDG-PET/CT in giant cell arteritis: assessing temporal and vertebral artery involvement with and without corticosteroid treatment, and the potential diagnostic value of adding quantitative analysis

M. Calls Calahorro[1], *M. Velasco-Nuño*[1], *H. Codés Mendez*[2], *P. Moya Alvarado*[2], *A. Barros*[3], *A. Fernández-León*[1], *P. Stefaneli*[1], *B. Serrallonga*[1], *Y. Delisau*[1], *S. Castejón*[1], *G. Guzmán*[1], *V. Camacho*[1], *A. Flotats*[1];
[1]*Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [2]*Rheumatology and Systemic Autoimmune Diseases Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [3]*Cardiology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

Aim/Introduction: To analyse the involvement of temporal and/or vertebral arteries in giant cell arteritis (GCA) and the diagnostic performance of [^{18}F]FDG-PET/CT by several quantification methods, as well as its relationship with corticosteroid treatment. ***Materials***

and Methods: Retrospective study of 60 patients (p) with GCA (ACR/EULAR 2022 criteria) and [^{18}F]FDG-PET/CT at diagnosis: 32p under corticosteroid treatment (corticosteroid) and 28p without corticosteroid treatment (naive). Visual assessment (parietal hypermetabolism in temporal and/or vertebral arteries was considered positive) and quantitative evaluation of SUVmax and its normalization to target-to-background ratio (TBR) of liver (TBR-H) and superior vena cava blood pool (TBR-SVC) were performed in 4 segments: right temporal (RT), left temporal (LT), right vertebral (RV) and left vertebral (LV). The area under the curve (AUC), cut-off point, sensitivity (S) and specificity (E) of the parameters quantified in each of the vascular segments were calculated using ROC curves. The influence of corticosteroid treatment on PET/CT positivity was studied using the Chi-Square test for qualitative variables (visual analysis) and the Mann-Whitney U test for quantitative variables (SUVmax, TBR-H, TBR-SVC). ***Results:*** 23 patients (38%) presented visual [^{18}F]FDG-PET/CT positivity: 12/32p corticosteroid (37%) and 11/28p naive (39%). The frequency of affected segments was: LV 20 (11 naive / 9 corticosteroid), RV 20 (11 naive / 9 corticosteroid), LT 14 (5 naive / 9 corticosteroid) and RT 13 (5 naive / 8 corticosteroid). In temporal arteries, the TBR-SVC was the parameter with the highest AUC, and in vertebral arteries, it was the TBR-H, with RT being the segment with the highest diagnostic accuracy (AUC: 1, cut-off: 1,01, S: 100%, and E: 100%). The mean and cut-off range for SUVmax, TBR-H, and TBR-SVC were 2.36 (2.01-2,72), 0.76 (0.57-0.90), and 1.26 (1.01-1.62), respectively. Corticosteroid treatment did not have any influence on PET/CT positivity based on visual analysis (p>0.05) but did have an influence based on quantitative analysis (TBR-H was significantly different in the RV (p=0.02) and LV (p=0.04) segments). ***Conclusion:*** In GCA patients with positive [^{18}F] FDG PET/CT, vertebral artery involvement was more frequent than temporal artery involvement. Corticosteroid treatment did not have any influence on PET/CT positivity based on visual analysis but did have an influence based on quantitative analysis, which can be used to support visual assessment, with good diagnostic performance.

OP-554

Value addition of [ga-68] fapi pet/ct in enhancing the detection of the inflammatory disease activity in patients suspected of takayasu arteritis- a pilot study

R. Maurya*, M. Ora, S. Gambhir, M. Rai, R. Mehra;*
Sanjay Gandhi post graduate institute of medical sciences, Lucknow, INDIA.

Aim/Introduction: Takayasu Arteritis (TA) is a rare inflammatory disorder of large arteries, typically presenting with non-specific symptoms and potentially progressing to arterial occlusion. Molecular imaging, particularly ^{18}F-FDG PET/CT, is increasingly used to detect vascular inflammation in large vessel vasculitis (LVV) like TA.However, ^{18}F-FDG PET/CT has limitations, including low specificity and limited utility in monitoring treatment response, as uptake may reflect both inflammation and vascular remodeling(1).New PET tracers targeting immune and stromal cells, such as Fibroblast Activation Protein Inhibitor (FAPI), have shown promise in inflammatory and fibrotic diseases due to FAP-alpha expression on activated fibroblasts.Ga-68 labeled FAPI PET/CT may offer better sensitivity and specificity for detecting vascular inflammation in TA. ***Materials and Methods:*** The study assessed 28 TA patients, collecting demographic and clinical data, including ESR and CRP levels.All patients first underwent F-18 FDG PET/CT scans, followed by Ga-68 FAPI PET/CT scans within a week using a consistent protocol. SUV max values and PETVAS scores were calculated for affected arterial segments in both scans.The Wilcoxon signed-rank test was used for statistical comparison of SUV max and PETVAS scores using SPSS. ***Results:*** Participants had a mean age of 31.1 ± 8 years (range: 18-49), with 25 females and 3 males. The mean SUV max was higher with Ga-68 FAPI (3.04 ± 1.59) compared to FDG (2.42 ± 0.97, p=0.008). The average number of arterial segments involved was significantly greater on FAPI PET/CT (5.96 ± 2.7) than FDG PET/CT (2.04 ± 3.12, p<0.001). PETVAS scores were also significantly higher for FAPI (15.57 ± 4.91) than for FDG (8.04 ± 7.39, p<0.001). Among patients with FDG PETVAS <9, 78.9% had FAPI PETVAS >9, indicating FAPI identified additional inflammation. Statistical analysis revealed a significant mean difference in the number of positive arteries between the scans (mean difference = -3.93, p=0.000). ***Conclusion:*** Ga-68 FAPI PET/CT outperformed F-18 FDG PET/CT in detecting arterial inflammation in Takayasu Arteritis, identifying more inflamed segments and yielding higher SUV max and PETVAS scores. Its effectiveness is attributed to targeting activated fibroblasts and reduced background uptake, improving visualization and suggesting it may be a superior imaging modality for assessing TA activity. ***References:*** FDG-PET/CT(A) Imaging in Large Vessel Vasculitis and Polymyalgia Rheumatica: Joint Procedural Recommendation of the EANM, SNMMI, and the PET Interest Group (PIG), and Endorsed by the ASNC." OP-555

^{18}F-FDG PET/CT value in the diagnosis evaluation of patients with polyarteritis nodosa

N. Martinage*, J. Guyot, G. Delaby, D. Huglo, E. Ledoult, C. Baillet;*
Centre Hospitalier Universitaire de Lille, Lille, FRANCE.

Aim/Introduction: Polyarteritis nodosa (PAN) is a rare necrotizing vasculitis affecting medium-sized arteries, with evolving clinical phenotypes that often complicate diagnosis. While ^{18}F-FDG PET/CT is a cornerstone in large-vessel vasculitis, its utility in PAN remains underexplored. A characteristic "ant-farm" hypermetabolism pattern has recently been associated with PAN. This study explores the value of ^{18}F-FDG PET/CT in PAN by describing metabolic abnormalities and correlating them with clinical and paraclinical features. ***Materials and Methods:*** Patients diagnosed for polyarteritis nodosa who underwent ^{18}F-FDG PET/CT between 2010 and 2025 were retrospectively included. All PET/CT were blindly reviewed by two nuclear medicine physicians using a standardized reading grid. Abnormal PET/CT uptakes were systematically recorded and correlated with technical, clinical, biological, and histopathological features. Patients were then compared according to the presence or absence of the ant-farm pattern. ***Results:*** Forty-seven patients were included. The most frequent metabolic abnormalities were osteomedullary (81%), lymph node (40%) and splenic (34%) uptakes. Vascular uptake was present in 17 (36%) patients, primarily involving femoral arteries (94%), tibial anterior and tibioperoneal arteries (71%), and humeral arteries (53%). In 10 patients, osteomedullary uptake extended to the humeral and femoral diaphyses; 6 of them had underlying myelodysplasia. Two patients had VEXAS syndrome associated with PAN. They both had pulmonary infiltrates, diffuse osteomedullary and nasal cartilages uptake. One of them had a diffuse muscular linear and patchy FDG uptake, known as a «tiger-man» pattern. Neurologic, cutaneous, renal, and testicular involvement were rarely detected by PET/CT. The ant-farm pattern was observed in 16 (34%) patients and showed excellent inter-observer reproducibility (kappa coefficient: 0.850; p< 0.0001). It was more frequently observed with newer PET/CT devices (45% vs. 7%; p = 0.011) and whole-body acquisition (56% vs. 10%; p = 0.001) and was associated with fewer PAN-suggestive biopsies (7% vs. 85%; p < 0.0001) and a higher increase of C-reactive protein levels (231 versus 134 mg/L; p = 0.008). ***Conclusion:*** ^{18}F-FDG PET/CT appears to be a valuable tool in the diagnostic assessment of PAN. The ant-farm pattern is highly reproducible and identifies a subset of patients with a more inflammatory phenotype and

negative biopsy findings. In addition, ^{18}F-FDG PET/CT can detect abnormal uptakes in bone marrow, lungs, or cartilage, suggestive of secondary PAN.

OP-556

Diagnostic Value of Splenic and Bone Marrow Metabolic Uptake on ^{18}F-FDG PET/CT in Patients with Suspected Infective Endocarditis

S. Capitanio[1], *A. Franchini*[1], *A. Spataro*[1], *L. Virdone*[2], *L. Airò Farulla*[1], *A. Scarale*[1], *G. Cabrini*[1], *E. Gay*[1], *C. Rossetti*[1];
[1]*Nuclear Medicine Unit, Dipartimento Ematologia, Oncologia e Medicina Molecolare, ASST Niguarda Hospital, Milan, ITALY,* [2]*School of Medicine and Surgery, University of Milan-Bicocca, Monza, ITALY.*

Aim/Introduction: ^{18}F-FDG PET/CT has gained a pivotal role in the diagnosis of infective endocarditis (IE), especially in patients with prosthetic valves or cardiac implantable electronic devices (CIED). However, the role of systemic metabolic response in this setting has not been fully clarified. The aim of this study was to evaluate the diagnostic contribution of increased FDG uptake in the spleen and bone marrow as markers of systemic metabolic responses, in suspected IE patients. ***Materials and Methods:*** We retrospectively analyzed 83 patients (mean age 68.5 ± 15.8 years) who underwent ^{18}F-FDG PET/CT for suspected IE. Among them, 21 had native valves, while 62 had prosthetic valves and/or CIEDs. Valvular or CIED uptake was considered positive and thus compatible with infective endocarditis when FDG uptake was at least greater than mediastinum blood pool activity with focal or heterogeneous uptake pattern. Splenic and bone marrow activity was considered increased if SUVmean spleen/liver or marrow/liver ratio was >1. ***Results:*** Among 83 patients enrolled in the study, 43 patients (51.8%) had a final diagnosis of IE (definite in 33 cases and possible in 10, according to ESC guidelines). Of 43 IE patients, 26 (63.4%) had spleen/liver >1, 21 (51.2%) had marrow/liver >1, and 30 (73.2%) had positive valvular uptake. At least one of these three parameters was positive in 90.2% of IE cases, two or more in 65.9%, and all three were positive in 31.7%. Multivariate logistic regression showed that spleen/liver ratio >1 (OR 3.46, p = 0.014) and valvular uptake (OR 3.56, p = 0.014) were independent predictors of IE. In contrast, marrow/liver >1 was not significantly associated (OR 1.46, p = 0.468). Among patients without IE (n=40), spleen/liver >1 was observed in 32.5%, and marrow/liver >1 in 30%. Increased spleen/liver ratio was significantly more frequent in IE (65.9%) compared to non-IE patients (32.5%, p = 0.0076), while the marrow/liver difference did not reach significance (46.3% vs. 30.0%, p = 0.074). 10/43 IE patients (23.3%) had native valves. Valvular FDG uptake, spleen/liver >1, and marrow/liver >1 were more frequent in patients with prosthetic valves or CIEDs, despite only the difference in valvular uptake was clinically relevant. ***Conclusion:*** Increased splenic FDG uptake and valvular involvement are the most supportive metabolic markers of IE on PET/CT. Bone marrow uptake showed a diagnostic but less significant trend. Integrating the evaluation of systemic and local metabolic activity may improve diagnostic confidence, especially in equivocal cases.

OP-557

Metabolic Signatures of Smoking-Induced Immune Suppression and Vascular Inflammation: Insights from ^{18}F-FDG PET/CT

E. Panagiotidis[1], *G. Angelidis*[1], *A. Paschali*[2], *T. Kalathas*[2], *A. Pipintakou*[2], *I. Tsougos*[1], *V. Valotasiou*[1], *V. Chatzipavlidou*[2], *P. Georgoulias*[1];
[1]*University Hospital, Larisa, GREECE,* [2]*Theageneio Cancer Center, Thessaloniki, GREECE.*

Aim/Introduction: Cigarette smoking is associated with immune dysregulation and increased vascular inflammation. However, the regional metabolic correlates of these effects, particularly in immune and vascular structures, remain insufficiently characterised. This study aimed to assess the impact of smoking on immune activity, evaluated via ^{18}F-FDG uptake in Waldeyer's ring, and on vascular inflammation, assessed through thoracic aortic wall uptake on ^{18}F-FDG PET/CT. ***Materials and Methods:*** A retrospective analysis was conducted on 444 adult patients (276 men; median age 65 years; range 26-87) who underwent ^{18}F-FDG PET/CT imaging. Exclusion criteria included any history of head and neck malignancy or surgery, lymphoma, cervical lymphadenopathy, tonsillectomy, recent upper respiratory infection, liver metastases, recent antibiotic use, or prior radiotherapy to the head and neck region. Patients were categorised as non-smokers (n=120), smokers (n=119), and ex-smokers (n=205). ***Results:*** Statistically significant differences in SUVmax values were found in all regions of Waldeyer's ring. Smokers demonstrated the lowest metabolic activity, followed by ex-smokers and non-smokers. For the right palatine tonsil, SUVmax values were: non-smokers 4.62, smokers 3.82, ex-smokers 4.10 (p<0.006); left palatine tonsil: 4.65, 3.86, 4.11 (p<0.007); and lingual tonsil: 4.62, 3.82, 4.10 (p<0.017). Multivariate analysis identified smoking as an independent predictor of reduced SUVmax in Waldeyer's ring. In contrast, smokers had significantly higher thoracic aortic wall uptake (SUVmax 2.90) compared to non-smokers (2.57) (p=0.001); ex-smokers showed values comparable to non-smokers (2.55). A dose-dependent effect was observed, with heavy smokers (>20 cigarettes/day) showing lower tonsillar SUVmax. Additionally, elevated BMI was associated with higher thoracic aortic SUVmax, suggesting a synergistic role of obesity and smoking in vascular inflammation. ***Conclusion:*** Smoking is associated with decreased metabolic activity in Waldeyer's ring, consistent with immune suppression, and increased aortic FDG uptake, reflecting vascular inflammation. These effects appear partially reversible following smoking cessation. ***References:*** Gomez R, et al. (2018). Immune function of Waldeyer's ring. Immunology 151(1):1-15.Mariani M, et al. (2017). Hybrid [18F]FDG-PET/MRI in Inflammatory Cardiac Disease: One Scan, Complete Insight

G. Argalia[1], *M. Fogante*[2], *G. Biscontini*[1], *A. Palucci*[1], *C. Romagnolo*[1], *C. Cottignoli*[1], *P. Esposto Pirani*[2], *C. Ventura*[2], *N. Schicchi*[3], *G. Argalia*[2], *F. M. Fringuelli*[1];
[1]*Nuclear Medicine, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY,* [2]*Maternal-Child-Senological-Cardiological Radiology and Outpatient Ultrasound, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY,* [3]*Cardiovascular Radiological Diagnostics, Department of Radiological Sciences, University Hospital of Marche, Ancona, ITALY.*

Aim/Introduction: Hybrid-PET/MRI is a multimodal imaging technique that enables the synchronous acquisition of metabolic PET data and high-resolution anatomical and functional MRI information. This integrated approach ensures excellent spatial and temporal correlation between molecular and structural findings, offering a comprehensive evaluation of cardiac inflammation. This study aims to evaluate the added diagnostic value of hybrid PET/MRI over standalone MRI and PET in assessing inflammatory heart diseases. ***Materials and Methods:*** This retrospective study included patients who underwent 18-fluorodeoxyglucose ([18F]FDG)-PET/MRI between September 2022-March 2025 for suspected acute/chronic myopericarditis or endocarditis. Patients followed a high-fat-carbohydrate-free diet for 72hours before the scan to suppress myocardial [18F]FDG-uptake. PET/MRI studies were performed using an integrated hybrid PET/3T-MRI scanner. Intravenous administration of a gadolinium-based-contrast-agent was performed to enhance myocardial tissue characterization.

Images were initially evaluated separately by a radiologist (MRI) and a nuclear medicine physician (PET). In myopericarditis MRI was positive= presence of LGE and edema; inconclusive= presence of LGE but not edema; negative= no LGE and no edema. In endocarditis MRI was positive= evidence of vegetations, valvular abscesses; inconclusive= subtle or nonspecific findings (minor thickening or ambiguous enhancement) or artifact limitations (prosthetic valves, arrhythmias); negative= normal valve morphology. PET was positive= presence of high-focal FDG uptake; inconclusive= mild-diffuse uptake or of uncertain anatomical location; negative= no FDG uptake. A multidisciplinary consensus meeting was held to integrate the findings and establish the final diagnosis. ***Results:*** 33patients were enrolled. 21(64%) with suspected myopericarditis and 12(36%) with suspected endocarditis. Common clinical indications included chest pain, fever of unknown origin, elevated inflammatory markers, and cardiac dysfunction. In patients with suspected myopericarditis, MRI was= positive 1/21, negative 4/21, inconclusive 16/21. PET imaging was= negative 19/21, inconclusive 2/21. The hybrid PET/MRI review led to a reclassification of 16/21(76%) cases, confirming the absence of active inflammation in most patients and precisely localizing tissue damage. In patients with suspected endocarditis, MRI was= positive 1/12, negative 1/12, inconclusive 10/12. PET was= positive 4/12, negative 7/12, inconclusive 1/12. The hybrid PET/MRI review was useful in 9/12(75%) cases, allowing to distinguish active/previous inflammation. ***Conclusion:*** The integrated approach offered superior spatial and temporal correlation between metabolic and anatomical findings, aiding in more accurate disease characterization. These results suggest that hybrid [18F]FDG-PET/MRI may be a valuable tool in the comprehensive evaluation of inflammatory heart diseases, facilitating better diagnosis and management of patients, when PET and MRI separately do not provide sufficient information to reach a conclusion.

OP-559

FDG PET/CT in Inflammatory Myopathies: Bridging Biochemistry and Imaging Clues

A. S Babu, *R. Karna, M. Umar, A. Mahalik, K. Bangkim Chandra, R. Kumar;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Polymyositis and dermatomyositis (PM/DM) are rare autoimmune inflammatory myopathies characterized by progressive muscle weakness and systemic involvement. While traditional diagnostic tools like enzyme assays and clinical assessment are central, FDG PET/CT is emerging as a promising modality for detecting active inflammation and guiding management. This study explores how metabolic imaging correlates with biochemical activity in suspected PM/DM patients. ***Materials and Methods:*** We retrospectively analyzed 52 patients who underwent FDG PET/CT between March 2023 and January 2025 for suspected or confirmed inflammatory myopathies. Clinical data, CK and/or CK-MB values, and PET scores were evaluated. Muscle uptake was visually graded using a 3-point scale: 0 (less than mediastinal blood pool), 1 (≥ mediastinal blood pool but less than liver), and 2 (≥ liver). A score of 1 or 2 was considered positive and PET findings were correlated with CK/CK-MB values. ***Results:*** Among 52 patients (mean age 46 years, range 18-78 years; 30 females, 22 males), CK and/or CK-MB values were available for 42 patients. Visual grading of muscle uptake on FDG PET/CT was done for the 42 patients with CK/CK-MB data. Among those with high-grade FDG uptake (score 2), 70% (14/20) had elevated CK and/or CK-MB, indicating active inflammatory myopathy. In contrast, low uptake (score 0) was observed in 16 patients, of whom 62.5% (10/16) had normal enzyme levels, suggesting minimal or no muscle inflammation. Intermediate uptake (score 1) was seen in six patients, with 83% (5/6) showing positive enzyme values, potentially reflecting early or mild disease. This trend highlights a strong correlation between PET metabolic activity and biochemical markers, supporting the utility of FDG PET/CT as a non-invasive tool for assessing disease activity in PM/DM. ***Conclusion:*** FDG PET/CT proves to be a valuable adjunct in evaluating inflammatory myopathies, offering a visual and quantifiable reflection of underlying muscle inflammation. Higher PET uptake scores align with increased CK/CK-MB positivity, reinforcing the utility of FDG PET/CT as a surrogate marker for disease activity in dermatomyositis. Its correlation with CK/CK-MB enhances diagnostic confidence and may assist in biopsy planning and monitoring therapeutic response. With standardized scoring, FDG PET/CT could play a more integral role in routine evaluation, especially in challenging or equivocal cases.

Scenario based uncertainty estimation of radionuclide therapy dose

F. Kähler*;*
RaySearch Laboratories, Stockholm, SWEDEN.

Aim/Introduction: Input data for radionuclide therapy (RNT) dose estimations inherently contain uncertainties. However, resulting uncertainties in dose are often not reported. Proposed methods for uncertainty estimations are not applicable without restricting the used fit function. To overcome this, in the here presented method, different dose scenarios are computed to estimate the dose uncertainty. The method was implemented in a research build of a commercial dosimetry software. ***Materials and Methods:*** Doses and uncertainties were estimated for the MRT dosimetry dataset as described of the supporting material[1]. The dataset contains six SPECT/CTs. The image data was quantified using SPECT data of a cylindrical Jaszczak phantom (injected activity A= 441.2±13.8MBq). The activity was recovery corrected using a two parameter (a,b) curve: $R(v,a,b)=1/(1+(a/v)^b)$. Estimation of the parameters was performed using the dataset of a NEMA phantom (a=2.80±0.38ml, b=0.48±0.01). Including the uncertainty of the injected reference activity, an uncertainty of the recovery function can be estimated for each volume. Activity was time-integrated using a mono-exponential fit for the mean intensities of the regions of interest (ROI). ROIs used for the study were a lesion (inside the liver), liver, spleen, medulla, and cortex (for left and right kidney). To simulate uncertainty in the fit and the segmentation, three mono-exponential fits were performed for each ROI, one for the original contours and for contours expanded or contracted by a margin. For overlapping ROIs, one ROI was expanded while the other one was reversed, to not over-count the activity. The scenario evaluation was repeated with margins (1mm, 2mm and 3mm). ***Results:*** 27 scenarios were created including all possible combinations for the calibration factor, recovery function and time-integrated activities from the fits. Doses were computed for the non-expanded ROI geometries using Monte Carlo simulation of all particles for a 1.5x1.5x2mm grid resulting in multiple DVH bands for the ROI. The dose uncertainty was computed from the

standard deviation of all scenarios. Uncertainties were compared to uncertainties computed for an analytical method[2]. Best agreement was achieved for 2mm margin where computed uncertainties were comparable to the reference values. Largest relative contribution to the uncertainties were fit/delineation (58.8%), then recovery correction (24.6%) and calibration factor (16.5%). ***Conclusion:*** The here presented methodology enables the estimation of dose uncertainty in RNT using different scenarios without with limited use of analytical methods. The methodology must be tested on non-phantom data. The uncertainty is expected to increase for small, uneven, diffuse ROIs. ***References:*** [1]DOI 10.17605/OSF.IO/69NGE;[2]https://doi.org/10.1186/s40658-020-00328-5.

A Unified MeshBased Modelling Framework for Age and AnatomySpecific Skeletal Dosimetry

R. Dawson[1], *C. Choi*[1], *Y. Wang*[1], *B. Shin*[1], *J. Tran-Gia*[2], *M. Salas-Ramirez*[2], *A. Theisen*[2], *M. Laßmann*[2], *W. E. Bolch*[1];
[1]*J. Crayton Pruitt Family Department of Biomedical Engineering, University of Florida, Gainesville, FL, UNITED STATES OF AMERICA,* [2]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.*

Aim/Introduction: Red bone marrow (RBM) and bone endosteum (BE) are key risk organs for radiogenic leukaemia and bone cancer, yet modelling the intricate trabecular bone (TB) microstructure has historically been challenging. Voxel-based computational phantoms enable Monte Carlo (MC) dosimetry but suffer from limited resolution and stair-step artefacts. This study developed an integrated programme to (i) generate highfidelity, ICRPconsistent polygonal and tetrahedral mesh (TM) models for adult and paediatric skeletons, (ii) extend to non-reference morphologies via systematic variation of bone volume fraction (BV/TV) and cellularity factor (CF), and (iii) couple selected bone site geometries to an agentbased bone remodelling framework linked with MC transport to predict time-resolved dosimetry for boneseeking αemitters. ***Materials and Methods:*** Adult reference TM models were created from segmented micro-CT images (30μm voxels) of cadaveric bone cores (35 sites male, 38 sites female). An automated C++/Python pipeline converted TB segmentations into smoothed surface meshes, populated marrow cavities with explicit, individual adipocyte models, and assembled multi-domain TM models. Adult meshes were morphed to match age-specific marrow metrics from skeletal morphology data, producing several hundred paediatric models representing newborns, 1-, 5-, 10-, and 15-year-old individuals consistent with ICRP mesh-type reference computational phantoms (MRCPs). Non-reference variants were generated by parametric BV/TV scaling (5-25%) and CF adjustment (0-100%), yielding a comprehensive library for sensitivity studies. A 10μm lattice agent-based model (ABM) simulated bone multicellular unit (BMU) formation-resorption cycles with Ra223/226 adsorption, incorporation, and release. Activity states from each ABM cycle drove Particle and Heavy Ion Transport code System (PHITS) MC simulations with paired TM models; resulting three-dimensional dose distributions iteratively updated cellular kill probabilities and remodelling dynamics. ***Results:*** TM models were generated for all imaged skeletal sites in adult, paediatric, and non-reference cases, eliminating voxel stair-step artefacts and anatomically unrealistic morphologies. BV/TV and CF parameters were tuned so embedded MRCPs matched ICRP Publication 89 TB and RBM masses within 0.5%. MC transport simulations of electron absorbed fractions (AFs) revealed substantial low-energy (10-30 keV) discrepancies between TM and voxel models across most source-target combinations. The coupled ABM-MC workflow captured temporal dose accumulation patterns linked to BMU dynamics. ***Conclusion:*** This study presents a harmonized framework of mesh-based skeletal models spanning paediatric to adult and encompassing non-reference morphologies, integrated with a mechanistic ABM-MC dosimetry engine. These tools reduce geometric bias, enable patient-specific sensitivity analyses, and open new avenues for dose optimisation in nuclear medicine, radiopharmaceutical therapy, and radiation protection.

EPS-180

Increasing Precision in Image-Based Bone Marrow Absorbed Dose Estimations following [^{177}Lu]Lu-DOTATATE Treatment

K. Smits[1], *F. Westerbergh*[1], *J. Hemmingsson*[1], *M. van Essen*[2], *J. Svensson*[3], *A. Theisen*[4], *J. Tran-Gia*[4], *T. Rydén*[5], *P. Bernhardt*[5];
[1]*Institute of Clinical Sciences, Gothenburg, SWEDEN,* [2]*Institute of Medicine, Gothenburg, SWEDEN,* [3]*Department of Oncology, Gothenburg, SWEDEN,* [4]*Department of Nuclear Medicine, Wurzburg, GERMANY,* [5]*Department of Medicial Physics and Biomedical Engineering, Gothenburg, SWEDEN.*

Aim/Introduction: Bone marrow absorbed dose estimates are susceptible to large uncertainties, mainly due to low uptake and thus high noise levels. This study examines how image-based bone marrow absorbed dose calculations are affected by the number of included vertebrae and the reconstruction parameters used in the absorbed dose calculations. ***Materials and Methods:*** We included 16 patients with advanced neuroendocrine tumors treated with [^{177}Lu]Lu-DOTATATE. After the first treatment cycle, all patients underwent 4 SPECT/CT scans (2, 24, 48, and 168 hours post-injection). SPECT data were reconstructed with 60 updates (in-house Monte Carlo-based OSEM with attenuation and scatter correction, and resolution modeling), using either 60 iterations with one subset (60i1s) or 5 iterations with 12 subsets (5i12s). The T8-L5 vertebrae were used to estimate the bone marrow activity concentrations. Absorbed dose estimates, and their precision, were assessed in relation to the number of vertebrae included in the calculation. Further evaluations were carried out using both measured (Lung-Spine phantom with spherical inserts) and simulated (digital XCAT phantom) SPECT data. Poisson noise (100 realizations per noise level) was added to the simulations to generate noise levels matching those observed in patients. While the impact of different volumes-of-interest (4-16 mL) on image-based activity concentration estimates was evaluated using the Lung-Spine phantom, the XCAT phantom served to evaluate the activity concentration within realistic vertebral geometries. ***Results:*** Increasing the number of vertebrae from one to six in the absorbed dose calculations substantially improved the precision in absorbed doses (coefficient of variation, COV, from 34% to 6.3%). Comparing reconstructions using 1 subset (60i1s) and 12 subsets (5i12s), only minor differences (0.1%) were observed. For the Lung-Spine phantom, smaller volumes (V = 4 mL, COV: 36%) were found more sensitive to noise compared to larger volumes (V = 16 mL, COV: 17%), at 60 updates. In the XCAT phantom, a decrease in recovery from 0.63 (L5) to 0.31 (T12) at 60 updates was seen in vertebrae adjacent to high-uptake organs. ***Conclusion:*** The precision in image-based bone marrow absorbed dose calculations is improved by including multiple vertebrae. However, careful selection of these vertebrae is needed, as closely located high-uptake organs can bias the absorbed dose estimates. Only minor differences were found between 60i1s and 5i12s, suggesting that bone marrow absorbed dose estimates are stable throughout different iteration-subset configurations.

Aim/Introduction: Practical, accurate and standardised renal dosimetry methods are needed for wider use of dosimetry in ^{177}Lu radiopharmaceutical therapy. We aimed to compare a semi-automated small-volume-of-interest dosimetry technique with

the conventional approach of whole-kidney segmentation on CT. ***Materials and Methods:*** Thirty patients enrolled in our clinical trial of personalised PRRT (NCT02754297) underwent quantitative SPECT/CT at ~24h and ~72h after their first ^{177}Lu-DOTATATE administration (2.2-13.2 GBq). Kidneys were manually segmented on CT and combined to compute the total renal volume. This contour was expanded by 1 cm to include spilled-out activity and obtain the "raw" total renal activity. The latter divided by the former defined the raw whole-kidney activity concentration (WK_{raw}). The expanded contour was trimmed to exclude areas of spilled-in activity from adjacent tumours, yielding the corrected activity concentration (WK_{cor}). The semi-automated small-volume (SV) method consisted in sampling activity concentration with a spherical 2-cm VOI (~4 mL) positioned concentric to the renal SUV_{peak} location across both kidneys, using the SUV_{peak}-finding tool that is available in most molecular imaging software. Dosimetry was performed by multiplying the area under the monoexponential time-activity concentration curve by 86 mGy·g/MBq·h. SUV_{mean}, effective half-life (T_{eff}) and specific absorbed dose (AD) were correlated between SV, WK_{raw} and WK_{cor} techniques. Kidney volume was compared between both timepoints. ***Results:*** The SV method yielded median (range) SUV_{24h} of 6.1 (3.1-12.9), SUV_{72h} of 4.1 (2.0-8.7), T_{eff} of 52 (38-113) hours and specific AD of 0.76 (0.35-1.89) Gy/GBq, which are consistent with published data. Moderate correlations were observed between SV and WK_{raw} (SUV_{24h} r=0.85, SUV_{72h} r=0.77, T_{eff} r=0.58 and specific AD r=0.67; P<0.001), which all improved substantially when SV was correlated to WK_{cor} (SUV_{24h} r=0.92, SUV_{72h} r=0.91, T_{eff} r=0.73 and specific AD r=0.92; P<0.001). SV method yielded dosimetry estimates that were on average 11% above those obtained with WK_{cor}. Total kidney volume was 307±73 mL and intra-patient discrepancies of up to 13% were observed between the two CT timepoints. SV sampling can be performed in about one minute, vs. 15-30 minutes for CT-based WK segmentation. ***Conclusion:*** The SV method yielded renal dose estimates that were comparable to those obtained with WK segmentation corrected for tumour spill-in, with only a small positive bias. It is easy to implement, software vendor-neutral, observer-independent in principle, considerably timesaving, and likely translatable to other radionuclides and target tissues. It could fulfil the need for a standardised dosimetry approach for monitoring and personalising radiopharmaceutical therapy. ***References:*** Sandström,EJNMMI2010;37:212. EPS-182

DBS sampling as a method for dosimetry in Lu-PSMA therapy.

K. Doornhof*, I. Bumanjal, M. Konijnenberg, S. Koolen;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Dosimetry enables detailed tracking of radiation exposure in patients undergoing radioligand therapy, potentially correlating this data with therapy outcomes and side effects. This correlation could facilitate personalized treatment plans. However, comprehensive dosimetry requires data collection at multiple time points, often necessitating additional hospital visits, thereby increasing patient burden. Dried Blood Spot (DBS) sampling offers a solution for blood-based bone marrow dosimetry by allowing patients to collect samples at home and send them to the hospital for analysis. This study aims to evaluate the feasibility of collecting and analyzing blood samples using DBS. ***Materials and Methods:*** Pre-clinical validation involved spiking blood samples with various concentrations of Lu-177. An initial 2MBq/mL sample of Lu-177-DTPA in blood was prepared using a dose calibrator, followed by serial dilutions until the concentration dropped below 1KBq/mL. These samples were spotted (volume 50 ± 0.4µL) on DBS paper (Whatman 903 protein saver cards) in triplicate. After drying, 6 mm punches of the DBS spot were measured using a gamma-scintillation counter for 1 and 10 minutes to assess repeatability and linearity. The effects of hematocrit (HT) and punch location (taken from the spot center or edge) were also examined by spotting samples with identical Lu-177 concentrations and HT levels of 0.15, 0.25, 0.3, 0.4, and 0.5. ***Results:*** A linear correlation was observed between Lu-177 concentration in the blood sample and CPM measured on the DBS punch using the gamma-counter (r^2=0.9981). CPM measurements were significantly correlated with blood hematocrit, with samples with lower hematocrit levels showing a lower measured CPM ($p < 0.0001$). The effect of hematocrit level on the measured CPM was linear within the validation range (r^2=0.9454). When counting for 10 minutes, blood concentrations measured on DBS spots consistently fell within 10% of the true concentrations for samples with Lu-177 concentrations above 15KBq/mL and within 20% for those above 4KBq/mL. ***Conclusion:*** Preclinical results indicate that DBS sampling could be a reliable method for determining Lu-177 concentrations in blood. While variations in HT impact measurements, the effect is linear, allowing for correction. This sampling method has the potential to enable more extensive dosimetry in patients undergoing radioligand therapy without placing additional burden on patients. The methods practical performance is currently being investigated in an ongoing clinical trial.

EPS-183

Assessing the Impact of Multi-Cycle Data Integration on the Accuracy of Single-Time-Point Dosimetry: A Non-linear Mixed-Effect Modeling Evaluation

I. Budiansah*[1], D. Hardiansyah[1], S. M. B. Peters[2], S. Ardjo Pawiro[1], B. Privé[2,3], J. Nagarajah[2,4], M. W. Konijnenberg[2,3], A. J. Beer[5], G. Glatting[5];*
[1]Universitas Indonesia, Depok, INDONESIA, [2]Radboud University Medical Centre, Nijmegen, NETHERLANDS, [3]Erasmus Medical Centre, Rotterdam, NETHERLANDS, [4]Röntgeninstitut Düsseldorf, Düsseldorf, GERMANY, [5]Ulm University, Ulm, GERMANY.

Aim/Introduction: This study investigated the impact of incorporating multi-cycle data on the accuracy of time-integrated activity coefficients (TIACs) in single-time-point (STP) dosimetry. ***Materials and Methods:*** Renal biokinetic data of [^{177}Lu]Lu-PSMA-617 were collected from ten patients with low-volume metastatic hormone-sensitive prostate cancer (mHSPC) at Radboud University Medical Centre (NCT03828838). Each patient underwent two therapy cycles, receiving (3.1±0.1) GBq and (5.9±0.4) GBq in the first and second cycles, respectively. Biokinetic data were obtained separately from the left and right kidneys in both cycles, yielding forty renal datasets. For each cycle, SPECT/CT scans were performed at five time points: TP1 (2.5±0.9)h, TP2 (23±2)h, TP3 (47±2)h, TP4 (71±2)h, and TP5 (167±2) h after injection. Population-based model selection using non-linear mixed-effect modelling (PBMS NLMEM) was applied to select the best fit function. Goodness-of-fit criteria were visual inspection, relative standard error (RSE) < 50%, and the absolute value of the off-diagonal elements in the correlation matrix < 0.8. Among the models that satisfied these criteria, the final selection was based on the highest Akaike weight. TIACs derived from the best fit function in all-time-point (ATP) dosimetry were designated reference TIACs (rTIACs). To evaluate the impact of multi-cycle population data on STP dosimetry accuracy, three STP scenarios were analysed: (1) first cycle STP dosimetry using parameters estimated from first cycle data; (2) second cycle STP dosimetry using parameters from second-cycle data; and (3) STP dosimetry in both cycles using parameters from the combined data of both cycles, applied separately to each cycle. In each scenario, the optimal time point was determined as the time point with the lowest root-mean-squared-error (RMSE) between STP-estimated TIACs (sTIACs) and the rTIACs. ***Results:*** Function $f_{6a}(t)=A_1e^{-(\lambda1+\lambda phys)}$

$^{t} + A_2e^{-(\lambda 2+\lambda phys)t} - A_3e^{-(\lambda 3+\lambda phys)t} - (A_1 + A_2 - A_3)e^{-(\lambda bc+\lambda phys)t}$ was selected as the best-fit function (Akaike weight ~ 100%). The optimal time points were (23±2)h and (71±2)h after injection for the first and second cycles, with RMSEs of (6.2±1.9)% and (6.7±1.9)%. Using parameters from the combined data yielded the same time points, with RMSEs of (6.0±2.7)% and (7.4±2.9)% for the first and second cycles, respectively. ***Conclusion:*** Incorporating multi-cycle data into STP dosimetry within the NLMEM framework yielded in the same optimal time point as using single-cycle data. The accuracy of the sTIACs remained comparable across scenarios, indicating that a single-cycle dataset is sufficient for accurate STP dosimetry.

EPS-184

Dosimetry-guided treatment planning for ^{177}Lu-labelled PSMA therapy based on a diagnostic ^{68}Ga-labelled PSMA PET/CT

E. Yousefzadeh-Nowshahr[1,2], *L. D. Jiménez-Franco*[3], *V. Vasic*[1], *A. Theisen*[4], *J. Tran-Gia*[4], *P. Hartrampf*[4], *A. J. Beer*[2], *M. Lassmann*[4], *G. Glatting*[1,2];
[1]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY,* [3]*ESQlabs GmbH, Saterland, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.*

Aim/Introduction: PSMA-targeted therapy with ^{177}Lu-labelled PSMA has demonstrated improved outcomes in castration-resistant prostate cancer. While major trials employed a fixed activity of 7.4 GBq, dosimetry-based individualisation may further optimise outcomes. This study aimed to develop a dosimetry-guided treatment planning approach based solely on a diagnostic [^{68}Ga]Ga-PSMA-I&T PET/CT. ***Materials and Methods:*** Data from ten patients with metastatic prostate cancer who had undergone [^{68}Ga]Ga-PSMA-I&T PET/CT (80±20 min p.i.; 2.8±0.8 nmol peptide; 117.0±18.6 MBq), followed by one cycle of [^{177}Lu]Lu-PSMA-I&T therapy (87.6±2.7 nmol peptide; 6.2±0.2 GBq), and two SPECT/CT scans at 2 and 4 days p.i. were included. Imaging was standardised according to EARL accreditation protocols to ensure quantitative harmonisation across PET/CT and SPECT/CT scans. Time-activity data for kidneys, liver, spleen, and two lesions per patient were extracted using 3D Slicer [1]. A whole-body PBPK model was implemented using MATLAB/SimBiology. Model parameters were fitted to the patient's time-activity data using a Bayesian population approach to create individual digital twins and to estimate reference absorbed doses (ADs) for kidneys and tumours. Next, model parameters were fitted using only PET/CT data to predict therapeutic time-activity curves. The resulting ADs for kidneys and tumours were then compared to the reference values. After evaluating the model's predictive performance, virtual treatment scenarios were simulated solely on PET/CT data, varying the peptide amount of [^{177}Lu]Lu-PSMA from 2-2048 nmol. For each patient, optimal combinations of peptide amount and administered activity were determined by maximising the tumour absorbed dose, while adhering to the therapy-limiting conditions described in [2]. ***Results:*** PET/CT-based AD predictions for [^{177}Lu]Lu-PSMA-I&T therapy showed good agreement for the kidneys, with a mean absolute percentage error (MAPE) of 9% (range: 2-26%). For tumours, deviations between predicted and reference ADs were more pronounced (MAPE: 38%, range: 20-80%). Virtual treatment planning identified a median optimal peptide amount of 111 nmol (range: 64-388) and a median administered activity of 10.3 GBq (range: 5.1-37.7 GBq). Compared to applied treatments involving 6.2±0.2 GBq of [^{177}Lu]Lu-PSMA-I&T, which resulted in tumour and kidney ADs of 3.3-17.6 Gy and 2.8-8.5 Gy, respectively, the optimised plans achieved higher tumour ADs (5.9-25.0 Gy) while maintaining stable kidney ADs (8.1-8.3 Gy). ***Conclusion:*** PET/CT imaging may support predictive dosimetry and individualised treatment planning in PSMA-targeted ^{68}Ga/^{177}Lu theranostics with PSMA-I&T. However, further refinement is needed, e.g. incorporating more patient data to improve precision and accuracy. ***References:*** [1] Fedorov et al. Magn Reson Imaging 2012;30(9):1323-1341 [2] Jiménez-Franco et al. Med Phys. 2018.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) labelled with lutetium-177 (^{177}Lu) is an established prostate cancer therapy, though variations in its effectiveness are not fully understood. Utilising a physiologically based pharmacokinetic (PBPK) model can aid in examining these differences and allows for safe delivery of high-dose radiation to tumours. The radiohybrid Lu-rhPSMA-10.1 is particularly advantageous as it shows identical pharmacokinetics for PET imaging as [^{18}F]^{nat}Lu-rhPSMA-10.1 and for therapy as ^{nat}F[^{177}Lu]rhPSMA-10.1. In addition, it exhibits low kidney uptake, rapid blood clearance, and high tumour accumulation. This preclinical study aims to find the best PET measurement schedule to predict the therapeutic absorbed dose from PET imaging data using digital twins for mice. ***Materials and Methods:*** The parameters of a physiologically based pharmacokinetic (PBPK) model were fitted to biodistribution study data to create digital twins of five mice injected with [^{177}Lu]Lu-PSMA10.1. With the digital twins, synthetic PET Time-Activity Curves (TAC) were generated. Sampling schedules were defined as time points being at least one hour apart, with a maximum of three time points at a combination of 15min, 30min, 90min, 3h30min, and 6h after injection. The kidneys, tumour, liver, and total body activities of each schedule were simulated using the digital twin and modified with 20% Gaussian noise. This was replicated 1000 times. Time-Integrated Activity (TIA) and absorbed dose were calculated for each replication and compared with the corresponding digital twin (ground truth). The mean absolute percentage error (MAPE) with the lowest value was ranked as the best schedule. ***Results:*** The mean absorbed dose was accurately predicted in all schedules, with differences between 0.8% and 4.3% for tumours and 2.8% and 4.2% for kidneys. However, the standard deviation exceeded 30% in all schedules, from 32.1% to 34.3% and 33.9% to 38.7% for tumours and kidneys, respectively. The 3 and 6 hours schedule yielded the lowest MAPE for both the tumour and the kidneys with 25.6% and 27.5%, respectively. The early time points of 15 and 30 minutes did not show improvements, and adding a 90-minute time point yielded equally good results to those at 3 and 6 hours for the tumour. ***Conclusion:*** This study demonstrates the potential of predicting absorbed doses from PET images using digital twins with a PBPK model. The 3 and 6-hour schedule is the best option adhering to animal welfare and working hours. Future research will include a Bayesian framework to improve accuracy and rRMSE.

EPS-186

Diagnostic ^{68}Ga-PSMA-11 PET/CT image-based dosimetry: a better estimate of ^{177}Lu-PSMA-617 therapy absorbed dose than PET uptake metrics

N. Payan[1,2], *C. Drouet*[1], *A. Jougla*[1], *A. Cochet*[1,2], *J. M. Vrigneaud*[1,2];
[1]*Centre Georges-François Leclerc, Dijon, FRANCE,* [2]*ICMUB UMR CNRS 6302, Université Bourgogne-Europe, Dijon, FRANCE.*

Aim/Introduction: Predicting treatment Absorbed Dose (AD) using diagnostic data could be a step forward in personalising ^{177}Lu-PSMA-617 radioligand therapy. Although numerous studies have investigated the predictive power of ^{68}Ga-PSMA-11 PET/CT uptake metrics, SUV values might not be the best candidate. The

aim of the present study was to assess the agreement between real pre-treatment dosimetry obtained using serial ^{68}Ga-PSMA-11 PET/CT acquisitions, and post-therapeutic mean AD coefficients (ADc), for Organs At Risk (OARs) and tumour lesions. ***Materials and Methods:*** Nine patients with metastatic, castration-resistant prostate cancer who underwent diagnostic ^{68}Ga-PSMA-11 PET/CT scans followed by a 7.4GBq ^{177}Lu-PSMA-617 therapy were included. Pre- and post-therapeutic dosimetry were obtained from six whole-body ^{68}Ga-PSMA-11 PET/CT acquisitions over one hour, and four SPECT/CT scans acquired at 5h, 24h, 4d and 8d after the first treatment injection, respectively. Kidneys, liver, spleen, Salivary Glands (SG) and SG with 3- and 5-mm isotropic margins (SG3 and SG5) were semi-automatically segmented on CT images using MIM® software. Large spheres were drawn around lesions on PET and SPECT images. Pre-therapeutic S-value-based dosimetry was performed in IDAC-Dose v2.1 using adjusted masses and cumulated activities fitted with the trapezoidal method. A voxel-level post-treatment dosimetry was performed with MIM® SurePlanMRT, using mono or bi-exponential fit for cumulated activities integration. Spearman correlations were calculated between treatment ADc, pre-therapeutic ADc and PET SUVmean/max values. ***Results:*** The mean(±SD) ADc for kidneys, liver and spleen were respectively 0.78(±0.18), 0.07(±0.04), 0.10(±0.04) before, and 0.43(±0.15), 0.13(±0.13), 0.08(±0.04) mGy/MBq after treatment. The larger the SG margin, the lower the corresponding ADc, with 0.42(±0.13), 0.32(±0.10), 0.26(±0.08) and 0.30(±0.17), 0.24(±0.13), 0.20(±0.11) mGy/MBq for SG, SG3 and SG5 pre- and post-treatment respectively. A total of 41 lesions (10 soft tissue, 31 bone) were analysed, with mean ADc values of 0.09(±0.05) before and 1,57(±1.17) mGy/MBq after therapy. Strong ($\rho>0.80$) significant ADc correlations were observed for kidneys, liver, spleen and SG3. High ($0.80>\rho>0.70$) significant correlations were also noted for SG, SG5, and all lesions combined. A stronger correlation was observed for soft tissue lesions than for bone lesions ($\rho=0.85$ vs 0.65, p-value<0.01). Post-therapeutic ADc showed stronger correlations with pre-treatment ADc than SUV values, except for SG and SG5. SG3 ADc however presented the highest correlation overall ($\rho=0.83$ vs 0.82 and 0.73 for SG3, SG and SG5 respectively). ***Conclusion:*** Pre-treatment dosimetry outperformed PET uptake values at estimating therapy's doses. The strong correlations between ADc support the potential of a pre-therapeutic dosimetry for a personalised medicine.

EPS-187

More Bang For Your Becquerel: A Novel Approach to "Dosing" in ^{177}Lu-PSMA Radioligand Therapy

N. Scott, *B. Fongenie, D. Stevens;*
Blue Earth Therapeutics, Oxford, UNITED KINGDOM.

Aim/Introduction: Current clinical approval for ^{177}Lu-PSMA Radioligand Therapy (RLT) follows a flat 6-cycle dosing regimen with limited investigation into optimum dosing strategies. ^{177}Lu-rhPSMA-10.1, a novel PSMA RLT, is under investigation in a Phase 1/2 trial. In Phase 1 (now completed) patients received 5.5-7.4 GBq per cycle for up to three cycles, with dosimetry performed throughout. Dosimetry results showed favourable normal organ doses that were consistent across cycles. However, tumour absorbed dose coefficients (Gy/GBq) peaked at cycle 1 and declined thereafter, suggesting that "front-loading" administered activity in early cycles could increase tumour absorbed dose without increasing normal organ doses. This work modelled the impact of front-loading activity to inform Phase 2 dosing strategies. ***Materials and Methods:*** Using Phase 1 dosimetry data, cumulative tumour absorbed doses were modelled for two dosing regimens: administering 10GBq in cycles 1 and 2, followed by five cycles of 7.4GBq; and administering 14.8GBq in cycles 1 and 2, followed by four cycles of 7.4GBq with all cycles at 6 weekly intervals. These regimens were compared against a flat dosing regimen fractionating 59.2GBq evenly across eight cycles. Adjustments were made accounting for relative differences in total administered activity. ***Results:*** Modelled cumulative organ absorbed doses remained well below the EBRT-derived dose limits for all dosing regimens explored. The relationship between cycle number and tumour absorbed dose was shown to follow a power-law trend of the form $y=An^{-0.74}$, with y being tumour absorbed dose (Gy), A being the baseline tumour absorbed dose at cycle 1 (Gy) and n being the cycle number. Tumour dose improvements were observed with front-loading the activity: Regimen 1 increased tumour dose by 15%, while Regimen 2 achieved a 34% increase compared to a flat dosing regimen, despite equivalent cumulative activity. ***Conclusion:*** Front-loading administered activity in PSMA targeted RLT appears to improve cumulative tumour absorbed dose compared to a flat dosing regimen, without any proportional increase in normal organ dose; this approach exploits the therapeutic index being at its peak during early cycles. This improvement correlates with the proportion of activity front-loaded. However, this approach must be carefully considered in the context of potential increased toxicity risks. The Phase 2 component of this study will compare the efficacy and safety of this dosing strategy with a fixed per-cycle activity approach, where the interval between the first 3 cycles is shortened to 3 weeks, to explore PSMA RLT dose optimisation with ^{177}Lu-rhPSMA-10.1.

EPS-189

Tumour Dosimetry - It's a Gray Area: Analysing the Importance of Lesion-Level Dosimetry Methods in ^{177}Lu-PSMA Targeted Therapy

B. Fongenie, *D. Stevens, N. Scott;*
Blue Earth Therapeutics, Oxford, UNITED KINGDOM.

Aim/Introduction: With the expanding use of radioligand therapy (RLT), dosimetry is increasingly playing a role as a method for drug pharmacokinetic comparisons and as a potential predictor of efficacy. Large cross-trial dosimetry comparisons would permit more robust analysis, but their validity may be undermined by methodological inconsistencies, particularly in tumour selection and contouring. This work analyses a range of tumour dosimetry methods used across ^{177}Lu-PSMA-targeted RLT studies and evaluates their impact within an ongoing Phase 1/2 study. ***Materials and Methods:*** Recent meta-analyses have collated ^{177}Lu-PSMA-targetted RLT dosimetry data from various studies. We categorized these studies by lesion dosimetry methods, focusing on lesion selection and contouring approaches. Absorbed dose estimates were compared across categories defined by significant methodological differences: CT-guided/manual selection and contouring, activity-guided/threshold-based selection and contouring and "other" representing any alternative or unknown approaches. Separately, a phase I experience assessed the impact of dosimetry method on tumour dose estimates. Two approaches were used for tumour selection and delineation. The first was an anatomy-based method; up to 5 tumours were selected blindly on CT (no detail on PSMA expression was provided to the reader) with contours defined by CT morphology. For the second, an activity-based method was used; up to 3 tumours were selected according to their relative uptake on SPECT-CT, tumour volume was determined using PSMA PET thresholding. ***Results:*** Of 16 dosimetry studies analysed, 5 used threshold-based contouring, 6 employed manual methods and 5 used alternative or unspecified methods. For tumour selection, 5 studies favoured avidity, 5 ignored avidity and 6 did not specify their approach. Whilst unknown methods limit statistical analysis of systematic differences, higher tumour absorbed doses were generated using threshold-based vs manual contouring. In the Phase I dosimetry experience, significant differences were found between methods. The anatomy-based method mean tumour dose was 2.4 Gy/GBq (0.4-6.7) compared to the activity-based method equivalent of 8.9 Gy/GBq (2.0-25.6). This represented a 3.7-fold increase in tumour dose. In a minority of cases, where the same lesion was

coincidentally selected for analysis by both methods, this was a 2.6-fold increase. ***Conclusion:*** These comparisons demonstrate the wide variance in dosimetry approaches and reporting. Without harmonisation of methods, the utility of dosimetry data, and the establishment of dose response relationships will remain confounded. At a minimum, studies employing dosimetry should clearly state their lesion selection and contouring methods to allow for more robust and unbiased comparisons.

Intraindividual tumor dosimetry of monomer [^{90}Y] Y-FAPI-46 vs dimer [^{90}Y]Y-DOTAGA-Glu-(FAPI)2 FAP radioligand therapy of advanced stage solid tumors

P. Fragoso Costa[1], *W. Jentzen*[1], *K. Pabst*[1], *I. Mavroeidi*[2], *H. Lanzafame*[1], *R. Hamacher*[2], *J. Siveke*[2], *S. Bauer*[2], *F. Rösch*[3], *J. Kurth*[4], *M. Heuschkel*[4], *K. Herrmann*[1], *D. Kersting*[1], *W. Fendler*[1];
[1]*Clinic for Nuclear Medicine, University Hospital Essen, University Duisburg-Essen, Essen, GERMANY,* [2]*Department of Medical Oncology, West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, GERMANY,* [3]*Department of Chemistry—TRIGA Site, Johannes Gutenberg-University Mainz, Germany, Frankfurt, GERMANY,* [4]*Department of Nuclear Medicine, Rostock University Medical Center, Essen, GERMANY.*

Aim/Introduction: Radioligand therapy with yttrium-90-labeled inhibitors of FAP (FAPI) was introduced clinically with the monomer ligand FAPI-46. The therapeutic value of this RLT is limited by the ligand short residence time in tumors. A promising strategy to enhance tumor retention is to improve the radioligand's pharmacology for its target by dimerizing the binding moiety. This has been demonstrated with [^{177}Lu]Lu-DOTAGA-Glu-(FAPI)2 dimer in patients with medullary thyroid cancer, sarcoma and breast cancer. We present tumor dosimetry in patients that received previous [^{90}Y]Y-FAPI-46 treatment but were excluded to further therapy due to insufficient tumor absorbed doses; thereafter, they were selected for treatment with [^{90}Y]Y-DOTAGA-Glu-(FAPI)2 dimer. ***Materials and Methods:*** Five patients who were pretreated with two cycles [^{90}Y]Y-FAPI-46 were enrolled. An activity of 3.1±0.9 GBq of [^{90}Y]Y-DOTAGA-Glu-(FAPI)2 was intravenously administered in the first cycle (n=5). At each treatment cycle, patients underwent 4 PET/CT scans (1, 4, 20 and 48 h post injection) of areas of tumoral manifestation (solitary fibrous tumors, cholangiocarcinoma and sarcoma). Tumor volumes were derived from intratherapeutic CT or pretherapeutic [^{68}Ga]Ga-FAPI-46 PET images. Effective half-lives and uptake were calculated. For tumor absorbed dose estimation, the sphere model implemented in OLINDA was applied. ***Results:*** Tumor dosimetry comparison was performed at lesion-per-lesion level. A total of 9 primary and metastatic lesions were analyzed (locations: lung, liver, muscle, fatty tissue, bone, and lymph nodes). At a lesion-per-lesion level, FAP-dimer dosimetry showed a mean fold-increase of 3.2 (max: 5.5) on lesion absorbed dose coefficients when compared to the last cycle of the monomer [^{90}Y]Y-FAPI-46. This increase was characterized by an average 1.4-fold increase in lesion maximal uptake and a 2.3-fold increase in lesion effective half-life.Lesions treated with [^{90}Y]Y-DOTAGA-Glu-(FAPI)2 displayed a mean ±SD absorbed dose coefficient of 4.68 (±3.03) Gy/GBq and effective half-lives of 18.9(±3.5) h, while those for [^{90}Y]Y-FAPI-46 displayed 1.77 (±1.23) Gy/GBq and effective half-lives of 8.2 (±2.1) h. ***Conclusion:*** [^{90}Y]Y-DOTAGA-Glu-(FAPI)2 exhibits both prolonged effective half-life as well as increased uptake in tumor, showing promise as an improved therapeutic agent for FAP-expressing tumors. Further absorbed dose-response analyses and dosimetry of organs at risk are warranted.

EPS-191

Stability, Biodistribution, and Patient Dosimetry of [^{177}Lu] Lu-FAP-2286 Radionuclide Therapy

K. Akçay*, T. Toklu, G. Beydagi, H. Adıgüzel, B. Caner, L. Kabasakal, N. Alan;*
Yeditepe University, İstanbul, TÜRKIYE.

Aim/Introduction: Fibroblast activation protein (FAP) is a promising target for the diagnosis and treatment of various tumors. Although the FAP-targeted peptides FAPi-04 and FAPi-46 labeled with ^{68}Ga are widely used for diagnostic purposes, their limited retention hampers their therapeutic utility. FAP-2286, on the other hand, is a promising candidate for therapeutic applications. This study aimed to evaluate the in-vitro and in-vivo stability, biodistribution, and organ and tumor dosimetry of the radiopharmaceutical [^{177}Lu] Lu-FAP-2286. ***Materials and Methods:*** A total of seven therapeutic administrations were performed in five patients (mean age: 61.0±15.3 years; F/M: 2/3) with positive uptake on [^{68}Ga]Ga-FAPi-46 or [^{68}Ga]Ga-FAP-2286 imaging. Each treatment involved an average administration of 215±14.7 mCi of [^{177}Lu]Lu-FAP-2286. Whole-body anterior and posterior planar scans and SPECT/CT images were acquired at 4, 24, 72, and 120 hours post-infusion. Photon attenuation, scatter, and detector/collimator response corrections were applied to the SPECT data. Blood samples were collected at multiple time points up to 120 hours post-infusion for red bone marrow dosimetry and in-vivo stability assessment. Whole-body regions of interest and volumes of interest for kidneys, liver, and tumor lesions were delineated. Time-activity curves were generated and fitted with mono- or bi-exponential functions using MATLAB R2013a to derive cumulative activities. Absorbed dose estimations were performed using IDAC-Dose 2.1 software. ***Results:*** Two patients had pancreatic adenocarcinoma, one had neuroendocrine carcinoma, and two had soft tissue sarcoma. The in-vitro stability of the radiopharmaceutical was determined to be at least 41 hours, while in-vivo stability in blood was confirmed for at least 24 hours. The mean absorbed doses were 0.50 ± 0.19 Gy/GBq for kidneys, 0.030 ± 0.014 Gy/GBq for liver, and 0.054 ± 0.014 Gy/GBq for red bone marrow. The mean tumor dose was calculated as 5.97±3.85 Gy (range: 1.10-18.52 Gy). ***Conclusion:*** No adverse events were observed during therapy, and all patients tolerated the treatment well. At the administered activity levels, toxicity thresholds were not exceeded for the kidneys or bone marrow. Compared to the only published study in the literature, similar bone marrow doses were observed, while renal doses were found to be lower in this study. However, due to the previous study reporting dose data only for bone metastases, a direct comparison with soft tissue tumor doses presented here is not feasible. In conclusion, [^{177}Lu]Lu-FAP-2286 appears to be a promising and safe radionuclide therapeutic agent with potential for clinical application in the treatment of various malignancies.

Aim/Introduction: The phase II LUNAR trial randomized (1:1) oligorecurrent hormone sensitive prostate cancer (HSPC) patients with 1-5 target lesions visible by PSMA-PET to neoadjuvant ^{177}Lu-PSMA-I&T and stereotactic body radiotherapy (SBRT) versus SBRT alone. Here we report a preliminary analysis of the ^{177}Lu-PSMA-I&T dosimetry estimates in organs and tumors. ***Materials and Methods:*** Patients randomized to the investigational group received 2 cycles of neoadjuvant 177Lu-PSMA-I&T (6.8 GBq/cycle) prior to treatment with SBRT. Quantitative SPECT images were acquired at 4, 24, and 72-96h post-injection of the first cycle of 177Lu-PSMA-I&T (vertex to mid-thighs; 60 projections per

detector; 10s per view; reconstructed with 48 iterations 1 subset and no filtering). A low-dose CT scan was performed directly after the SPECT for attenuation correction. Kidneys, salivary glands, lacrimal glands and liver were delineated with deep learning-assisted segmentation, while lumbar vertebrae were manually segmented as a surrogate for bone marrow. Tumor segmentations were transferred from SBRT target volumes to the SPECT/CT series. Multiple timepoint voxel-based dosimetry was used to estimate the absorbed doses (AD). Registration between timepoints was manually verified for each segmentation. Time-activity curves were fit using a mono-exponential function. Partial volume effects were accounted for using a phantom-based recovery coefficient function (using identical SPECT acquisition and reconstruction parameters). ***Results:*** From September 2022 to November 2023, 92 patients were randomized (n=47 SBRT alone, n=45 177Lu-PSMA+SBRT). Median age was 69 and median PSA was 1.1 ng/dL. 38% of patients had M1b disease and 43% of had solitary lesions. The median number of lesions per patient was 2 (1-9): with a PSMA PET median SUVmax of 3.6 (1.1 - 45.3). A total of 15/45 patients from the investigational arm were included in this preliminary analysis. The AD to the kidneys, parotid glands, submandibular glands, lacrimal glands, liver, and bone marrow were 0.36 ± 0.11; 0.21 ± 0.10; 0.26 ± 0.10; 0.74 ± 0.48; 0.03 ± 0.02; and 0.01 ± 0.002 Gy/GBq, respectively. The mean dose and volume of bone (n=10), lymph node (n=16), and soft tissue (n=1) lesions were 0.33 ± 0.65 Gy/GBq (8.67 ± 3.43 mL), 0.58 ± 0.76 Gy/GBq (3.95 ± 2.90 mL), and 0.79 Gy/GBq, (3.76 mL), respectively. ***Conclusion:*** In this preliminary report of 15 patients with oligorecurrent prostate cancer treated with ^{177}Lu-PSMA-I&T, the dose estimates to organs at risk were comparable to previously published data. There was substantial heterogeneity in tumor absorbed dose estimates on both inter- and intra- patient levels.
