the generalizability of DL-PVC in ^{177}Lu SPECT across systems from the two main manufacturers and evaluated whether transfer learning can improve cross-scanner performance. ***Materials and Methods:*** Realistic SPECT projections of 2500 random ^{177}Lu activity distributions within extended cardiac-torso phantoms were generated for two scanners (GE Discovery D670 + MEGP and Siemens Intevo Bold + MELP) as described previously using the SIMIND Monte Carlo program [1, 2]. Reconstructions were performed with PyTomography (OSEM, 20i, 4s, AC, TEW-SC, resolution modeling) [3]. Scanner-specific R2UNet models were trained separately on 1900 ground-truth/simulation pairs. Transfer learning was applied by further training each model using 25/50/100/200/500 datasets specific to the other scanner, with scanner-specific sensitivity differences accounted for. Performance was assessed on 100 independent test datasets using SSIM, NRMSE, and VAA (volume activity accuracy**,** defined as the fraction of voxels with estimated activity deviations ≤ 5% from the true value). ***Results:*** The GE-trained model achieved SSIM/NRMSE/VAA of 0.92/4.8%/21.7% on GE and 0.91/5.4%/17.0% on Siemens test data. Similarly, the Siemens-trained model yielded 0.94/5.6%/25.4% on Siemens and 0.93/5.0%/18.1% on GE data (without PVC: 0.88/5.8%/7.4% for GE and 0.89/5.7%/8.4% for Siemens). Transfer learning notably improved cross scanner performance: On the new scanner, performance increased substantially with as few as 25 training samples and approached that of natively trained models with more data, following non-linear, saturating trends (0.93/4.8%/21.7% to 0.93/4.7%/22.6% for GE-to-Siemens transfer using 25 to 500 samples). Meanwhile, performance on the original scanner gradually declined (0.92/4.8%/19.3% to 0.92/4.8%/17.6%), indicating a trade-off during adaptation. A similar pattern was observed for Siemens-to-GE transfer, with improvements on GE and slight performance loss on Siemens. ***Conclusion:*** Transfer learning substantially improves the generalizability of DL-PVC across SPECT/CT systems, with most benefit achieved using as few as 25 datasets from the new scanner. However, this comes at the cost of reduced performance on the original scanner, highlighting a trade-off between domain adaptation and retention. These findings support transfer learning as a promising strategy for cross-scanner harmonization, while underlining the need for balanced adaptation in clinical deployment. ***References:*** [1] Leube et al. Feasibility of artificial deep learning based 220 ps time-of-flight (TOF)

F. Kaser[1,2,3], *M. Pires*[1], *S. Gutschmayer*[1], *D. Ferrara*[1], *B. Geist*[4], *W. Langsteger*[4], *T. Beyer*[1], *I. Rausch*[1];
[1]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*University of Kaiserslautern-Landau, Kaiserslautern, GERMANY,* [3]*OMS HTS GmbH, Wels, AUSTRIA,* [4]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Recent advances in PET detector development have paved the way for clinical TOF resolutions of ~200 ps. Furthermore, advances in AI have led to the integration of AI-based TOF simulations in non-TOF PET systems of 385 ps and 550 ps timing resolutions [1]. In this study, the feasibility to emulate a 220 ps TOF using AI was assessed. ***Materials and Methods:*** Whole-body [18F]FDG-PET data of 130 examinations (training: 126, testing: 4) from two PET systems with the same detector technology with 220 ps TOF resolution were reconstructed with and without TOF information using the same parameters (OSEM+PSF: 21 subsets 2 iterations). The images were normalised using standard score and divided into patches of 96 slices. A classic 3D U-net structure was used as the base of the model to predict TOF from non-TOF images. The model was adapted to 3D images, kernel size 3, going from 64, 128, 512 to 1024 kernels in the respective layers, and using residual connections. For model optimisation a variation of hyperparameters and input resolutions were tested. The holdout datasets were evaluated visually, through %-difference images and performance parameters of mean square error (MSE) and structural similarity index measurement (SSIM). ***Results:*** Two models with different input resolutions (1.65 and 3 mm) with a learning rate of 0.05, and 100 and 200 Epochs were selected for their performance. In high-activity regions, like brain and bladder, perceived image quality improved, while there was minimal impact on low uptake regions. The DL-TOF models reduced the MSE compared to the non-TOF reconstructions by 21% (SD= 2%) and 26% (SD= 5%) respectively, while only minor changes in SSIM were observed. ***Conclusion:*** The current implementation of a 220 ps DL-TOF improves non-TOF image quality and the MSE in areas of high tracer activity areas without yielding true TOF accuracy. Since the quality and spread of the training data affect model performance, separate models would need to be trained for different image resolutions. ***References:*** [1] Mehranian, A., Wollenweber, S.D., Walker, M.D. et al. Deep learning-based time-of-flight (ToF) image enhancement of non-ToF PET scans. EJNMMI, 2022;49:3740-3749.

Accelerated PET Imaging with a Gated Autoregressive Diffusion Network

X. Xie[1,2], *Y. Gao*[1,2], *N. Zhang*[3], *Y. Yang*[1,2], *H. Zheng*[1,2], *D. Liang*[1,2], *Z. Hu*[1,2];
[1]*Research Center for Medical AI, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA,* [2]*Key Laboratory of Biomedical Imaging Science and System, Chinese Academy of Sciences, State Key Laboratory of Biomedical Imaging Science and System, Shenzhen, CHINA,* [3]*Lauterbur Research Center for Biomedical Imaging, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA.*

Aim/Introduction: Prolonged PET acquisition times often cause discomfort and motion artifacts, limiting its use in vulnerable patients. Clinically, there is a growing need for faster, safer imaging without compromising diagnostic quality. To address this, we propose a gated autoregressive diffusion model that reconstructs high-quality images from short-duration scans by modeling the PET formation process and temporal dynamics. This approach enhances image quality under low-dose conditions and improves the clinical usability of PET. ***Materials and Methods:*** We used the Ultra-low Dose PET Challenge Dataset with 1060 whole-body [18F]FDG PET scans. Data were normalized to SUV units to enable clinical interpretability and efficient comparison. Experiments focused on DRFs of 20 to simulate 20× scan time reduction. We propose a Gated-Autoregressive Diffusion framework to reconstruct high-quality PET images from short-duration scans. First, we introduce a pixel-wise degradation operator that models photon accumulation as a Poisson-Gaussian process, enabling realistic simulation of PET signal degradation across acquisition durations. This operator ensures alignment between forward degradation and reverse reconstruction trajectories. The degradation operator is as follows: $x_t(i,j)=(1-\alpha(i,j)(t))x_0(i,j)+\alpha(i,j)(t)x_T(i,j)+\eta_t(i,j)$, where $x_0(i,j)$ is the pixel intensity from a short-duration PET scan,$x_T(i,j)$ is the corresponding pixel intensity from a full-duration PET scan,$\alpha(i,j)$ is a pixel-specific normalized weight dictating the transition from $x_0(i,j)$ to $x_T(i,j)$. $\alpha(i,j)(t) = N(i,j)(t)/N(i,j)(T)$,$N(i,j)(t)\sim Poisson(\lambda(i,j)t)$ $\eta_t(i,j)$ is a Gaussian-distributed noise term that simulates system and detector noise. To restore lost information, we embed a Gate-Autoregressive Module (GAM) within a cold diffusion framework. At each step, an intermediate full-scan estimate is obtained via a restoration network and then redegraded for consistency. GAM, inspired by LSTM, integrates

CBAM and GLU-based attention to retain temporal context and suppress cumulative errors. ***Results:*** Experiments on the Ultra-low Dose PET Challenge dataset demonstrate that our model outperforms state-of-the-art methods in SSIM, PSNR, and RMSE. Compared to UNN and CoreDiff, our model achieves improved structural fidelity and reduced error. Our method generalizes well across different scan durations, producing reliable outputs, highlighting its clinical robustness and adaptability. ***Conclusion:*** Our proposed gated autoregressive diffusion model enables accurate PET reconstruction from short-duration scans. It effectively reduces noise, preserves anatomical details, and outperforms existing methods across multiple metrics. The model also generalizes well to different scan durations, demonstrating strong clinical potential for fast, low-dose PET imaging applications.

A Quantitative CT-less Reconstruction Workflow for Long-axial Field-of-view PET Scanners with Enhanced Scaling

M. Teimoorisichani[1], *J. Schaefferkoetter*[1], *V. Panin*[1], *H. Sari*[2,3], *A. Rominger*[2];
[1]*Siemens Medical Solutions USA Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [2]*Bern University Hospital, Bern, SWITZERLAND,*
[3]*Siemens Healthineers International AG, Zurich, SWITZERLAND.*

Aim/Introduction: The joint estimation problem in maximum likelihood estimation of activity and attenuation (MLAA) is ill-posed and non-unique, leading to scaling issues in MLAA-reconstructed images. While time-of-flight (TOF) improves spatial localization and mitigates scaling, it may not fully resolve the issue, particularly with inconsistent or noisy data. This work introduces a quantitative CT-less reconstruction workflow based on TOF-MLAA, incorporating a novel approach to address scaling. ***Materials and Methods:*** The proposed method is designed for PET scanners with lutetium-based scintillators. We use attenuation maps (μ-maps) derived from lutetium background radiation as an initial condition in TOF-MLAA [1]. To further mitigate scaling issues, a partially known μ-map is employed to determine and apply a scaling factor to reconstructed images. In the absence of ground-truth μ-maps in CT-less PET, we utilize a deep learning (DL)-based organ segmentation algorithm to segment non-attenuation-corrected PET images. The mean attenuation coefficient of an organ minimally affected by MLAA cross-talk (the liver in ^{18}F-FDG studies) is then compared to a nominal value (0.1 cm^{-1} for the liver). The resulting offset is used to calculate and apply a scaling factor within MLAA. This approach is particularly suited for lutetium-based long-axial field-of-view (FOV) PET scanners, where the high lutetium background radiation flux allows for a transmission reconstruction with acquisitions as short as a few minutes. We evaluated the proposed CT-less reconstruction framework on three patients scanned with ^{18}F-FDG using a long-axial FOV PET/CT scanner (Biograph Vision Quadra, Siemens Medical Solutions USA, Inc.). ***Results:*** Evaluation of reconstructed PET images from the three patients indicates that the proposed CT-less approach yields images comparable to CT-based PET images. Reconstructed μ-maps from MLAA showed excellent consistency with CT-based μ-maps, with minimal inconsistencies due to cross-talk. The final PET images were comparable to reference images both qualitatively and quantitatively, with individual organ uptake values within 5% of those from CT-based reconstructions. ***Conclusion:*** A CT-less PET reconstruction workflow based on lutetium background radiation and TOF-MLAA is proposed in this work in which a novel approach is used to address the problem of scaling. ***References:*** [1] Teimoorisichani M, et al. Segment-wise loss function and object informed deep learning improves the preservation of small details in PET image denoising

Y. Salimi, *Z. Mansouri, H. Zaidi;*
Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: Faster PET image acquisition or lower radiotracer is desired PET imaging. Deep learning (DL) has shown a promise, however, conventional DL training focusing on voxel-wise metrics and loss functions have limitations in preserving small or low contrast details and tend to over-smooth images. In this study, we implemented prior knowledge of all details in a PET image through delineation of every structures with nn-interactive model and used them for training. ***Materials and Methods:*** We used a sample of publicly available dataset from the Ultra-Low-Dose PET Challenge (1) to train two models, conventional training and segment-wise loss training. In the first strategy, five-fold cross-validation was performed using U-Net models trained to map 10%-dose PET images to full-dose equivalents. Each model trained for 100 epochs with an L1 loss. In the second strategy, full-dose PET images were segmented using nn-interactive models (2) prompted every 20 mm along the body contour which resulted in about 2000 objects detected in each PET image. These objects were used to train models using the same data split. Segment-wise loss function was computed separately for each segmented object and used for training the same model. Both strategies were evaluated on an external test set using voxel-wise and segment-wise performance metrics calculated in all segmented objects. ***Results:*** The model trained with segment-wise loss outperformed the conventional model by better preserving image details, as evidenced by improved segment-wise relative absolute error (7.3 ± 6.7% vs. 13.1± 8.8%, respectively). In addition, the voxel-wise RMSE was reduced by 24% in segment-wise loss models. Visual assessment further confirmed reduced over-smoothing and enhanced structural detail in segment-wise loss models. ***Conclusion:*** Deep learning denoising task can be viewed as a decision-making process about an object in noisy PET image to be kept as important detail or to be removed as a noise. The whole image loss function averaged over all voxels in an image tend to smooth the images because they return a better overall score when small objects are removed. Our innovative method for segmenting all objects in PET images and using that information to guide the DL model and loss function to preserve the small details in the image showed a better performance in comparison with the conventional training method. ***References:*** 1.Xue S, et al. High-Quality Cardiac SPECT Reconstruction from Half-Projections Using a U-Net with Difference Mask: A Deep Learning Approach for Fast Cardiac Scan

P. Sheikhzadeh[1], *S. Khalili*[1], *N. Seyyedi*[2];
[1]*Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Health Management Research Institute, Iran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: This study aimed to develop and evaluate a deep learning method based on a U-Net neural network with a difference mask approach to reconstruct high-quality cardiac SPECT images from half-projection data. The primary goal was to reduce scanning time and patient radiation dose while maintaining diagnostic image quality. ***Materials and Methods:***

The dataset comprised 362 DICOM images from cardiac SPECT scans, with each image available in full-projection (64 projections) and half-projection (32 projections) versions. Half-projection data were upsampled to generate input images. A U-Net model with a difference mask approach was designed to predict the difference between upsampled and full-projection images. The model was trained using 5-fold cross-validation, with a combined loss function (50% MAE, 25% ME, 25% SSIM) and the AdamW optimizer. Performance was evaluated using mean absolute error (MAE), mean error (ME), root mean square error (RMSE), structural similarity index (SSIM), and peak signal-to-noise ratio (PSNR). ***Results:*** The U-Net model successfully reconstructed high-quality images closely resembling full-projection images from half-projection data. In cross-validation, the average SSIM was 0.9346, and the average PSNR was 40.32 dB. The average MAE was 0.006839, and the average RMSE was 0.020174, indicating high reconstruction accuracy. Model predictions for all original data were saved in DICOM format. ***Conclusion:*** Quantitative results demonstrate that the U-Net model with a difference mask approach can reconstruct high-quality cardiac SPECT images from half-projection data, preserving structural similarity and minimizing errors. This method offers potential for reducing scanning time and radiation dose without compromising critical diagnostic information. ***References:*** 1. Aghakhan Olia, Narges, et al. Aim/Introduction: This study aimed to evaluate the diagnostic reliability and image quality improvement of a deep learning-based denoising method applied to myocardial perfusion SPECT, particularly under conditions of reduced radiotracer dose or acquisition time. ***Materials and Methods:*** A total of 294 cardiac SPECT exams were retrospectively selected from two imaging systems (Siemens Symbia Intevo and GE Millennium MG). A total of 260 exams were used to train a dual-domain AI model, yielding 46,800 projections via synthetic noise simulation at 25% and 50% count levels[1]. The validation set included 34 patients (n=10 GE; n=24 Siemens). A nuclear medicine physician assessed subjective image quality using a 5-point Likert scale. Myocardial ischemia was evaluated using the Summed Stress Score (SSS) for both original and AI-enhanced images. ***Results:*** Standard [MM1] SPECT images received an average Likert score of 3.6, while AI-enhanced half-time images achieved 4.0. The mean difference in SSS between the methods was 1.2 (95% CI: ±4.8). Only 9% of patients changed risk classification between the AI-reconstructed and standard methods. This variability is lower than the inter-observer variability reported in the literature for standard clinical reads (13-20%)[2]. ***Conclusion:*** The deep learning-based denoising method preserved diagnostic performance in low-count cardiac SPECT while enhancing subjective image quality. The AI reconstruction introduced less variability than that associated with expert interpretation, supporting its clinical viability in dose/time-reduction protocols. ***References:*** 1. PET quantification accuracy using FastPET in ultra-short frames on the Biograph Vision Quadra PET/CT

V. Nadig[1,2], *D. Darian*[1], *Y. Zheng*[3], *M. Zhang*[3], *D. Bharkhada*[3], *M. Millardet*[4,3], *G. Krokos*[2], *L. Davies*[2], *P. Marsden*[2], *M. Conti*[3], *P. Schleyer*[3];
[1]*Siemens Healthcare Limited, Camberley, UNITED KINGDOM,* [2]*PET Centre, School of Biomedical Engineering and Imaging Sciences, King's College London, London, UNITED KINGDOM,* [3]*Siemens Medical Solutions USA Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [4]*Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: With convolutional neural networks (CNN) becoming increasingly important for near real-time image reconstruction, their applicability for ultra-fast dynamic imaging requires investigation. We assess the image quality and quantitative accuracy of FastPET [1,2], a CNN for direct reconstruction from histoimages, in comparison to ordered-subset estimation maximization (OSEM). ***Materials and Methods:*** On a Biograph Vision Quadra PET/CT (Siemens Healthineers), we acquired a ten-minute scan of a NEMA-IQ phantom (18F-FDG, 5:1-ratio, 82 MBq, CT: 120 kV/50 mAs) covered in 3-5 cm tissue-equivalent material. FastPET images were reconstructed in 1.65 mm x 1.65 mm x 1.65 mm voxels and in 15 frame lengths between 0.1-600 s. We provide OSEM reconstructions (4i5s, PSF-TOF, UHS) for frame lengths between 1-600 s. For both methods, fixed 50%-threshold-3D-sphere-isocontours were determined from the ten-minute scan. Mean standard uptake values (SUV_{mean}) and contrast recovery ratio (CRC_{mean}) were evaluated as a function of number of the prompts in each frame. The background variability (BV) was examined using twelve spherical regions (10-37 mm diameter). ***Results:*** For the ten-minute scan (~10^9 prompts), OSEM and FastPET resolve all six spheres (diameters: 10,13,17,22,28,37 mm). For frames ≤5 s (≤10^7 prompts), the smallest sphere becomes undetectable for both reconstructions. For 1-s OSEM images (~$1.5x10^6$ prompts), we can identify the 22-37-mm spheres. For 200 ms (~$3x10^5$ prompts), FastPET detects the 17-37-mm spheres. The spheres show Gibbs artifacts and are slightly non-uniform, probably due to the phantom being out-of-distribution data. The OSEM BV increases to 6.2-46.3 % in low-count regimes ($1.5x10^6$ prompts), whereas FastPET maintains a much smoother background (BV 1.5-3.2 % for $1.5x10^6$ prompts). With OSEM, the SUV_{mean} remains stable for 5-600 s frames (~10^7-10^9 prompts) for 17-37-mm, before deteriorating for shorter frames. For 10-13-mm spheres, OSEM maintains this performance except for 1-5-s frames (~$1.5x10^6$-10^7 prompts). For FastPET, the SUV_{mean} behaves the same, except for the two smallest spheres, where it continuously decreases until reaching background level for frames ≤5 s. For the 37-mm sphere, the CRC_{mean} with FastPET in 100 ms frames (~$1.5x10^5$ prompts) is 75 %. ***Conclusion:*** FastPET provides comparable quantitative metrics and improved image quality to OSEM for a wide range of count regimes. Recent studies have shown improved quantification on patient data [3]. FastPET is therefore an attractive solution for near real-time reconstruction in dynamic applications requiring ultra-short frames, such as kinetic analysis or gating. ***References:*** [1] Whiteley et al. 10.1109/TRPMS.2020.3028364 [2] Whiteley et al. patent 11164344 [3] Millardet et al. 10.1109/NSSMICRTSD49126.2023.10338495.

Low-Dose to Standard-Dose PET Reconstruction Using Cross-Slice Diffusion TransformerAim/Introduction

T. Sun, *X. Chen, S. Wang;*
Chinese Academy of Sciences, Shenzhen, CHINA.

Aim/Introduction: Low-dose PET (LD-PET) is a promising approach for reducing radiation exposure in clinical imaging, particularly for patients requiring repeated scans. However, LD-PET often suffers from degraded image quality, which compromises diagnostic accuracy. This study presents CrossVision-DT, a novel diffusion-based Transformer model that incorporates Cross-Slice Attention to reconstruct standard-dose PET (SD-PET) images from LD-PET inputs, achieving improved image quality while maintaining efficiency and interpretability. ***Materials and Methods:*** CrossVision-DT follows a two-stage training strategy: first, a diffusion Transformer is pre-trained on 2D slices to capture intra-slice details; second, the model is fine-tuned using a novel Cross-Slice Attention Layer to learn inter-slice dependencies across consecutive PET slices. The architecture includes a patch-based noise prediction module with cross- and self-attention mechanisms, and a customized attention layer designed to align adjacent slice features through dimensional transformation. The model was trained and evaluated on the publicly available Ultra-Low Dose PET Imaging Challenge dataset and further tested on a local clinical dataset. Reconstruction performance was quantitatively assessed using NMSE, SSIM, and PSNR, while diagnostic utility was evaluated using SUVR consistency and AUC from classification tasks. ***Results:*** CrossVision-DT achieved superior performance on both datasets. On the public dataset, it reached an NMSE of 0.191, SSIM of 0.966, and PSNR of 34.616 dB. On the local dataset, it achieved NMSE of 0.321, SSIM of 0.912, and PSNR of 30.214 dB, without additional fine-tuning. The model maintained excellent SUVR consistency (mean difference: 0.04; 95% limits of agreement: -0.29 to 0.37) and even surpassed standard-dose PET in downstream diagnostic classification tasks. ***Conclusion:*** CrossVision-DT introduces a new paradigm for LD-PET reconstruction by integrating a diffusion Transformer architecture with a cross-slice attention mechanism. The model delivers robust reconstruction quality and strong clinical interpretability, outperforming existing LD-PET reconstruction methods on both quantitative metrics and diagnostic relevance. This method offers a practical and effective solution for reducing radiation dose in clinical PET imaging without compromising diagnostic accuracy.

Feasibility of Pediatric Brain Imaging with a Palm-Sized Dual-Head PET: Monte Carlo-based Evaluation of Limited Angle and Attenuation Effects

V. Sihotang[1,2], *M. George*[3,2], *K. Brazenski*[4,2], *Y. Ni*[5], *C. Zorraquino*[2], *M. Nemallapudi*[6,2], *H. Lin*[1,7];
[1]*Chang Gung University, Taoyuan, TAIWAN,* [2]*PraanaTech, Chicago, IL, UNITED STATES OF AMERICA,* [3]*Institute of Physics Academia Sinica, Taipei, TAIWAN,* [4]*Instituto de Fisica Corpuscular (IFIC), Universitat de València, Valencia, SPAIN,* [5]*National Atomic Research Institute, Taoyuan, TAIWAN,* [6]*University of Chicago, Chicago, IL, UNITED STATES OF AMERICA,* [7]*Chang Gung Memorial Hospital Linkou Branch, Taoyuan, TAIWAN.*

Aim/Introduction: Palm-sized dual-head PET systems offer a promising solution for pediatric brain imaging due to their small form factor, portability, and potential cost-effectiveness. However, the limited angular coverage of such ultra-compact systems may compromise image quality and quantitative accuracy. This study investigates the feasibility of pediatric brain imaging using a palm-sized dual-head PET system through GATE-based Monte Carlo simulations, focusing on the effects of limited angle acquisition and attenuation correction. ***Materials and Methods:*** The proposed PET system was designed as a palm-sized module with a 10 cm x 5 cm Field of View (FOV), suitable for pediatric applications. The system was configured with 2 detectors acquiring data at varying numbers of angular views (1, 2, 4, 6, and 12), uniformly distributed over 180°. This design simulates limited-angle acquisition scenarios and evaluates the angular range required for adequate image reconstruction. Two simulation datasets were generated using the GATE Toolkit: one with a non-attenuating phantom and the other with attenuation phantom to model phantom absorption and scatter in brain tissue. Image reconstruction was performed using a 3D Maximum Likelihood Expectation Maximization (MLEM) algorithm. For the attenuation dataset, a Gaussian kernel was applied during reconstruction to reduce image noise and enhance smoothness. ***Results:*** Preliminary results demonstrated the effectiveness of a compact PET system in reconstructing brain structures from attenuated data across varying angular distributions. Comparing the reconstructions using 6 and 12-angle configuration shows that increasing number of angles improves structural similarity while maintaining consistent variability across slices. The evaluation of SSIM values for deeper brain regions showed that 12 angle configurations achieved higher mean SSIM of 0.84 ± 0.014 compared to 0.75 ± 0.013 for the 6 angle configurations. These results indicate that higher number of angular views is essential for enhanced image quality, especially for deeper brain regions, where attenuation effects are more significant. The MLEM algorithm effectively enhanced reconstruction fidelity, but further optimization of attenuation and scatter corrections is necessary for quantitative accuracy. ***Conclusion:*** This study supports the feasibility of using a palm-sized dual-head PET system for pediatric brain imaging. With continued refinement of quantification correction techniques, the system has the potential to offer portable, cost-effective alternative for pediatric neuroimaging in both clinical and research settings.

EP-0977

Clinical Reliability of Half-dose Rubidium-82 Perfusion Imaging with Positron Range Correction

M. Omaygenc[1], *Y. Kadoya*[1], *M. E. Casey*[2], *M. Conti*[2], *R. S. B. Beanlands*[1], *R. A. DeKemp*[1];
[1]*University of Ottawa Heart Institute, Ottawa, ON, CANADA,* [2]*Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: Rubidium-82 is the most used Positron Emission Tomography (PET) tracer in myocardial perfusion imaging. However, the spatial resolution of Rb-82 images is limited by the high energy positrons with a longer positron range (~7 mm in water). Therefore, positron range correction (PRC) reconstruction algorithms may improve the image quality and allow further dose reduction. ***Materials and Methods:*** The vendor point spread function (PSF) reconstruction method was adapted to include a Gaussian model for Rubidium-82 positron range correction (PRC) that varies with the radial offset (Panin et al. IEEE 2006). Twenty-one patients (61±11 years, 29% female, BMI 42.7 ±13.2) were scanned with half-dose and full-dose rubidium-82 at rest. The noise level of PRC half-dose (HD) rest images was compared visually to the standard full-dose (STD-FD) rest images (without PRC) by two level 3 readers using a scale of 1-5. Their preference for clinical interpretation was also recorded. ECG-gated images were analyzed for quadrant values of relative perfusion, summed rest score (SRS), and functional measures. ***Results:*** The readers had good agreement (κ: 0.61-0.69) on the noise levels scored on each image set (4.4 ± 0.7 vs 4.3 ± 0.7). There was no preference between PRC-HD or STD-FD images for clinical interpretation in 16/21 patients, and a small bias toward PRC-HD in 3 of the 4 remaining patients. There was no significant difference in SRS scores (1.2 ± 3.5 vs 1.1 ± 3.9; p=0.540). Left ventricle function measures were also similar between image sets. The relative perfusion values for PRC-HD and STD-FD images were comparable in all four left ventricular

walls (septum: 85.7 vs 87.3, p=0.084; lateral: 88.0 vs 88.3, p=0.61; anterior, 86.3 vs 88.3, p=0.88; inferior. 86.8 vs 87.8, p=0.079). There was good uniformity across the walls (ANOVA F=1.93; p=0.13). No differences between PRC-HD vs STD-FD were significantly greater than 2% using 2-sided test of equivalence. ***Conclusion:*** PRC-HD imaging provided comparable image quality with STD-FD imaging and yielded similar interpretation results in terms of relative perfusion and LV function measures. Dose reduction with preserved image quality is of particular importance for the patients with higher body mass index and it may allow exponential dose titration in the entire spectrum without exceeding the limits of generator elution and detector saturation. ***References:*** Panin VY, Kehren F, Michel C, Casey M. Robust self-supervised deep learning reconstruction model for reduced ^{89}Zr-girentuximab PET scan time

C. Pain[1,2], *S. Wail*[3], *T. Sepehrizadeh*[3], *Z. Chen*[1,2];
[1]*Monash Biomedical Imaging, Melbourne, AUSTRALIA,* [2]*Faculty of Information Technology, Monash University, Melbourne, AUSTRALIA,* [3]*Telix Radiopharmaceuticals, Melbourne, AUSTRALIA.*

Aim/Introduction: This study aims to implement scan time reduced ^{89}Zr-girentuximab PET imaging using robust self-supervised deep learning with latent-space kernel functions , by recovering 20-minute acquisition quality images from 5-minute acquisition data. The approach aims to provide more robust performance relative to conventional supervised deep learning in terms of lesion recovery and requires no 20-minute acquisition data in training. ***Materials and Methods:*** N=49 patients were administered between 20 and 47 MBq of ^{89}Zr-girentuximab and received a 20-minute PET and low-dose CT 3 to 4 days post radiopharmaceutical administration, with 5-minute data reconstructed from the first 5 minutes of acquisition. A deep kernel network [1,2] was trained with 5-minute PET scans and low-dose CT using self-supervised learning. Subject-specific fine tuning was implemented for tunable lesion recovery. A UNet trained with supervised learning was used as a reference method. Five-fold cross validation with a training, evaluation and testing split of 41,3,5 was used for all training tasks. Methods were evaluated in terms of lesion SUV_{max} and SUV_{mean} with reference to corresponding 20-minute scans. A total of 21 lesions were segmented from 19 evaluation subjects. Robustness was evaluated by comparing performance in three test cases with lowest quantitative accuracy. The peak signal-to-noise ratio (PSNR) across test subjects was evaluated. ***Results:*** Comparing with the 20-minute scans, the mean (standard deviation) of relative error of the 5-minute scan in SUV_{mean} for lesions was 0.06 (0.03) and 0.05 (0.02) and mean (standard deviation) of relative error in SUV_{max} for lesions was 0.10 (0.05) and 0.08 (0.04) for supervised learning and the proposed method, respectively. The three cases with lowest accuracy for both deep learning methods had a mean (standard deviation) in SUVmax relative error of 0.13 (0.05) and 0.10 (0.04) for the supervised method and the proposed method, respectively. The mean (standard deviation) of PSNR across the evaluation set was 29.6 (0.5) and 28.7 (0.8) for supervised learning and the proposed method, respectively. ***Conclusion:*** Self-supervised latent-space kernel functions demonstrate tunability and improved lesion recovery from fast acquisition data as compared with supervised learning, while demonstrating robust performance for out-of-distribution cases. Further work to regularise reconstruction for noise control may improve trade-offs between lesion recovery and PSNR. The authors acknowledge 89Zr-DFO-girentuximab PET datasets used in this study were provided by Telix Pharmaceuticals. ***References:*** [1] C.D Pain, et al., 2024, arxiv, https://arxiv.org/abs/2409.06198[2] C.D Pain, et al., 2024, IEEE ISBI, pp. 1-4.

Wavelet Diffusion Modeling Enables Individualized FDG-PET Synthesis for Early Diagnosis of Neurodegenerative Diseases

J. Ding[1], *X. Song*[2], *M. Marcus*[2], *X. Li*[2], *J. Zhao*[1];
[1]*Department of Nuclear Medicine, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, CHINA,* [2]*Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Neurodegenerative diseases such as Alzheimer's disease (AD) and Parkinson's disease (PD) are irreversible, but early intervention during the presymptomatic stage can slow disease progression. FDG-PET enables the detection of glucose metabolism changes in the brain, offering potential for early diagnosis. However, individual variability in FDG metabolism poses challenges for quantitative assessment. This study aims to develop a deep learning model capable of generating individualized healthy FDG-PET templates to facilitate voxel-wise comparison and precise identification of metabolic changes. ***Materials and Methods:*** A Wavelet Diffusion Model (WaveDM) was employed to synthesize FDG-PET images from T2-weighted MRI. This generative framework combines wavelet decomposition and diffusion modeling for high-resolution 3D image-to-image translation. A dataset of 1,060 paired PET/MRI scans was used for training and validation (9:1 split), with an additional 158 AD cohort scans (Normal Control (NC), Mild Cognitive Impairment (MCI), and AD) for testing. Model performance was compared to a 3D U-Net baseline using normalized root mean square error (NRMSE), peak signal-to-noise ratio (PSNR), and structural similarity index measure (SSIM). Qualitative assessments are ongoing, with physicians reviewing the synthesized PET images and evaluating diagnostic accuracy in differentiating AD, MCI, and NC using voxel-wise difference maps from the individualized healthy templates. ***Results:*** The WaveDM model demonstrated superior performance compared to the baseline U-Net model on the validation dataset, achieving a 12.3% increase in PSNR, a 6.6% improvement in SSIM, and a 20.5% reduction in NRMSE. Testing on the AD cohort demonstrated the model's ability to differentiate between NC, MCI, and AD through voxel-wise difference map analysis. ***Conclusion:*** The WaveDM framework offers a robust approach for generating individualized FDG-PET templates from MRI data. By enabling precise voxel-wise metabolic assessment, it holds promise for improving the early diagnosis and management of neurodegenerative diseases. ***References:*** Rau A, Schröter N, Blazhenets G, Maurer C, Urbach H, Meyer PT, Frings L. PET-like images from ^{177}Lu-PSMA post-therapeutic SPECT showing increased contrast of metastatic lesions

F. Moradi, *T. Otani, H. Song, G. Davidzon, K. Guja, A. Iagaru;*
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Post-therapeutic SPECT/CT is useful for monitoring radioligand therapy in prostate cancer. However, lesions have low contrast compared to pre-treatment PSMA PET, limiting longitudinal comparison. Image-to-image translation models with paired or unpaired data can produce PET-like images (synthetic PET) which could be easier to assess. We examined how synthetic PET affects the contrast of metastatic lesions. ***Materials and Methods:*** 72 prostate cancer patients treated with ^{177}Lu-PSMA therapy were used for development and training Pix2Pix[1] and CycleGAN[2] image-to-image translation models. Each model was trained multiple times with small changes in parameters and randomizing the order of training. For Pix2Pix, the post therapy SPECT/CT after 1st cycle of Lu177-PSMA-611 was paired

with anatomically co-registered pre-treatment PSMA PET in the same patient. For CycleGan, the same data without pairing and in a randomized order was used. Models were then tested in 10 patients that were not included in the training dataset. For each patient, up to 6 dominant lesions were included in the analysis. Contrast was defined as the ratio between uptake in the lesion ROI and blood pool. Sensitivity of lesion uptake to training was quantified using coefficient of variation. Synthetic images were subjectively evaluated by four nuclear medicine physicians for realism and similarity to PET. ***Results:*** Of 7 models trained using unpaired data, one failed to produce realistic looking images. All 5 models trained using paired data produced realistic-looking PET-like images. We therefore included these 5 models in subsequent analysis. Of 58 lesions, the average lesion to blood pool ratio was 2.63±0.13 times higher on synthetic PET compared to the original SPECT (5.42±4 vs. 2.17±1.44, R^2=0.88, p<0.0001). Only two lesions had similar or lower contrast compared to SPECT. The liver to blood pool ratio on synthetic PET was also higher than on SPECT as the models captured the differences between physiologic distribution of PET vs therapy radiopharmaceutical (2.5 vs. 1.2). The median coefficient of variation for lesion uptake was 0.39 (IQR 0.31 - 0.49). ***Conclusion:*** SPECT-to-PET translation with conditional adversarial networks using paired training data is feasible and not sensitive to the order of training or minor changes in model parameters. Resulting images demonstrate markedly improved contrast of metastatic lesions. ***References:*** 1) Isola, Phillip, et al. Proceedings of the IEEE conference on computer vision and pattern recognition. 2017. 2) Zhu, Jun-Yan, et al. Proceedings of the IEEE international conference on computer vision. 2017.

Low-Dose Dynamic [^{18}F]FDG Brain PET Imaging: Near Real-Time Reconstruction with FastPET

M. Kvistholm[1], *N. Overbeck*[1], *A. B. Rodell*[2], *D. Bharkhada*[2], *N. Murthy*[2], *Y. Zheng*[2], *M. Conti*[2], *U. Lindberg*[1], *T. L. Andersen*[1,3], *F. L. Andersen*[1,3];
[1]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital, Copenhagen, DENMARK,* [2]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [3]*Department of Clinical Medicine, Copenhagen University, Copenhagen, DENMARK.*

Aim/Introduction: Positron emission tomography (PET) enables dynamic imaging of metabolic processes using radiotracers. Accurate tracer kinetic modelling requires high temporal resolution images, which are computationally demanding to reconstruct using conventional iterative methods such as Ordinary Poisson Ordered Subsets Expectation Maximisation (OP-OSEM). Low-dose PET introduces more noise, which challenges its use in clinical and research settings. FastPET, a deep learning-based reconstruction method trained to transform histo-images into converged OSEM reconstructions, offers a faster alternative [1]. This study evaluates FastPET's ability to reconstruct low-dose dynamic 2-[^{18}F]fluoro-2-deoxy-D-glucose ([^{18}F]FDG) brain PET images and generate accurate time-activity curves (TACs) suitable for kinetic modelling compared to OSEM. ***Materials and Methods:*** Nine healthy subjects underwent 60-minute dynamic PET scans using a long axial field-of-view (LAFOV) PET/CT system following injection of 3 MBq [^{18}F]FDG per kg body weight. The dynamic PET series was divided into 67 frames: 20 × 2 s, 10 × 5 s, 15 × 10 s, 6 × 60 s, 10 × 120 s, and 6 × 300 s. Simulated low-dose scans (20, 50, 100, 200 MBq) were generated by sampling list-mode events. Data were reconstructed using 3D-OP-OSEM with 4 iterations and 5 subsets, including time-of-flight (TOF) information, point spread function (PSF) modelling, and a 2 mm Gaussian post-filter; and FastPET, which operates on 3D histo-images and attenuation maps for inference of PET images. TACs were extracted from the whole brain using CT-based masks (TotalSegmentator [2]) and from subregions using activity-based masks derived from the PET images. TACs across regions and dose levels were compared between FastPET and OSEM to evaluate consistency, bias, and noise characteristics. ***Results:*** FastPET produced TACs that more accurately reflected the expected metabolic kinetics of [^{18}F]FDG, especially under low-dose conditions where OSEM reconstructions yielded erratic and discontinuous TACs possible due to scatter correction failure. Across all doses, FastPET maintained high temporal resolution and generated curves with reduced noise. A consistent bias (≈5%) in FastPET compared to OSEM was observed in whole-brain TACs. This bias was dose-independent but varied locally, with greater deviations in low-activity regions such as ventricular space. ***Conclusion:*** FastPET enables fast and robust reconstruction of dynamic [^{18}F]FDG brain PET at low doses, providing improved TAC quality and a stable, predictable bias. Its speed and reliability support its use in quantitative low-dose PET and kinetic modelling. ***References:*** [1] Whiteley W. et al. (2020). IEEE Trans Radiat Plasma Med Sci, 5(1):65-77. The Clinical Application of Brain Motion Management for Improving Quantification of Brain Amyloid PET

Y. Li, *J. Li, Z. Wang, X. Lu, H. Pang;*
Department of Nuclear Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: Precise quantification of amyloid PET imaging has become increasingly essential in Alzheimer's Disease (AD) management for patient care, treatment evaluation, and anti-amyloid clinical trials. Head motion-induced image artifacts are a major factor compromising image quality and quantification accuracy, particularly in dementia populations. The Brain Motion Management (BMM) algorithm, which has been incorporated into our long-axis (with a lenth of 148cm) PET/CT system, effectively tackles head motion artifacts and PET-CT misalignment through data-driven and AI-based approaches. This study aims to evaluate the clinical efficacy of BMM in enhancing amyloid PET quantification accuracy. ***Materials and Methods:*** This ongoing observational study employing BMM was initiated on March 14, 2025. Patients with cognitive impairment requiring diagnostic evaluation or disease monitoring underwent ^{18}F-Florbetapir PET scans. Image quality and amyloid deposition status were visually assessed by experienced nuclear medicine physicians. Scans deemed suboptimal or non-diagnostic due to motion artifacts were reconstructed again with BMM. Global and regional amyloid deposition (SUVr values in composite cortex, frontal, cingulate, parietal, precuneus, and lateral temporal cortices, using whole cerebellum as reference) were compared between the non-motion-managed (NMM) images and BMM images. ***Results:*** As of April 24, 2025, a total of 35 ^{18}F-Florbetapir PET/CT scans have been acquired. Six scans (three male patients, mean age 72 ± 5 years) exhibited significant head motion artifacts. All six patients were diagnosed as AD (one with Clinical Dementia Rating score of 2, the others, score 3). In BMM-incorporated images, image blur was effectively reduced in all six cases, significantly improving image quality. Global SUVr values were significantly higher in BMM images compared to NMM images (1.36 ± 0.17 vs.1.26 ± 0.29, P = 0.047). Using a commonly used threshold of 1.11, all BMM images were correctly classified as amyloid-positive, whereas one NMM image was misclassified as negative (SUVr = 0.75). BMM images also showed higher mean SUVr values across all five analyzed subregions compared to NMM images. ***Conclusion:*** The BMM algorithm demonstrates significant potential for improving amyloid PET image quality and quantification accuracy in patients with AD. This enhancement may have important implications for

treatment response monitoring in AD. The ongoing study will continue to evaluate the clinical impact of BMM in a larger patient cohort.

EP-0983

Enhancing Deep Learning-based Partial-Volume Correction for ^{177}Lu SPECT by Incorporating Multiple Reconstruction Convergence Stages

A. Gehring[1], *J. Leube*[1], *M. Laßmann*[1], *J. Gustafsson*[2], *M. Salas-Ramirez*[1], *J. Tran-Gia*[1];
[1]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY,* [2]*Medical Radiation Physics, Lund University, Lund, SWEDEN.*

Aim/Introduction: Accurate SPECT activity quantification is critical for patient-specific dosimetry in radiopharmaceutical therapies but is challenged by partial-volume effects that blur object edges and introduce errors. Traditional correction methods often rely on simplifying assumptions or segmented images, limiting their clinical applicability. Deep learning (DL) offers a data-driven alternative, though model performance depends on the training data. This work investigates an enhanced version of an existing DL-based partial-volume correction (DL-PVC) [1], focusing on more realistic training data and examining the influence of different convergence stages—via varying update numbers—on model performance regarding resolution and noise. ***Materials and Methods:*** The DL-PVC model was trained as described in [1], using 10,000 XCAT [2] body phantoms with randomly shaped activity distributions (256x256x256 matrix, 2.4x2.4x2.4mm^3 voxels). To improve performance, a refined dataset (N=10,000) incorporating overlapping smaller activity shapes was created. These datasets underwent SPECT simulations with the SIMIND Monte Carlo program [3] and were reconstructed using PyTomography [4] (OSEM, 5/20/50 iterations (i), 4 subsets (s), attenuation correction, triple-energy-window scatter correction, resolution modeling). Four u-nets with differently reconstructed data as input were trained (60 epochs, L1 loss function, 9,000/500/500 for training/validation/testing) to predict activity distribution: 20 updates (5i4s), 80 updates (20i4s), 200 updates (50i4s), and a combination of 20/80/200 updates as three input channels. The performance of all models was evaluated on the test dataset using SSIM, NRMSE and voxel activity accuracy (VAA), a previously defined measure of spatial correction quality (proportion of voxels with deviation of <5% between predicted and ground-truth activity distribution [1]). ***Results:*** The 20-update u-net achieved mean performance measures of 0.852/12.4%/27.4% for SSIM/NRMSE/VAA, compared to the 80-update u-net with 0.858/12.2%/28.7% and the 200-update u-net with 0.857/12.2%/28.7%. The multi-update u-net performed best (0.859/12.1%/29.2%). Performances across the single-update models plateaued beyond 80 updates, indicating diminishing returns with higher update numbers. In contrast, the multi-update input showed slightly better performance, highlighting its potential to capture complementary information from different convergence stages. ***Conclusion:*** Reconstructions with 80 updates (20i4s) showed best performance among single-reconstruction u-nets, indicating a good balance between convergence and noise while minimising reconstruction time. The inclusion of multiple update numbers yielded only minor additional benefits. Future work will explore generalizability across reconstruction settings and patient-specific datasets to further support clinical translation. ***References:*** [1] Leube et al. JNM 2024;65(6):980. Joint dual modality information for^{131}I SPECT/CT images enhancement based on a deep-learning method allows 75% reduction of scan time

H. Yang[1], *M. Guo*[2], *L. Xiang*[2];
[1]*Nuclear Medicine Department, Southwest Hospital (the First Affiliated Hospital), Third Military Medical University (Army Medical University), Chongqing, CHINA,* [2]*Subtle Medical Inc., Shanghai, CHINA.*

Aim/Introduction: ^{131}I SPECT/CT is an effective method for postoperative assessment and visiting of thyroid cancer patients. However, long acquisition time of standard scan and discomfort after taking iodine may lead to inconvenience to patients and reduce work efficiency. While using a fast-scan protocol may be a substitute, it may lead to issues such as noise, and artifacts, which may have a risk of diagnostic errors.To address these issues, a deep-learning based method utilizing CT and fast SPECT scan images as joint inputs to denoise low-duration SPECT scan was proposed. ***Materials and Methods:*** 72 patients in total diagnosed with thyroid cancer in Southwest hospital of China, who required 131ISPECT/CT imaging after surgery, were selected as training and testing datasets in this study. Each patient underwent a standard scan with 60 views, each lasting 12 seconds. Subsequently, one of three different acceleration plans was adopted: (1) 30 views, each lasting 6 seconds; (2) 30 views, each lasting 12 seconds; (3) 60 views, each lasting 3 seconds. 24 patients were scanned for each acceleration plan separately. 8:1:1 random splits of the subjects were regarded as training, validating, and testing datasets. During the network training phase, fast SPECT scan images and corresponding CT images were concatenated along the channel dimension as a joint input to the MPRNet. Model with only SPECT input was also trained as a comparison to find the effect of involving CT information. PSNR, SSIM and NMSE were used as quantitative objective evaluation metrics. 2 experienced nuclear medicine physicians also scored the enhanced images of two networks. The grading criteria including the clarity, contrast, and edge sharpness of residual thyroid tissue and cervical metastatic lesions. ***Results:*** Among the 3 acceleration protocols, nuclear medicine physician ratings for the low-duration scans enhanced by the proposed method are consistent with standard scan images, which does not affect clinical diagnosis.The difference map and essential physiological and pathological details preserved indicates the advantage of leveraging CT information in network training.From quantitative perspective, the PSNR, SSIM and RMSE were improved by 26%, 9% and 36% separately on average. ***Conclusion:*** The qualitive and quantitative results showed that the proposed deep-learning method with SPECT and CT input effectively suppressed noise, enhanced image quality for low-duration scans while maintained high diagnostic quality, which indicates the work efficiency could be effectively promoted and the waiting and scanning time of patients could be reduced up to 75%.

Breaking Barriers in PET: Deep Progressive Reconstruction Achieves Diagnostic-Quality ^{18}F-FDG Imaging at Half the Dose and Time in India

N. Jain[1], *S. S. Singh*[2], *A. Agarwal*[1], *D. Kumar*[3], *P. Wadhwa*[3];
[1]*Molecular Imaging & Therapy, New Delhi, INDIA,* [2]*Globe Healthcare, Lucknow, INDIA,* [3]*United Imaging Healthcare, New Delhi, INDIA.*

Aim/Introduction: Digital PET technology offers improved sensitivity and resolution, enabling low-dose ^{18}F-FDG PET imaging with reduced acquisition times—an advantage for resource-limited settings. This dual-centre study evaluates the diagnostic performance of AI based reconstruction algorithm, uAI® HYPER DPR versus conventional reconstruction methods using digital

uMI 550 PET/CT system in India, with a focus on reduced dose and acquisition time protocols. ***Materials and Methods:*** We collected over 120 patient datasets undergoing oncologic ^{18}F-FDG PET scans from two centres in India, a hospital set-up (Globe healthcare, Lucknow, India) and a diagnostic centre (Molecular Imaging, Delhi, India) with high patient throughput. All scans were conducted using a digital uMI 550 PET/CT system with low-dose protocols (reduced activity and acquisition time). Images were reconstructed using HYPER DPR (deep learning-based) and conventional methods (OSEM, post processed with Gaussian filter). Quantitative metrics (SNR, SUVmax, lesion detectability) and qualitative assessments (clinical readability, noise levels) were compared. ***Results:*** Molecular Imaging, Delhi, India conducts about 50 scans per day with a low dose of 3-5 mCi and the acquisition time of 30-45 sec per bed position. Similarly, Globe hospital, Lucknow, India has a throughput of 25 scans per day with a a low dose of 3-5 mCi and the acquisition time of 45 sec-1 min per bed position. We collected preliminary datasets from both the centers for 5 mCi scans and 45 sec per bed position with mean uptake time of 60±10 minutes. It was observed that all lesions >1 cm were detectable by both sets of images. Overall, there was significant difference between SUVmax of liver and mediastinum between all subsets of DPR based and conventional reconstruction methods, however difference in SUVmean was non-significant. SNR was observed to be two-folds higher with HYPER DPR as compared to OSEM. Qualitative assessments demonstrated that with low dose protocols, there is no significant difference in the clinical readability between the two reconstruction algorithms, whereas the noise levels with HYPER DPR were 35% reduced as compared to OSEM making it a preferred choice as reporting image. ***Conclusion:*** Deep progressive reconstruction enables reliable low-dose, rapid-acquisition ^{18}F-FDG PET imaging without compromising diagnostic quality, and can be very beneficial in resource-constrained settings. This approach may expand PET accessibility in developing regions by reducing costs and scan times while maintaining accuracy. ***References:*** Ew-Jun Chen, et al Radiation Physics and Chemistry, 2024.

EP-0986

Impact of Deep Learning Denoising on Image Quality and Semiquantitative Parameters in Low-Count/ Reduced-Time ^{18}F-FDG Digital PET/CT Scans

S. Shekhar Singh[1], *N. Jain*[2], *S. Nigam*[1], *P. Wadhwa*[3];
[1]Globe Healthcare, Lucknow, INDIA, [2]Molecular Imaging & Therapy, Delhi, INDIA, [3]United Imaging Healthcare, Delhi, INDIA.

Aim/Introduction: To evaluate the effect of a deep learning (DL)-based denoising method on image quality and semiquantitative parameters in low-count/reduced-time ^{18}F-FDG PET/CT scans using a digital PET/CT system. ***Materials and Methods:*** This retrospective multi center study (Globe healthcare, Lucknow and Molecular Imaging, Delhi, India) included 140 patients who underwent ^{18}F-FDG PET/CT imaging on a digital PET/CT scanner (United Imaging uMI550) with a standard acquisition time of 120 seconds per bed position. List-mode data were rebinned into five datasets: 120s (reference), 90s, 60s, 45s, and 30s, corresponding to 100%, 75%, 50%, 37.5%, and 25% of total counts, respectively. Images were reconstructed using OSEM and post-processed with DL-based denoising and Gaussian filtering (GS). Quantitative analysis included SUVmax, SUVmean, liver/mediastinal signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Subjective image quality was assessed using a 5-point Likert scale for noise, lesion detectability, and overall diagnostic confidence. ***Results:*** The mean injected ^{18}F-FDG dose was 3.0 ± 0.5 MBq/kg, with an uptake time of 60 ± 10 minutes. DL-denoised images demonstrated significantly lower noise ($p < 0.05$) and higher SNR compared to GS across all reduced-count subsets. No significant differences in SUVmean were observed between DL and GS methods. Lesion CNR and subjective contrast were preserved in DL-processed images down to 45s (37.5% counts), with significant degradation only at 30s (25% counts). Compared to the reference (120s), the 90s (75% counts) DL-denoised images showed no significant differences in SUV, SNR, or lesion detectability ($p > 0.05$). ***Conclusion:*** DL-based denoising significantly improves image quality in low-count ^{18}F-FDG PET/CT scans, allowing for a reduction in acquisition time to 90s per bed position (75% counts) without compromising diagnostic accuracy or semiquantitative metrics. This approach may enable faster scans or lower-dose protocols while maintaining diagnostic confidence. ***References:*** Xing, Y. et al,, Clinical evaluation on image quality of a deep learning-based denoising algorithm in ^{18}F-FDG PET/CT studies JNM 2021.

EP-0987

Quantitative Accuracy in Preclinical SPECT/CT Imaging: Partial Volume Effects, Reconstruction Parameters, and Radiotracer Concentration

A. Ebrahimifard[1], *S. Bagheri*[1], *D. Librizzi*[2], *F. Eilsberger*[1], *M. Luster*[1], *B. Hooshyar Yousefi*[1,3];
[1]Department of Nuclear Medicine, School of Medicine, Philipps university Marburg, Marburg, GERMANY, [2]Department of Nuclear Medicine, University Hospital OWL, Evangelical Hospital Bethel, Bielefeld, GERMANY, [3]Preclinical Imaging of Core Facility, Center for Tumor Biology and Immunology (ZTI), Philipps University Marburg, Marburg, GERMANY.

Aim/Introduction: High quantitative accuracy in preclinical SPECT imaging is essential for translating molecular imaging findings into clinical impact. However, partial volume effects (PVE), particularly in small organs and at low uptake levels, remain a major challenge often leading to inaccurate results. This study investigates how reconstruction parameters and radiotracer concentration affect quantitative parameters. Through comprehensive analysis, we optimised the imaging protocol to enhance quantitative accuracy across varying organ sizes. ***Materials and Methods:*** The Digimouse (28g) mouse-model phantom was filled with ^{99m}Tc-pertechnetate at 1, 5, and 10 MBq/ml densities. Imaging was performed using Mediso-nanoScan SPECT/CT system with pinhole collimators. Three reconstruction settings were applied: 32i3s (minimum), 48i3s (typical), and 64i3s (maximum), incorporating attenuation and scatter correction. VOIs for the liver (large), heart (medium), and thyroid (small) were defined using PMOD (v4.3) on CT images. Quantitative parameters, including recovery coefficient (RC), signal-to-noise ratio (SNR), contrast, and contrast-to-noise ratio (CNR) were calculated. ***Results:*** RC in the liver remained stable across all reconstruction settings and activity concentrations, while thyroid RC increased significantly from 1 to 5 and 10 MBq/ml (both $p<0.01$) in all settings. Heart RC increased significantly from 1 to 5 MBq/ml ($p<0.01$) and from 1 to 10 MBq/ml ($p<0.05$). SNR peaked at 5 MBq/ml across all organs but decreased significantly at 10 MBq/ml. Liver and heart SNR increased from 1 to 5 MBq/ml ($p<0.01$), while thyroid SNR changes were only observed from 5 to 10 MBq/ml ($p<0.05$). Liver contrast improved at 5 MBq/ml ($p<0.05$) but decreased at 10 MBq/ml, with no changes in the thyroid or heart. CNR peaked at 5 MBq/ml and decreased significantly at 10 MBq/ml ($p<0.05$). ***Conclusion:*** This study highlights the effects of organ size, radiotracer concentration, and reconstruction parameters on quantitative accuracy in preclinical imaging. RC remained stable in large organs but varied in small structures under low-radioactivity conditions. SNR and CNR peaked at 5 MBq/ml across all organs, with declines at 10 MBq/ml likely due to system dead-time effects. Contrast enhancement in larger organs suggests reduced PVE with increasing size. A radioactivity density of 5 MBq/ml, combined with 48i3s or 64i3s reconstructions, provided a favorable set-up in our study, highlighting the importance of protocol optimisation for accurate quantification of small volumes with low-uptake levels in preclinical studies.

Enhanced parametric imaging from low-dose dynamic Long-Axial-Field-of-View PET studies using a suitably weighted 3-D gaussian smoothing process

Q. Wu[1,2], *F. Gu*[3], *K. Shi*[4], *A. Rominger*[4], *F. O'Sullivan*[1];
[1]*School of Mathematical Sciences, University College Cork, Cork, IRELAND,* [2]*Insight SFI Centre for Data Analytics, Cork, IRELAND,* [3]*School of Mathematics and Physics, North China Electric Power University, Beijing, CHINA,* [4]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND.*

Aim/Introduction: Dynamic positron emission tomography (PET) imaging is vital for estimating metabolic parameters like flux and distribution volume, which inform clinical decisions in oncology. Low-dose PET protocols, increasingly adopted to reduce patient radiation exposure, suffer from lowcounts that amplify noise in image. Conventional Gaussian smoothing potentially blurring reliable estimates, this study proposes a weighted Gaussian smoothing method incorporating inverse-variance weighting derived from image-domain bootstrap estimates, aiming to enhance the accuracy and clinical utility of dynamic low-dose PET parametric maps by prioritizing reliable data. ***Materials and Methods:*** The method was applied to a dynamic low-dose FDG PET data from Biograph Vision Quadra scanner. Metabolic parameters were estimated using non-parametric residue mapping (NPRM). Variances were calculated via image-domain bootstrapping, which models errors with a subordinate Gaussian process and accounts for spatial correlations using a Kronecker tensor product and 3D Fast Fourier Transform. Smoothing was performed using 3D Gaussian kernels, with weights inversely proportional to the bootstrap-estimated variances. The FWHM of the Gaussian kernel was optimized using generalized cross-validation, a data-driven technique that balances noise reduction with the preservation of structural details, eliminating the need for manual tuning. To quantify the effectiveness of the weighted Gaussian smoothing, the signal-to-noise ratio (SNR) was evaluated based on a suitable homogeneous region within the parametric map. ***Results:*** Weighted Gaussian smoothing significantly reduced noise in high-variance regions while preserving details in low-variance areas. A 2-fold improvement in SNR was achieved, demonstrating the method's effectiveness in enhancing the quality of parametric maps from low-dose PET data. This noise reduction directly enhances the visualization of kinetic parameters, making subtle features more distinguishable, which is critical for accurate clinical interpretation. ***Conclusion:*** By integrating inverse-variance weighting with Gaussian smoothing and leveraging efficient image-domain bootstrap variance estimation, this method provides a robust approach to denoising PET parametric maps. Its computational efficiency makes it suitable for routine clinical use, with potential extensions to other modalities. The method improves the visualization of kinetic parameter maps in low-dose PET and aligns with efforts to reduce patient radiation exposure. Future work will validate its performance in simulation setting and larger cohorts. ***References:*** O'Sullivan, F., et al. (2021). Color of Radiation: Redesign of Established Colormaps in the Oklab Color Space for Perceptual Accuracy and Inclusive Design for Color Vision Deficiency

M. Gammel[1], *W. A. Weber*[1], *S. G. Nekolla*[1], *B. M. Gammel*[2];
[1]*TUM Klinikum, Rechts der Isar, Department of Nuclear Medicine TUM School of Medicine and Health, Munich, GERMANY,* [2]*Infineon Technology AG, Munich, GERMANY.*

Aim/Introduction: In medical imaging, misinterpretation may result not only from acquisition or reconstruction artifacts, but also from suboptimal color maps (CMAPs). Their diagnostic impact is well established in other scientific fields, where non-perceptual uniform CMAPs are well known to result in pseudo-contours, masked gradients, or contrast distortions. Many standard CMAPs lack perceptual uniformity: they exhibit non-linear luminance and irregular perceptual spacing (ΔE), introducing similar risks in medical imaging. Sixteen CMAPs commonly used in clinical software were systematically examined. The three most frequent variants were reconstructed in the perceptually uniform Oklab color space, ensuring linear luminance and constant perceptual steps while preserving familiar appearance. Oklab is increasingly adopted in digital workflows and is part of the W3C CSS Color Module Level 4. Additionally, perceptual accessibility was assessed under simulated color vision deficiencies (CVD) to enable inclusive interpretation. ***Materials and Methods:*** Sixteen clinical CMAPs were evaluated for luminance linearity and perceptual spacing (ΔE) using the CIE L*a*b* color space. The three most frequent variants (thermal, cool, grayscale) were transformed into the perceptually uniform Oklab space, where ΔE can be calculated directly via Euclidean distance—unlike CIE-based models that require complex correction formulas (CIEDE2000). They were then optimized for linear luminance and constant ΔE using a Python-based workflow with parametric color paths and ΔE-controlled interpolation, and converted to sRGB.CVD (prot-, deuter-, tritanomaly) were simulated using the physiologically based Machado model (Matpack, C++). Additional CMAPs were developed for each deficiency, based on perceptual adaptation and visual similarity, fulfilling the same criteria of luminance linearity and equidistant steps. ***Results:*** All 16 CMAPs showed significant deviations from perceptual uniformity, leading to the artifacts described above. The three optimized variants met both criteria within Oklab while maintaining their visual identity. Each was defined by a parameterized path in Oklab's extended gamut, enabling algorithmic reproducibility, reliable design, and conversion to other color spaces. For each CVD, adapted CMAPs were created to preserve discriminability and visual similarity. ***Conclusion:*** CMAPs are not decorative - they are diagnostic tools. Many established variants exhibit perceptual flaws that may impair interpretation. This work presents optimized versions of widely used CMAPs that preserve their familiar appearance, allowing users to retain established interpretation patterns without retraining. Dedicated variants for CVD enable perceptual accessibility across user groups. All designs are based on the Oklab color space, which is internationally standardized (W3C CSS Color Module Level 4), ensuring long-term compatibility and integration into future imaging systems.

EP-0990

Evaluation of FastPET reconstruction method using multiple tracers and LAFOV PET

N. Overbeck[1], *U. Lindberg*[1], *I. Law*[1], *Y. Zheng*[2], *D. Bharkhada*[2], *M. Zhang*[2], *V. Panin*[2], *P. Schleyer*[2], *M. Millardet*[3], *T. L. Andersen*[1], *F. L. Andersen*[1];
[1]*Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK,* [2]*Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA,* [3]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Positron Emission Tomography (PET) enables visualization of physiological processes using radiotracers tailored to specific diagnostic applications. The large data volumes cause challenges through the image reconstruction due to the computational demands of methods such as Ordered Subsets Expectation Maximization (OSEM). To address this, a deep learning-based algorithm, FastPET, utilizing a U-Net architecture, was developed to significantly reduce computation time [1].

This study evaluates FastPET's performance against the clinical standard, OSEM, using PET/CT scans across multiple tracers. ***Materials and Methods:*** The Long Axial Field-of-View PET scans included in the study were performed using the following tracers and approximate post injection (p.i.) times: [^{18}F]FDG 60 min, [^{18}F]FET 30 min, [^{18}F]FE-PE2I 35 min, [^{15}O]H_2O 60s, [^{68}Ga]Ga-DOTATOC 60 min, and [^{11}C]PiB 50 min p.i. All reconstructions included 300s of PET data, except for [^{15}O]H_2O where 60s was selected. One patient per tracer was investigated. OSEM reconstruction was performed with 4 iterations, 5 subsets, PSF, TOF, and a 2 mm Gaussian filter. FastPET reconstruction used a 10-view histoimage corrected for attenuation and normalization to infer the PET image [2]. Images were masked to include voxels with at least 5% of the maximum OSEM intensity. Normalized root mean square error (NRMSE) was calculated to assess similarity between methods. ***Results:*** The comparisons showed agreement between FastPET and OSEM in high-uptake regions, preserving image quality and tracer distribution. In low-uptake areas, FastPET showed up to a 10% average bias. NRMSE values for each tracer were as follows: [^{18}F]FDG: 0.10, [^{18}F]FET: 0.11, [^{18}F]FE-PE2I: 0.12, [^{15}O]H_2O: 0.08, [^{68}Ga]Ga-DOTATOC: 0.22, and [^{11}C]PiB: 0.13. Additionally findings were the significant reduction in computation times when using FastPET. ***Conclusion:*** FastPET significantly reduces reconstruction time while preserving image quality and tracer uptake accuracy in high-uptake regions. However, the bias observed in low-uptake areas indicates some limitations in localized quantitative performance. The NRSME showed that the FastPET images had image quality comparable to the gold standard. ***References:*** [1]W. Whiteley, V. Panin, C. Zhou, J. Cabello, D. Bharkhada, and J. Gregor, "FastPET: Near Real-Time Reconstruction of PET Histo-Image Data Using a Neural Network," IEEE Trans Radiat Plasma Med Sci, vol. 5, no. 1, pp. 65-77, Jan. 2021, doi: 10.1109/TRPMS.2020.3028364. Optimal reconstruction algorithm for amyloid PET with short acquisition time

K. Tsuda[1], *K. Koyama*[1], *S. Takemoto*[2], *K. Onuki*[2], *S. Kimura*[2], *T. Harada*[3];
[1]*Juntendo University, Tokyo, JAPAN,* [2]*Juntendo Hospital, Tokyo, JAPAN,* [3]*PDRadioPharma, Tokyo, JAPAN.*

Aim/Introduction: Disease-modifying therapy for Alzheimer's disease was approved in September 2023 for manufacture and sale in Japan, and diagnostic amyloid PET imaging (^{18}F-Florbetapir [FBP] and ^{18}F-Flutemetamol [FMM]) was approved for coverage by insurance in June 2024. The JSNM PET imaging Site Qualification Program (J-PEQi) was introduced to optimize testing, and an increasing number of facilities have obtained J-PEQi. In this program, phantom images corresponding to the acquisition time for each drug are submitted, with standard acquisition times of 10-20 min for FBP and 20-30 min for FMM. In clinical practice, however, it is unreasonable to expect patients with Alzheimer's disease to remain motionless on the PET bed for the specified time. The aim of this study was therefore to establish an optimal reconstruction algorithm for use with a short acquisition time that could ensure image quality and quantitativeness in the case that the specified acquisition time is not met. ***Materials and Methods:*** Images of two phantoms (Hoffman and cylindrical, both certified for use in J-PEQi) were acquired using either a Celesteion PMT-PET/CT (Canon) or Cartesion Prime SiPM-PET/CT (Canon) system. For both PMT-PET/CT and SiPM-PET/CT, standard image data acquisition times are 10 for FBP and 20 min for FMM. Assuming a short acquisition time, phantom image data were extracted with acquisition times of 5 min for FBP, and 10 and 15 min for FMM. The reconstruction algorithm was the same as for J-PEQi (PMT-PET/CT: TOF-OSEM, PSF-, Gaussian 4.0 mm; SiPM-PET/CT: TOF-OSEM, PSF-, Gaussian 4.0 mm). A new noise reduction method, Clear adaptive Low-noise Method (CaLM; mild, standard, and strong), was additionally applied. All obtained images were investigated visually and quantitatively as specified in J-PEQi, using visual resolution, %contrast, uniformity, and coefficient of variation (CV). ***Results:*** The pass criteria for J-PEQi are visual resolution, ≤8 mm; %contrast, ≥55%; uniformity, ≤0.0249; and CV, ≤15%. With PMT-PET/CT, 5-min FBP (Gaussian, CaLMstandard, CaLMstrong), 10-min FMM (CaLMstrong), and 15-min FMM (CaLMstrong) passed the criteria. With SiPM-PET/CT, 5-min FBP (Gaussian, CaLMstandard, CaLMstrong), 10-min FMM (CaLMstandard), and 15-min FMM (Gaussian, CaLMstandard, CaLMstrong) passed the criteria. ***Conclusion:*** The optimal reconstruction algorithm differed according to acquisition time for each PET/CT device, but appears to be suitable with short acquisition times. These findings will contribute to the acquisition of high-quality amyloid PET imaging in Japan, thereby improving the standard of dementia treatment.

EP-0992

The Impact of Reconstruction Parameters on Radiomic Features in ^{18}F-FET-PET Imaging of Glioma

D. Kalaeva[1,2], *G. Danilov*[1], *N. Vikhrova*[1], *I. Pronin*[1];
[1]*National Medical Research Center for Neurosurgery named after N.N. Burdenko, Moscow, RUSSIAN FEDERATION,* [2]*National Research Nuclear University MEPhI, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: To investigate the variability of ^{18}F-FET-PET radiomic features in metabolic tumor volume of IDH-wildtype and IDH-mutant gliomas depending on the applied filters and PSF modeling. The prognostic significance in predicting IDH status was assessed. ***Materials and Methods:*** 40 adult patients with IDH-wildtype glioblastomas (n=30) and ^{18}F-FET positive (TBR>1,6) IDH-mutant astrocytomas (n=10) were retrospectively enrolled. PET data (20-40 min p.i.) were obtained in list mode and reconstructed using a reference algorithm 3D OSEM 5i8s with applied 5 mm Gaussian filter. Variation over the reference setting: 2 and 7 mm Gaussian filter; 5mm Hann and Shepp filter; using PSF modeling. A threshold value TBR(tumor-to-brain ratio)=1,6 was used for tumor segmentation. A total of 4,838 radiomic features were extracted using the RIA R library. To evaluate their reliability, intraclass correlation coefficients (ICCs) were calculated. The Friedman test was used to assess differences in radiomic features obtained from variously filtered images, statistical significance was set at $p<0.05$. ***Results:*** The radiomic features demonstrated strong agreement across different reconstructions, though 159 radiomic features exhibited poor to moderate reliability (ICC<0,75). Statistically significant differences were found for 2674 radiomic features, which indicates the presence of variability depending on the reconstruction parameters and likely attributable to variations in noise levels among the compared images. While statistically significant predictors of IDH genotype were identified in this analysis, further validation in larger cohorts remains necessary. ***Conclusion:*** Radiomics provides important diagnostic information for noninvasive prediction of the IDH type, but the reconstruction parameters affect the radiomic features of PET imaging. Further studies should evaluate radiomic features reproducibility in various reconstructions and segmentation.

Optimisation of 123I FP-CIT SPECT-CT Reconstruction for a multi-site clinical service

J. Dixon, *C. Brown, R. Gillen, J. Dennis, N. Fullerton, F. Hendry, I. Andrews, A. Nicol;*
NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.

Aim/Introduction: A review was undertaken to optimise and standardise 123I FP-CIT procedures across a large multi-site organisation (NHS Greater Glasgow and Clyde (NHSGGC) with five hospitals servicing a population of around 3 million and performing approx. 1,500 123I FP-CIT scans per annum). Whilst each site was individually generally compliant with the EANM/SNM guidelines [1], reconstruction for visual assessment was variable: filtered back-projection (FBP) and iterative reconstruction (IR) methods; 24-120 equivalent iterations; various attenuation correction (AC) methodologies; variable smoothing filters; variable application of scatter correction (SC) and resolution recovery (RR). This work aimed to introduce an optimised, standardised reconstruction for use at all NHSGGC sites. ***Materials and Methods:*** Practice at each site, including reconstruction settings, was compared with standards based on the EANM/SNM guidelines. All reconstructions were performed on vendor-neutral software. Three reconstruction protocols utilising CTAC, SC (including full collimator modelling) and RR were developed and assessed (Table 1). As these images have improved contrast, a revised colour scale was developed to display the CTAC, SC and RR reconstructions, maintaining the sensitivity of detecting subtle differences in striatal-to-background uptake of 123I FP-CIT. Test cases (n=4) were collated that covered a range of diagnoses (normal, weak comma, abnormal 'full stop'). Six reporting radiologists reviewed the test cases using the three reconstruction options, rating each on a 10-point Likert scale as to whether they considered the reconstruction suitable for clinical use. The current clinical visual assessment reconstructions of each case at each site were available for reference. Statistical significance was assessed using a t-Test. ***Results:*** Likert scores are shown in Table 2. Reconstruction protocols 1 and 3 scored positively, with no statistically significant difference (p=0.41). ***Conclusion:*** Iterative reconstructions using CTAC, SC and RR were developed, displayed with a modified colour scale and two were assessed to be suitable for use for clinical practice. Further work is underway to determine a final choice and managed rollout into routine clinical practice at all sites is planned. ***References:*** 1. Morbelli et al (2020). EANM practice guideline/SNMMI procedure standard for dopaminergic imaging in Parkinsonian syndromes 1.0. European Journal of Nuclear Medicine and Molecular Imaging, 47, 1885-1912.

Systematic Optimization of PET Quantitative Imaging using Realistically Inserted Synthetic Lesions: A Standardized Approach

N. Aghakhanolia[1], *A. Rahmim*[1], *P. L. Esquinas*[2];
[1]*UBC - School of Biomedical Engineering, Vancouver, BC, Canada,* [2]*BC Cancer - Molecular Imaging and Therapy, Vancouver, BC, CANADA.*

Aim/Introduction: Quantitative accuracy in PET imaging is essential for clinical diagnosis, treatment monitoring, and personalized care. However, systematically evaluating and optimizing reconstruction methods remains challenging due to the lack of realistic, standardized tools for performance assessment. Conventional approaches (physical phantoms or numerical simulations) often fail to capture the anatomical and physiological complexity of clinical images.To address this challenge, we present a lesion-insertion framework that enables embedding synthetic lesions with known characteristics into real patient PET images. This tool supports task-specific evaluations in a realistic and controlled setting. ***Materials and Methods:*** We developed a Python-based lesion-insertion toolbox integrated into PyTomography, an open-source framework for tomographic image reconstruction. The toolbox was inspired by Gabrani-Juma et al 2020 method. Our toolbox enables users to embed synthetic lesions with user-defined size, location, and intensity into real PET datasets. Synthetic lesions are then forward-projected and merged with real list-mode data (currently supports GATE and GE DMI data), simulating realistic acquisitions. Reconstructed images are subsequently generated using both OSEM and BSREM algorithms, with tunable parameters including point spread function width, number of iterations, subsets, and regularization strength.Quantification accuracy was assessed using recovery coefficient (RC) and detectability was evaluated using contrast-to-noise ratio (CNR) across varied reconstruction settings to assess the quantification performance. ***Results:*** All experiments utilized NEMA IQ data with a 10:1 lesion-to-background ratio. For a 25mm synthetic lesion (0.5MBq/mL) inserted in the uniform background (0.04MBq/mL), RC values remained close to unity (0.96-1.00) across all OSEM reconstructions, confirming accurate activity recovery. However, as the number of iterations increased, CNR values dropped significantly due to noise amplification.In another scenario, an 11mm lesion (0.65MBq/mL) was embedded within a high-intensity lesion (I0.4MBq/mL, 33mm). RC values remained around 0.96-0.98, indicating effective recovery in a high-intensity background. CNR values stayed within detectable ranges (4.62-5.81) for all OSEM settings, peaking at 2 iterations and 24 subsets. In contrast, for a lower-intensity lesion (0.25MBq/mL), RC values slightly decreased (0.92-0.95), and the standard deviation dropped, resulting in a lower CNR (~2). To further assess this case, BSREM reconstructions were also performed, yielding higher CNR (~3) and smoother noise profiles at optimized β values, highlighting the advantage of BSREM in low-uptake lesion detectability. ***Conclusion:*** Based on the results, our open-source lesion-insertion platform provides a basis for optimizing PET imaging protocols for specific clinical goals. Future efforts will concentrate on automated detection, large-scale validation, and comparisons with studies using anthropomorphic phantoms and real patient data.

Quantitative Evaluation of Motion Correction for ^{18}F-FEMPA PET Brain Imaging in Huntington's and Friedrich Ataxia

G. Yar[1], *C. Pain*[1], *H. Peiris*[1], *I. Harding*[2], *J. Jones*[3], *I. Hong*[3], *D. Staeb*[4], *H. Moradi*[4], *K. O'Brien*[4], *Z. Chen*[1];
[1]*Faculty of IT, Monash University, Melbourne, AUSTRALIA,* [2]*QIMR Berghofer Medical Research Institute, Brisbane, AUSTRALIA,* [3]*Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA* [4]*Siemens Healthcare Pty Ltd, Melbourne, AUSTRALIA.*

Aim/Introduction: This study presents a quantitative evaluation of motion correction (MoCo) for ^{18}F-FEMPA brain imaging in control subjects and subjects with Friedrich Ataxia (FA), and Huntington's disease (HD). We examine improved quantitative PET accuracy in brain regions related to these diseases using MoCo. ***Materials and Methods:*** The cohort for this study consists of 61 patients (FA-controls, FA-positive, HD-controls, HD-positive) each administered with a mean bolus of 249.2MBq (SD=5.3Mbq). The MoCo method in this study is the summing tree structural motion correction algorithm [1], where 2D image projections are used to iteratively correct 3D moving images on the basis of a target 3D image. Thalamus and brainstem are selected as regions of interest (ROIs) for evaluating HD. Cerebellum and brainstem are selected as ROIs for evaluating FA. Standardized-uptake-value (SUV) in ROIs is compared across MoCo and non-MoCo images for control subjects and subjects with HD or FA, to evaluate the effect of motion correction on recovering PET signals for disease. ***Results:*** Quantitative results showed an improvement in SUV uptake across different disease specific regions. For the HD group, compared with motion corrupted images, brainstem reported an increase of 5.25±2.32% in SUV measurements and thalamus recovered 4.62±2.01% SUV after MoCo. For the HD control group, brainstem SUV was recovered by 4.30±1.36% and thalamus SUV was recovered

by 3.95±1.45% with MoCo. For FA, brainstem improved 3.28±2.13% and cerebellum recovered 2.06±1.41% SUV after MoCo. For the FA control group, brainstem SUV was recovered by 2.01±1.46% and cerebellum SUV was recovered by 1.20±0.77%. In both datasets, MoCo consistently improved SUV measurements. FA patients showed higher uptake in the brainstem and cerebellum, while HD patient showed increased uptake in brainstem only, compared to their respective controls, regardless of motion correction. Further visual comparison between MoCo and non-MoCo images shows marginal improvements on image sharpness. These results were consistent in quantitative PET imaging for patients with neurological diseases. Future work will further investigate different MoCo pipelines, including MR-guided motion correction [2]. ***Conclusion:*** Motion correction has demonstrated the recovery of the SUV uptake measurements across all patient groups. These improvements are consistent across regions associated with disease biomarkers, suggesting an improved sensitivity in PET quantification following MoCo. The results support the application of MoCo in improving reliability of PET imaging for neurological conditions. ***References:*** [1] I. Hong, et al., 2019, IEEE NSS/MIC, pp. 1-3, doi: 10.1109/NSS/MIC42101.2019.9060017[2] Z. Chen, et al., 2019, Human Brain Mapping, doi.org/10.1002/hbm.24497.

Machine Learning-based denoising of low-count [^{177}Lu] Lutetium SPECT/CT images: evaluating the quantitative accuracy of denoised outputs for dosimetry'

C. Gascoigne[1], *A. L. Smith*[2], *E. Varzakis*[1], *K. Thielemans*[1], *J. C. Dickson*[2], *S. Arridge*[1], *J. Bomanji*[2], *D. Deidda*[3], *B. Fongenie*[4], *H. A. Williams*[5,6];
[1]*University College London (UCL), London, UNITED KINGDOM,* [2]*University College London Hospitals NHS Foundation Trust, London, UNITED KINGDOM,* [3]*National Physical Laboratory (NPL), Teddington, UNITED KINGDOM,* [4]*Blue Earth Therapeutics Ltd, Oxford, UNITED KINGDOM,* [5]*The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM,* [6]*The University of Manchester, Manchester, UNITED KINGDOM.*

Aim/Introduction: A 2-dimensional U-Net algorithm was trained to denoise simulated and clinical reconstructed [^{177}Lu] Lutetium SPECT/CT images. The purpose of this work was to determine whether quantitative accuracy in low-count studies can be improved using machine learning denoising techniques to reduce scan time for dosimetry. ***Materials and Methods:*** Fifty volumes (128×128×128 voxels) containing random ellipsoids were generated in Python, with voxel values representative of clinical SPECT/CT studies. Fifty 'attenuation' arrays were generated with voxel values equivalent to Hounsfield Units in clinical CT scans. Pairs of 'activity' and 'attenuation' arrays were used as inputs for the SIMIND Monte Carlo program, to simulate 'noise-free' [^{177}Lu] Lutetium SPECT/CT acquisitions (30 seconds/projection). 'Noisy' simulations, approximating 11 seconds/projection with Poisson noise, were derived. Simulations were reconstructed using 'Software for Tomographic Image Reconstruction' (STIR) via the 'Synergistic Image Reconstruction Framework' (SIRF) platform. Reconstruction parameters were optimised for best achievable quantitative accuracy in volumes greater than 5.6 ml. A U-Net algorithm submitted to the Ultra-Low Dose PET Imaging (UDPET) Challenge 2022 was trained to generate a 'denoised' output from a 'noisy' input, using 45 pairs of 'noisy' and 'noise-free' slices of the reconstructed ellipsoid simulations. The trained model's weights were saved, and its performance evaluated on 5 held-out samples. The algorithm's ability to denoise clinical data was investigated using 'transfer learning.' Model training was continued using thirty-five pairs of 'noisy' and 'reference' [^{177}Lu] Lutetium-DOTATATE SPECT/CT patient images. The 'reference' images (30 seconds/projection) were Poisson resampled using Xeleris 5.0 (GE Healthcare) to generate 'noisy' representations equivalent to 6 seconds/projection. Images were reconstructed using MIM software, with parameters optimised for quantitative accuracy. Denoised model outputs for a held-out dataset (4 patients) were evaluated. Clinically relevant regions of interest were drawn to assess quantitative accuracy compared to the 'reference' images. This study received ethical approval from a UK Research Ethics Committee via the IRAS process (REC reference: 22/HRA/3556). ***Results:*** After training with simulated images, the mean peak signal-to-noise ratio (PSNR) for the 'ellipsoid' test images was 37.73 and the mean structural similarity index measure (SSIM) was 0.91. After further training with clinical images, the mean PSNR for the clinical test images was 36.30 and the mean SSIM was 0.96. Visually, the model outputs appear less noisy. The quantitative accuracy in test cases was evaluated. ***Conclusion:*** A U-Net was implemented and trained to denoise simulated and real patient data. Further optimistion and evaluation remains necessary before clinical deployment. ***References:*** 1. https://github.com/junqiangchen/Ultra-low-Dose-PET-Imaging-Challenge.

MedMimic: A Physician-Inspired Multimodal Fusion Framework for Early Diagnosing Fever of Unknown Origin

Y. Zhou;
West China Hospital, Chengdu, CHINA.

Aim/Introduction: Fever of unknown origin (FUO) poses a significant diagnostic challenge, often requiring extensive evaluations. While recent efforts integrating clinical features with ^{18}F-FDG PET/CT imaging have improved diagnostic accuracy, conventional feature extraction methods based on manually defined features often lack robustness and generalizability. Furthermore, the scarcity of annotated ^{18}F-FDG PET/CT datasets limits the effective training of deep learning models.To overcome these challenges, we propose Medical Mimicry (MedMimic), a framework inspired by real-world diagnostic processes. ***Materials and Methods:*** MedMimic leverages pre-trained models—including DINOv2, Vision Transformer, and ResNet-18—to transform high-dimensional ^{18}F-FDG PET/CT imaging data into low-dimensional, semantically meaningful feature tensors. A learnable self-attention based fusion network then integrates these imaging features with clinical data, producing compact yet discriminative representations for downstream classification. Our dataset was collected from Sichuan University West China Hospital, one of China's top-tier medical institutions, and comprised 607 consecutive FUO patients who underwent ^{18}F-FDG PET/CT. After excluding cases that did not meet the inclusion criteria, 416 patient admissions from January 2017 to December 2023 were included in the study. ***Results:*** Our proposed multimodal fusion classification network (MFCN) achieved macro-averaged area under the receiver operating characteristic curve (AUROC) values ranging from 0.8654 to 0.9291 across all seven decomposed tasks, outperformingcompeting machine learning (ML) and single-modality deep learning (DL) methods. Additionally, ablation studies validated the effectiveness of the proposed MFCN model. Furthermore, we employed a five-fold cross-validation strategy to ensure the robustness of our results. ***Conclusion:*** By integrating thestrengths of pre-trained large models and deep learning, MedMimic offers a novel perspective and an effective solution for disease classification.

Organ Network Disruptions in Parkinson's Disease Revealed by [18F]-FEOBV Whole-Body PET Imaging

M. Rusaas[1,2], *J. Horsager*[1], *N. Okkels*[1,3], *P. Borghammer*[1,2], *O. L. Munk*[1,2];
[1]*Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK,* [2]*Department of Clinical Medicine, Aarhus University Hospital, Aarhus, DENMARK,* [3]*Department of Neurology, Aarhus University Hospital, Aarhus, DENMARK.*

Aim/Introduction: PET imaging with the [18F]-FEOBV radiotracer has been proposed as a method for evaluation of peripheral autonomic degeneration in patients with Parkinson's disease (PD), but no individual organ had significantly reduced uptake in PD [1]. This study is the first to investigate molecular inter-organ correlation patterns and their disruptions in PD. ***Materials and Methods:*** 22 healthy controls (HC) and 15 PD patients were [18F]-FEOBV PET/CT scanned (26.3cm FOV, 214ps TOF), and we used SUV image from 60-70 min post injection [1]. Low-dose CT scans were segmented using TotalSegmentator [2], VOIs were eroded and visually inspected to minimize the effects of CT-PET mismatch, and organ SUV values were extracted from 7 organs and 8 regions in the brain. HCs were used to calculate a reference network using Spearman correlation between mean regional SUVs [3]. Individual patient disruptions were found by adding each patient into the control group, recalculating the inter-organ correlations, and subtracting the reference network [4]. Jackknife resampling generated individual networks for HCs, providing a reference distribution for evaluating PD-specific disruptions. Consistent disruptions were identified based on the number of patients with significant differences in organ-pair correlation and statistical testing, followed by ROC-curve analysis between PD and HC. ***Results:*** In general, correlation deviations involving the pancreas displayed the biggest differences between the HC and PD groups. The involvement of the pancreas is consistent with single-organ analysis in studies of parasympathetic denervation [1,5]. The most notable deviations were the pancreas-lung and pancreas-blood correlations, with a majority of patients exhibiting significantly weaker correlations for these organ pairs. These organ-pair means were also significantly different from zero after false discovery rate (FDR) correction across 105 different inter-organ correlations (T-test, p=0.01). The distribution of the identified organ-pairs deviated from the HC reference distribution, showing potential for classification (AUC=0.84). These results are an improvement compared to single-organ analysis of the pancreas (p=0.16, AUC=0.65). ***Conclusion:*** Whole-body inter-organ network analysis of FEOBV PET may be a promising approach for detecting PD-specific abnormalities involving organs with parasympathetic innervation. ***References:*** [1] Jacob Horsager et al., 2022, doi: 10.1016/j.parkreldis.2022.09.016. EP-0999

Impact Of The Healthy Control Database On Brain [18F] FDG PET Quantification

E. Fernández-Zorrilla[1], *C. Domínguez-Borrero*[1], *J. Silva-Rodríguez*[2], *A. Moscoso*[1], *P. Aguiar*[1];
[1]*IDIS Research Institute, Santiago de Compostela, SPAIN,* [2]*Fundación CIEN, Madrid, SPAIN.*

Aim/Introduction: Quantification improves the precision of brain [18F]FDG PET, but its accuracy may depend on the choice of healthy control (HC) database [1-2]. The aim of this work is to assess the impact of the scanner used for HC database acquisition of quantification performance. ***Materials and Methods:*** We use a pioneering methodology based on a simulated-based gold standard [3]. First, 25 brain PET/CT/MR images from volunteers were used to generate 25 HC digital phantoms [4]. These phantoms were modified by two experienced physicians to add 75 small and 25 extended hypometabolic areas. Modified phantoms were simulated on the GE DST 1 scanner, while HC phantoms were simulated on 6 scanner models (GE Advance, GE DST 1, GE DST 1, GE DSTE, GE DST and Biograph mMR). VOI-wise quantification was used to generate mean values for 83 VOIs and a paired t-test was performed for comparing between HC databases (alpha = 0.01, and Bonferroni). In addition, each patient's VOIs were compared with 6 HC datasets to localize the hypometabolic areas and voxel-wise analysis was applied to generate z-score maps. ***Results:*** Paired t-test showed differences in a sustantial number of VOIs between HC database acquired on the GE DST 1 (used for patients) and those acquired on all other scanners: GE Advance (33/83 VOIs), GE DST (49/83 VOIs), GE DSTE (36/83 VOIs), GE DST 2 (28/83 VOIs) and Biograph mMR (50/83 VOIs). In terms of localization of extended hypometabolic areas, HC database acquired on GE DST 1 and Biograph mMR achieved the highest AUC, all scanners achieved AUC > 0.9. For localization of small hypometabolic areas, HC database acquired on GE DST 1 also achieved the highest AUC. Hypometabolic area was detected in all z-score maps, it was uniquely identified only when HC database was acquired on the same scanner as the patients (GE DST 1). In contrast, the use of HC databases acquired on scanners other than the one used for the patients resulted in the detection on false hypometabolic areas. ***Conclusion:*** The use of HC databases acquired on a scanner different from that used for patient acquisition have a significant impact on [18F]FDG PET quantification performance, particularly for the detection of smaller hypometabolic areas. ***References:*** [1] Guedj et al. Automated clinical AI workflow for real-time detection of myocardial uptake in bone scintigraphy

H. Halme, *V. Uusitalo, E. Hippeläinen;*
Clinical Physiology and Nuclear Medicine, Helsinki University Hospital and University of Helsinki, Helsinki, FINLAND.

Aim/Introduction: Incidental myocardial uptake of bone-avid ^{99m}Tc-labeled radiotracers is indicative of transthyretin amyloidosis (ATTR). Detection of such uptake is important for early diagnosis and treatment of ATTR. Myocardial uptake in planar bone scans should be confirmed by SPECT-CT to exclude false positive findings due to blood pool uptake. Failure to detect incidental cardiac uptake may lead to delayed diagnostics, and increased radiation dose if the patient is referred to additional SPECT-CT later. We have developed an artificial intelligence (AI)-based workflow for detection of myocardial uptake in bone scintigrams. The workflow processes whole-body bone scans in real time, defines myocardial uptake, and, in case of abnormal uptake, alerts radiographers and physicians about the possible need for SPECT-CT. ***Materials and Methods:*** The workflow consists of: 1) acquisition of whole-body scintigraphy, 2) automatic export of the image to the analysis server, 3) preprocessing and classification of the image with in-house developed convolutional neural network (CNN) [1], 4) transfer of the classification result (myocardial uptake/no uptake) to a Power Automate flow, 5) in case of detected myocardial uptake, an alert message to a Teams channel available for radiographers and physicians. DICOM data handling, database usage, image preprocessing, and classification with a pre-trained CNN occur within a Docker container. This workflow is designed for easy clinical deployment. The container can be exported to any workstation, used via Docker Desktop, and configured to output results based on local needs (email, database, office software). It also allows for quick retrospective analysis of numerous bone

scans. ***Results:*** Successful feasibility tests were conducted using data from two scanners. Total processing time between image export and alert message was less than one second for a single image. AI performance was retrospectively tested with 12 000 unseen bone scans. A nuclear medicine physician validated all AI-classified positive cases (n=372) and 1000 randomly selected negative cases. The AI correctly classified all 30 true positive and 1000 negative images; however, there were 342 false positives. ***Conclusion:*** Despite the AI producing many false positive results, it successfully detected all true myocardial uptakes from bone scans. Our method is feasible for a standard nuclear medicine setup. It alerts about myocardial uptake suggestive of ATTR cardiomyopathy. It could increase the detection rate of ATTR and decrease the need for repeated cardiac SPECT-CT. ***References:*** [1] Halme, Hanna-Leena, et al. Automated DICOM-Based Quantitative Assessment of NEMA PET IQ Phantom Images for Harmonized Recovery Coefficient Analysis According to EARL Standards

A. Silva Oliveira, *V. de Oliveira Menezes, A. dos Santos Filho; Hospital das Clínicas, Federal University of Pernambuco, Recife, BRAZIL.*

Aim/Introduction: This study aimed to develop and validate an automated method for analyzing PET images of the NEMA Image Quality (IQ) phantom directly from raw DICOM data. The objective was to reliably compute recovery coefficients (RCs) and lung-to-background contrast to meet the harmonization standards set by the European Association of Nuclear Medicine Research Ltd. (EARL). ***Materials and Methods:*** A Python-based algorithm was developed to automatically process PET DICOM datasets. The algorithm identifies the specific slice containing the six fillable spheres within the NEMA IQ phantom and calculates a calibration factor by comparing measured background activity against decay-corrected theoretical activity concentration. This calibration factor is then used to compute 2D and 3D RCs, including peak RCs determined by a 50% isocontour threshold. The lung-equivalent contrast was assessed using fixed-size circular regions of interest (ROIs). This approach was tested on 36 PET/CT image series. ***Results:*** The automated algorithm successfully identified and quantified all phantom spheres across the evaluated image series. Metrics computed included RC2D (mean, max, standard deviation), RC3D (mean, max, peak, standard deviation), background contrast, and the system calibration factor. The mean calibration factor across all series was 1.08 ± 0.04. Recovery coefficients were within EARL2 specifications for spheres ≥17 mm in 92% of cases. The average lung-to-background contrast measured across 17 slices was 0.74 ± 0.03. Results were presented visually through overlays and exported as structured CSV files. ***Conclusion:*** The developed automated algorithm offers a robust and reproducible method for PET IQ phantom analysis, significantly reducing operator-induced variability. By aligning measurements with EARL-defined recovery coefficient thresholds, this tool supports harmonization in multicenter PET studies and facilitates standardized scanner optimization and routine quality assurance. ***References:*** 1. Automatic diagnosis of obstruction in Tc99m-EC renal scanning by the aid of deep learning

A. Aghaee, *P. Sahafi, S. Bagheri, S. Soltani, T. Shooshtari; Nuclear Medicine Research center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: In the context of renal disease, accurate diagnosis of complications associated with hydronephrosis is crucial for timely intervention and improved patient outcomes. Nuclear medicine scans are commonly used to assess the possibility of obstruction at UVJ or UPJ or less commonly in the pathway of the ureters. This research endeavor aims to develop and apply a deep learning algorithm to detect obstructive processes and differentiate them from non-obstructive diseases in Tc-99m ethylene dicysteine (EC) scans. By leveraging the power of deep learning, early detection of these complications could be achieved, leading to more effective and prompt treatment strategies for patients. ***Materials and Methods:*** Participating in this research were 317 patients who had undergone EC renal scans (173 patients with abnormality). Image acquisition was performed after administering 4 to 7 mCi of Tc-99m EC intravenously gamma camera in two phases. The image had a matrix dimension of 128 x 128. Flow phase data was collected for one minute (60 frames), while second phase data was collected for thirty to sixty minutes (thirty to sixty frames). Figure 1 shows example of a normal and abnormal patients. To standardize and normalize each phase for individual patients, we scaled them to their maximum values across all frames. Following this, 60 frames were added to the uptake phase, and the flow and uptake phases were concatenated to create a single 120-frame frame. The patients were divided into two distinct groups including training (75%), and test (25%). Fifteen percent of the training dataset was selected for validation. The InceptionResNet model was utilized for backbone of deep learning. We implemented two 128 dense layers and sigmoid dense layer for final layer. For model training, 2 batch size and 300 epochs were utilized. As performance metrics, the area under the curve (AUC), recall, f1 score, precision, and accuracy were utilized to assess the model's performance on the test data. ***Results:*** The accuracy and AUC were 0.67 and 0.69 for the InceptionResNet model. Using InceptionResNet, recall (0.58 and 0.66), precision (0.58and 0.66), and f1-score (0.58 and 0.66) were resulted for obstructive and normal patterns, respectively (Figure 2). ***Conclusion:*** The findings of this inquiry suggest that deep learning models may have utility in identifying and diagnosing irregularities occurring in renal abnormalities. Nevertheless, it is feasible to attain superior outcomes through the implementation of alternative filtering, using other artificial intelligence algorithms, and augmenting the data set.

Lung Cancer Classification from PET-CT Images Using Transfer Learning

M. Azizkhani[1], *P. Azarbar*[2], *M. Shahrbabaki Mofrad*[3], *M. Sharbatdar*[1], *P. Sheikhzadeh*[4]; *[1]K. N. Toosi University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medical Physics and Biomedical Engineering, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Nuclear Medicine, IKHC, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Lung cancer is one of the most serious causes of cancer-related mortality. Early diagnosis through PET-CT scans can significantly reduce the mortality rate. However, evaluating PET-CT images is a time-consuming process that is prone to human error. Therefore, the use of artificial intelligence and deep learning

algorithms can play a crucial role in analyzing and interpreting these images. ***Materials and Methods:*** One of the most valuable aspects of this research is the use of real-world and specialized data from patients with challenging tumor diagnoses. These data include PET and CT images that were acquired separately and later fused to create combined PET-CT representations for each patient. The dataset consisted of 2349 PET-CT images, including 1098 tumor-class samples and 1251 normal-class samples. In this study, convolutional neural networks (CNNs) were employed to detect lung cancer-related abnormalities in the patients PET-CT scans. Specifically, the MobileNetV2 model was used in conjunction with the Transfer Learning technique to leverage pre-trained knowledge in this domain. In addition, Data Augmentation methods were utilized to effectively expand the training dataset. To prevent overfitting and enhance the generalization ability of the model, regularization techniques such as Dropout were applied. ***Results:*** Ultimately, the proposed model achieved an accuracy of 79%, precision of 84%, recall of 78% and an F1-score of 78% on the collected dataset. ***Conclusion:*** The results indicate that the proposed deep learning approach, based on MobileNetV2 and Transfer Learning, is effective in detecting lung cancer in PET-CT scans. ***References:*** 1. Development of an automatic detection tool for hyperfunctioning parathyroid glands in dual-isotope parathyroid scintigraphy

L. Hassler[1], *D. Chardin*[1], *D. Benisvy*[1], *G. D'andrea*[1,2], *J. Darcourt*[1], *O. Humbert*[1];
[1]*Centre Antoine Lacassagne, Nice, FRANCE,* [2]*Institut de Lla Faceet du Cou, Nice, FRANCE.*

Aim/Introduction: Dual-isotope parathyroid scintigraphy is a key imaging technique for locating hyperfunctioning glands in the context of primary hyperparathyroidism before surgery. Artificial intelligence (AI), particularly through convolutional neural networks (CNNs), shows increasing potential to improve the interpretation of medical images. ***Materials and Methods:*** This retrospective study included 456 patients who underwent dual-isotope parathyroid scintigraphy at the Centre Antoine Lacassagne between 2019 and 2023. CNNs were used to classify subtraction images as positive/negative and to localize parathyroid lesions between the right and left sides. The models were trained using various labeling methods based on visual analysis and SPECT/CT data. The performance of the models was then evaluated using histological, biological, or PET-FCH results as reference. ***Results:*** The VGG19-based model achieved the best performance, particularly for right/left localization, with an overall accuracy of 92.5%, reaching 95.5% for left-sided lesions and 88.9% for right-sided lesions. The positive/negative classification achieved an accuracy of 77% and sensitivity of 81.4%. Expert SPECT/CT analysis displayed the best overall results, with a sensitivity of 95.3% and specificity of 88.9%. ***Conclusion:*** This study, the first to use convolutional neural networks to detect and localize hyperfunctioning parathyroid glands in dual-isotope scintigraphy, shows promising results, especially for left/right localization.

EP-1005

Contrast agnostic AI-based extraction of image-derived input function from dynamic PET scans

T. Andersen*, N. Evenstuen, C. Ladefoged, U. Lindberg;*
Rigshospitalet, Dept. of Clinical Physiology & Nuclear Medicine, Copenhagen, DENMARK.

Aim/Introduction: Accurate quantification in positron emission tomography (PET) requires reliable input functions. With recent advancements, image-derived input functions (IDIFs) have become feasible [1], often extracted using anatomical segmentations like the aorta from CT scans. However, reliance on structural imaging can introduce motion mismatch, bias from image quality, and limit applicability. We propose a contrast-agnostic method to extract IDIFs directly from dynamic PET images using an AI model. ***Materials and Methods:*** Aorta segmentations were obtained using TotalSegmentator (TS) [2] on CT images. A manually PET-guided segmentation (PGS) of the aorta was also performed for 35 test datasets. Of 244 total datasets, 16 with poor CT segmentations were excluded from training and treated separately as an outlier dataset. The remaining 198 datasets (108 [18F]FDG, 68 [15O]H2O, 5 [18F]PE2I, 1 [11C]PIB, 7 [68Ga]FAPI, 9 [64Cu]DOTATATE) were used for model training. CT-based aorta masks were resliced to a 0-40 s summed PET image. A 5-fold cross-validation with data augmentation was used. Segmentation performance was assessed using Dice similarity coefficients (DSCs), and IDIF quality was evaluated via maximum peak height (MP) and area under the curve (AUC) using an approach akin to [1]. ***Results:*** In the test set, mean DSCs vs. PGS were 0.83 (TS) and 0.82 (AI). In the outlier set, the AI model outperformed TS (DSC: 0.86 vs. 0.79). For IDIFs, the TS approach showed MP and AUC biases of -2.6% and -1.3%, respectively, compared to PGS, while the AI model showed smaller biases of 1.6% (MP) and 0.6% (AUC). On the outlier dataset, the TS had MP and AUC differences of -3.0% and -1.4%, while the AI model maintained higher accuracy (0.5% MP, -0.1% AUC). ***Conclusion:*** We developed a robust AI model that extracts IDIFs directly from PET, reducing reliance on structural imaging. The model performs comparably to CT-based methods on standard cases and significantly better on outliers, improving robustness in challenging scenarios. ***References:*** [1] Andersen, T.L., Andersen, F.L., Haddock, B., Rosenbaum, S., Larsson, H.B.W., Law, I. & Lindberg, U. (2024), Automated Quantitative Image-Derived Input Function for the Estimation of Cerebral Blood Flow Using Oxygen-15-Labelled Water on a Long-Axial Field-of-View PET/CT Scanner. EP-1006

Improving Planar Lung Scintigraphy Interpretation with artificial intelligence (AI): An Educational and Clinical Utility Tool for Pulmonary Embolism Detection

B. Duchaj[1], *L. Noskovičová*[2], *J. Veselý*[1], *S. Balogová*[2,3];
[1]*St. Elisabeth Oncology Institute, Bratislava, SLOVAKIA,* [2]*Department of Nuclear Medicine, Comenius University Bratislava, St. Elisabeth Oncology Institute and Bory Hospital, Bratislava, SLOVAKIA,* [3]*Department of Nuclear Medicine, Hôpital Tenon GH AP.SU, Paris, FRANCE.*

Aim/Introduction: The interpretation of planar ventilation/perfusion (VQ) scans poses significant challenges for young nuclear medicine (NM) physicians and medical students. This study investigates the potential of using deep learning to assist in the identification of acute pulmonary embolism (PE) in planar scans. We are developing an in-house educational tool that not only correlates these imaging projections with planar lung segments but also provides practical engagement with medical AI, thereby actively involving the students in the learning process and evaluating their knowledge. ***Materials and Methods:*** From 2020 to 2023, we conducted a retrospective analysis of 287 patients who underwent VQ lung scanning using [99mTc]-MAA / [81mKr] without SPECT or SPECT/CT. The NM reports served as the reference standard for diagnosing acute PE or alternative conditions. We subsequently obtained 74 perfusion scans categorized into acute PE and non-acute PE, alongside 64 ventilation scans comprising cases with and without ventilation defects. These studies were systematically extracted utilizing a configurable DICOM tag, yielding a sequence of 8 planar projections for perfusion and 6 for ventilation, effectively creating

a "quasi" SPECT dataset. A 3D sequential convolutional neural network was developed with a binary classification output, with each dataset trained independently. The model demonstrating the best validation accuracy, loss and AUC was evaluated against the validation dataset. ***Results:*** The perfusion model has demonstrated an accuracy/loss of 0.88/0.24 and an AUC of 0.96, correctly evaluating 30 cases of PE versus non-PE with a sensitivity of 96.6% (1 false negative) and 86.6% (4 false positives). The ventilation model exhibited an accuracy/loss of 0.84/0.35 and an AUC of 0.90, successfully categorizing 26 cases of normal versus abnormal with a sensitivity of 88.4% (3 false positives) and 76.9% (6 false negatives). We developed an in-house web application to facilitate the importation of V/Q scans as DICOM instances for processing and analysis of the acute PE probability. This application enables semi-manual mapping of planar scintigrams to lung segment representations, providing a practical platform for image analysis and serving as an educational resource and quiz tool for medical students. ***Conclusion:*** To increase the adoption of AI systems among physicians in NM, it is essential to engage medical students in a more effective understanding of medical data and image analysis. This can be operationalized through the creation of interactive educational tools, such as in-house applications, that promote the practical application of these advanced technologies within the medical community.

EP-1007

Radiomics Analysis for Differentiate Benign and Malign Pulmonary Nodules Using Tumoral, Peritumoral and Peribronchovascular Segmentation with Machine Learning Approaches

A. Inanir[1], *K. Dizdar*[2], *N. Dizdar*[1], *N. Coşkun*[3], *E. Tatçı*[1], *Ö. Özmen*[1]; *[1]Etlik City Hospital, Ankara, TÜRKIYE, [2]ASELSAN INC. Software Engineering, Ankara, TÜRKIYE, [3]Ankara City Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: The present study aimed to evaluate the potential contribution of peritumoral and peribronchovascular PET/CT-based radiomics analyses in differentiating malignant pulmonary nodules from benign ones, beyond the information provided by intralesional radiomic features alone. Additionally, radiomics analysis was employed to differentiate benign from malignant nodules within both FDG-positive and FDG-negative groups. Furthermore, the diagnostic performance of radiomics analysis was evaluated across nodules of varying sizes. ***Materials and Methods:*** A total of 163 patients with nodules 6 to 30 mm, who had either histopathological diagnosis or at least two years of CT follow-up, were included in the study retrospectively. Three different VOI were manually delineated for each nodule: intralesional, perilesional, and peribronchovascular. The perilesional VOI was drawn around the periphery of the lesion, excluding the FDG uptake area, with a thickness of one voxel. A linear VOI was created along the peribronchovascular bundle nearest to the nodule. Radiomic parameters were evaluated using the Python Scikit-learn library. Significant parameters were determined using the Mann-Whitney U test and filtered through PCA regression analysis. The radiomic parameters were tested using machine learning classifiers. The SVM classifier achieved best prediction performance, and this model was used in the analyses. ***Results:*** A total of 163 cases (119 male, 44 female) with an average age of 65.7 ± 10.7 years were included in the study. Of the nodules, 96 were benign and 67 were malignant. Significant differences were found in more than 40 radiomics parameters for all 3 segmentation models. With joint model that includes all parameters gathered from three segmentations, 70 parameters were significantly different. The F-measure and AUC values for the intralesional, perilesional, peribronchovascular and joint model were found to be 0.79/0.87, 0.73/0.75, 0.75/0.77 and 0,76/0,82 respectively. For the differentiation of FDG-positive nodules, the AUC and F-Measure found to be 0.77/0.71 respectively. Models obtained with all three segmentations were unsuccessful in differentiating benign and malignant lesions in the FDG-negative group.In the differentiation of benign and malignant nodules, the AUC value for <1cm, 1-2cm and 2-3 cm groups was 0.67/0.82/0.86 respectively. ***Conclusion:*** In our study, it has been demonstrated that segmentation of the nodule in PET-based radiomics analysis can be effective in differential diagnosis. Additionally, it was found that radiomic parameters may contribute to showing inflammation in the peritumoral microenvironment and tumor cell spread through airways (STAS). It was also determined that radiomics could be helpful in preventing false positives in FDG-positive nodules. ***References:*** doi: 10.1111/crj.13751.

FDG PET/CT-Based Machine Learning Modelling and Texture Features in Risk Stratification of Thymomas

B. Bozca[1], *K. Dizdar*[2], *N. Aydinbelge Dizdar*[1], *E. Tatci*[1], *T. Inal Cengiz*[3], *O. Ozmen*[1], *N. Gurcay*[4], *P. Tari*[5], *U. Yilmaz*[3], *L. Acar*[6]; *[1]Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Department of Software Engineering, ASELSAN Inc., Ankara, TÜRKIYE, [3]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Department of Chest Diseases, Ankara, TÜRKIYE, [4]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Department of Pathology, Ankara, TÜRKIYE, [5]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [6]Ataturk Chest Diseases and Thoracic Surgery Training and Research Hospital, Department ofThoracic Surgery, Ankara, TÜRKIYE.*

Aim/Introduction: Thymoma is the most common primary tumour of anterior mediastinum. Considering their prognosis and recurrence, thymomas are classified into two groups: low-risk (types A, AB, B1) and high-risk (types B2, B3). Aim of this study is to evaluate a prediction model based on radiomics parameters obtained from FDG PET/CT images for differentiating between low and high-risk thymomas. The study also examines the effectiveness of conventional FDG PET/CT parameters in risk assessment. ***Materials and Methods:*** Patients who underwent FDG PET/CT between January 2017-December 2023 for differential diagnosis of mediastinal mass and were diagnosed with thymoma through histopathological analysis. Lesions were manually segmented using LIFEx v7.4.0 software. Total of 111 radiomics features were extracted and evaluated using the Python Scikit-learn library. Parameters showing statistically significant differences were identified using the Mann-Whitney U test. Feature selection was then performed using LASSO regression analysis to reduce the number of variables and determine the most significant radiomics features. Selected features were tested with various machine learning classifiers: Random Forest, Support Vector Machine (SVM), Logistic Regression, Multilayer Perceptron, and XGBoost. Model performance was evaluated using the following metrics: ROC curve, accuracy, precision, recall, F-measure. Among all models, the SVM classifier provided the best prediction performance and was used for final analyses. Conventional parameters (SUVmax, SUVmean, SUVpeak, MTV, TLG) were compared between the low and high-risk thymoma groups using Mann-Whitney U test. ROC analysis was applied to calculate AUC values and optimal cut-off points. ***Results:*** Total of 69 patients diagnosed with thymoma with a mean age of 53.88±13 were included in the study. Patients were classified histologically into two groups. Statistically significant differences were found in 24 CT-based and 62 PET-based radiomics features. The most significant performance parameters are listed in Table 1. Radiomics performance metrics in distinguishing low from high-risk thymomas for CT images were: AUC:0.79, Accuracy:0.67, Precision:0.72, Recall:0.70, F-measure:0.67. For PET images: AUC:0.74, Accuracy:0.71, Precision:0.72, Recall:0.71, F-measure:0.71. No statistically significant differences were found

between the patient groups for conventional PET parameters (Table 2). Cut-off value for SUVmean in detecting high-risk thymomas was calculated as 3.47, with 57% sensitivity and 56% specificity (AUC 0.659, p=0.0027). ***Conclusion:*** In this study, no significant difference was detected between low and high-risk thymomas using conventional PET metrics. However, FDG PET/CT-based texture analysis, which more precisely evaluates tumour heterogeneity, may serve as a potentially stronger biomarker in risk classification. Further large-scale studies including broader patient populations are needed.

EP-1009

Automated AI-Based PET/CT Analysis for Monitoring Immunotherapy Response in Metastatic Melanoma

L. Förner[1,2], *J. Bäßler*[1], *C. Sulski*[1], *J. Enke*[1], *C. Lapa*[1], *T. Wendler*[1,2], *LF and JB are first authors with equal contribution;*
[1]*University Hospital Augsburg, Augsburg, GERMANY,* [2]*Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: FDG-PET/CT plays a pivotal role in evaluating response and guiding complementary therapies in metastatic melanoma under immunotherapy. Quantitative PET metrics are central to this process but require time-consuming whole-body lesion segmentation. This study evaluates whether AI-based PET segmentation reliably reproduces manual metrics and reflects clinically relevant response patterns. ***Materials and Methods:*** 76 patients with metastatic melanoma undergoing immunotherapy were scanned with FDG-PET/CT before and during therapy. Six of them additionally underwent lymph node dissection (LND). A pipeline including automatic segmentation of FDG-positive lesions [1] was used to process all baseline (BL) and follow-up (FU) images. All BL images were also segmented manually. Lesion count (LC), SUVmax, SUVmean, total metabolic tumor volume (TMTV), total lesion glycolysis (TLG), Dmax, and total surface area (TSA) were calculated for all images. To validate the automatic pipeline, the metrics derived from the manual segmentations were compared with those from the AI-based segmentations. Differences in metrics between BL and FU were then analyzed with respect to clinical outcome, categorized as stable disease (SD, n=6), progressive disease (PD, n=19), partial metabolic response (PMR, n=15), or mixed response (MR, n=27), using imaging and S100 protein levels. LND patients were evaluated separately. ***Results:*** There was good agreement between manual and AI segmentations. LC matched in 40 patients, while in 26, the AI identified 2.35 more lesions on average. SUVmax and TLG showed no statistically significant difference (SSD), while TMTV and TLG demonstrated strong agreement (R^2 =0.89 and 0.86). Dmax showed SSD (45 ± 35 cm vs. 70 ± 47 cm), attributable to methodology: manual Dmax was measured on coronal MIP images, while the AI measured the 3D maximal distance between tumor voxels. When comparing BL-FU changes, SSD between PMR and SD were found for LC, SUVmean, and TLG; between SD and PD for LC, SUVmean, TMTV, TLG, and TSA. LND patients showed improved metrics compared to SD, with SSD in SUVmax, SUVmean, TMTV, TLG, and TSA. ***Conclusion:*** The automatic pipeline did not yield identical results to manual annotations but produced qualitatively good segmentations with closely matching SUVmax, TMTV, and TLG. The observed Dmax difference reflects definitional discrepancies. Automatically derived metric changes aligned well with clinical outcome, showing SSD across response groups. While limited by dataset size and human annotation density, this study demonstrates that fully automatic PET metric evaluation is feasible and already offers valuable support in resource-constrained clinical settings. ***References:*** [1] Rokuss M et al. arXiv preprint arXiv:2409.09478, 2024.

EP-1010

AI automation in Segmentation and Interpretation of PSMA PET-CT Imaging

K. Doornhof*, S. Koolen, A. Schrik, S. Veldhuijzen van Zanten, M. Segbers, M. Konijnenberg;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Accurate segmentation of PET-CT images is crucial to determine the absorbed dose delivered to various tissues. Traditionally, segments were manually drawn, a time-consuming process that often limited dosimetry to selected lesions rather than all visible tumor tissue. AI segmentation tools can expedite and expand segmentation, enabling more comprehensive interpretation of PSMA scans. ***Materials and Methods:*** PSMA PET-CT images were obtained from patients undergoing Lu-PSMA treatment as part of the LUTRAC trial. Initial segmentation of CT images was performed using TotalSegmentator [1]. Segments corresponding to kidneys, bladder, liver, spleen, intestines, parotid and submandibular glands were refined based on PET imaging data to exclude non-malignant PSMA uptake. Non-physiological tracer uptake, likely indicative of tumor tissue, was classified using an SUV cutoff. Volume, SUV mean, and SUV max were determined for organs, bones, and tumor tissue. Segments generated by TotalSegmentator v2.5.0 and tumor segments identified using the SUV cutoff method were manually inspected for accuracy. ***Results:*** PSMA PET-CT images from 50 patients were segmented and analyzed using the automated pipeline. While manually drawing and analyzing of segments typically takes around 90 minutes, this analysis could be completed in under 10 minutes using TotalSegmentator based segmentation. A visual inspection was performed on the generated segments of different organs to confirm that that their placement matched expectations. Abnormal uptake identified by the analysis pipeline was checked by a nuclear radiologist for the initial three scans analyzed. The model's identification of abnormal uptake closely matched manual assessments in these cases. ***Conclusion:*** AI methods for analyzing PSMA PET-CT imaging can significantly reduce the time required to determine PSMA uptake in various tissues. These methods could also be applied to SPECT-CT imaging and other tracers. This could allow for quicker and more extensive dosimetry, which could enhance clinical decision-making. ***References:*** 1.Wasserthal, J., Breit, H.-C., Meyer, M.T., Pradella, M., Hinck, D., Sauter, A.W., Heye, T., Boll, D., Cyriac, J., Yang, S., Bach, M., Segeroth, M., 2023. AI-assisted treatment response assessment to disease-modifying therapy in 99mTc-DPD SPECT/CT markers in transthyretin cardiac amyloidosis enabled by artificial intelligence

C. Spielvogel*, M. Koefler, D. Haberl, J. Ning, J. Yu, Z. Jiang, K. Kluge, R. Calabretta, M. Hacker, R. Rettl;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Transthyretin cardiac amyloidosis (ATTR-CM) is a progressive and underdiagnosed condition associated with significant morbidity and mortality. Disease-modifying therapies (DMTs) targeting transthyretin have demonstrated efficacy in slowing disease progression, but robust markers for early treatment response remain limited. This study evaluates the impact of DMTs on 99mTc-DPD SPECT/CT-derived markers quantified through artificial intelligence (AI), providing insights into their role as non-invasive biomarkers for monitoring therapeutic efficacy. ***Materials and Methods:*** This longitudinal study included patients with confirmed ATTR-CM undergoing DMTs (transthyretin stabilizers, RNA interference or antisense oligonucleotids). Participants underwent 99mTc-DPD SPECT/CT imaging at baseline and

follow-up after therapy initiation. AI-based segmentation of cardiac structures enabled the measurement of 23 quantitative parameters, including uptake-intensity and uptake volume metrics, as well as the retention index across cardiac substructures. Functional parameters, including echocardiography and cardiac MRI metrics were integrated for correlative analysis. Univariate and multivariate Cox proportional hazards models were performed for death or heart failure-associated hospitalization. ***Results:*** This study analyzed longitudinal data from 45 patients with a median time between baseline and follow-up scans of 9 months (IQR 7-10). Post-treatment assessments revealed significant reductions in 14/16 (88%) of SPECT/CT markers ($p<0.0001$), including notable decreases in uptake of the left ventricle (SUVmax 18.6 to 14.1) and myocardium (SUVmax 19.5 to 15.5) while uptake area metrics increased in 5/7 (71%) markers after treatment initiation, however not significantly (all $p>0.05$). These changes corresponded to improvements in functional parameters, including an association of reduced NT-proBNP with lower uptake in terms of SUVpeak of the myocardium ($p=0.007$), SUVmax of the myocardium ($p=0.018$), right ventricle ($p=0.029$), and left ventricle ($p=0.039$) as well as an association of a reduced retention index with lower new york heart association (NYHA) stage ($p=0.016$). Associations between atrial and right ventricular uptake showed a tendency to be associated with prognosis but were not significant ($p=0.08$ and $p=0.07$ respectively). ***Conclusion:*** This study underscores the utility of AI-enhanced 99mTc-DPD SPECT/CT imaging in capturing treatment-induced changes in cardiac amyloid burden. By automating marker extraction, AI mitigates inter-rater variability, increases efficiency, and enhances reproducibility. Our findings highlight the potential of SPECT/CT markers to serve as sensitive, non-invasive biomarkers for early treatment response assessment, offering an alternative to cardiac MRI in patients with implanted devices. These findings pave the way for personalized treatment strategies and broader clinical adoption of AI in nuclear medicine.

EP-1012

Accuracy and Precision of Lung Lobe Function Measurements from SPECT/CT Using Openly Available and Task Trained AI Segmentation Models

E. Amini[1], *R. Klein*[2];
[1]*Ottawa Hospital Research Institute, Ottawa, ON, CANADA,* [2]*The Ottawa Hospital, Ottawa, ON, CANADA.*

Aim/Introduction: Lung lobe segmentation is essential for assessing lobar function before surgery. This tedious task can now be automated using AI models, though accuracy depends on training data qualities. Given the low spatial resolution of SPECT, exact segmentation may be unnecessary. We sought to compare the accuracy and precision of lung lobe function quantification using general radiology and ad-hoc trained AI segmentation models. ***Materials and Methods:*** We retrospectively collected 160 pairs of CT-SPECT scans from patients who underwent lung function imaging. Ground-truth segmentations were derived semi-automatically using clinical software. Data was split 80/20 for training/testing (N=128/32), with test cases stratified by segmentation difficulty into three grades (7 Easy, 9 Moderate, and 16 Hard). Models compared included open-source (MOOSE, TotalSegmentator, Vista3D), and locally trained using our training data (Vista3D fine-tuned and an nnUNet-based LocalModel). Segmentation results were automatically co-registered to SPECT using affine transforms to extract lobe function (%) as counts per lobe divided by total lung counts. Lobe function error (%) was calculated as the difference between model and ground-truth. Error bias and error spread were assessed using the Wilcoxon signed-rank and Ansari-Bradley tests, respectively. Mean absolute error (MAE) was used to assess precision. Lobe function errors <5% were considered clinically insignificant. ***Results:*** Across the 32 cases, no model-specific bias was observed for median lobe function error whether stratified by difficulty group ($p=1$) or by lobe ($p>0.05$). Error spread significantly increased from Easy to Hard cases only for MOOSE ($p=0.005$, MAE:0.57%→2.29%) and Vista3D ($p=0.004$, MAE:0.44%→2.40%), with significance only in the right-middle lobe (Easy-Hard) for MOOSE, TotalSegmentator, and Vista3D ($p<0.02$). In Hard cases, absolute errors as large as 17% were observed for non-locally trained models and <5% for our locally trained model. No significant model-specific bias was observed between 5-lobe (n=25) and missing lobe (n=7) ($p=1$). However, error variability was significantly higher in missing-lobe cases for all models ($p<0.03$) except LocalModel ($p=0.4$), indicating robustness in these challenging scenarios through representative training data. Clinically significant errors in at least one lobe occurred in 19% of MOOSE and Vista3D cases, 16% of TotalSegmentator, 6% of fine-tuned Vista3D, and none for LocalModel. ***Conclusion:*** Despite differences in segmentation quality between AI models, lobar function estimates from SPECT rarely vary in a clinically significant manner. Results suggest publicly available segmentation tools can be reliable for most clinical use, but are outperformed by ad-hoc trained models. Regardless, oversight by clinicians for gross errors is still required.

Providing anatomical context for longitudinal lesion assessment: comparison of two deep learning models

P. Patil[1], *P. Khobragade*[2], *H. Yerebakan*[3], *G. Platsch*[4], *N. Vargese*[2], *M. Rashmi*[1], *M. S. Chakragiri*[2], *A. Shanker*[2], *B. Spottiswoode*[5], *A. Soliman*[5];
[1]*Manipal Institue of Technology, Manipal, INDIA,* [2]*Siemens Healthcare Private Ltd., Bangalore, INDIA,* [3]*Siemens Medical Solutions USA, Inc., Malvern, PA, UNITED STATES OF AMERICA,* [4]*Siemens Healthcare GmbH., Erlangen, GERMANY,* [5]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: Accurate anatomical localization of lesions in PET/CT scans is important for disease staging and prognosis, and needs to be consistent across serial scans for treatment response assessment. CT-based deep learning segmentation is a well-established method for providing anatomical context but can be computationally intensive, especially with widely distributed lesions across multiple time points. This study compares a conventional UNet-based whole body segmentation (WBS) method with a novel, fast organ classification (FOC) approach[1] for anatomical localization in longitudinal PET/CT scans. ***Materials and Methods:*** A dataset of 75 ^{18}F-FDG PET/CT scans was collected from 25 patients, each having at least two longitudinal scans corresponding to different therapy cycles. A total of 246 lesions were segmented by a nuclear medicine physician and the linking between corresponding lesions in each scan pair was established. Two methods were used to identify the lesion location in longitudinal scans based on CT information: (1) The WBS method which segments the entire CT volume into 79 regions. The anatomical location of a lesion is determined by the mapping of its centroid onto the 79-class segmentation map. (2) The FOC method determines the anatomical location through the classification of the lesion centroid only. FOC extracts a hierarchical multi-resolution descriptor for a given location and feeds it into a classifier to predict one of 117 anatomical locations. The accuracy of each method is assessed based on the ability to correctly identify the same anatomical location for each pair of linked lesions in the two timepoints. The processing times for both techniques were also recorded. ***Results:*** The mean processing time for the WBS method to segment all organs was 3.9±0.8 minutes, while the FOC method averaged 0.25±0.17 seconds per scan (69±42 millisecond per lesion), demonstrating a more than 3,000-fold improvement in processing speed. For correctly identifying the same location for both linked lesions in the two longitudinal scans, the FOC achieved an accuracy of 82.1%, while the standard method achieved 87.8%. ***Conclusion:*** The performance of two methods for anatomical localization was evaluated based on computational efficiency

and accuracy in identifying the same location for linked lesions. The fast organ classification method showed a significant gain in processing speed over the standard approach, with a slight trade-off in lesion identification accuracy. Both methods may support disease restaging and therapy response assessment. ***References:*** [1] Yerebakan, Halid, et al. "Real Time Multi Organ Classification on Computed Tomography Images." EP-1014

PET Radiotracer Image-based Classification Using Convolutional Neural Network

L. Partin[1], *K. Chiam*[2], *B. Spottiswoode*[1], *R. Fahmi*[1], *V. Shah*[1];
[1]*Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA,* [2]*Department of Bioengineering, University of California, Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: For accurate quantitation and customized downstream processing of PET images, the radiotracer and isotope must be known. Traditionally, this information is saved in the DICOM header, but this can be erroneously misassigned or missing altogether. This challenge is further exacerbated by varying geographical conventions and languages. We seek to automate the classification of the radiotracer with deep learning. To our knowledge, this is the first work to explore this task. ***Materials and Methods:*** A 2D convolutional neural network (CNN) was trained to classify the radiotracer. Training images were augmented by random rotations, translation, and zooming before converting to a coronal maximum intensity projection (MIP) as input to the network. Our dataset comprised of 876 images across 15 radiotracers: 18F-PSMA-1007, 18F-FES, 82Rb, 68Ga-PSMA-11, 18F-FACBC, 68Ga-Dotatate, 18F-PI-2620, 18F-FDOPA, 18F-DCFPyl, 18F-FDG, 13N-Ammonia, and amyloid tracers 18F-florbetapir, 18F-flutemetamol, 18F-florbetaben, and 11C-PiB. Cases were split into training, tuning, and test and stratified by radiotracer. To verify generalizability of the network, a network was first trained on 12/15 radiotracers that span whole body, cardiac, and neurology use cases and tested on ^{18}F-FDG and 82Rb from two external sites. Grad-CAM [1] was used to highlight areas of the image useful for classification. To demonstrate specialization, a separate network was trained on amyloid-only tracers to showcase if different amyloid tracers can be distinguished. For the amyloid network, the inputs of MIP versus 16 center coronal slices were compared. ***Results:*** The generalized network correctly classified 66/73 test cases. Misclassified cases corresponded to either tracers with the same isotope or PSMA tracers confused with another PSMA tracer. For the external site tracers, 7/11 ^{18}F-FDG and 14/15 82Rb were classified correctly, demonstrating that the network is robust to cross-site protocols. Use of the MIPs or the central slices for amyloid characterization yielded similar results (37/40 and 36/40 correct classifications, respectively). Grad-CAM demonstrated that the network capitalized on regions that a reader would use to distinguish tracers, e.g., the brain in ^{18}F-FDG and the salivary glands in 18F-PSMA. ***Conclusion:*** A CNN showed promising results to classify between PET radiotracers, although further work is needed to improve and validate robustness across sites and reconstruction protocols. This introduces a quality control metric to ensure accurate quantitation and applicability for radiotracer-specific downstream applications. Future work could include incorporating domain knowledge so that the algorithm can justify its classification through user-friendly explanations. ***References:*** [1] R. R. Selvaraju et al.: http://arxiv.org/abs/1610.02391.

EP-1015

Revisiting the Segmentation Threshold for Lu-177 SPECT

Y. Liu[1], *J. Yang*[2], *P. Wang*[2,1], *Y. Wang*[2], *K. Shi*[3], *Y. Chen*[2], *G. Mok*[1];
[1]*Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Macao Sar, MACAO,* [2]*Department of Nuclear Medicine, Affiliated Hospital of Southwest Medical University, Luzhou, CHINA,* [3]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Currently, tumor segmentation on SPECT images is still mainly based on a fixed threshold, i.e., 42% of the maximum intensity, which was derived primary for Tc-99m (1) and may not be directly applicable to Lu-177, one of the most widely used theranostic tracers today. This study aims to revisit the optimal segmentation threshold value for Lu-177 SPECT. ***Materials and Methods:*** A cylindrical Jaszczak phantom with six spheres (2-113 mL) was imaged using a clinical dual-head NaI SPECT/CT system with medium-energy and low-penetration parallel-hole collimators. The spheres were filled with 44 μCi/mL Lu-177, with sphere-to-background ratios (SBRs) of infinite, 10:1, 5:1, 3.5:1, and 2:1. A total of 120 projections with 25 s/projection acquired over 360° at a fixed radius-of-rotation of 24 cm were reconstructed using 3D FBP and OS-EM algorithms with attenuation and scatter corrections, followed by Gaussian filtering (σ=3.4 mm). Segmentation thresholds from 1% to 100% of the maximum voxel intensity were applied to minimize volume errors relative to ground truth. Pearson correlation was assessed between the optimal thresholds and sphere volume/SBR. The newly derived and conventional Lu-177 thresholds were further validated on a total of 41 tumors on 17 patients with Lu-177-PSMA-617 SPECT using Dice, Hausdorff Distance at 95th percentile (HD95) and mean absolute volume error (MAVE). using manual segmentations based on consensus from three clinicians as the gold standard. A Mann-Whitney U test was performed between results from 2 threshold approaches. ***Results:*** The optimal thresholds showed a negative correlation ($r<0$) to both sphere volume and SBR. For SBR ≥3.5:1 and volume ≥16 mL, the mean optimal threshold of Lu-177 converged to 56% for FBP and 50% for OS-EM. The derived 50% threshold significantly improved tumor segmentation performance compared to the conventional 42% threshold on the clinical study, with a higher Dice (0.71 ± 0.10 vs 0.67 ± 0.13), lower HD95 (2.40 ± 1.57 mm vs 2.54 ± 1.58 mm), and lower MAVE (0.44 ± 0.35 vs 0.83 ± 0.66) (all $p < 0.05$). ***Conclusion:*** The optimal threshold value substantially deviated from that of Tc-99m for Lu-177 SPECT and can be used to enhance subsequent tumor quantification analysis in Lu-177 SPECT. ***References:*** 1. Erdi, Y E et al. "Threshold estimation in single photon emission computed tomography and planar imaging for clinical radioimmunotherapy." Cancer research vol. 55,23 Suppl (1995): 5823s-5826s. EP-1016

Enabling Lesion-Level Dose-Response Analysis in RPTs: Topology-Aware Tracking of Metastases Using Spectral Graph Matching

F. Yousefirizi[1], *P. Fernandez*[2], *S. Kurkowska*[1], *F. Benard*[1], *A. Rahmim*[1], *C. Uribe*[2];
[1]*BC Cancer Research Institute, Vancouver, BC, CANADA,* [2]*BC Cancer, Vancouver, BC, CANADA.*

Aim/Introduction: Accurate dose-response assessment in radiopharmaceutical therapy (RPT) hinges on reliable lesion segmentation and longitudinal tracking, a process that becomes increasingly burdensome in metastatic castration-resistant prostate cancer (mCRPC) due to high lesion counts and anatomical changes over treatment cycles. To address this, we propose an automated, structure-aware tracking pipeline using Spectral Graph Matching (SGM), which integrates spatial and radiomic features while preserving global lesion topology. We compare it to a pairwise feature-based matching (PFM) approach to assess the added value of incorporating contextual graph-based information for robust lesion correspondence. ***Materials and Methods:*** Our method was evaluated on longitudinal post-therapeutic quantitative SPECT scans from five mCRPC patients treated with [^{177}Lu]Lu-HTK03170, totaling 30 imaging time points across up to six therapy cycles. Lesions were segmented using the qPSMA workflow in MIM and refined by physicians, with manual lesion correspondence as reference. Each of the 175 tracked lesions (~35 per patient) was represented by a feature

vector comprising centroid coordinates, volume, and a radiomics-derived heterogeneity score combining entropy and Gray-Level Co-occurrence Matrix (GLCM) features. Baseline PFM method (Yousefirizi et al. SNMMI 2025) used weighted cosine similarity and centroid distance, followed by spatial filtering and Hungarian assignment. In contrast, our SGM method embedded each scan into a lesion graph, with edge weights defined by Gaussian affinities between feature vectors. Spectral decomposition of graph Laplacian yielded low-dimensional eigenvectors capturing global lesion topology. Matching was then performed using cosine similarity between these embeddings, combined with spatial proximity, and optimized via the Hungarian algorithm. This structure-aware formulation enables resilience to lesion displacement, morphological variability, and changes such as splitting or merging. ***Results:*** PFM algorithm correctly tracked 166 of 175 lesions, yielding a mean per-lesion Connected Lesion (CL) accuracy (Santoro-Fernandes et al. 2024) of 0.788. PFM resulted in 9 missed lesions, where no corresponding lesion was identified in the subsequent time point, and no incorrect assignments. In comparison, SGM correctly tracked 153 lesions, missed 3, but produced 22 incorrect assignments. Despite more incorrect links, SGM achieved a higher CL accuracy of 0.893, driven by fewer missed matches. This suggests incorporating global graph-based context improves lesion recall at the expense of increased assignment ambiguity. ***Conclusion:*** We developed a structure-aware lesion tracking framework using SGM and benchmarked it against PFM. While PFM showed higher precision, SGM demonstrated greater robustness to lesion evolution, spatial shifts, and morphological change, supporting scalable, automated analysis of longitudinal SPECT/CT for RPT response evaluation.

Evaluation of combined or separate automatic segmentation models for ^{68}Ga-PSMA PET/CT and ^{177}Lu-PSMA SPECT/CT

S. Perret[1,2], *L. Albe*[3], *A. Edet-Sanson*[3,1], *D. Tonnelet*[3], *T. Carlier*[4,5], *C. Kohi*[4], *M. Barbaud*[4], *R. Modzelewski*[3,1], *P. Vera*[3,1], *C. Bailly*[4,5], *A. Dieudonné*[3,1], *P. Decazes*[3,1];
[1]*QuantIF-AIMS, University of Rouen, Rouen, FRANCE,* [2]*Siemens Healthineers, Courbevoie, FRANCE,* [3]*Nuclear Medicine Department, Henri Becquerel, Rouen, FRANCE,* [4]*Nuclear Medicine Department, University Hospital, Nantes, FRANCE,* [5]*Nantes Université, INSERM, CNRS, CRCINA, Université d'Angers, Nantes, FRANCE.*

Aim/Introduction: The manual segmentation of prostate cancer metastases on PET/CT and SPECT/CT images with PSMA radiotracers is laborious. The aim of this study is to evaluate the automatic segmentation models nnUNet trained on the two modalities, PET and SPECT, separately and jointly. ***Materials and Methods:*** The dataset consists of 48 patients from Henri Becquerel Cancer Center (HBCC) and 16 patients from the Nantes University Hospital (NUH). For each patient, both a 68Ga-PSMA PET/CT image and a 177Lu-PSMA SPECT/CT image were acquired during the first treatment cycle. These data were segmented by four nuclear medicine specialists. Three nnUNet models were trained for PET/CT and SPECT/CT: Model 1 (using PET/CT images only), Model 2 (using SPECT/CT images only), and Model 3 (combining PET/CT and SPECT/CT images). Additionally, two other models were specifically designed for SPECT: Model 4, a dual-head architecture that segments both lesions and organs simultaneously, and Model 5, which uses PET-based lesion segmentation as input to guide SPECT lesion segmentation. The models underwent both internal (dataset from the HBCC) and external validation (dataset from the NUH) to assess their generalizability. The volumes segmented automatically were assessed using the mean Dice coefficient (DSC). ***Results:*** Internal and external validations were performed to evaluate lesion segmentation on PET/CT and SPECT/CT. The PET/CT-specific model (1) achieved the best performance (DSC: 0.908 internal, 0.809 external), while the multi-modality model (3) also performed well. For SPECT/CT images, the best performance was achieved by the SPECT/CT with PET-guided segmentation model (5) with DSCs of 0.742 (internal) and 0.806 (IQR = 0.086) (external). The Dual-Head Model also performed well with DSCs of 0.730 (internal) and 0.790 (IQR=0.1172) (external). Moreover, both models showed more tightly clustered DSC values around the mean, indicating greater robustness and consistency compared to the SPECT/CT-specific model (2) (IQR=0.176). ***Conclusion:*** In this study, we evaluated different segmentation methods for lesion segmentation in PET/CT and SPECT/CT. For PET/CT images, the PET/CT-specific and multi-modality models showed the best results. Our findings also demonstrate that incorporating PET/CT-based guidance (5) or anatomical context through Dual-Head segmentation (4) significantly enhances lesion segmentation in SPECT/CT, leading to improved performance. This approach is particularly relevant since PET imaging offers superior spatial resolution compared to SPECT, and the PET scan is performed beforehand. ***References:*** Isensee, F., Jaeger, P. F., Kohl, S. A., Petersen, J., & Maier-Hein, K. H. (2021). nnU-Net: a self-configuring method for deep learning-based biomedical image segmentation. Nature methods, 18(2), 203-211.

EP-1018

A method for separating lesions from physiological uptake in PET segmentation

A. Soliman[1], *H. Yerebakan*[2], *B. Spottiswoode*[1];
[1]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [2]*Siemens Medical Solutions USA, Inc., Malvern, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: The characterization of lesion volumes and SUV parameters on PET images requires accurate segmentation. A significant challenge during this process is separating a lesion from high physiological uptake in close proximity, which often demands careful manual intervention. While deep learning methods offer partial solutions, their accuracy and interpretability of lesion contours still needs improvement. The international TMTV benchmark for lymphoma patients proposes a fixed SUV threshold for segmentation, which is prone to merging structures with high uptake. This study presents a method that refines a segmentation by separating multifocal regions and removing physiological uptake. ***Materials and Methods:*** The Auto Split algorithm comprises three steps: (1) Identify local maxima and grow controlled regions from each one of them. This incremental growth analyzes the voxels in descending order and the region growth freezes once a region touches another one that precedes it. (2) Use the local maxima within the two largest regions as anchor points to define markers for new regions. In case the difference between the anchor points is greater than a specific threshold, additional maxima are added for each marker group based on their SUV proximity to these points. (3) Apply watershed segmentation using the identified markers to separate the selected candidate. The selection of the candidates requiring separation can be initiated automatically using a fast organ classification approach which extracts a multi-level hierarchical descriptor for a given voxel and classifies it into one of 117 organs. The SUV_{max} locations for all candidates are classified to detect the physiological uptake. Then, the Auto Split is initiated if the candidate contains a local maximum with the classification of a different anatomical location from the rest. Auto Split has been evaluated on the international TMTV dataset, where 8/60 (13%) subjects have lesions connected to physiological uptake at the recommended 4 SUV threshold. Separation accuracy was assessed based on the algorithm's ability to retain lesion voxels, using F1-score, precision, recall, and volume similarity as evaluation metrics. ***Results:*** The algorithm achieved an average of 0.96±0.06, 0.94±0.11, 0.98±0.03, and 7.00%±12.68% for the F1-score, precision, recall, and volume similarity, respectively. Automated removal of coupled physiological uptake is correctly

performed 83% of the time. ***Conclusion:*** This work presents a novel and radiotracer agnostic method for separating lesions from adjacent physiological uptake. The need for manual editing of these connected physiological structures is reduced by 83% in the international lymphoma TMTV dataset.

EP-1019

Comparison of SUVmax threshold Based vs. Patient-Specific Segmentation for Lesion Delineation in Post^{177}Lu-DOTATATE whole body 3D SPECT/CT in Neuroendocrine Tumors

H. Noamen, *Y. Cras, M. Longo, C. Garcia, J. Hadoux, L. Lamartina, S. Moog, E. Baudin, D. Deandreis;*
Gustave Roussy Cancer Campus, Villejuif, FRANCE.

Aim/Introduction: Accurate lesion segmentation in post-^{177}Lu-DOTATATE SPECT/CT plays a crucial role in dosimetry and eventually in treatment response in neuroendocrine tumors. Nevertheless there is still a lack of a defined and standardized methodology. This study aimed to compare 3 segmentation methods to obtain reliable quantitative parameters from whole body 3D SPECT/CT images. ***Materials and Methods:*** A total of 62 post-treatment whole body 3D SPECT/CT images obtained at 24 hours after ^{177}Lu-DOTATATE injection by CZT gamma camera were retrospectively analyzed. Three segmentation methods were employed: Fixed SUVmax Method (A): Lesions were defined using a fixed SUVmax threshold of 3. Patient-Specific Method (B): A 3 cm^3 VOI was placed in the liver to calculate the SUVmean, and lesions were defined by applying the liver SUVmean as a cutoff.Patient-Specific Method with 10% threshold (C): An empiric 10% threshold evaluation was applied to the liver SUVmean. All the methods were followed by manual adjustments to exclude physiological uptake. Whole body lesion volumes (SSTR-TV) and SUVmean values were extracted for comparison between the three methods. A nuclear medicine physician validated the results of the three segmentation methods through visual inspection, evaluating lesion delineation and assessing any underestimation or overestimation of the lesions. Paired t-tests was used to compare significant differences. ***Results:*** Visual correct whole-body lesion segmentation was found in 19/62 (31%) cases with method (A), in 24/62 (39%) cases in method (B) and 47/62 (76%) cases in method (C). Visual concordance in lesion segmentation was observed only in 5/62 cases between method (A) and (B) and in 13/62 cases between (A) and (C). The median SUVmean liver was 1.42 [0.5; 16.18]. The median STTR-TV values obtained using three segmentation methods were 807.73 ml for (A) , 1287.59 ml for (B) ,and 914.01 for (C) method respectively. The median SUVmean values obtained were 6.87 for (A), 5.615 for (B) and 6.24 for (C) method. Statistical analysis revealed significant differences STTR-TV values between methods (A) and (B) ($p<0.0001$) and between methods (A) and (C) ($p=0.001$). No significant differences in lesion SUVmean between the three methods were shown. ***Conclusion:*** This study demonstrates that the segmentation method is a fundamental step for quantification in SPECT images. Patient-specific segmentation method may improve the accuracy in delineating lesions compared to the fixed SUVmax approach in^{77}Lu-DOTATATE SPECT/CT. Even if the fixed SUVmax method remains a simpler option, the patient-specific method seems to offer enhanced precision for dosimetry and clinical decision-making.

EP-1020

Automated lesion segmentation in ^{18}F-FDG PET/CT scans of patients with esophageal cancer

A. Soliman[1], *A. Nawwar*[2,3,4], *N. Thompson*[2], *V. Shah*[1], *B. Spottiswoode*[1], *I. Lyburn*[2,5,6];
[1]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [2]*Cobalt Medical Charity, Cheltenham, UNITED KINGDOM,* [3]*University Hospitals Bristol and Weston, NHS Foundation Trust, Bristol, UNITED KINGDOM,* [4]*Clinical Oncology and Nuclear Medicine Department, Cairo University, Cairo, EGYPT,* [5]*Gloucestershire Hospitals, NHS Foundation Trust, Gloucestershire, UNITED KINGDOM,* [6]*Cranfield Forensic Institute, Cranfield University, Wiltshire, UNITED KINGDOM.*

Aim/Introduction: Esophageal cancer is one of the leading causes of cancer-related deaths. Neoadjuvant chemoradiation is common prior to surgery, and accurate delineation of gross tumor volume is essential for effective treatment planning. Such delineation is also important for quantification of tumor burden and SUV-parameters which may have prognostic value. This study presents a deep learning model based on the nnU-Net framework for segmenting lesions from ^{18}F-FDG PET/CT scans in patients with esophageal cancer. ***Materials and Methods:*** With IRB approval, ^{18}F-FDG PET/CT data were collected from 94 patients with esophageal cancer, each undergoing scans before and after neoadjuvant chemoradiation and prior to surgery. There was a total of 376 lesions in this dataset of 188 scans (min=0, max=36, avg=2 lesions per-scan). Lesions were segmented on PET images by two experienced board-certified PET/CT readers following PERCIST criteria, using a 42% of SUV_{max} threshold. We used the nnU-Net (3D full-resolution) framework to train a deep learning model that uses both functional(PET) and anatomical(CT) information as two input channels. This dual-channel input enables the model to learn both metabolic activity patterns and anatomical structures. The output is a segmentation map containing the lesions and 10 organs (several having physiological uptake on FDG PET). The anatomical context facilitates faster convergence during training and enhances the network's ability to handle negative cases, where no lesions are present. The model was trained using 5-fold cross-validation on the entire dataset. Segmentation performance was evaluated using the Dice similarity coefficient (DSC), average false positive (FP) volume, false negative (FN) volume. Lesion identification performance was evaluated using average true positive (ATP), average FP (AFP), average FN (AFN), precision, recall, and F1-score. ***Results:*** The five-fold cross validation of the 3D-nnU-Net model achieved an average of 61.46% DSC, with average FP and FN volumes of 1.01 cm^3 and 1.62 cm^3 respectively. The lesion identification performance achieved 1.5, 0.71, and 0.64 for ATP, AFP, and AFN per subject, and 0.64, 0.72, and 0.68 for precision, recall, and F1-score, respectively. Results demonstrate an acceptable degree of overlap between predicted and ground-truth segmentations for a research-stage model. A notable proportion of false positives arose in follow-up scans, largely due to treatment-related inflammation which remains challenging to interpret even for clinicians. ***Conclusion:*** This work presents a deep learning model for lesion delineation in esophageal cancer from ^{18}F-FDG PET/CT, aiming to reduce manual workload and observer variability, while supporting treatment monitoring and response assessment.

EP-1021

Automated NSCLC Segmentation with Deep Learning: Evaluating ^{18}F-FDG PET/CT Volumetric Consistency and Proposing Optimal Thresholdsfor ^{68}Ga-FAPI Quantification

Y. Liu[1], *X. Zhou*[1], *Y. Liu*[1], *Y. Cui*[1], *Y. Song*[1], *Z. Cao*[2], *N. Li*[1];
[1]*Peking University Cancer Hospital, Beijing, CHINA,* [2]*Siemens Healthineers Ltd., Shanghai, CHINA.*

Aim/Introduction: In NSCLC management, PET/CT volumetric metrics exhibit significant prognostic validity yet suffer from quantification inefficiencies. Advanced deep learning models may address these limitations through automated parameter segmentation and calculation. This study aimed to validate the PET Assisted Reporting System (PARS) for ^{18}F-FDG PET/CT auto-segmentation and to explore optimal ^{68}Ga-FAPI PET/CT quantification thresholds in NSCLC. ***Materials and Methods:*** This retrospective study enrolled 50 patients (25 in the early-

stage group and 25 in the late-stage group) undergoing ^{18}F-FDG and ^{68}Ga-FAPI PET/CT (Mar-Dec 2020). Manual and PARS-based segmentations were compared for lesion counts, metabolic tumor volume (MTV), total lesion glycolysis (TLG), and segmentation time for ^{18}F-FDG PET/CT. Six SUV_{max} thresholds (four absolute values: 2.0, 2.5, 3.0, 3.5; two biological references: blood pool and muscle) were evaluated for ^{68}Ga-FAPI PET/CT auto-segmentation. The resulting fibrotic tumor volume (FTV) and total lesion FAPI (TL-FAPI) were compared with the manual segmentation. Quantitative performance assessment was conducted through comparative analysis of mean time expenditure and computation of classification parameters (sensitivity, specificity, accuracy), complemented by Pearson correlation coefficients and Bland-Altman analysis to validate statistical consistency. ***Results:*** For ^{18}F-FDG PET/CT, the PARS threshold showed strong agreement with manual segmentation (sensitivity = 92.0%, specificity = 93.0%, accuracy = 92.8%). MTV_{manual} and TLG_{manual} correlated highly with MTV_{PARS} (r = 0.975, CI [0.954-0.987]) and TLG_{PARS} (r = 0.992, 95% CI [0.985-0.996]). Moreover, segmentation time decreased significantly in the late-stage group (64.0 ± 56.6 vs. 105.0 ± 113.4 seconds, P = 0.032). For ^{68}Ga-FAPI PET/CT, PARS (using SUV_{max} = 3.0) yielded optimal results with the lowest false-positive rate (lesion count: r = 0.964, CI [0.937-0.979]; FTV: r = 0.868, CI [0.775-0.924]; TL-FAPI: r = 0.928, CI [0.874-0.959]). ***Conclusion:*** PARS enabled efficient, accurate ^{18}F-FDG PET/CT segmentation and significantly reduced segmentation computation time in patients with advanced NSCLC at the same time. The optimal SUV_{max} threshold of 3.0 for ^{68}Ga-FAPI PET/CT was determined via PARS-assisted volumetric parameter computation, demonstrating balanced sensitivity and specificity. Integrating deep learning tools into clinical workflows may improve staging accuracy and efficiency.

EP-1022

Comparison of direct Patlak parametric imaging with early and late SUV imaging in metastatic uveal melanoma patients with a long axial field-of-view (LAFOV) PET/CT

L. Pan[1], *C. Sachpekidis*[1], *J. Hassel*[2], *A. Dimitrakopoulou-Strauss*[1];
[1]*German Cancer Research Center, Heidelberg, GERMANY,*
[2]*University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: New Long Axial Field-of-View (LAFOV) PET-CT scanners allow, for the first-time, whole-body (WB) dynamic scanning, as well as WB pharmacokinetic studies and WB parametric imaging. We, herein, aimed to evaluate whether WB direct Patlak imaging is feasible with the LAFOV Biograph Vision Quadra PET/CT system (Siemens Healthineers) (106 cm FOV) and whether it improves lesion detectability compared to 50-60 min and 70-80 min standard uptake value (SUV) images in patients with multiple liver metastases from uveal melanoma prior to tebentafusp therapy, which is a first-in-class TCR-CD3 bispecific immunotherapy. ***Materials and Methods:*** 17 uveal melanoma patients with 89 lesions were enrolled in the study. All patients underwent [^{18}F]FDG PET/CT (skull to upper thigh). Three sets of images were compared: direct Patlak K_i images, 70-80 min SUV (late SUV) images, and 50-60 min SUV (early SUV) images. All three sets of images were visually (qualitatively) reviewed by the reading physicians. Furthermore, 89 individual liver lesions were quantitatively analyzed using the target-to-background (TBR). ***Results:*** No significant differences were observed between the three group of images regarding the number of liver lesions. However, we found two discordant results: two true positive liver lesions were identified on Patlak K_i images, one in each of the two patients, which were not delineated on the SUV images. Quantitatively, parametric imaging showed that direct Patlak K_i images and late SUV images had superior TBR compared to early SUV images (2.3- and 1.3-fold mean increase in TBR, respectively). In addition, Patlak K_i TBR was significantly higher than late SUV images in 81/89 lesions and higher than early SUV images in 88/89 lesions. ***Conclusion:*** Dynamic [^{18}F]-FDG with the new LAFOV PET/CT scanner allows the calculation of Patlak K_i images with better lesion contrast than SUV images, but does not significantly increase the lesion detection rate. In addition, late (70-80 min) SUV images have better contrast than early (50-60-min) SUV images. In a small number of cases, Patlak images revealed discordant findings compared to SUV images, adding further useful clinical information.

EP-1023

Deep Learning-Based Detection and Classification of Thyroid Scintigraphy Images Using Convolutional Neural Networks

I. Rogic[1], *D. Huic*[1,2];
[1]*University Hospital Centre Zagreb, Zagreb, CROATIA,* [2]*School of medicine, Zagreb, CROATIA.*

Aim/Introduction: Artificial intelligence (AI) and convolutional neural networks (CNNs) offer promising tools in the analysis and classification of medical images (1). In this study, we developed a system powered by CNN for automatic analysis and classification of thyroid scintigraphy images. CNNs are deep learning network architectures that showed promise for imaging analysis due to their ability to detect and extract patterns and spatial features, enabling classification and pathology detection. Our pre-trained neural network aims to identify and classify the most common patterns of thyroid scintigram: cold nodule, hot nodule, normal thyroid function, subacute thyroiditis, and multinodular goiter. ***Materials and Methods:*** To process and classify images, a convolutional neural network (CNN) was implemented and trained on DICOM images organised into five categories of thyroid function. Input images were first normalised, resized to 224x224 pixels, and divided into training and validation datasets. We collected 700 thyroid scintigrams from our department as a training cohort and an additional 90 as a validating cohort. To improve model generalisation and performance, data augmentation was applied. The model was trained from scratch using TensorFlow (2) and Keras (3). The system was run with a simple graphical interface built in Streamlit. The interface allows for manual testing of images, classification prediction display, as well as on-the-fly training with new datasets. ***Results:*** The model achieved an overall classification accuracy of 80.25 % in recognising common patterns in thyroid scintigraphy. The highest performance was observed in detecting hot nodules, with an accuracy of 91.6 %, while the lowest was in the detection of normal thyroid function (no nodes or scintigraphic patterns typical for diffuse pathology), with an accuracy of 66.67 %. Our model achieved a negative predictive value (NPV) of 94.7 %, which indicates a high reliability in ruling out pathological findings on thyroid scintigraphy. ***Conclusion:*** Our CNN model showed promising performance in diagnosing thyroid diseases based on thyroid scintigraphy images. The results demonstrate the potential of this approach to assist and improve accuracy in clinical diagnosis of thyroid diseases. Further improvements may be achieved by increasing size of the training cohort, integrating pretrained models such as MobileNet, AlexNet, and ResNet and validation with external datasets. ***References:*** 1. EP-1024

Decoupling Alzheimer's Disease Pathology from Physiological Uptake in Brain PET via Interpretable Adversarial Decomposition Learning

A. Tang, *C. Tang, W. Ruan, Z. Liang, X. Sun, X. Lan;*
Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Reliable detection of amyloid-β (Aβ) and tau pathology in PET is critical for Alzheimer's disease (AD) diagnosis, yet current quantification relies on semi-quantitative metrics requiring rigid spatial normalization and predefined templates, which fail to address heterogeneous biomarker deposition or visualize pathology. Meanwhile, deep learning models achieve

high diagnostic accuracy but lack interpretability due to "black-box" attributions, hindering clinical trust. Critically, neither approach disentangles AD-specific pathology from confounding physiological/off-target uptake—a key limitation in borderline cases and therapy monitoring. ***Materials and Methods:*** We propose Adversarial Decomposition Learning (ADL), an interpretable framework to isolate AD-related tracer signals under explicit pathophysiological constraints, enabling both visual and quantitative biomarker mapping. Trained on 5,364 Aβ and 1,159 tau scans, ADL employs a U-Net-based decoupler to generate pathology probability maps and a discriminator to classify AD vs. cognitively normal (CN) images. The derived Alzheimer's Disease Adversarial Decomposition (ADAD) score quantifies AD-specific tracer deposition by summing decomposed signals. Performance was validated via AUC analysis, correlations with semi-quantitative metrics (Centiloid/CenTauRz), neuropsychological scores, CSF biomarkers, and hippocampal volume. ***Results:*** ADL achieved superior diagnostic performance (AUC=0.94 for Aβ, 0.98 for tau) on external testing. The ADAD score correlated strongly with Centiloid (R^2=0.64) and CenTauRz (R^2=0.68) but outperformed both in clinical relevance, showing tighter associations with MMSE (ρ=−0.71 vs. Centiloid's ρ=−0.53), CSF Aβ (ρ=−0.68 vs. −0.45), and hippocampal atrophy (ρ=0.62 vs. 0.41, p<0.001). Visual analysis confirmed ADL's precise spatial mapping of Aβ (frontal/precuneus) and tau (parahippocampal/parietal), resolving ambiguities in borderline cases (e.g., Centiloid=39 vs. ADAD=101, flagged as early Aβ deposition). Longitudinal monitoring of anti-Aβ therapy revealed ADAD's sensitivity to treatment effects (post-treatment ADAD=211 vs. Centiloid=69), aligning with slowed cognitive decline. ***Conclusion:*** ADL bridges the interpretability gap in AD PET by enabling pathology-specific decomposition validated against gold-standard semi-quantitative metrics. The ADAD score, harmonizing with Centiloid/CenTauR while offering enhanced clinical correlation, provides a transparent tool for diagnosis, therapy evaluation, and biomarker discovery. This framework advances precision neurology by integrating deep learning with pathophysiological priors.

EP-1025

Classification of Lower Extremity Deep Vein Thrombosis Using Ensemble Deep Learning on Radionuclide Venography

H.-j. Chen[1,2], *C.-Y. Wang*[3], *Y.-H. Huang*[3], *Y.-C. Huang*[2], *S.-Y. Hsu*[1];
[1]*Department of Information Engineering, I-Shou University, Kaohsiung, TAIWAN,* [2]*Department of Nuclear Medicine, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, TAIWAN,* [3]*Department of Medical Imaging and Radiological Sciences, I-Shou University, Kaohsiung, TAIWAN.*

Aim/Introduction: Deep vein thrombosis (DVT) of the lower extremities and pelvis is a potentially life-threatening condition that requires timely and accurate diagnosis. However, its clinical presentation—such as leg swelling, pain, and edema—is often nonspecific and overlaps with other conditions, making diagnosis challenging. Radionuclide venography serves as a valuable imaging tool, but its interpretation can be limited by variations in image quality. To address this, the present study aimed to develop and evaluate a deep learning-based model for the automated classification of radionuclide venography images, with the goal of enhancing diagnostic consistency and supporting clinical decision-making in cases of suspected DVT. ***Materials and Methods:*** A total of 2,765 radionuclide venography images were retrospectively collected from Kaohsiung Chang Gung Memorial Hospital and categorized into DVT-positive and DVT-negative groups. Four pre-trained convolutional neural networks (ResNet50, DenseNet201, and MobileNetV2) were adapted via transfer learning for model development. The dataset was divided into 80% for training and 20% for testing. Model performance was assessed based on accuracy, precision, and recall. In addition to developing single models, an ensemble learning approach was implemented, combining outputs from these four models using a majority voting mechanism to further improve classification accuracy. ***Results:*** Among the individual models, DenseNet201 achieved the best performance with an accuracy of 0.907, a recall of 0.746, and a precision of 0.977 in a single model. For the ensemble model integrating MobileNetV2, ResNet50, and DenseNet201, the classification results improved, achieving an accuracy of 0.917, a recall of 0.780, and a precision of 0.971. ***Conclusion:*** This study demonstrates that deep learning models are effective in classifying radionuclide venography images for DVT detection. While DenseNet201 performed well individually, the ensemble model further enhanced accuracy and recall. The ensemble model achieved a high precision, but relatively lower recall. It contributes to reducing false positives. Clinically, this characteristic could be valuable for confirming DVT diagnoses with high confidence.

EP-1026

PSMA PET Evaluation with a Deep Learning Platform Compared to a Standard Image Viewer and Histopathology

D. Koehler[1], *F. Shenas*[1], *M. Sauer*[1], *I. Apostolova*[1], *L. Budäus*[2], *F. Falkenbach*[2], *T. Maurer*[2];
[1]*Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY,* [2]*Martini-Klinik Prostate Cancer Center, University Hospital Hamburg-Eppendorf, Hamburg, GERMANY.*

Aim/Introduction: Standardized prostate-specific membrane antigen (PSMA) PET/CT evaluation and reporting was introduced to aid interpretation, reproducibility, and communication. Artificial intelligence may further enhance these efforts. The aim of this study was to evaluate the performance of aPROMISE, a deep learning segmentation and reporting software for PSMA PET/CT, compared to a standard PACS viewer (IntelliSpace Portal [ISP]) in patients undergoing salvage PSMA-radioguided surgery. ***Materials and Methods:*** [^{68}Ga]Ga-PSMA-I&T PET/CT of 96 patients with biochemical persistence or recurrence after prostatectomy (median prostate-specific antigen 0.56 ng/ml, interquartile range 0.31 - 1.24) were retrospectively analysed (2 x aPROMISE, 2 x ISP) by two independent readers. Cohens's κ with corresponding 95% confidence intervals were calculated to assess the intra- and inter-rater agreement for T-/N-/M-stagings. Differences between TNM codelines were classified into "no difference", "minor difference" (change of lymph node region without N-/M-change), and "major difference" (T-/N-/M-change). ***Results:*** Intra-rater agreement rates were high for all categories, both readers, and systems (≥91.7%) with moderate to almost perfect κ-values (Reader 1: aPROMISE ≥0.64, 0.41 - 0.99, ISP ≥0.51, 0.21 - 0.9; Reader 2: aPROMISE ≥0.78, 0.63 - 1, ISP ≥0.83, 0.69 - 1). Major differences occurred more frequently for Reader 1 than for Reader 2 (aPROMISE 22.9% vs. 12.5%; ISP 26% vs. 13.5%). Inter-rater agreement rates were high with both systems (≥92.2%), demonstrating substantial κ-values (aPROMISE ≥0.74, 0.54 - 1; ISP ≥0.73, 0.47 - 0.99) with major TNM-staging differences in 21 (21.9%) cases, respectively. In their consensus, readers identified 140 lesions, of which aPROMISE automatically segmented 129 (92.1%). Unsegmented lesions were either adjacent to high urine activity or demonstrated low PSMA expression. Agreement rates between imaging and histopathology were substantial (≥86.5%), corresponding to moderate to substantial κ-values (≥0.6, 0.45 - 1) with major TNM-staging differences in 33 (34.4%) patients. This included 13 (13.5%) cases with metastases distant from targets identified on imaging. One of these lesions was automatically segmented by aPROMISE. ***Conclusion:*** Intra- and inter-reader agreement for PSMA PET/CT evaluation was similarly high with aPROMISE and ISP. The algorithm segmented 92.1% of all identified lesions and a relevant

metastasis that was missed by the readers. Software solutions with artificial intelligence could be applied as support tools in PSMA PET/CT evaluation of early prostate cancer.

First Real-world Clinical Evaluation of a Deep Learning-based Respiratory Motion Correction Algorithm of ^{18}F-FDG PET/CT in Lung Lesions

J. Wang[1], *J. Wang*[2], *Z. Quan*[1], *Y. Wang*[1], *F. Zhang*[1], *T. Ma*[1], *G. Li*[1], *M. Liu*[1], *Y. Li*[2], *Y. Lu*[2], *F. Kang*[1], *J. Wang*[1];
[1]*Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi, CHINA,* [2]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: To evaluate the clinical diagnosis impact of a vendor-provided data-driven solution for respiratory motion correction (uRMC) in lung lesions on the uMI Panorama PET/CT. ***Materials and Methods:*** PET/CT analysis included subjective and quantitative evaluations. Two experienced nuclear medicine physicians independently assessed the overall image quality, PET-CT alignment, and PET distortion of both no motion correction (NMC) and uRMC PET/CT images. Semi-quantitative parameters: a. lesion metabolism [SUVmax, SUVmean, and target-to-background ratios (TBR)]; b. PET-CT lesion alignment [PET-centroid to CT-centroid distance (CCD) was calculated based on the lesion coordinates.]; c. lesion distortion [transverse to longitudinal axis ratio (T/L), and metabolic tumor volume (MTV)]. Percentage changes in semi-quantitative parameters were compared between the two groups based on lesion location compared to the trachea carina. ***Results:*** A total of 136 patients with 165 lung lesions were retrospectively included. Subjective scores were significantly improved in uRMC compared to NMC for overall image quality, PET-CT alignment, and PET distortion (all $P < 0.0001$). The lesion metabolism values were significantly increased in uRMC compared to NMC (SUVmax: 8.46 [5.81, 14.34] vs. 8.40 [5.22, 13.25], SUVmean: 5.75 [3.99, 9.65] vs. 5.60 [3.58, 8.73], TBR: 3.31 [2.25, 5.43] vs. 3.17 [2.18, 5.42], all $P < 0.01$). uRMC detected 28.6% (10/35) more lesions than NMC. Quantitative analyses revealed uRMC reduced CCD by 38.9% with NMC (2.73mm [1.46, 4.67] vs. 4.47mm [2.29, 7.51], $P < 0.0001$), along with completely corrected 88.9% (8/9) fused to the liver in NMC and altered the PET/CT imaging staging determination in 37.1% (33/89) of the lesions. The T/L was significantly larger in uRMC than NMC (0.92[0.84, 1.00] vs. 0.88[0.78, 1.01], $P < 0.01$), achieving comparable quantification accuracy to CT (0.92[0.84, 1.00] vs. 0.94[0.84, 1.00], $P = 0.573$). In addition, the percent changes of metabolism values were higher in lower lung lesions compared to upper lung (median, SUVmax: 14.71% vs. -2.43%, SUVmean: 16.68% vs. -2.43%, TBR: 11.86% vs. -6.92%, all $P < 0.0001$), while MTV showed a significant decrease (median, -2.38% vs. 5.01%, $P < 0.01$). ***Conclusion:*** Compared with NMC, uRMC not only enhances image quality and semi-quantitative metabolic parameters of lung lesions but also reduces CCD and increases T/L of PET to make it close to CT, thus modifying benign/malignant diagnosis and PET/CT imaging staging of lesions. Our findings suggest potential clinical benefits of uRMC for lung lesions, particularly those located in the lower lungs.

EP-1028

A new approach to PET/CT registration which accounts for region-specific motion constraints

J. Schaefferkoetter, *P. Schleyer, M. Conti;*
Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: A method based on convolutional neural networks (CNN), for inter-modal registration was previously presented for spatially aligning structures across the subject's whole-body (WB), and therefore also improving PET attenuation correction (AC) [1-3]. The limitation of this approach was that elastic registration produces unrealistic deformations for the head, a rigid structure. The work here presents an approach to register WB CT to PET, considering local elastic and rigid constraints. ***Materials and Methods:*** Segmentation was first performed using a dedicated CNN to delineate 2 regions: the body and the head. Then, rigid registration was performed on the head, and elastic registration was performed on the remainder. Elastic registration was performed using a CNN to generate a dense, voxel-wise motion field, and rigid registration used a CNN with image similarity maximization. Once the two motion fields were computed separately, the head segmentation was used to blend them together into a single motion field. ***Results:*** A dedicated testing set of 15 whole-body subjects with multiple PET tracers was used for evaluation. The segmentation was robust for delineating the head from the body, even for challenging cases in which the subjects' hands were touching the top of the head. The subsequent registrations improved misalignments between CT and PET across the whole-body (elastic) and in the head (rigid). Blending the 2 motion fields together produced a smooth and continuous result, with no visible boundaries. The registered CTs improved AC artifacts in the PET reconstruction. ***Conclusion:*** This presents a registration approach which constrained the type of motion based on region-specific physical movement. It leveraged CNNs in a multistep approach, performing segmentation to classify the "elastic" and "rigid" regions, estimating the motion differently for each and then combining them into a single, seamless registration grid. A more extensive evaluation is needed to consider subjects with abnormal morphology or pathology and with different PET tracers. ***References:*** [1] Schaefferkoetter, Joshua, et al. EP-1029

Improving data-driven gated (DDG) PET and CT registration in thoracic lesions: a comparison of AI registration and DDG CT

T. Pan[1], *M. A. Thomas*[2], *Y. Lu*[1], *D. Luo*[1];
[1]*The University of Texas, Houston, TX, UNITED STATES OF AMERICA,* [2]*Washington University School of Medicine, St. Louis, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: Misregistration between CT and PET can result in mis-localization and inaccurate quantification of the tracer uptake in PET. Data-driven gated (DDG) CT can correct registration and quantification but requires a radiation dose of 1.3 mSv and 1 minute of acquisition time. AI registration (AIR) does not require an additional CT and has been validated to improve registration and

reduce the 'banana' misregistration artifacts around the diaphragm. We aimed to compare a validated AIR and DDG CT in registration and quantification of avid thoracic lesions misregistered in DDG PET scans. ***Materials and Methods:*** Thirty PET/CT patient data (23 with ^{18}F-FDG, 4 with ^{68}Ga-Dotatate, and 3 with ^{18}F-PSMA piflufolastat) with at least one misregistered avid lesion in the thorax were recruited. Patient studies were conducted using DDG CT to correct misregistration with DDG PET data of the phases 30 to 80% on GE Discovery MI PET/CT scanners. A maximum of three lesions per patient were selected for comparison. Non-attenuation correction DDG PET and misregistered CT were input to AIR and the AIR-corrected CT data were output to register and quantify the DDG PET data. Registration quality and quantification of lesion SUV_{max} and signal-to-background ratios (SBR) were compared for each of the 51 avid lesions. ***Results:*** DDG CT outperformed AIR in misregistration correction and quantification of avid thoracic lesions. The sizes of this cohort of lesions were 1.16±0.45 cm. Most lesions (46/51, 90%) showed improved registration from DDG CT relative to AIR, with 10% (5/51) being similar between AIR and DDG CT. AIR increased SUV_{max} by 18.1±15.3%, while DDG CT increased it by 34.4±25.4% (P=0.0002). There was a statistically significant increase of SBR between AIR 10.5±12.1% and DDG CT 21.1±20.5% (P=0.0021). Many registration improvements by AIR were still left with misregistration. AIR incorrectly localized one infra-hilar lymph node to the lung parenchyma, one para-aortic lymph node to the vertebral body, and one supradiaphragmatic lymph node to the ribs. AIR also consistently distorted the rib cage. ***Conclusion:*** DDG CT outperformed AIR in both localization and quantification of the thoracic avid lesions. Registered lymph nodes could be falsely misregistered by AIR. AIR-induced distortion of the rib cage can also negatively impact image quality. Further research on AIR's accuracy in modeling true patient respiratory motion without introducing new misregistration or anatomical distortion is warranted. ***References:*** 1. Schaefferkoetter, et al., Deep learning for improving PET/CT attenuation correction by elastic registration of anatomical data. EJNMMI, 2023.

EP-1030

Improved attenuation correction registration for FDG PET/CT images using data-driven gating (DDG)-based motion match.

Z. Wilson[1], *M. Kuhar*[2], *K. Su*[3], *R. Johnsen*[3], *K. M. Bradley*[4,1], *D. McGowan*[1,5];
[1]*Oxford University Hospital NHS FT, Oxford, UNITED KINGDOM,* [2]*University Hospital Southampton NHS, Southampton, UNITED KINGDOM,* [3]*GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA,* [4]*Cardiff University, Cardiff, UNITED KINGDOM,* [5]*University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Advancements in PET technologies and reconstruction methods have improved spatial resolution and noise in PET/CT, making respiratory motion artefacts more impactful on image quality. The motion-matched CT (MMCT) algorithm can phase-match a helical CT to the end expiration of a ground truth 4DCT, as shown in FMISO data [1]. The MMCT-attenuation correction (MMCTAC) will then be used to reconstruct whole body FDG PET/CT data. The performance of these images will be compared to those reconstructed using the uncorrected clinical standard attenuation correction from helical CT (normAC), identifying the proportion of cases where MMCTAC images could reduce motion artefact and improve lesion detectability. ***Materials and Methods:*** This study analysed a sequential cohort of 145 whole-body FDG scans. PET images were previously assessed for a data-driven gating study, identifying the gated region of interest (ROI) in 98 high-motion patients (R>15) [2]. 23 of these high motion patients had lesions (n=36) identified in the ROI by a clinician to undergo qualitative analysis. PET data were reconstructed using BSREM iterative reconstruction with 3 different portions of the data: 1. Ungated 6 minutes, 2. Ungated 3 minutes, 3. Quiescent period gated. These reconstructions were generated using normAC or MMCTAC, totalling 6 reconstructions for semi-quantitative analysis and clinician assessment. An experienced radiologist ranked the 6 images and scored them on a 5-point Likert Scale for lesion detectability, diagnostic confidence, and image quality. ***Results:*** In 65% (n=15) of the patients with lesions, the clinician ranked all three MMCTAC images higher than the three normAC equivalent reconstructions. Lesion detectability and diagnostic confidence scores retained positive mean differences across the three MMCTAC reconstructions compared to normAC. Similarly, the SUVmax values compared across the 6 reconstructed images for 36 lesions demonstrated a significant increase ($p<0.05$) for MMCTAC versus normAC images across all three reconstructions. ***Conclusion:*** The MMCT algorithm successfully enables the phase-matching of a helical CT to the PET data to reduce the presence of respiratory motion artefact for FDG PET/CT images. Overall, the motion matched CTAC image scores demonstrated the algorithm's efficacy at reducing the motion artefacts present in FDG PET/CT images, improving diagnostic capability for assessment of lesions in the thorax and upper abdomen. ***References:*** [1] Cook, E.L. et al. Integrating PET/CT Imaging and Machine Learning to Enhance Early Diagnosis of Pulmonary Nodules in various types of cancers

N. Kapsoritakis[1], *F. Tsitoura*[2], *G. Barmparis*[2], *S. Koukouraki*[1], *G. Tsironis*[2];
[1]*Nuclear Medicine Department, Medical School Univercity of Crete, Heraklion, Crete, GREECE,* [2]*Department of Physics, Medical School, University of Crete, Heraklion, Crete, GREECE.*

Aim/Introduction: Differentiating benign from malignant solitary pulmonary nodules (SPNs) remains a major challenge in thoracic oncology. Traditional PET/CT metrics like Standardized Uptake Value (SUV), Metabolic Tumor Volume (MTV), and Tumor Lesion Glycolysis (TLG) offer limited diagnostic accuracy, requiring biopsy for confirmation. This project aims to enhance diagnostic precision by extracting features from PET-CT fusion images and combining them with clinical data and quantitative measures. Using machine learning (ML), we seek to improve early, non-invasive prediction and support timely clinical decisions. ***Materials and Methods:*** Early (1hr) and delayed phase (2hrs) p.i 18F F FDG PET-CT scans were acquired in 91pts with PNs using a digital PETCT (GE discovery MI4R Gen 2). A region of interest (ROI) was drawn over the lesion with high metabolic activity in both PET scans . Metabolic metrics such as SUV, TLG, and MTV were measured and recorded for each nodule. In addition, morphological characteristics, including size and density, were also incorporated into the dataset. Following ROI extraction, advanced image processing techniques were applied to derive radiomic features. The most important features were identified using a Random Forest classifier and were primarily related to first-order statistics and texture analysis. The final dataset consisted of 90 records, each representing a unique patient nodule, with a total of 20 features per record. These included the selected radiomic features, clinical data, and metabolic and morphological characteristics. ***Results:*** Several ML models—including SVM, Random Forest, Gradient Boosted Trees, and XGBoost—were evaluated to predict biopsy outcomes. Hyperparameters were optimized using grid search with cross-validation. Gradient Boosted Trees achieved the best performance, with 95% accuracy when radiomic features were

included, compared to 82% without, highlighting their significant contribution to predictive accuracy. ***Conclusion:*** Incorporating image-derived information, significantly improves the model's ability to distinguish between benign and malignant SPNs, with a 15% increase in accuracy. This highlights the value of combining image-derived features with clinical data for more accurate, non-invasive diagnosis.

The Impact of Post-reconstruction Filtering on Radiomics-Based Coronary Artery Disease Prediction Using Myocardial Perfusion SPECT

R. Huang[1,2], *B. Wang*[1,2], *M. Gutierrez*[3], *G. Hung*[4], *G. Mok*[1];
[1]*Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Macau SAR, MACAO,* [2]*Lauterbur Research Center for Biomedical Imaging, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA,* [3]*Biomedical Informatics Lab, Heart Institute, University of São Paulo Medical School, São Paul, BRAZIL,* [4]*Department of Nuclear Medicine, Chang Bing Show Chwan Memorial Hospital, Changhua, TAIWAN.*

Aim/Introduction: Myocardial perfusion (MP) SPECT is an effective diagnostic tool for coronary artery disease (CAD), yet concerns remain regarding its high radiation dose and long acquisition time. Low dose and fast SPECT are desirable without jeopardizing image quality. Post-reconstruction filter is commonly applied on clinical MP SPECT images to reduce noise and enhance image quality. This study aims to investigate the effect of using post-reconstruction filter on full-view and sparse-view MP SPECT images for radiomics-based CAD prediction. ***Materials and Methods:*** We retrospectively analyzed SPECT/CT data of 212 patients who underwent a one-day ^{99m}Tc-sestamibi stress/rest protocol using a conventional dual-head NaI SPECT/CT scanner, with invasive coronary angiography (ICA) conducted within 90 days following the scan. Different projection views, i.e., 64 (Full-Projection, FP), 32 (Half-Projection, HP) and 8 (one-Eighth Projection, EP) projections, were reconstructed using OS-EM algorithm (6 iterations, 8 subsets) with CT-based attenuation correction. Reconstructed stress images were processed by Gaussian filters with varying standard deviations (σ, 0.5 to 5.0 voxels, 0.5 voxel interval) and converted into polar plots, which were split into 8:2 for training and testing. All polar plots were segmented into regions-of-interest (ROI) of left anterior descending artery (LAD), right coronary artery, and left circumference. A total of 558 radiomics features were extracted for each ROI before feature selection using Least Absolute Shrinkage and Selection Operator regression and Recursive Feature Elimination. Features were adaptively input for training from different ROIs based on the ICA diagnosis, while testing was performed using features solely from the LAD ROI [1]. Prediction models were constructed using logistic regression with five-fold cross-validation and evaluated using the area under the receiver operating characteristic curve (AUC) and accuracy (ACC). ***Results:*** AUC/ACC values of all datasets initially increased and then subsequently decreased with increasing σ. FP, HP and EP achieved their optimal performance with σ of 1.0 voxel (AUC: 0.84, ACC: 0.78), 2.0 voxels (AUC: 0.81, ACC: 0.76) and 2.5 voxels (AUC: 0.78, ACC: 0.73) respectively. AUC/ACC values of FP consistently surpass those of HP and EP for different σ. ***Conclusion:*** Optimal post-reconstruction filtering can enhance diagnostic accuracy for radiomics-based CAD prediction models using MP SPECT. Funding: This work was supported by the Science and Technology Development Fund of Macau 0016/2023/RIB1. ***References:*** [1] Wang, B., et al., Prediction of Coronary Artery Stenosis Using Myocardial Perfusion Stress/Rest SPECT: a Radiomics Study. AI for Cardiac PET Imaging: Predicting Summed Rest Scores Using Stress PET Image

M. Mokri[1], *D. Juneau*[1], *A. Sanaat*[2], *S. Kaviani*[1], *C. Cohalan*[3], *M. Léger*[3], *J. Carrier*[1];
[1]*University of Montreal, Montreal, QC, CANADA,* [2]*Geneva University Hospital, Geneva, SWITZERLAND,* [3]*Hospital Center of University of Montreal, Montreal, QC, CANADA.*

Aim/Introduction: Myocardial perfusion imaging (MPI) with ^{13}N-ammonia PET enables high-resolution assessment of coronary artery disease (CAD) through stress and rest imaging. However, the two-phase protocol increases radiation dose, prolongs imaging time, and burdens clinical workflows. This study proposes an AI-based approach to predict the Summed Rest Score (SRS) directly from stress-phase images, aiming to eliminate the need for rest-phase acquisition while maintaining diagnostic accuracy. ***Materials and Methods:*** Dynamic ^{13}N-ammonia PET-CT scans were collected from 280 patients. For each scan, polar maps were generated from reconstructed 3D stress-phase PET data using the 17-segment model established by the American Society of Nuclear Cardiology. These maps were annotated by nuclear medicine specialists to assign segmental scores, from which the Summed Stress Score (SSS) and Summed Rest Score (SRS) were derived. Four deep convolutional neural networks _ResNet-50, ResNet-101, VGG19, and VGG11-bn _were adapted for this task using transfer learning from pretrained medical imaging models. Each network was trained to predict the SRS from the stress-phase image, incorporating the SSS as an auxiliary input to enhance performance. An ensemble model was then constructed by averaging the predictions of all four networks to improve robustness and generalizability. Model performance was assessed using mean absolute error (MAE), root mean square error (RMSE), and classification accuracy across four infarction severity categories. ***Results:*** The ensemble model achieved the highest clinical performance with an MAE of 0.09, RMSE of 0.18, and classification accuracy of 94.1%. ResNet-101 was the best-performing individual model (accuracy = 89.3%).Importantly, the ensemble predicted infarction severity with high clinical fidelity: sensitivity ranged from 96% to 100% and specificity from 98% to 99% across all infarction categories. enhanced model robustness, especially for borderline cases of mild-to-moderate infarction. Inclusion of the SSS improved accuracy by 5 to 10%; for example, ResNet-101 rose from 80.2% to 89.3% with SSS integration. Classification analysis across infarct severity categories further validated the clinical applicability of the proposed method. The ensemble model correctly identified "No Infarct" and "Mild Infarct" cases with 100% sensitivity, while achieving sensitivities of 97% and 96% for "Moderate" and "Heavy Infarct" groups, respectively. Specificity exceeded 98% across all categories. ***Conclusion:*** In conclusion, the proposed ensemble learning framework shows strong potential for accurately predicting SRS from stress-phase ^{13}N-ammonia PET scans. This approach may support the adoption of single-phase imaging protocols by reducing the need for rest acquisitions, thereby lowering radiation exposure and streamlining clinical workflows.

Quantifying the relationship between [^{177}Lu]Lu-PSMA-I&T exposure and neutrophil dynamics using a population pharmacokinetic-pharmacodynamic analysis

D. van Asten[1,2], *M. Dotinga*[2], *B. J. de Wit-van der Veen*[2], *A. D. R. Huitema*[1,3,4], *H. Huisman-Siebinga*[1,2];

Aim/Introduction: [^{177}Lu]Lu-PSMA is a radioligand therapy that prolongs survival in metastatic castration-resistant prostate cancer (mCRPC) patients. While well tolerated, some patients experience dose-limiting hematological toxicities, potentially due to considerable variability in bone exposure. This study aimed to quantify the impact of [^{177}Lu]Lu-PSMA-I&T exposure in bones and bone metastases on neutrophil levels using a semi-physiological population pharmacokinetic-pharmacodynamic (PK-PD) model. ***Materials and Methods:*** SPECT/CT scans (4h, 24h, 6 days post-treatment) and neutrophil counts (up to 3 months post-treatment) were retrospectively collected from mCRPC patients receiving 1-8 cycles of ~7.4 GBq [^{177}Lu]Lu-PSMA-I&T (September 2019-March 2024). Organ (aorta, bones, kidneys, salivary glands) and tumor segmentation was performed semi-automatically using MIM (version 7.3.6) to obtain volumes (L) and mean uptake (MBq/mL) in organs and tumors (≥2.5mL). An existing PK-model (NONMEM 7.5) was optimized with seven compartments representing blood, salivary glands, kidneys, bones, bone metastases, other tumors and a rest compartment[1]. Structural parameters included volume of distribution (V_1), renal excretion (k_{10}) and rate constants (k_{in}, k_{out}) between compartments. A previously developed PD-model was sequentially used to link bone PK (healthy and metastatic tissue) to neutrophil data and included a delayed linear or sigmoidal effect-relationship, resulting in reduced neutrophil proliferation[2]. The model was used for simulations (n=1000) to predict clinically relevant neutropenia (≤1.5×10^9/L) compared to observations. ***Results:*** Data from 139 patients were analyzed (average 3.2 cycles). The PK-model demonstrated good fit and precision (RSEs<20%). Uptake rates varied between compartments, with relative faster rates for bone metastases and kidneys (0.041 and 0.044h^{-1}) and slower rates for salivary glands, other tumors and healthy bone (0.005, 0.009, 0.023h^{-1}, respectively). High inter-individual variability (IIV) was estimated for uptake in bones, bone metastases and other tumors (145%, 67%, 79%, respectively). A linear PK-PD relationship best captured neutrophil dynamics, with a baseline neutrophil count of 4.2×10^9/L (41% IIV). The estimated impact of [^{177}Lu]Lu-PSMA-I&T (slope: 0.00106 MBq^{-1}) led to a maximum neutrophil proliferation reduction of 15% (median 1.8%). Simulations predicted a median 6.6% of patients (80% prediction-interval: 4.4%-9.5%) would experience clinically relevant neutropenia, aligning with the observed 7.2% (≤1.5×10^9/L). These results demonstrate the feasibility of predicting individual neutrophil levels. ***Conclusion:*** Our PK-PD model quantified the [^{177}Lu]Lu-PSMA-I&T exposure-neutrophil relationship of mCRPC patients, highlighting substantial variability in bone exposure and feasibility of predicting individual neutrophil levels. These findings suggest that with further optimization the model could help predict neutropenia from first-cycle data and establish toxicity thresholds to guide personalized treatment. ***References:*** [1]Siebinga et al.EJNMMI-Phys.2024;11(1):39,[2] Friberg et al.JClinOncol.2002;20(24):4713-21.

[^{18}F]FET PET Radiomics-Based Prediction of IDH Mutation Status in Glioma Patients: Impact of Inter-scanner Harmonisation, Clinical Data and Integration of [^{18}F]FET-negative Cases

A. Zounek[1], *E. Barci*[1], *E. Istrefi*[1], *J. Isakaj*[1], *K. J. Mueller*[2], *M. J. Mair*[1,3], *I. von Polenz*[1], *S. Ziegler*[4,1], *N. L. Albert*[1,5,6], *L. Kaiser*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Neurology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [3]*Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, AUSTRIA,* [4]*Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY,* [5]*German Cancer Consortium (DKTK), Partner Site Munich, a partnership between German Cancer Research Center (DKFZ) and LMU Munich, Munich, GERMANY,* [6]*Bavarian Cancer Research Center (BZKF), Partner Site Munich, Munich, GERMANY.*

Aim/Introduction: Accurate assessment of Isocitrate dehydrogenase (IDH) mutation status plays a critical role in the clinical management of glioma patients. This study aims to apply a machine learning (ML) model for non-invasive prediction of IDH mutation status using O-(2-[^{18}F]fluoroethyl)-L-tyrosine ([^{18}F]FET) PET radiomics combined with patient age and sex, and to evaluate the impact of scanner harmonisation and inclusion of [^{18}F]FET-negative cases on model performance. ***Materials and Methods:*** [^{18}F]FET PET and multimodal MRI data (T1, contrast-enhanced T1, T2, and FLAIR) from 507 glioma patients were retrospectively analysed. PET images from two different PET/CT systems were reconstructed as late static scans (20-40 min post-injection). Tumour delineation was performed according to PET RANO 1.0 criteria using a semi-automatic threshold-based method on the PET data [1]. Volumes of interest smaller than image resolution were defined as [^{18}F]FET-negative and replaced by MRI-based VOIs generated via BraTS-toolkit. PET radiomic features were extracted using pyradiomics. Scanner-related variability was addressed through ComBat harmonisation. A nested ML pipeline was applied using 50-repeated 5-fold cross-validation with stratification by scanner and IDH mutation status. Input features included radiomics, patient age, and sex. Ground truth IDH status was determined by neuropathological analysis of tissue samples. Model performance was assessed via area under the ROC curve (AUC) and compared across multiple factors: inter-scanner harmonisation, inclusion of [^{18}F]FET-negative patients, and inclusion of patient sex and age as predictive variables. ***Results:*** Across all experimental conditions, ComBat harmonisation led to improved AUC scores, though the magnitude of improvement varied. The highest overall AUC of 85% was observed in the harmonised [^{18}F]FET-positive subgroup with the inclusion of age. Including [^{18}F]FET-negative patients (n=94) generally improved model performance across most settings, particularly for unharmonised data. However, when using harmonised features and including patient age, performance slightly decreased to 83% compared to using [^{18}F]FET-positive cases only. Inclusion of patient sex had negligible effect on predictive accuracy, with AUC differences consistently below 0.2%. ***Conclusion:*** This study demonstrates that ComBat is effective in reducing scanner-related variance by improving performance for non-invasive prediction of IDH mutation status in glioma patients. However, its impact was less pronounced after the inclusion of [^{18}F]FET-negative patients, indicating that harmonisation efficacy may be limited in more heterogeneous cohorts. Inclusion of patient sex did not enhance model performance. These findings suggest that harmonisation strategies should be applied in radiomics-based prediction frameworks for neuro-oncology to improve generalizability across scanning devices. ***References:*** [1]Albert et al., PET-based_response_assessment_criteria_for_diffuse_gliomas(PET_RANO1.0):a_report_of_the_RANO_group. Lancet Oncol.2024;25(1):e29-e41.

Genetic algorithm vs. gradient descent for training a novel neural network architecture with low trainable parameters count for small datasets

A. Boukhari[1,2], *B. Ecsedi*[3,4], *Z. Ritter*[5], *L. Papp*[4], *M. Hatt*[1,2];
[1]*Laboratory of medical information processing (LaTIM), Brest, FRANCE,* [2]*University of Western Brittany, Brest, FRANCE,* [3]*Georga Institute of Technology, Atlanta, GA, UNITED STATES OF AMERICA,* [4]*University of Vienna, Vienna, AUSTRIA,* [5]*Medical University of Pécs, Pécs, HUNGARY.*

Aim/Introduction: Distance-encoding biomorphic-informational neural network (DEBINN) is a novel architecture where neurons' 3D coordinates are trained via a genetic algorithm (GA) and the distance between neurons define weights. It matches the performance of classical NNs while requiring fewer parameters, making it especially effective for small datasets[1]. Since gradient

descent (GD) remains the prevailing optimization method for NN, our objective was to design and evaluate a GD for DEBI-NN. ***Materials and Methods:*** We compared GD with GA in a nonlinear synthetic dataset (2 interleaving halfcircles) and 2 PET/CT radiomics datasets: outcome prediction in DLBCL (train=41, test=44) [2] and HPV classification in HECKTOR (train=158, test=74) [3]. As DEBI-NN neurons are arranged in 3D space and connections depend on interneuronal distances, standard backpropagation is not directly applicable. Hence, we designed and implemented a modified backpropagation procedure that accounts for the spatial dependencies between neurons and ensures correct propagation of gradients. Both GA and GD were optimized in each dataset by exploring a large range of hyperparameters and configurations. All reported performance metrics were computed on test sets. ***Results:*** GA consistently outperformed GD. In the synthetic data, although GD achieved 83% balanced accuracy (BAcc) (84% sensitivity, 82% specificity), it failed to fully capture the nonlinear patterns. In contrast, GA classified all samples with BAcc of 100%. In DLBCL, GA achieved a BAcc of 83% (sensitivity 86%, specificity 80%), vs. 78%, 79%, and 77% for GD. In HECKTOR, GA reached 80% BAcc (sensitivity 60%, specificity 100%), while GD obtained 66%, 58%, and 74%, respectively. ***Conclusion:*** Our results suggest that GA is more appropriate for training DEBI-NN than GD. This may be explained by the structural constraints of DEBINN, where neurons are interdependent due to their spatial configuration. Modifying the weight of a single connection affects all other weights in the same layer, making optimization using gradientbased methods more complex. These dependencies make the DEBINN architecture more suitable for evolutionary approaches such as GA. ***References:*** 1)Papp, Laszlo, et al. Aim/Introduction: Radiomics model (RM) and deep learning (DL) are two artificial intelligence approaches for obstructive coronary artery disease (CAD) predictions. This study aims to compare their invasive coronary angiography (ICA) outcome predictive performance from myocardial perfusion (MP) SPECT. ***Materials and Methods:*** We retrospectively enrolled 515 patients from 3 centers (primary: 212, external-1: 108, external-2: 195) undergoing a one-day ^{99m}Tc-sestamibi or ^{201}Tl stress/rest SPECT protocol. ICA was performed within 90 days following the MP SPECT. The primary dataset with CT-based attenuation correction was split into 7:1:2 for training, validation and testing, while both external datasets with DL-based attenuation correction were tested. Five-fold cross validation was performed to test all datasets in the primary dataset. For RM, polar plots were segmented into regions-of-interest (ROI) of left anterior descending (LAD), right coronary artery (RCA), and left circumference (LCx). Stress and rest polar plots were stacked as 2-channel input with 903 radiomics features (RF) extracted, followed by Least Absolute Shrinkage and Selection Operator regression and Recursive Feature Elimination for feature selection and logistic regression for classification. For per-patient analysis, RF extracted from the adaptive ROI defined based on ICA diagnosis of the primary dataset were used for training, while RF from the LAD ROI were input for testing. For per-vessel analysis, RM were trained on RF extracted from the LAD, RCA and LCx ROIs, and tested on each ROI respectively. For DL, a 2D DenseNet was trained for per-patient analysis and a multi-input multi-output DenseNet was trained for per-vessel analysis, with the same 2-channel polar plot data without segmentation as input. Area under the receiver operating characteristic curve (AUC) and accuracy (ACC) were assessed for different models on all datasets. Delong's test was employed to compare the ROC curves of RM and DL. ***Results:*** For per-patient analysis, RM (28 RF) achieved AUC/ACC of 0.85/0.82, 0.68/0.67 and 0.66/0.65 for the primary, external-1 and external-2 datasets, while DL achieved 0.83/0.85 (p=0.462), 0.66/0.68 (p=0.136) and 0.68/0.69 (p=0.010) respectively. For per-vessel analysis, RM (19 RF) achieved AUC/ACC of 0.74/0.73, 0.65/0.63 and 0.61/0.63 for the primary, external-1 and external-2 datasets, while DL achieved 0.74/0.76 (p=0.572), 0.62/0.66 (p=0.129) and 0.65/0.72 (p=0.024) respectively. ***Conclusion:*** RM shows comparable performance as compared to DL for obstructive CAD prediction using stress/rest MP SPECT. This work was supported by the Science and Technology Development Fund of Macau (0178/2024/AMJ).

Radiomic Analysis of Tumor Invasiveness and Staging in Nasopharyngeal Carcinoma Using a FAPI PET/CT Dataset

D. Ruan[1], *Z. Luo*[1], *R. Su*[1], *W. Zhou*[2], *L. Yu*[1], *J. Cai*[1], *Q. Lin*[1], *L. Zhao*[1], *Y. Pang*[1], *L. Sun*[1], *H. Ye*[2], *H. Chen*[1];
[1]*The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, CHINA,* [2]*Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, CHINA.*

Aim/Introduction: The tumor immune microenvironment has clinicopathological significance for assessing tumor invasiveness and predicting metastasis. Quantitative imaging biomarkers facilitate robust, reproducible, and reliable in vivo assessments of tumor heterogeneity, offering critical insights into tumor growth, metabolism, metastasis, and treatment response. Radiomics, the high-throughput extraction of quantitative imaging features, has gained significant attention as a noninvasive tool for predicting cancer outcomes and informing therapeutic strategies. However, effective imaging biomarkers for predicting tumor invasiveness and metastasis potential remain lacking. This study aimed to analyze ^{68}Ga-FAPI-46 PET/CT radiomic data to identify features that differentiate nasopharyngeal carcinoma (NPC) with varying levels of invasiveness. ***Materials and Methods:*** ^{68}Ga-FAPI-46 PET/CT images of NPC patients were preprocessed to extract radiomic features, including first-order, texture, and shape features from the primary tumor. Six machine learning models: Logistic Regression, Random Forest, XGBoost, Naive Bayes, Support Vector Machine, and KNN, were employed to classify the T, N, and M stages of

NPC. A training set (n = 137) was used for model training and an external test set (n = 53) for evaluation. Metrics included accuracy, sensitivity, specificity, and AUC. The best-performing model was analyzed for interpretability. ***Results:*** Image-interpolated_Mean of ^{68}Ga-FAPI-46 PET images was a key feature for assessing tumor infiltration, while original_shape_Elongation was a significant predictor of lymph node and distant metastasis. A retrospective analysis of 190 treatment-naïve NPC patients revealed that ^{68}Ga-FAPI-46 PET/CT radiomic features exhibited strong predictive performance for the T stage, with 86% (24/28) [67%-96%] sensitivity, 88% (22/25) [69%-97%] specificity, 87% (46/53) [75%-95%] accuracy, and an AUC of 0.94 [0.87-0.94]. For the N stage, sensitivity was 86% (36/42) [71%-95%], specificity was 73% (8/11) [39%-94%], accuracy was 83% (44/53) [70%-92%], and AUC was 0.88 [0.77-0.99]. The M stage showed 50% (3/6) [12%-88%] sensitivity, 100% (47/47) [92%-100%] specificity, 94% (50/53) [84%-99%] accuracy, and an AUC of 0.76 [0.51-0.76]. ***Conclusion:*** This exploratory study highlights the feasibility of ^{68}Ga-FAPI-46 PET/CT radiomic analysis in assessing NPC invasiveness and predicting metastasis potential. However, further validation using larger and more balanced datasets is required to confirm these findings. Despite these challenges, this study successfully identified key radiomics features that significantly contribute to NPC stage classification.

Prediction of EGFR Mutation Status and Subtypes in Lung Adenocarcinoma Using PET/CT Deep Learning stacked with Radiomics

L. Huang[1], *J. Liu*[1], *J. He*[2], *Y. Luo*[1];
[1]The Second Hospital & Clinical Medical School, Lanzhou University, Lanzhou, CHINA, [2]Lanzhou University of Finance and Economics, Lanzhou, CHINA.

Aim/Introduction: Targeted therapy is the standard treatment for patients with advanced lung cancer, and the mutation status and subtypes of epidermal growth factor receptor (EGFR) gene is a key factor in predicting efficacy. This study aimed to develop and validate deep learning models using PET/CT imaging to predict EGFR mutation status and two sensitive mutation subtypes (exon 19 deletion and 21L858R point mutation) in patients with lung adenocarcinoma. ***Materials and Methods:*** A total of 117 patients with pathologically confirmed lung adenocarcinoma who underwent EGFR mutation testing and ^{18}F-FDG PET/CT scans were included. Patients were divided into training (70%) and validation (30%) cohorts using randomized stratified sampling. A residual network was used to develop models for four tasks: predicting EGFR mutation status (Task 1), distinguishing wild-type from exon 19 deletion (Task 2), distinguishing wild-type from 21L858R point mutation (Task 3), and identifying the two mutant subtypes (Task 4). For Task 1, three models were built: Model 1 used only PET/CT images; Model 2 combined PET/CT images with clinical variables; Model 3 integrated PET/CT images, clinical variables, and radiomics features. For Tasks 2-4, only the combined model (similar to Model 3) was constructed. Model performance was evaluated using ROC, AUC, accuracy, precision, recall, and F1 values. ***Results:*** In Task 1, the combined model (Model 3) achieved the highest performance, with AUC values of 0.928 in the training cohort and 0.832 in the validation cohort, and accuracies of 0.805 and 0.675, respectively. The model using only PET/CT images (Model 1) had AUC values of 0.916 and 0.676, and accuracies of 0.802 and 0.566 in the training and validation cohorts, respectively. The model with clinical features (similar to Model 2) had AUC values of 0.895 and 0.733, and accuracies of 0.801 and 0.670. In Task 2, the combined model achieved AUC values of 0.906 and 0.828, and accuracies of 0.868 and 0.767, demonstrating high prediction efficiency and robustness. In Task 3, the combined model had AUC values of 0.909 and 0.785, and accuracies of 0.850 and 0.700. In Task 4, the combined model achieved AUC values of 0.951 and 0.800, and accuracies of 0.732 and 0.533. ***Conclusion:*** The combined deep learning model integrating PET/CT images, clinical variables, and radiomics features showed the best performance in predicting EGFR mutation status and different mutation subtypes, maintaining stability in the validation cohort.

EP-1040

Prediction of 3-year overall survival based on dissemination features of bone scintigraphy in metastatic prostate cancer

J. Ning[1], *D. Haberl*[1], *M. Hacker*[2], *L. Kenner*[1], *C. Spielvogel*[2];
[1]Christian Doppler Lab for Applied Metabolomics, Vienna, AUSTRIA, [2]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-Guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Despite high overall survival rates across all stages (98%), patients with metastatic prostate cancer (PCa) reach a five-year relative survival of only 30%. These disparities highlight the need for advanced prognostic tools to guide treatment decisions in metastatic PCa (mPCa). Recent studies validated the reproducibility of the automated Bone Scan Index (BSI) and its association with survival outcomes in PCa patients, highlighting its potential as a prognostic biomarker. Similar to findings in other malignancies, features reflecting tumor volume and spread—such as maximum lesion size (Dmax)—have been associated with overall survival (OS). Translating these insights into PCa, BS-derived dissemination metrics may provide a robust framework for predicting three-year OS in mPCa patients. This study aims to evaluate the prognostic value of dissemination metrics derived from 99mTc-DPD bone scintigraphy (BS) and 68Ga-PSMA-11 PET in predicting three-year overall survival in mPCa. ***Materials and Methods:*** This retrospective study included 2,652 mPCa patients who underwent planar BS between January 2010 and February 2023, with 362 patients also undergoing prostate-specific membrane antigen (PSMA) PET imaging within 100 days of BS. For the preliminary cohort including 163 BS and 26 PSMA PET/CT or PET/MR images, the suspected metastasis lesions were manually delineated via ITK-SNAP. Dissemination metrics included tumor burden, Dmax_patient (distance between the two farthest metastatic lesions), Dmax_p-f (distance from primary lesion to the farthest metastatic lesion), and SPREAD metrics (sum and average distances between lesions). Survival endpoints—three-year OS, were assessed using Kaplan-Meier analysis. ***Results:*** In the preliminary cohort, dissemination metrics, particularly tumor burden and Dmax_patient, demonstrated significant associations with three-year OS. Patients with high tumor burden exhibited markedly reduced survival probabilities compared to those with lower tumor burden, as evidenced by a log-rank p-value of <0.001. Similarly, greater Dmax_patient values were strongly correlated with poorer OS, emphasizing the prognostic relevance of spatial dissemination patterns. Patients with more widely distributed metastatic lesions, as indicated by larger Dmax_patient values, had significantly worse survival compared to those with more localized disease. Multivariate Cox proportional hazards analysis further validated the independent prognostic value of tumor burden and Dmax_patient after adjusting for established clinical covariates, including age, PSA levels, and the use of systemic therapies. ***Conclusion:*** BS-derived dissemination features, including tumor burden and spatial metrics, provide critical insights into the prognosis of metastatic PCa patients, which enable effective risk stratification, guiding personalized treatment for metastatic tumor burden assessment, particularly in resource-limited settings.

FDG PET/CT radiomics-based prognostic models for early-stage Non-Small Cell Lung Cancer: impact of segmentation method

J. Meynen[1], *K. Claesen*[1], *E. Derveaux*[1], *R. Boellaard*[2], *L. Mesotten*[3]; *[1]Hasselt University, Diepenbeek, BELGIUM, [2]Amsterdam UMC, Amsterdam, NETHERLANDS, [3]Ziekenhuis Oost-Limburg, Genk, BELGIUM.*

Aim/Introduction: Lung cancer remains the leading cause of cancer-related mortality worldwide. Even though that surgery remains the most effective treatment, about 30-55% of the patients with NSCLC develop disease recurrence. Accurate risk stratification through prognostic models is therefore essential to identify high-risk patients who are likely to experience recurrence. Current prognostic tools often fail to fully capture the underlying tumor biology and spatial heterogeneity. Radiomics offers a non-invasive way to probe this tumor biology and heterogeneity beyond what's visible to the human eye, therefore serving as a promising alternative for improved prognosis making. This study aims to identify the effect of different segmentation methods on the performance of multiple radiomics-based prognostic models for early-stage Non-Small Cell Lung Cancer (NSCLC). ***Materials and Methods:*** F^{18}-FDG PET/CT images were obtained from a total of 89 patients with pathology-confirmed early-stage NSCLC (stage I-IIIa) (patient inclusion at Ziekenhuis Oost-Limburg). All images were segmented using three different segmentation methods (SUV4.0, MV2, AI-based tool LIONZ which is developed at the Medical University of Vienna by Sundar et al). Radiomic features were extracted using RaCaT (an open source radiomics tool developed by Pfaehler et al) from all different segmentations, resulting in more than 500 features per scan, per segmentation. Logistic regression models with six different feature selection approaches were tested with overall survival (OS) and/or time to progression (TTP) greater than 36 months as the outcome. All models were trained using ten times repeated five-fold cross validation (CV) and upsampling of the minority class. Model performances were evaluated using the CV area under the curve (AUC) values. ***Results:*** Prognostic models showed CV-AUCs ranging from 0.52 to 0.79. Differences in model performances assessed by CV-AUC are mainly caused by the applied feature selection approach and to a much lesser degree by the segmentation method used to extract the radiomic features. The best performing model (CV-AUC=0.79) was found using a model based on SUVmax, TLG, and DmaxBulk, which were measured using MV2 segmentations, with only a small decrease in performance using other segmentation methods. ***Conclusion:*** This study shows the feasibility of all three segmentation methods for the development of radiomic-based prognostic models for early-stage NSCLC patients.

EP-1042

Prognostic value of primary tumour quantitative indices on 68GaDOTANOC PET/CT in pediatric patients with neuroblastoma

N. Kundu, *D. Khan, S. Sagar, A. Mahalik, A. Roy, A. K. Pandey, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Neuroblastoma (NB) is the most common extracranial malignant solid tumour of childhood and exhibits both biological and clinical heterogeneity. Among the multitude of radiotracers available for imaging NB, the radiolabeled somatostatin analogue 68Ga-DOTANOC PET/CT has shown promise as a new tracer which maybe considered in mIBG negative tumors. In our study we aim to investigate whether quantitative DOTANOC parameters of the primary mass predict metastatic propensity at diagnosis in paediatric neuroblastoma. ***Materials and Methods:*** Thirty five treatment naïve children with known neuroblastoma underwent 68GaDOTANOC PET/CT scanning on a dedicated scanner (Biograph 2, Siemens Medical Solutions). A dose of 1.5 MBq/kg body weight with a mean dose range of 11.1-111 39 MBq of 68Ga-DOTANOC was injected intravenously. After a 45-60-minute uptake period, the patients were taken for PET/CT acquisition. Attenuation-corrected PET and fused PET/CT images were reviewed in the axial, coronal, and sagittal planes and in MIP. (VOIs) were carefully drawn over the primary tumour, with special attention paid to exclude areas of high physiological uptake in the neighbouring areas such as liver, spleen, uncinate process of pancreas and urinary tract. Parameters such as SUVmax, SUVmean of primary tumour, SUVmean of blood pool (VOI of 1cm3 drawn over descending aorta), tumour to blood pool ratio (SUVr=SUVmax tumour/SUVmax background), SSTR expressing tumour volume (STV), and total lesion SSTR expression. (TLS= SUVmean primary x STVprimary) were recorded with a 40 % SUVmax threshold. Tumourtobloodpool ratio (SUVr) served as a receptordensity surrogate. Metrics were compared between metastatic (n = 26) and nonmetastatic (n = 9) groups and subjected to ROC analysis.mIBG planar scans of the patients were also available for analysis. ***Results:*** Quantitative parameters of 35 patients with SSTR expressing primary tumours were calculated on 68Ga-DOTANOC PET/CT. SUVr was significantly higher in metastatic patients (15 ± 15) than in localised cases (7.1 ± 4.6; P = 0.04), whereas SUVmax, STV and TLS did not differ. An SUVr cutoff of 6.65 yielded 77 % sensitivity and 88 % specificity for predicting disseminated disease (AUC = 0.73). High SUVr correlated with elevated wholebody extratumour burden and with nonmIBGavid biology. ***Conclusion:*** DOTANOC SUVr—reflecting somatostatinreceptor density relative to background—emerges as an independent imaging biomarker of metastatic potential, outperforming absolute uptake or volume alone. Incorporation of SUVr into baseline assessment could help tailor induction intensity and surveillance frequency.

CNN-based prediction of Clinical Relapse in Takayasu Arteritis from [^{18}F]FDG PET scans

C. Bezzi[1], *A. Tomelleri*[2], *S. Resta*[3], *F. Fallanca*[1], *C. Campochiaro*[2], *E. Baldissera*[2], *S. Ghezzo*[1], *L. Dagna*[2], *A. Chiti*[1], *P. Mapelli*[1], *M. Masseroli*[3], *M. Picchio*[1];
[1]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [2]Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Department of Electronics, Information and Bioengineering (DEIB), Politecnico di Milano, Milan, ITALY.

Aim/Introduction: To investigate the potential of convolutional neural networks (CNNs) applied to [^{18}F]FDG PET imaging to predict clinical relapse in Takayasu arteritis (TAK) patients within 12 months post-scan. The goal is to improve patient monitoring and therapeutic decision-making. ***Materials and Methods:*** A retrospective analysis was conducted on 306 [^{18}F]FDG PET scans from 74 patients diagnosed with TAK. The scans, obtained between 2013 and 2023 across 4 different PET systems, were preprocessed through resizing and cropping, and harmonized using different strategies, including discretization and histogram equalization methods, and a customized liver-based standardization approach. Multiple CNN architectures were investigated for the prediction: a custom "Baseline Model" with 4 convolutional layers, a residual bottleneck model built with 3 residual bottleneck blocks, and two pre-defined architectures from the MONAI framework [1]: ResNet18 and DenseNet121. Data were divided into training, validation, and testing sets. To increase reliability, the test set was resampled 10 times with a random under-sampling of the majority class to ensure class balance. Class weighting, early stopping, and data augmentation were employed to reduce overfitting. Performance was evaluated using accuracy, precision, recall, specificity, and normalized Matthew's correlation coefficient (nMCC). ***Results:*** Among the 306 scans, 64 were associated with

clinical relapse within 12 months. An expert Nuclear Medicine Physician, blinded to clinical data, classified 39/64 as negative and 25/64 as positive. The iver-based standardization method optimized in this study successfully eliminated inter-scanner voxel intensity discrepancies and was used to harmonize the scans. Overall, the best performing models were the Baseline Model (monitored metric: accuracy; data augmentation: RandAffine) and DenseNet121 (monitored metric: accuracy; data augmentation: RandAxisFlip). Specifically, on test set, the Baseline Model reached an accuracy of 82%, with class-wise precision of 85% (class_0) and 62% (class_1), 38% recall, 94% specificity, and an 0.70 nMCC. DenseNet12, while achieving 81% accuracy, proved particularly effective for predicting complete remission, with 80% precision_class_0, 100% precision_class_1, 8% recall, 100% specificity, and 0.62 nMCC, maintaining 100% precision_class_0 and specificity in the resampled test sets. ***Conclusion:*** This work represents the first implementation of CNN-based analysis of [^{18}F]FDG PET imaging in TAK. Despite limitations including the retrospective design and class imbalance, findings suggest that CNNs can effectively support relapse prediction, potentially guiding decisions to reduce overtreatment and unnecessary follow-up in specific patient subgroups. ***References:*** [1] Cardoso, M. J. et al. MONAI: An open-source framework for deep learning in healthcare. (2022).

Prognostic Value of First Order Radiomic Features in Multiple Myeloma: Data Analysis from the CONPET Trial

J. Blakkisrud[1], *J. Nørgaard*[2,3], *J. Connelly*[1], *M. Revheim*[1,4], *F. Schjesvold*[2], *C. Stokke*[1,5];
[1]*Division for Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [2]*Oslo Myeloma Center, Oslo University Hospital, Oslo, NORWAY,* [3]*Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY,* [4]*The Intervention Centre, Oslo University Hospital, Oslo, NORWAY,* [5]*Department of Physics, University of Oslo, Oslo, NORWAY.*

Aim/Introduction: [^{18}F]FDG PET/CT is increasingly used for staging and prognostication in multiple myeloma, but conventional assessments may not fully reflect disease heterogeneity. The CONPET trial used [18F]FDG PET positivity status as indication for consolidation therapy after first-line treatment with autologous stem cell transplantation. This study explores whether first order radiomic features from PET/CT after first-line treatment provide additional prognostic value. ***Materials and Methods:*** We retrospectively analysed 114 patients enrolled in the CONPET study (1). Patients underwent [^{18}F]FDG PET/CT and were classified as PET-positive (n=33) or PET-negative (n=81). PET-positive patients were scheduled for 4 cycles of KRd (carfilzomib, lenalidomide and dexamethasone) consolidation. The skeleton from atlas to mid thighs excluding the skull was segmented using TotalSegmentator (2). First-order histogram features were extracted from the PET corresponding volume of interest (VOI). Difference between features of PET-positive and PET-negative patients were tested using the student t-test. A LASSO-penalized Cox model identified imaging features associated with progression-free survival (PFS) and overall survival (OS). Selected features were refitted using standard Cox regression on the same data in an exploratory analysis to estimate Hazard Ratios (HRs). Analyses were performed separately for the PET-positive and PET-negative subgroups. ***Results:*** Out of 18 features, Skewness ($p = 0.045$) and 10-percentile ($p = 0.039$) were different between PET-negative and PET-positive patients. In PET-positive patients, Skewness, representing an asymmetrical histogram distribution, was a significant prognostic feature for both PFS and OS (HR: 0.49, $p = 0.0076$ for OS; HR: 0.49, $p = 0.0043$ for PFS). In PET-negative patients, Interquartile Range (HR: 9.31, $p = 0.0009$) and Variance (HR: 0.145, $p = 0.0059$) were associated with PFS, though none were prognostic for OS. ***Conclusion:*** The first order radiomic features Skewness, Interquartile Range and Variance extracted from [^{18}F]FDG PET/CT after first-line treatment show potential as prognostic biomarkers in multiple myeloma. Validation in independent cohorts and analyses of feature stability and reproducibility are needed to confirm clinical applicability. ***References:*** 1) Nørgaard et al. Leukemia 2023 2) Wasserthal et al. Radiol Artif Intell 2023.

EP-1045

Single-time-point dosimetry during [^{177}Lu]Lu-PSMA-617 therapy using machine learning and population-based model selection with non-linear mixed-effects modelling

D. Hardiansyah[1], *T. M. Y. Polem*[1], *E. Yousefzadeh-Nowshahr*[2], *U. Nemer*[3], *F. Kind*[3], *A. J. Beer*[2], *P. T. Meyer*[3], *G. Glatting*[2], *M. Mix*[3];
[1]*Universitas Indonesia, Depok, INDONESIA,* [2]*Ulm University, Ulm, GERMANY,* [3]*University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: This study aimed to study the accuracy of renal dosimetry in [^{177}Lu]Lu-PSMA-617 therapy using single-time-point (STP) imaging data from SPECT/CT, machine learning, and population-based model selection (PBMS) with non-linear mixed-effects (NLME) modelling in a population of 101 patients. ***Materials and Methods:*** Renal time-activity data for [^{177}Lu]Lu-PSMA-617 were acquired using SPECT/CT imaging at five post-injection time points:TP1=(1.9 ± 0.8) h, TP2=(18.9 ± 1.0) h,TP3=(43.1 ± 1.5) h,TP4=(66.4 ± 1.4) h,and TP5=(165.8 ± 24.7) h. Six sum-of-exponentials functions (SOEFs), each with different parameterisations, were fitted to the renal time-activity data using the NLME. A PBMS approach—combining goodness-of-fit tests and Akaike weights—was employed to identify the SOEF most supported by the data. This SOEF was then fitted to all data points to derive the reference time-integrated activities (rTIAs). Three STP approaches were evaluated in this study: 1) NLME-based STP using the optimal SOEF from PBMS (STPN), 2) STP with Support Vector Regression machine learning approach (STPML), and 3) STPNML (A hybrid of STPN and STPML). For the STPML and STPNML methods, optimal combinations of patient-specific covariates—such as age, weight, administered activity, platelet count, haemoglobin, hematocrit, creatinine, prostate-specific antigen (PSA), kidney volume, and glomerular filtration rate—as well as machine learning hyperparameters, were selected. Additional covariate of fitted parameters from STPN was used for the calculation of STPNML. The accuracy of calculated TIAs from STPN (sTIAN), STPML (sTIAML), and STPNML (sTIANML) methods was evaluated against the rTIA using root-mean-square errors (RMSEs) of relative deviations and mean absolute percentage errors (MAPEs). ***Results:*** A seven-parameter SOEF was identified as the best model using the PBMS-NLME method. Time-integrated activity estimates derived from the STPN, STPML, and STPNML approaches were evaluated. For STPN, the RMSEs (MAPEs) of sTIAN relative to rTIA at TP1-TP5 were: 30% (22%), 18% (13%), 16% (11%), 18% (13%), and 32% (20%). The RMSEs (MAPEs) of sTIAML were: 28% (21%), 17% (13%), 15% (11%), 17% (12%), and 30% (21%). The hybrid STPNML method consistently outperformed the STPN and STPML methods, achieving lower errors across all time points. The RMSEs (MAPEs) of sTIANML at TP1-TP5 were: 14% (10%), 14% (9%), 13% (9%), 16% (12%), and 14% (10%). ***Conclusion:*** This study demonstrates that using pharmacokinetic modelling and machine learning, accurate renal TIA estimation from sparse time-point imaging is feasible. The hybrid STPNML approach achieved the highest accuracy among the tested methods, consistently yielding low errors across all investigated time points. This robustness enables reliable STP dosimetry to be performed at any imaging time point, offering maximum flexibility for clinical workflows.

EP-1046

An interpretable machine learning model assists in predicting bone marrow invasion for lymphoma using ^{18}F-FDG PET/CT: a multicenter study

X. Mu, *X. Zhu, W. Fu;*
Department of Nuclear Medicine, Affiliated Hospital of Guilin Medical University, Guilin, CHINA.

Aim/Introduction: This study aimed to develop and evaluate a machine learning model combining clinical, radiomics, and deep learning features derived from ^{18}F-FDG PET/CT imaging to predict bone marrow involvement (BMI) in patients with lymphoma. We compared model predictive capability with human visual interpretation. ***Materials and Methods:*** Our retrospective study encompassed 159 lymphoma patients who underwent ^{18}F-FDG PET/CT imaging at two tertiary hospitals. We extracted clinical, radiomic, and deep learning features from the PET/CT images. Specifically, radiomic features were derived utilizing the PyRadiomics package, whereas deep learning features were obtained using a ResNet50 model. A machine learning model, based on the Extra Trees algorithm, was developed to predict BMI. The model's performance was assessed using receiver operating characteristic (ROC) curves, the area under the curve (AUC), calibration curves, and decision curve analysis (DCA). To enhance model interpretability, Shapley Additive Explanations (SHAP) were employed. Additionally, we conducted a comparative study where PET readers first diagnosed BMI using visual PET/CT interpretation alone and then diagnosed with the assistance of the prediction model, to evaluate the model's impact on clinical decision-making. ***Results:*** The combined model, which fusion clinical, radiomics, and deep learning features, exhibited the highest AUC in the training set (0.954), internal validation set (0.900), and test set (0.886), outperforming single-modality models. Model-assisted diagnosis improved PET readers' accuracy compared to visual PET/CT interpretation alone ($p < 0.05$, McNemar's test). SHAP analysis identified B symptoms, platelet count (PLT), and PET-derived texture features as key predictors, enhancing model transparency and physician trust. ***Conclusion:*** The proposed combined model improves non-invasive BMI prediction and significantly enhances physicians' diagnostic performance. The integration of SHAP interpretation increases model transparency, making it more clinically applicable. This approach demonstrates strong theoretical predictive capability and shows great potential for real-world implementation, reducing the reliance on invasive bone marrow biopsy. ***References:*** [1]The role of bone marrow biopsy and FDG-PET/CT in identifying bone marrow infiltration in the initial diagnosis of high grade non-Hodgkin B-cell lymphoma and Hodgkin lymphoma. ^{177}Lu-labeled PSMA-targeted radioligand therapy in metastasic castration-resistant prostate cancer: external validation of a baseline^{68}Ga-PSMA-11 PET-based predicition models using^{18}F-Flotufolastat PET

Ö. Coban[1], *A. Karimzadeh*[1,2], *C. Fütterer*[3], *K. Hansen*[1], *M. Heck*[4], *R. Tauber*[4], *C. D´Alessandria*[1], *W. Weber*[1], *M. Eiber*[1], *I. Rauscher*[1];
[1]*Technical University Munich (TUM) - Department of Nuclear Medicine, Munich, GERMANY,* [2]*Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY,* [3]*Technical University Munich (TUM) - Institute of AI and Informatics in Medicine, Munich, GERMANY,* [4]*Technical University Munich (TUM) - Department of Urology, Munich, GERMANY.*

Aim/Introduction: ^{177}Lu-labeled prostate-specific membrane antigen (PSMA)-targeted radioligand therapy (RLT) has become a recognized treatment option for patients with metastatic castration-resistant prostate cancer (mCRPC). Since not all patients respond to PSMA-RLT, predictive nomograms including baseline ^{68}Ga-PSMA-PET parameters were developed by Gafita et al. (Lancet Oncol 2021; 22:1115-25). With the increasing use of ^{18}F-labeled PSMA ligands, these models require adaptation. This retrospective analysis aimed to validate a recently published nomogram for application with ^{18}F-Flotufolastat PET prior to PSMA-RLT in a large cohort of mCRPC patients. ***Materials and Methods:*** A total of 174 patients were retrospectively included in this single-center analysis. A Cox proportional hazard model was used for overall survival (OS) and PSA-progression-free survival (PSA-PFS), with hazard ratios and the baseline hazard extracted from Gafita et al. Variables used for model fitting included clinical factors (e.g., time since diagnosis) and imaging data from 18F-rhPSMA-7.3 PET (e.g., whole-body SUVmean). Model performance was evaluated using Harrell's C-index and calibration plots. In addition, OS and PFS were compared, stratifying patients in high- and low-risk groups based on cut-off values determined by Gafita et al. ***Results:*** The estimated OS rates were 60% at 12 months (95% CI, 53%-68%) and 40% at 18 months (95% CI, 33%-49%). External validation yielded a C-index of 0.71 (95% CI, 0.71-0.72) for OS prediction, comparable to the validation cohort of Gafita et al. (C-indices of 0.72). For PSA-progression-free survival (PSA-PFS), the estimated survival rates were 56% at 3 months (95% CI, 49%-65%) and 34% at 6 months (95% CI, 27%-42%), with a C-index of 0.63 (95% CI, 0.62-0.63), lower than the C-index of 0.71 (95% CI, 0.65-0.78) in the validation cohort of Gafita et al. Low-risk patients presented with a significantly longer OS than high-risk patients (16.5 months (95% CI, 15.1-17.8) vs. 8.8 months (95% CI, 7.7-9.9), respectively; p-value < 0.0001). Corresponding PSA-PFS was also significantly longer in the high-risk vs. the low-risk group (5.4 months (95% CI, 4.7-6.1) vs. 2.6 months (95% CI, 1.9-3.2); p-value = 0.003). ***Conclusion:*** Using ^{18}F-Flotufolastat PET instead of ^{68}Ga-PSMA PET in a recently developed prediction model performs well for assessing outcomes of ^{177}Lu-PSMA RLT, with similar C-index scores indicating reliability. However, the model's predictive accuracy remains suboptimal, regardless of the PSMA-ligand used, so it should be applied with caution, and further refinements are advisable.

EP-1048

Incorporating deep features in radiomics for predicting coronary artery disease using myocardial perfusion stress/rest SPECT

B. Wang[1,2], *Y. Du*[3], *C. Lin*[4], *M. Gutierrez*[5], *G. Hung*[6], *Z. Hu*[2], *G. S. P. Mok*[1];
[1]*Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Macau SAR, MACAO,* [2]*Lauterbur Research Center for Biomedical Imaging, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA,* [3]*Department of Nuclear Medicine, The First Affiliated Hospital of Army Medical University, Chongqing, CHINA,* [4]*Department of Nuclear Medicine, Show Chwan Memorial Hospital, Changhua, TAIWAN,* [5]*Biomedical Informatics Lab Heart Institute, University of São Paulo Medical School, São Paulo, BRAZIL,* [6]*Department of Nuclear Medicine, Chang Bing Show Chwan Memorial Hospital, Changhua, TAIWAN.*

Aim/Introduction: Myocardial perfusion (MP) SPECT is a well-established technique to diagnose coronary artery disease (CAD), while invasive coronary angiography (ICA) still serves as the gold standard for obstructive CAD. This study aims to investigate the ICA prediction performance from MP SPECT using

radiomics incorporated with deep features (DF). ***Materials and Methods:*** We retrospectively enrolled 212 patients undergoing a one-day 99mTc-sestamibi SPECT/CT stress/rest protocol. ICA was performed within 90 days following the MP SPECT, with obstructive CAD defined as stenosis ≥70% in the left anterior descending artery (LAD)/left circumflex artery (LCx)/right coronary artery (RCA) or ≥50% in the left main artery. Polar plots with CT-based attenuation correction were segmented into regions-of-interest (ROI) of LAD, RCA and LCx, where 903 radiomics features (RF) were obtained from the 2-channel stress+rest input [1]. Additionally, 1024 DF generated by a 2-channel 2D U-net [2] were incorporated in the feature selection together with RF using Least Absolute Shrinkage and Selection Operator and Recursive Feature Elimination, followed by logistic regression for classification. The datasets were split into 8:2 for training and testing. For per-patient analysis, DF and/or RF extracted from adaptive ROI defined based on ICA diagnosis were used for training, while DF and/or RF from LAD ROIs were input for testing. For per-vessel analysis, models were trained on DF and/or RF extracted from the LAD, RCA and LCx ROIs, and tested on each ROI respectively. Five-fold cross-validation was performed to test all datasets. Area under the receiver operating characteristic curve (AUC) and accuracy (ACC) were assessed for different models. Delong's test was employed to compare the ROC curves of 3 models built from RF, DF and RF+RF respectively. ***Results:*** For per-patient analysis, RF+DF model (18 RF+12 DF) achieved AUC/ACC of 0.92/0.86, higher than RF-only model (28 RF) (0.87/0.82, p=0.063) and DF-only model (18 DF) (0.75/0.73, p=0.037). For per-vessel analysis, RF+DF model (16 RF+7 DF) also achieved the highest AUC/ACC of 0.85/0.81, followed by 0.78/0.74 (p=0.011) and 0.71/0.71 (p<0.001) for RF-only (19 RF) and DF-only model (21 DF) respectively. ***Conclusion:*** Incorporation of DF further enhances the radiomics prediction model performance for CAD using stress/rest MP SPECT. ***References:*** 1.Wang, B., et al., Prediction of Coronary Artery Stenosis Using Myocardial Perfusion Stress/Rest SPECT: a Radiomics Study. Evaluation of locoregional invasiveness of early lung adenocarcinoma manifesting as ground-glass nodules via ^{68}Ga-FAPI-46 PET/CT imaging

D. Ruan, *S. Shi, W. Guo, Y. Pang, L. Yu, J. Cai, Z. Wu, H. Wu, L. Sun, L. Zhao, H. Chen;*
The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, CHINA.

Aim/Introduction: Accurate differentiation of the histologic invasiveness of early-stage lung adenocarcinoma is crucial for determining surgical strategies. This study aimed to investigate the potential of ^{68}Ga-FAPI-46 PET/CT in assessing the invasiveness of early lung adenocarcinoma presenting as ground-glass nodules (GGNs) and identifying imaging features with strong predictive potential. ***Materials and Methods:*** This prospective study (NCT04588064) was conducted between July 2020 and July 2022, focusing on GGNs that were confirmed postoperatively to be either invasive adenocarcinoma (IAC), minimally invasive adenocarcinoma (MIA), or precursor glandular lesions (PGL). A total of 45 patients with 53 pulmonary GGNs were included in the study, consisting of 19 patients with GGNs associated with PGL-MIA and 34 patients with IAC. Lung nodules were segmented using the Segment Anything Model in Medical Images (MedSAM) and the PET Tumor Segmentation Extension. Clinical characteristics, along with conventional and high-throughput radiomics features from High-resolution CT (HRCT) and PET scans, were analyzed. The predictive performance of these features in differentiating between PGL or MIA (PGL-MIA) and IAC was assessed using 5-fold cross-validation across six machine learning algorithms: Random Forest, Logistic Regression, XGBoost, Naive Bayes, Support Vector Machine, and K-Nearest Neighbors. Model validation was performed on an independent external test set (n=11). The Chi-squared test, Fisher's exact test, and the DeLong test were employed to compare the performance of the models. ***Results:*** The SUVmax derived from ^{68}Ga-FAPI-46 PET was identified as an independent predictor of IAC. A cutoff value of 1.82 yielded a sensitivity of 94% (32/34), specificity of 84% (16/19), and an overall accuracy of 91% (48/53) in the training set, while achieving 100% (12/12) accuracy in the external test set. Radiomics-based classification further improved diagnostic performance, achieving a sensitivity of 97% (33/34), specificity of 89% (17/19), accuracy of 94% (50/53), and an area under the receiver operating characteristic curve (AUC) of 0.97 [95% CI: 0.93-1.00]. Compared with the CT-based radiomics model (accuracy: 94% vs. 92%, P = 0.99; AUC: 0.97 vs. 0.96, P = 0.88) and the PET-based model (accuracy: 94% vs. 92%, P = 0.99; AUC: 0.99 vs. 0.97, P = 0.36), the combined PET/CT radiomics model did not show a statistically significant improvement in predictive performance. The key predictive feature was 68Ga-FAPI-46 PET log-sigma-7-mm-3D_firstorder_RootMeanSquared. ***Conclusion:*** The SUVmax derived from ^{68}Ga-FAPI-46 PET/CT can effectively differentiate the invasiveness of early-stage lung adenocarcinoma manifesting as GGNs. Integrating high-throughput features from ^{68}Ga-FAPI-46 PET/CT images can considerably enhance classification accuracy.

Optimized Ensemble Learning Models for Predicting ISUP>3 in Prostate Cancer A Radiomics and Clinical Integration Study

C. Jianbo[1,2,3], *C. Zhang*[1], *G. Wang*[1], *J. Zhang*[1], *Y. Han*[1], *Y. Liu*[1], *B. Xu*[1];
[1]*Chinese PLA General Hospital, Beijing, CHINA,* [2]*Nuclear Medicine Department, The 983rd Hospital of the Joint Logistic Support Force, TianJin, CHINA,* [3]*Graduate School, Chinese PLA General Hospital, Beijing, CHINA.*

Aim/Introduction: Prostate cancer remains a major global health challenge, with accurate high-grade classification crucial for treatment and prognosis. While PSMA PET radiomics aids tumor phenotyping, integrating it with clinical biomarkers to predict International Society of Urological Pathology (ISUP) >3 grades remains an area of unmet need. We developed an ensemble model combining 18F-PSMA-3Q PET radiomics and clinical data to improve ISUP>3 prediction. ***Materials and Methods:*** We analyzed 243 treatment-naïve prostate cancer patients who underwent 18F-PSMA-3Q PET imaging prior to radical prostatectomy. Patients were randomized into training (80%) and testing (20%) cohorts. Radiomic features were extracted from tumor volumes segmented at 45% SUVmax thresholds. Five sub-models (AdaBoost, decision tree, random forest, support vector machine, and XGBoost) were trained, followed by the construction of two integrated models: a radiomics-only model (FMA) and a hybrid radiomics-clinical model (FMB) incorporating prostate-specific antigen density (PSAD), systemic immune-inflammation index (SII), and total/free PSA ratios. Model performance was rigorously assessed using AUC, sensitivity, specificity, accuracy, precision, F1-score and recall. ***Results:*** The hybrid FMB model outperformed other approaches, achieving an AUC of 0.836 (95% CI: 0.71-0.962) with balanced sensitivity (0.729) and specificity (0.750). Comparatively, the radiomics-only FMA model showed higher recall (0.812) but significantly lower precision (0.634 vs 0.765) and accuracy (0.694 vs 0.755), indicating notable false-positive tendencies. The clinical-only model demonstrated the weakest performance (AUC = 0.746, 95% CI:0.595-0.898). Decision curve analysis confirmed FMB's superior clinical utility across probability thresholds. ***Conclusion:*** Our findings establish that integrating PSMA PET radiomics with clinical biomarkers (FMB) provides more accurate ISUP>3 prediction than unimodal approaches. The FMB framework

offers optimal balance for clinical decision-making, particularly in selecting patients for treatment intensification. These results highlight the importance of combining imaging and clinical data for reliable risk stratification. Multicenter prospective validation is warranted to confirm generalizability across diverse populations and imaging protocols, a critical next step for clinical translation. This approach may significantly improve personalized treatment strategies in prostate cancer management.

EP-1051

The prognostic value of PSMA-PET-derived information in predicting ADT-free survival in oligorecurrent prostate cancer treated with metastasis-directed SBRT

T. D. van Bergen[1], *Y. E. van den Heuvel*[2], *A. J. A. T. Braat*[3], *C. A. T. van den Berg*[1], *T. F. W. Soeterik*[2];
[1]*Computational Imaging Group for MR Diagnostics and Therapy, Center for Image Sciences, University Medical Center Utrecht, Utrecht, NETHERLANDS,* [2]*Department of Radiation Oncology, University Medical Center Utrecht, Utrecht, NETHERLANDS,* [3]*Department of Radiology and Nuclear Medicine, Division of Imaging and Oncology, University Medical Center Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: Patients with oligorecurrent prostate cancer (PCa) could benefit from receiving metastasis-directed therapy (MDT) to delay or even avoid androgen deprivation therapy (ADT) and its morbidities. The aim of this study is to evaluate the prognostic value of prostate-specific membrane antigen positron emission tomography (PSMA-PET)-derived radiomic features to predict ADT-free survival (AFS). ***Materials and Methods:*** PCa patients with oligorecurrent (≤5 lesions) disease who were staged with PSMA-PET/CT and treated with stereotactic body radiotherapy (SBRT) to all metastatic sites (without systemic therapy) were retrospectively enrolled. Lesions were delineated on planning CT or MRI scans by radiation oncologists and registered onto the PSMA-PET using MIM Software. Metabolic tumour volumes (MTV) were calculated by thresholding 40% of the maximum standardized uptake value (SUVmax). Mean SUV (SUVmean), total lesion uptake (TLU), and total lesion quotient (TLQ), were calculated on a patient basis over the total MTV. Clinical parameters, including prostate-specific antigen (PSA) at SBRT, MRI-staging, clinical staging, and ISUP grade group (GG) at biopsy were retrospectively collected per patient. Univariate and multivariate Cox proportional hazard regression and Kaplan Meier methods were used to examine associations between the outcome measure AFS, and baseline clinical/PET parameters. ***Results:*** A total of 210 patients were included in the study. The mean age was 70.8 years (±5.8 years). The mean AFS was 33.8 months (±20.5 months). Need for ADT was initiated in 114 (54.3%) of the patients. A total of 295 lesions were found of which 291 (98.6%) were PSMA positive. The mean number of lesions, SUVmax, TLQ, TLG, and total MTV was 1.4 (±0.7), 8.4 (±8.9), 0.77 (±1.0), 9.7 (±22.8), 1.9 (±2.1), respectively. Univariate cox analysis showed no statistically-significant differences between the survival curves for AFS for SUVmax, and number of lesions (p=0.95, p=0.19, respectively). Univariate cox analysis was significant for AFS in TLQ (HR: 1.21, 95% CI 1.05-1.39, p=0.01), TLU (HR: 1.01, CI 1.01-1.02, p<0.005), and MTV (HR: 1.21, CI 1.12-1.30, p<0.005). On multivariable cox-regression analysis, we observed PSA (HR: 1.14, CI 1.07-1.22, p<0.005), GG (HR: 1.25, CI 1.07-1.46, p=0.005), and MTV (HR: 1.19, CI 1.11-1.28, p<0.005) to be significantly associated with ADT-free survival. ***Conclusion:*** This study showed strong prognostic performance of PSMA-PET features in predicting AFS with total MTV having the highest prediction performance in multivariate analysis. Including PSMA-PET-derived information can be prognostic to determine AFS after MDT-SBRT. A final risk classification system will be developed by ongoing studies in the future.

Unsupervised clustering of short-chain fatty acid transcellular flux identifies oligoclonal metabolic phenotypes in intracratial metastatic disease

M. Inglese[1,2], *S. Islam*[2], *L. McLeavy*[2], *F. Mauri*[2], *T. M. Barwick*[2], *A. D. Waldman*[2,3], *K. O'Neill*[2], *M. Williams*[2], *E. O. Aboagye*[2], *N. Toschi*[1,4];
[1]*University of Rome Tor Vergata, Rome, ITALY,* [2]*Imperial College London, London, UNITED KINGDOM,* [3]*University of Edinburgh, Edinburgh, UNITED KINGDOM,* [4]*Athinoula A. Martinos Center for Biomedical Imaging, Boston, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Brain metastases (IMDs) occur in 10-30% of adult cancer patients and often carry a poor prognosis[1]. Treatment impact on overall survival (OS) depends on factors like metastasis number, primary tumour type, and patient performance status[2]. Given the wide prognostic variability[3], accurate characterization of intracranial metastases is essential for therapy planning and response assessment. Recently, [^{18}F]fluoropivalate (FPIA) PET imaging has emerged as a promising modality for assessing short-chain fatty acid transcellular flux in brain tumours[4,5,6]. This study offers a methodology for characterizing metabolic phenotypes in oligo metastatic brain metastases associated with patient survival in IMD non-invasively, within a timeframe when biopsy or resection is often not feasible. ***Materials and Methods:*** We analyzed ^{18}F-FPIA PET/MRI data of two cohorts of patients with IMD: 12 treatment-naïve and 10stereotactic radiosurgery (SRS)-treated patients for a total of 35 lesions (n=22 from lung, n=6 breast, n=6 melanoma, and one from colorectal cancers). Only one patient contributed to both cohorts. Voxelwise extraction yielded 79,801 FPIA SUV time-activity curves (TACs): 65,131 from untreated lesions(41,299 from lung, 11,062breast, 7,232 colorectal, 5,538 melanoma) and 14,670 from treated ones (6,978 lung, 6,235 melanoma and 1,457 breast). Two time-series unsupervised k-means clustering analyses grouped the normalized TACs of untreated (KMPre,N=17 lesions) and treated (KMPost,N=18 lesions) patients[7], respectively, optimizing the cluster numbers ks using the elbow method[8]. Cluster prevalence was correlated with OS using Spearman and Kendall's Tau tests. Perfusion and diffusion parameters from dynamic contrast enhanced, susceptibility contrast and diffusion weighted DCE/DSC/DWI-MRI were extracted from the cluster-defined lesions' subregions for additional multiparametric and diffusion radiomic analyses. ***Results:*** KMPre identified three kinetic subtypes: intermediate (Cluster1, 30.29%), fast (Cluster2, 25.79%), and slow (trapping-like[6]) (Cluster3, 43.92%). In treated lesions, KMPost identified two kinetic subtypes (Cluster A and B) and revealed a loss of the fast component, with trapping-like ClusterA (70.84%) prevailing. Higher Cluster1 prevalence correlated positively with OS, while Cluster 3 correlated negatively, suggesting less responsive tumour subregions. Validation of KMPre on treated lesions' FPIA SUV TACs confirmed a shift toward Cluster3 (70.57%) after treatment, indicating SRS-induced metabolic changes. Multiparametric MRI supported these findings, showing reduced perfusion and increased apparent diffusion coefficient in slow FPIA regions. Radiomic analysis further revealed changes in heterogeneity after treatment, consistent with prior findings linking such patterns to immune response activity[9]. ***Conclusion:*** SUV kinetic profiling combined with MRI emerges as a promising approach to assess treatment response and stratify patients based on metabolic and vascular changes.

EP-1053

Uncertainty-Quantified Dynamic PET Biomarker for Robust Prediction of Treatment Response and Survival in Precision Breast Cancer Medicine

F. Gu[1], *Q. Wu*[2,3], *F. O'Sullivan*[2], *M. Muzi*[4], *D. Mankoff*[5];
[1]*School of Mathematics and Physics, North China Electric Power University, Beijing, CHINA,* [2]*School of Mathematical Sciences, University College Cork, Cork, IRELAND,* [3]*Insight SFI Center for Data Analytics, Cork, IRELAND,* [4]*Department of Radiology, University of Washington, Seattle, WA, UNITED STATES OF AMERICA,* [5]*Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Dynamic PET imaging captures tracer kinetics, enabling the development of advanced biomarkers with superior predictive power for treatment response and survival in breast cancer. However, single-point estimates of biomarkers near decision boundaries can be unreliable, compromising clinical decisions. This study introduces an uncertainty-aware framework for dynamic PET-derived biomarkers to enhance prognostic precision in breast cancer, advancing personalized oncology. ***Materials and Methods:*** A retrospective analysis was conducted on 53 breast cancer patients who underwent baseline ^{18}F-FDG dynamic PET imaging prior to neoadjuvant chemotherapy (NAC) at the University of Washington [1]. Pathologic complete response (pCR) was assessed from surgical specimens, with 11 of 53 patients achieving pCR. Disease-free survival (DFS) was calculated in years, with 17 of 52 patients relapsing (one patient's survival data was incomplete). Parametric images were generated using the non-parametric residue mapping technique [2]. Kinetic parameters were extracted from primary tumors, and binary logistic regression and Cox proportional-hazards models were used to predict pCR and DFS, respectively. Patient-specific uncertainty in kinetic parameters was quantified using an efficient image-domain bootstrap method [3]. ***Results:*** A novel biomarker, flow distribution, outperformed conventional static SUV and influx rate (Ki), showing strong associations with both treatment response and survival. In cases where biomarker values approached classification thresholds, single-value predictions were ambiguous. By integrating uncertainty quantification, we provided confidence intervals for predicted pCR probabilities and survival time, refining risk stratification. Patients with high flow distribution but elevated uncertainty exhibited heterogeneous outcomes, enabling more tailored treatment strategies. ***Conclusion:*** Incorporating uncertainty quantification into dynamic PET biomarker analysis significantly enhances the robustness of treatment response and survival predictions in breast cancer. This approach mitigates the limitations of single-point estimates, paving the way for reliable, individualized treatment decisions in precision oncology. ***References:*** [1] Mankoff DA, et al. Exploring Contrast-Enhanced Computed Tomography as a Local Predictor of Lung Shunt Fraction in ^{90}Y Liver Radioembolization

B. Mehadji[1], *T. Marx*[1], *A. Carter*[1], *R. Goldman*[1], *C. Vu*[1], *E. Roncali*[2];
[1]*University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [2]*University of California Davis, Davis, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Pretreatment estimation of the Lung Shunt Fraction (LSF) for yttrium-90 (^{90}Y) radioembolization allows to minimize the risk of excessive lungs irradiation, especially in the context of repeated treatments. Standard practice relies on injection of ^{99m}Tc-macroaggregated albumin (^{99m}Tc-MAA) into the lobe intended for treatment, followed by imaging. Gabr et al. have shown that selective treatments of UNOS T1/T2 hepatocellular carcinoma can be safely performed without LSF estimation [1]. Consequently, the number of facilities adopting this technique is increasing [2]. A limitation of that study is that the post-treatment LSF was not measured. Unlike the lobar administration of ^{99m}Tc-MAA that avoids the risk of embolizing peritumoral vessels and altering vascular architecture prior to the ^{90}Y treatment, segmentectomy involves injecting ^{90}Y microspheres into a limited liver volume. Although no complications have been reported and direct comparative studies are lacking, selective injections may lead to higher LSF due to the disproportion between the perfused volume and the hypervascular territory responsible for shunting. This study investigates the feasibility of using contrast-enhanced computed tomography (CECT) to compute a localized LSF; more consistent with hyperselective treatments. ***Materials and Methods:*** Hypervascular volumes were computed by subtracting the portal phase from the arterial phase of the 4-phase abdominal CECT. They were then normalized by the perfused liver volume to compute the hypervascular-to-perfused volume ratio (HVTP). Unlike tumor-based segmentation, this approach identifies regions that actively contribute to LSF. As a result, hypoxic tumor areas unlikely contributing to LSF were excluded, while normal parenchyma and tumor vascular invasion showing hypersignal in arterial phase were included. As a proof of concept, in a retrospective study of 30 liver cancer patients, we compared LSF estimated using CECT and lobar ^{99m}Tc-MAA imaging. ***Results:*** The study showed a strong correlation (R^2=0.946, p<0.001) between the HVTP derived from CECT and the LSF obtained via standard ^{99m}Tc-MAA planar imaging. The predictive power of the HVTP demonstrated a 1-sigma uncertainty of 3%. ***Conclusion:*** This study presents the methodology and early validation of a CECT-based method for LSF estimation. By leveraging differences between the arterial and portal phases, the approach enables visualization of highly vascularized volumes and offers potential for LSF estimation in the context of hyper selective treatments. The method is aimed to be further validated using direct comparison with post treatment measurement of the true LSF. ***References:*** [1] A. Gabr et al., Jun. 2020, doi: 10.1016/j.jhep.2020.02.024. Utrecht, NETHERLANDS, [14]Department of Nuclear Medicine and Radiology, University Medical Center Utrecht, Utrecht, NETHERLANDS, [15]Unité de Genomique du Myélome, IUC-T Oncopole, Toulouse, FRANCE, [16]Erasmus MC Cancer Institute, Rotterdam, NETHERLANDS, [17]Hematology, University Hospital Hôtel-Dieu, Nantes, FRANCE.

Aim/Introduction: This study aims to evaluate the added value of 2-[^{18}F]fluoro-2-deoxy-D-glucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) radiomics in the analysis of overall survival (OS) in patients with multiple myeloma (MM) treated by Daratumumab. ***Materials and Methods:*** Patients with focal, paramedullary and/or extramedullary lesions treated with Daratumumab were selected from the prospective CASSIOPET study sponsored by the IFM group. All patients underwent whole-body ^{18}F-FDG PET/CT imaging at baseline, and radiomics features were extracted from the largest and hottest lesions. Four machine learning (ML) algorithms were used to model patient survival outcomes, namely Cox proportional hazards, support vector machine, random survival forest, and gradient boosting with component-wise least squares as the base learner. Each model was trained on three different feature sets, including clinical and PET-derived features (referred to as conventional), radiomics features, and a combination of both. A new PET-derived feature, total metabolic tumor volume of the bone marrow (TMTV-BM), was extracted automatically and defined as the number of segmented skeletal voxels with uptake greater than the median liver uptake. Uncorrelated features were selected using bootstrap-based consensus clustering and feature selection. A stratified nested cross-validation strategy with three outer and three inner folds was implemented. Model hyperparameters and the maximum number of selected features were optimized using Bayesian search. An ensemble technique was performed by averaging the predicted risk scores from the four optimized ML models within each outer fold. Feature importance was evaluated using Shapley Additive Explanation values. ***Results:*** A total of 112 patients (59 [54, 62] years old, 46 women) out of 274 patients from the CASSIOPET study were included in the analysis. The highest performance was obtained using conventional features, with a concordance index (C-index) of 0.668±0.047. When considering both the largest and hottest lesions, the radiomics+conventional feature set (largest: C-index = 0.627±0.040, hottest: C-index = 0.585±0.080) outperformed radiomics features alone (largest: C-index = 0.556±0.101, hottest: C-index = 0.531±0.068). The TMTV-BM feature was identified as the most informative across both the conventional and radiomics+conventional feature sets, with additional contributions from radiomics features in the latter. ***Conclusion:*** Among patients with newly diagnosed MM treated with Daratumumab, conventional features demonstrated the best performance for OS prediction. When combined with conventional features, radiomics features extracted from the largest and hottest lesions showed an improvement over radiomics alone, suggesting limited added value of the radiomics features.

Prospective Dual-Tracer ^{18}F-FDG/^{68}Ga -FAPI PET/CT Biomarkers Enable Early Prediction of Immunotherapeutic Response in Advanced Gastric Adenocarcinoma

C. Zhang[1], *X. Lin*[1], *J. Hao*[2], *H. Zhao*[1], *T. Han*[1], *L. Qi*[2], *C. Wang*[1], *Y. Zhang*[1], *M. Xin*[1], *J. Liu*[1], *X. Xiao*[1];
[1]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, CHINA, [2]United Imaging Healthcare, Shanghai, China, Shanghai, CHINA.

Aim/Introduction: While immunotherapy has emerged as a promising therapeutic strategy for advanced gastric cancer, there remains a lack of precise tools for its efficacy evaluation. ^{18}F-FDG and ^{68}Ga-FAPI (fibroblast activation protein inhibitor), as two tracers targeting distinct molecular pathways in PET imaging, reflect distinct tumor biological characteristics and potentially provide complementary insights into clinical diagnosis and efficacy evaluation of gastric cancer. This study aims to investigate the clinical utility of the dual-tracer PET imaging in assessing immunotherapy response and predicting survival outcomes in patients with advanced gastric cancer. ***Materials and Methods:*** This prospective dual-imaging cohort study included 20 advanced gastric adenocarcinoma patients who underwent sequential ^{18}F-FDG/^{68}Ga-FAPI PET/CT scans at baseline and post-immunotherapy timepoints, with a subgroup (n=6) additionally receiving baseline ^{18}F-FDG PET/MR for multimodal validation. The tumor target lesions on the FDG PET and FAPI PET images were segmented using the relative threshold method and the parameters including SUVmax, MTV, FAPI-positive tumor volume (GTV-FAPI), total lesion glycolysis (TLG) and FAPI-positive total lesion accumulation (TLF) were obtained. Survival outcomes, including overall survival (OS) and progression-free survival (PFS) were collected. ***Results:*** Quantitative analysis revealed distinct metabolic dynamics: while baseline FDG/FAPI parameters showed inter-tracer concordance ($p>0.05$), baseline FDG SUVmax demonstrated PERCIST-stratified escalation (CMR< PMR < PMD: 7.1±2.3 vs 19.2±5.9 vs 28.5±14.6, $p=0.028$).Demographic analysis revealed comparable age and gender distributions between progression (n=8) and non-progression (n=12) cohorts ($p>0.05$). Baseline dual-tracer PET parameters showed limited predictive value (FDG-SUVmax: 21.41±4.93 vs 15.65±2.54; FAPI-SUVmax: 19.96±2.60 vs 15.84±1.25; $p>0.05$). Longitudinal analysis revealed significant metabolic response stratification: post-treatment FDG-SUVmax (12.63±2.55 vs 5.25±0.96) and FAPI-SUVmax (15.47±1.92 vs 7.99±0.78) differed markedly between progression/non-progression groups, with ΔFDG-SUVmax% showing superior discrimination (62.6±5.9% vs 38.7±7.5%) compared to ΔFAPI-SUVmax% ($p>0.05$). ROC optimization identified post-treatment FDG-SUVmax >6.47 (Se=87.5%, Sp=70%) and FAPI-SUVmax >12.22 (Se=87.5%, Sp=90%) as optimal thresholds for predicting treatment resistance. Notably, FDG-SUVmax reduction >67% achieved 100% specificity for therapeutic efficacy (Se=50%). Longitudinal radiomic evolution demonstrated superior prognostic value over baseline metrics. While baseline PET parameters showed no significant association with OS/PFS ($|r|<0.3$, $p>0.1$), treatment-induced metabolic alterations revealed strong survival correlations: ΔFDG-MTV (r=-0.472 for OS vs r=-0.537 for PFS, $p<0.05$), ΔFDG- TLG (r=-0.535 for OS vs r=-0.518 for PFS, $p<0.05$), and ΔFAPI-TLF (r=-0.466 for OS vs r=-0.466 for PFS, $p<0.05$),ΔFDG- SUVmax(r=-0.584 for OS vs r=-0.584 for PFS, $p<0.05$, $p<0.05$) exhibited linear relationships with PFS/OS. ***Conclusion:*** This multimodal approach provides critical decision-support for optimizing treatment sequencing and combination strategies in advanced disease management.

Development of a Clinical-Radiomic Model for Recurrence Prediction in Head and Neck Cancer Using Multi-Scanner PET Imaging

N. González-Cuesta[1], *G. Reynés-Llompart*[2], *L. Rodriguez-Bel*[1], *V. Carrero-Vásquez*[1], *M. Zamorano-Rivas*[1], *A. Bagán-Trejo*[1], *I. Martínez-Zalacaín*[3], *P. Naval-Baudín*[4], *M. Cortés-Romera*[1];
[1]Nuclear Medicine Department, ICS-IDI, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN, [2]Medical Physics Department, Institut Català d'Oncologia-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [3]Department of Clinical Sciences/School of Medicine, University of Barcelona, Barcelona, SPAIN, [4]Radiology Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Recurrence in patients with head and neck cancer presents a challenge to clinicians due to its poor prognosis. The availability of a single model, user-friendly, and capable of predicting recurrence across different types of head and neck cancer, is clinically valuable, supporting risk stratification and personalized decision-making. This study aims to develop a robust and generalizable machine learning model for predicting recurrence in head and neck cancer, integrating clinical and radiomic data extracted from multi-scanner PET images (Discovery ST, Discovery IQ and Discovery MI). ***Materials and Methods:*** A

database of 134 PET images from patients with head and neck cancer (49 oropharyngeal and 83 nasopharyngeal) was used, all patients presented locoregional tumour involvement with no distant lesions suspicious of malignancy. Tumour lesions and lymph nodes were semi-automatically segmented, followed by spatial standardisation. Radiomic features were extracted using PyRadiomics and normalised using the ComBat method, due to variability between PET scanners. To develop the models—based on clinical, radiomic, or combined data—the data was split into training and testing sets. For the radiomic data, collinearity was eliminated using a correlation matrix, and ANOVA was applied to select the most relevant variables. A random forest was trained with repeated cross-validation and validated with test data. ***Results:*** The performance of three predictive models was evaluated. The clinical model achieved a sensitivity of 0.80, a specificity of 0.82, an accuracy of 0.81, and an AUC of 0.82. The radiomic model also demonstrated a sensitivity of 0.80, a specificity of 0.79, an accuracy of 0.79, and an AUC of 0.81. The combined model, integrating both clinical and radiomic data, maintained sensitivity of 0.80 but has a specificity of 0.85, an accuracy of 0.84, and an AUC of 0.85.The results indicate that a unified model based on heterogeneous data from multiple PET scanners is feasible and clinically beneficial. The combination of clinical and radiomic variables enhances predictive performance compared to models using only radiomic or clinical data. Although sensitivity remains constant across all three approaches, the increase in specificity, accuracy, and AUC of the combined model positions it as the most promising for predicting recurrence in head and neck cancer patients. ***Conclusion:*** This study demonstrates the feasibility of implementing a single recurrence prediction model for head and neck cancer, applicable to different tumour subtypes and imaging sources. The clinical-radiomic approach enhances clinical practice, with the potential for integration into healthcare workflows for personalized decision-making.

EP-1058

Predictive Accuracy and Clinical Benefit of a Nomogram Aimed at Predicting Radioiodine-Refractory Differentiated Thyroid Cancer: Independent External Validation Using a Single Institution Database

F. Yu;
Department of Nuclear Medicine, Xijing Hospital, Air Force Military Medical University, Xi'an, CHINA.

Aim/Introduction: To perform an external validation of a recently published nomogram aimed to predict radioiodine refractory differentiated thyroid cancer (RAIR-DTC) in DTC patients with distant metastases after at least two courses of RAI treatment by Meng Chao et al. (Front Endocrinol (Lausanne) 14, 1109439, 2023). ***Materials and Methods:*** Overall, 156 DTC patients were included and divided into RAIR (n=67) and non-RAIR (n=89) according to 2015 ATA guidelines. All included patients were enrolled according to the inclusion criteria defined by Meng Chao et al. First, we calculated the predicted probability of RAIR for each patient using the nomogram based on indicators Age upon diagnosis and Δs-Tg/Δs-TSH<1.50, as proposed by Meng Chao et al. Then, using R software, we plotted ROC curve, calibration plot, and DCA curve based on the predicted probabilities and actual outcomes, and completed the evaluation of external validation. ***Results:*** In the external cohort, the overall diagnosis rate of RAIR was 42.9% vs. 57.3% in the original population. Compared to the original model report, the ROC curve demonstrated suboptimal diagnostic performance, with AUC values of 0.735 and 0.830, and corresponding sensitivity and specificity of 0.656, 0.726, and 0.775, 0.830, respectively. The calibration curve indicated poor consistency. In the DCA curve, the net benefit was lower than that reported originally across most threshold ranges, particularly within the 0.25 to 0.75 range. ***Conclusion:*** We observed relatively poor suboptimal predictive accuracy in the external cohort compared to the original cohort. Future research should aim to identify additional prognostic factors and validate the model in broader cohorts to improve its applicability in clinical practice.

EP-1059

Differentiation between bipolar and major depressive disorders with [^{11}C]K-2 AMPA receptor PET imaging

H. Abe[1], *S. Tsugawa*[1], *Y. Kimura*[2], *J. Chikazoe*[3], *T. Arisawa*[1], *M. Hatano*[1], *W. Nakajima*[1], *T. Miyazaki*[1], *T. Takahashi*[1];

Aim/Introduction: Bipolar disorder is frequently misdiagnosed as major depressive disorder, leading to increased risk of rapid cycling, reduced quality of life, and heightened suicide risk. Therefore, an earlier and more accurate diagnostic method using biological indicators is critically needed. Our recently developed PET tracer, [^{11}C]K-2, enables the quantitative visualization of glutamate α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid receptor (AMPAR) distribution and is considered useful for characterizing regional synaptic phenotypes in psychiatric disorders.[1-4] This study aims to develop a machine learning-based method to differentiate bipolar disorder from major depressive disorder using AMPAR density. ***Materials and Methods:*** Twenty-seven patients with major depressive disorder(MDD) and 16 patients with bipolar disorder (BD) in depressive episodes underwent PET scans with [^{11}C]K-2 to measure AMPAR density. AMPAR density was compared between the two groups using SPM. A partial least squares (PLS) model was trained to predict diagnoses based on AMPAR density, with performance evaluated using leave-one-pair-out cross-validation. ***Results:*** In this cross-sectional study of 16 patients with BD and 27 patients with MDD (all in a depressive phase), a partial least squares (PLS) classification model using [^{11}C]K-2 PET-derived AMPA receptor density successfully differentiated BD from MDD with an area under the curve of 0.80, a sensitivity of 75.0%, and a specificity of 77.8%. ***Conclusion:*** Our findings suggest that AMPAR density, measured with [^{11}C]K-2, offers modest discrimination between BP and MDD. This model could aid in diagnosis, particularly for individuals with ambiguous clinical symptoms or in whom symptoms have yet to manifest fully. ***References:*** 1. Miyazaki, T. et al. Impact of Scan Duration on Kinetic Modelling Parameters in Dynamic [^{68}Ga]-PSMA-11 PET Imaging for Prostate Cancer

E. A. M. Kile[1,2], *R. Sundset*[1,2], *S. Kuttner*[1,2,3];
[1]*The PET Imaging Center, University Hospital of North Norway, Tromsø, NORWAY,* [2]*Nuclear Medicine and Radiation Biology Research Group, Department of Clinical Medicine, UiT the Arctic University of Norway, Tromsø, NORWAY,* [3]*UiT Machine Learning Group, Department of Physics and Technology, UiT the Arctic University of Norway, Tromsø, NORWAY.*

Aim/Introduction: The clinical guidelines for prostate cancer imaging using [^{68}Ga]-PSMA-11 recommend performing static PET (sPET) scans between 50 and 100 minutes post tracer injection. However, while sPET shows merely a snapshot of the tracer uptake, dynamic PET (dPET) combined with tracer

kinetic modelling, provides quantitative information about the tracer uptake, internalisation, and retention. A standard 60-minute dPET acquisition is infeasible for routine clinical implementation. This study aimed to evaluate the impact of scan duration on kinetic modelling parameters to explore the potential of shortened routine dPET protocols. ***Materials and Methods:*** In this prospective clinical study, nine prostate cancer patients underwent 60-minute [^{68}Ga]-PSMA-11 dPET imaging. Arterial blood sampling was performed to form the arterial input function (AIF). The prostate lesion was delineated and the time-activity curve was extracted from the dPET images. A shortened, 15-minute acquisition was simulated for each patient by removing the last 45 minutes of data from both the time-activity curves and the AIF. A hybrid dPET+sPET acquisition was simulated by retaining the last 5-minute data point at 55-60-minutes in addition to the 15-minute dPET data. Tracer kinetic modelling, using a two-tissue compartment model, was performed for prostate lesion using both the full-length, 15-minute, and 15+5-minute data. The kinetic parameters K_1, k_2, k_3, and K_i, were compared using linear regression and correlation analysis. ***Results:*** A strong linear relationship and strong correlation was found between full-length and 15-minute data for K_1 and K_i (K_1: Slope: 1.27, correlation coefficient: 0.98, K_i: slope: 1.8, correlation coefficient: 0.89). In contrast, k_2 and k_3 showed no significant linear relationship or correlation. The differences between full-length and shortened data were statistically significant for K_1, k_2 and k_3 ($p < 0.05$). When adding a late 5-minute data point, a strong linear relationship and a moderate to strong correlation was found between full-length and 15+5-minute data for all kinetic parameters (K_1: slope: 1.01, correlation coefficient: 0.99, k_2: slope: 1.42, correlation coefficient: 0.92, k_3: slope: 0.94, correlation coefficient 0.68, K_i: slope: 0.83, correlation coefficient: 0.91). No significant differences between full-length and 15+5-minute data were found for any of the k-values. ***Conclusion:*** We found significant differences in several kinetic parameters when comparing 15-minute and 60-minute [^{68}Ga]-PSMA-11 dPET data for prostate cancer patients. However, adding a short, 5-minute, sPET acquisition at 55-60-minutes provided consistent kinetic modeling parameters compared to full-lenth scans, suggesting clinical feasibility of a shortened dynamic PET protocol with maintained quantitative accuracy.

EP-1061

Comparison of uncertainty quantification methods for kinetic parameters derived from dynamic long-axial-field-of-view PET scans.

F. Gu[1], *Q. Wu*[2,3], *F. O'Sullivan*[2], *A. Rominger*[4], *K. Shi*[4];
[1]*School of Mathematics and Physics, North China Electric Power University, Beijing, CHINA,* [2]*School of Mathematical Sciences, University College Cork, Cork, IRELAND,* [3]*Insight SFI Center for Data Analytics, Cork, IRELAND,* [4]*Department of Nuclear Medicine, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Dynamic PET imaging with long axial field-of-view (LAFOV) scanners enables simultaneous, high-resolution assessment of tracer kinetics across the entire body. This advancement offers substantial benefits in clinical and research settings, particularly for multi-organ quantitative analysis. However, accurately estimating the uncertainty of kinetic parameters remains a major challenge due to the high-dimensional, spatiotemporal complexity of dynamic PET data. Robust uncertainty quantification is essential for physiological interpretation, model validation, and the clinical translation of parametric imaging results. ***Materials and Methods:*** This study systematically compares three uncertainty quantification methods for kinetic parameters derived from dynamic LAFOV PET data: (1) image-domain bootstrap based standard error (Boot-SE): based on a generalized linear model that incorporates both systematic and stochastic components, effectively capturing spatiotemporal dependencies [1,2]; (2) autocorrelation function-based standard error (ACF-SE): estimated using the product of mean voxel-wise variance within a region and a correction term that accounts for spatial autocorrelation between voxel pairs [3]; (3) crude standard error (Crude-SE): defined as the standard deviation divided by the square root of the number of voxels within the region. We applied voxel-level kinetic analysis to a dataset of 24 dynamic ^{18}F-FDG LAFOV PET scans, quantifying six physiological parameters. Uncertainty for each parameter was assessed across multiple organs, including the liver, lungs, kidneys, spleen, bones, brain (gray matter and white matter), bladder, and tumors, by applying above three approaches. ***Results:*** Boxplot comparisons across these organs revealed distinct patterns among the three methods. Crude-SE consistently underestimated the standard errors, failing to account for temporal and spatial dependencies in the data. ACF-SE, in contrast, tended to yield more conservative estimates, particularly in regions with high physiological variability. Boot-SE provided a balanced estimation with good robustness across organs and parameters. Notably, organs with high tracer heterogeneity (e.g., tumors) exhibited larger variability in SE estimation across all methods. ***Conclusion:*** Our findings highlight the limitations of relying solely on crude analytic error estimation for PET kinetics, especially in the era of whole-body LAFOV acquisition. We recommend Boot-SE as a practical and computationally feasible approach for general applications. ***References:*** [1]A generalized linear modeling approach to bootstrapping multi-frame PET image data. Discriminating Inflammation from Malignancy with Short-Dynamic Patlak Parametric FDG PET/CT

A. Artesani[1], *J. Jandric*[2], *L. Leonardi*[2], *R. Barisonzi*[2], *C. Vallone*[2], *L. Muraglia*[2], *M. Rodari*[2], *L. Evangelista*[1];
[1]*Humanitas University, Pieve Emanuele, ITALY,* [2]*IRCCS Humanitas Research Hospital, Rozzano, ITALY.*

Aim/Introduction: Dynamic ^{18}F-FDG PET/CT is increasingly employed in diagnostic workup and treatment response evaluation in oncology. Although previous studies have demonstrated the feasibility of dynamic acquisitions, the clinical added value of Patlak parametric imaging remains under active debate [1],[2]. In this study, we investigated whether parametric imaging from short-duration dynamic PET/CT protocol can reliably differentiate malignant lesions from inflammatory processes by quantitatively comparing the Patlak influx rate (K_i) and the volume of unmetabolized tracer (V_b) to the standardized uptake value (SUV). ***Materials and Methods:*** Patients with suspected solid tumors underwent a 20-min dynamic ^{18}F-FDG PET/CT scan. Dynamic data were subdivided into 5-min frames, and a Patlak analysis was performed to derive parametric images of K_i (ml/min/100ml) and V_b (arbitrary units). In selected cases, patients with inflammatory rectal changes—characterized by a modestly increased SUV relative to normal tissue—were compared with colon tumor lesions used as malignant references. Quantitative comparisons were made by evaluating the ratios between SUV and the parametric metrics within the same volume of interest. ***Results:*** In healthy liver tissue, SUV and K_i values were linearly correlated, yielding a conversion factor of about 0.3 between these metrics. In regions showing inflammatory rectal uptake, SUV values were moderately elevated (2.5-3.2 g/mL), and K_i values changed in accordance with the same conversion factor observed in healthy tissue (0.5-1.2 ml/min/100ml). In contrast, colon tumors demonstrated a different relationship, with SUV and K_i values

correlating according to a conversion factor of about 0.5; for example, a mean SUV of 12 g/mL corresponded to a K_i of roughly 7 ml/min/100ml. Moreover, the distribution and absolute values of V_b differed markedly between tissue types: inflammatory tissues exhibited higher V_b values, whereas malignant tissues showed comparatively reduced and peripherally localized V_b, reflecting underlying differences in vascular delivery and cellular FDG phosphorylation. ***Conclusion:*** The observed inverse relationship in the ratio of irreversibly metabolized tracer (K_i) to unmetabolized tracer (V_b) between inflammatory and tumor tissues is consistent with the expected higher vascular tracer availability but low metabolic trapping in inflammation versus enhanced cellular FDG phosphorylation in malignancy. This study proposes a 'reading method' for clinical differentiation of tumor versus inflammation. Further studies are warranted to validate whether the K_i/V_b ratio can become a reliable metric in more complex diagnostic scenarios. ***References:*** [1] S. Skawran et al., Life, 12, 9, 2022, 10.3390/life12091350 [2] A. H. Dias et al., EJNMMI Phys., 9, 1, 2022, 10.1186/s40658-022-00490-y.

EP-1063

Spill-over correction in [^{15}O]H_2O small animal studies

R. Siekkinen[1], *T. Uurasmaa*[2,1], *I. Heinonen*[1], *H. Iida*[1];
[1]Turku PET Centre, Turku, FINLAND, [2]Department of Biology, University of Turku, Turku, FINLAND.

Aim/Introduction: Quantitative perfusion imaging using [^{15}O]H_2O-PET has been widely applied to clinical research. However, its application to mice-sized rodents has been limited due to their small size, making the determination of input function (IF) challenging. Many studies, therefore, have relied on using standardized uptake values (SUV). We aimed assessing the systematic underestimation in left ventricular blood (LV) radioactivity concentration (RC) for enabling to determine IF from [^{15}O]H_2O images. ***Materials and Methods:*** Female FVB/N-mice (N=22) underwent two dynamic PET/CT imaging following [^{15}O]-H_2O injection and gaseous [^{15}O]CO inhalation with Molecubes system (Molecubes NV, Gent, Belgium).Three sizes of regions-of-interest (ROIs) were selected on LV, and one on myocardium, brain, and liver. RC (MBq/ml) within LV ROI was assumed to contain activity from the LV chamber and the myocardium. Recovery coefficient (β) expresses the underestimation of LV chamber's RC due to partial-volume-effect, and the spill-over fraction the amount of myocardium activity signal in LV ROI (γ). Spill-over was modeled following earlier works, where β+γ=1.0 [1,2]. β was estimated from [^{15}O]CO images at 5-8 min post initiation, by dividing LV ROI's RC with total blood's RC. Blood volume (ml/ml) for myocardium, brain, and liver was calculated by dividing organ ROI's RC with total blood RC. Spill-over-corrected K_1-flow (ml/min/g), k_2-flow (1/min), and arterial blood volume V_a (ml/ml) were calculated for myocardium, followed by calculation of spill-over-corrected IF [1]. This IF was applied to calculate K1, k2, and Va in brain and liver. Mean transit time (MTT) was calculated by dividing organ's blood volume with K1. ***Results:*** K1, k2, and Va decreased after the correction and showed small inter-subject variation regardless the correction for all organs, as in Iida et al. [1]. MTT increased after the correction, as expected. Brain MTTs are in accordance with what previously reported for mice [3]. However, myocardium MTTs were higher than previously reported [4], presumably because myocardium is affected by partial-volume effect. The smallest LV ROI showed fluctuation in time-activity-curves likely affecting the modelling accuracy, whereas no fluctuation was seen on medium and large-size ROIs. ***Conclusion:*** The method was considered effective in quantitatively assessing the tissue perfusion and MTT in total body organs in mice, though further evaluation studies are warranted. ***References:*** 1. A Simple Bone Marrow Kinetic Modelling Method in Patients with Symptomatic Multiple Myeloma

C. Nanni[1], *I. Brusa*[1], *D. Dall'olio*[2], *S. Peluso*[2], *M. Di Franco*[3], *M. Stasolla*[3], *E. Zamagni*[2], *M. Talarico*[2], *G. Wang*[4], *B. Spencer*[4], *A. Farolfi*[1], *M. Assenza*[5], *E. Fortunati*[1], *S. Civollani*[1], *L. Nardo*[4], *G. Castellani*[2], *S. Fanti*[1];
[1]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY, [3]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [4]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [5]Professional Development and Implementation of Research in Health Professional Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Bone Marrow (BM) FDG uptake can be within normal limits (Deauville Score DS 2 and 3) in patients with symptomatic Multiple Myeloma (sMM) at staging or relapse not identifying its pathological nature, especially if plasma cell infiltration is moderate. We seek to preliminary observe the kinetic of FDG BM-uptake in sMM patients at staging or disease relapse as compared to normal patients to increase FDG sensitivity for detecting bone marrow infiltration through Multi-Time Graphical Analysis (MTGA) and late short dynamic acquisitions applicable in the clinical routine and in the setting of pain patients such as MM patients. ***Materials and Methods:*** We enrolled 29 pts (18M,11F, mean age 72) with sMM at staging or disease relapse and 15 healthy controls. All patients underwent a 30' dynamic acquisition on LAFOV PET/CT (uExplorer, United) starting 35' post FDG injection. DS was established on a static reconstruction of the last 5' acquisition. L3 was manually segmented and, if L3 included a focal lesion, the closer vertebral body without lesions was considered. FDG uptake and pharmacokinetics were evaluated by MTGA (Patlak and RE-plots). Mean absolute scaled error (MASE) and Akaike Information Criterion (AIC) were used to perform model selection, alongside Vuong's test. Patients were divided into: Group 1 with BM-DS 2,3 (Low-DS, n=21); Gr2 with BM-DS 4 (High DS, n=8); Gr3 including healthy controls (HC, n=15). ***Results:*** Reversible uptake (RE-plots) resulted as the best fit in all groups. Average DV for Low-DS was (0.667±0.081), while it was (0.984±0.282) for High-DS and (0.227±0.229) for HC. Testing distribution volumes (DV) revealed that both Low-DS and High-DS had a significantly higher DV than HC ($p<10^{-5}$ for both). In addition, High-DS also reported a significantly higher DV than Low-DS ($p<10^{-5}$). ***Conclusion:*** These preliminary results suggest that in patients with MM, infiltrated BMs with low FDG uptake (false negatives) show a reversible kinetic behaviour significantly different from HC. In clinical practice, a late dynamic acquisition instead of a static acquisition may be proposed to add sensitivity and specificity to the FDG scan for discriminating normal vs infiltrated BM. The fitting can be performed without considering the initial non-equilibrium phase (i.e., approximately 10' p.i.), which considerably simplifies the modelling process. This possibility is particularly relevant in case of clinical disease relapse rather than disease staging.

EP-1065

A comparison of renograms: posterior only and geometric mean imaging

R. Feathers, *W. Morton, P. Bartholomew;*
South Tyneside and Sunderland Foundation Trust, Sunderland, UNITED KINGDOM.

Aim/Introduction: To evaluate the utility of using a geometric mean of posterior and anterior imaging for a nuclear medicine MAG3 renogram to properly assess the relative function and drainage of the kidneys. The current standard is posterior only imaging which may not fully capture the functionality of the

kidney as depth and kidney movement away from the camera head cannot be accounted for. For every 1 cm of depth, there is a 10% loss of counts due to attenuation, so small movements could change the recorded values. ***Materials and Methods:*** A cohort of 100 patients underwent a renogram study where both anterior and posterior projections were acquired after an intravenous injection of ^{99m}Tc MAG3. For each patient a standard posterior only renogram was processed alongside a geometric mean of the posterior and anterior images. Regions of interest were drawn over the kidney to create a time activity curve (TAC), and the relative kidney function was calculated. Each TAC generated was assessed by an experienced nuclear medicine reporter and graded on the level of obstruction observed. The renal pelves were measured on a CT IVU to assess renal dilation. ***Results:*** Processing the renograms as a geometric mean showed a change in function for most patients, with varying significance in scale. The addition of the anterior data brought some clarity to previously equivocal TACs. ***Conclusion:*** For certain patients a large difference was seen between the relative function calculated by the posterior only against the geometric mean renogram analysis. For patients undergoing kidney assessment for a nephrectomy, a change in relative function may change the available surgical options. Some TACs saw changes to their equivocal results, which can change patient outcomes and subsequent medical management.

EP-1066

Comparative Performance of ^{68}Ga-FAPI-04 Versus ^{18}F-FDG PET/CT in Thyroid-Associated Orbitopathy: A Prospective Pilot Study with Dynamic/Static Parametric Validation

L. Yang, *L. Guan;*
Nuclear Medicine, the First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: To prospectively compare the diagnostic efficacy of ^{68}Ga-FAPI-04 and ^{18}F-FDG PET/CT in thyroid-associated orbitopathy (TAO), and to evaluate whether dynamic PET parameters provide incremental value over conventional static metrics. ***Materials and Methods:*** Six treatment-naive TAO patients (3 active [CAS≥4], 3 chronic [CAS≤1+MRI fibrosis]) underwent sequential PET/CT scans (median interval: 3 days, range: 1-7) using: 1. Dynamic Protocol: 60-min list-mode acquisition on a long-axial PET/CT scanner; frame sequence: 30×10s, 10×30s, 5×60s, 5×300s; reconstruction: OSEM + TOF + PSF. 2. Static Protocol: standard whole-body acquisition at 60-min post-injection. 3. Image Analysis: maximum standardized uptake value (SUVmax) in extraocular muscles; target-to-background ratio (TBRmuscle/brain); Patlak-derived metabolic influx rate (Ki) using image-derived input function; two-tissue compartmental K1 (perfusion parameter). 4. Statistical Note: all values reported as mean ± standard deviation. No inferential statistics were applied per STROBE guidelines for pilot studies. ***Results:*** In active TAO patients (n=3), ^{68}Ga-FAPI-04 demonstrated significantly higher uptake than ^{18}F-FDG, with mean SUVmax values of 7.1 (±0.3) versus 4.0 (±0.2), representing a 78% increase in tracer avidity. Chronic TAO cases (n=3) showed low uptake for both tracers (FAPI-SUVmax: 2.1±0.2; FDG-SUVmax: 1.9±0.1). Dynamic analysis revealed a 3.3-fold difference in Patlak-derived Ki values between active (0.013±0.001 min^{-1}) and chronic phases (0.004±0.001 min^{-1}), marginally outperforming the 3.0-fold contrast observed with static FAPI-SUVmax. ***Conclusion:*** This pilot study demonstrates: 1. ^{68}Ga-FAPI-04 provides higher lesion conspicuity than ^{18}F-FDG in TAO. 2. Dynamic parameters offer modest but measurable advantages over static indices. 3. The proposed protocol is technically robust for multicenter validation. ***References:*** 1.Buber J, Robertson HT. Organ-based normative values in healthy subjects derived from whole-body [18F]FDG-PET/CT

C. Loisel[1], *M. Pires*[2], *R. Seban*[3], *F. Orlhac*[4], *S. Gutschmayer*[5], *I. Buvat*[4], *T. Beyer*[2];
[1]*Institut Curie, Orsay, FRANCE,* [2]*Medical University of Vienna, Vienna, AUSTRIA,* [3]*Dpt of Nuclear Medicine, Institut Curie, Saint Cloud, FRANCE,* [4]*Institut Curie, Inserm, Orsay, FRANCE,* [5]*Dept of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: [18F]FDG-PET/CT is a widely used imaging modality for assessing metabolic activity over the whole body. However, organ-specific normative values have not been reported extensively. This study aims to establish organ-specific normative uptake values and their variability using whole-body [18F]FDG-PET/CT in a cohort of healthy subjects. ***Materials and Methods:*** Forty-eight healthy subjects (25 females, 23 males; mean age: 38 ± 14 years) underwent dynamic [^{18}F]FDG PET/CT imaging using a Siemens Biograph Vision Quadra PET/CT scanner at the Medical University of Vienna. Each subject completed a test and retest whole-body scan 5 weeks apart. From the 55-60-minute post-injection list-mode data, static PET images were reconstructed. Twenty-seven anatomical volumes of interest (VOIs) were segmented from the CT images using two automated algorithms: TotalSegmentator v2.8.0 and MOOSE v3.0.13. The volume (mL) and mean Hounsfield unit (HUmean) in each VOI were calculated from the CT, together with the mean SUV (SUVmean) obtained from the PET. Differences between test and retest values for males and females separately were evaluated using relative %-differences, t-tests and Wilcoxon signed-rank tests including Benjamini-Hochberg correction for multiple comparisons. Additionally, robustness across segmentation methods was investigated. ***Results:*** There were no significant differences between test and retest measurements for organ SUVmean, HUmean, and volume whatever the segmentation algorithms. However, high inter-subject SUVmean variability (>15%, defined as the mean of $\sigma_{SUVmean}$/SUVmean over the test and retest groups) was observed in 15/27 VOIs including the heart, kidneys, bladder, fat, skull and VOIs in the digestive system regions. In contrast, 12/27 VOIs demonstrated low (<15%) SUVmean inter-subject variability (mean %difference range in test and retest groups: [8.6,13.8]%) including the brain, liver, pancreas, spleen or muscles. Volumes were generally higher in men, probably due to BMI differences (BMI=26±3 for men and 23±3 for women, $p<0.001$). Significant difference in SUVmean was found between men and women in the test and retest groups only in the subcutaneous fat (p_{test} and $p_{retest}<10^{-4}$) with a low

inter-subject variability (<15%) in each gender group. SUVmean values were not affected by the segmentation algorithms (<10%), except for small bowel, and for skeletal muscles, subcutaneous fat and torso fat that are segmented across the entire body by TotalSegmentator but using only the L3 region in MOOSE. ***Conclusion:*** All organs demonstrated reproducible SUVmean, HUmean and volume measurements across test-retest analysis. However, only twelve organs demonstrated consistent SUVmean measurements, with low inter-subject and inter-segmentation-method variability, making them strong candidates for establishing organ-based normative reference standards.

EP-1068

A Novel Variance Reduction Technique for Efficient Monte Carlo Simulation of SPECT Images

D. Sarrut, *A. Etxebeste, M. Jacquet, J. Letang;*
CREATIS CNRS, Villeurbanne, FRANCE.

Aim/Introduction: This study introduces a novel Variance Reduction Technique (VRT) called FF-AA for Monte Carlo simulation of SPECT images. The aim is to enhance simulation efficiency and accuracy, particularly in low-count regions, while maintaining broad applicability across different geometrical elements. Monte Carlo simulations are indispensable in SPECT imaging but are often computationally demanding. Traditional methods typically rely on Forced Detection and/or detector response functions like ARF, which generally depend on an analytical model of the detector response. Other methods leverage GPU acceleration to provide significant speedups but are constrained by specific implementations and hardware requirements. Additionally, GAN-based approaches have been proposed; however, they also depend on detector models and require neural network training for each different phantom. Our proposal, implemented in GATE based on Geant4, addresses these limitations. This reliance on specific models and implementations limits the flexibility of these methods, particularly when users aim to optimize collimator design. ***Materials and Methods:*** The FF-AA method employs a two-step approach: primary and scatter. Primary gamma photons are tracked linearly towards the detector with forced detection and free flight weighted contributions. Free Flight, a concept from Geant4, allows particles to be tracked through various elements such as phantoms and collimators. This approach enables particles to travel in a straight line, updating their weight as they traverse different materials. Scatter is simulated using split Compton and Rayleigh interactions, which are also free-flighted towards the detector. This method was benchmarked against analog Monte Carlo simulations to evaluate its performance. ***Results:*** The FF-AA method demonstrated a significant speedup of approximately 20-30 times compared to analog Monte Carlo simulations. In low-count regions, this speedup was even more pronounced, reaching around 40 times. The optimal splitting factor was evaluated and found to be surprisingly low, around 20 to 40, despite the low acceptance angle. Additionally, statistical relative uncertainties were integrated and computed using a history-by-history method, providing pixel-based uncertainty in the generated projection images. ***Conclusion:*** The primary advantage of the new FF-AA method is its ability to achieve significant speedups, particularly in low-count regions. Its generic applicability to various geometrical elements makes it a valuable tool for SPECT collimator design development. Additionally, the implementation is open-source and available in the new Python-based GATE version 10. ***References:*** - Cajgfinger2018. PMB, 63(5), 055011 - Beck1982. EP-1069

Artificial Intelligence Analysis of Nuclear Medicine Perception on Social Media

D. Yahiro, *C. T. Mesquita;*
Universidade Federal Fluminense, Niterói, BRAZIL.

Aim/Introduction: Nuclear Medicine is an evolving medical specialty that plays a crucial role in diagnostic and therapeutic conditions. Despite its importance, public awareness remains limited, particularly among younger generations and medical students. Social media platforms like Reddit are valuable repositories of real-time discussions, where users share opinions, experiences, and questions related to multiple subjects, including healthcare. With recent advancements in Natural Language Processing (NLP), particularly transformer-based models, it is possible to extract meaningful insights from these large, unstructured text datasets. This study aims to identify and analyze nuclear medicine discussions on Reddit using AI-based topic modeling to better understand public perceptions of the exam and the nuclear medicine field more broadly. ***Materials and Methods:*** Since June 2013, ten relevant subreddits focused on nuclear medicine, medical school, and related specialties were selected. Posts and comments were filtered using a predefined set of nuclear medicine-related keywords to extract pertinent discussions. After preprocessing, the data was analyzed using BERTopic, an unsupervised topic model that utilizes transformer-based embeddings and clustering algorithms to identify underlying themes. Visualization of topic similarity was performed using Uniform Manifold Approximation and Projection (UMAP), a dimensionality reduction tool. Sentiment analysis was conducted to classify each post or comment as positive, negative, or neutral. ***Results:*** A total of 4,602 discussions from 2,792 unique users were included after duplicate removal. The model identified 80 unique topics, which were further grouped into 7 major themes, including training pathway, economic considerations, workload and scheduling hours, career development, financial compensation, test preparations, and moderation of discussion. Clustering performance showed a silhouette score of 0.866 and a Davies-Bouldin score of 0.132, indicating strong model performance. Sentiment analysis revealed that 30.57% of discussions were negative, 58.41% neutral, and 11.02% positive. While neutral sentiment dominated across all themes, negative sentiments were more prominent in discussions related to group moderation, training limitations and financial concerns. ***Conclusion:*** With social media platforms, it is possible to understand public and trainee perspectives on nuclear medicine. By applying AI-based topic modeling and sentiment analysis, this study demonstrates the utility of NLP in identifying public sentiment and thematic concerns about the specialty. Such insights may inform targeted strategies to improve awareness, engagement, and recruitment, particularly among medical students and early-career professionals.

EP-1070

Identification and Validation of Robust FDG-PET/MR Texture Biomarkers in Uterine Cervical Cancer

U. Björeland[1,2], *K. Sandgren*[2], *S. Strandberg*[2];
[1]*Medical Physics, Sundsvall Hospital, Sundsvall, SWEDEN,*
[2]*Department of Diagnostics and Intervention, Umeå University, Umeå, SWEDEN.*

Aim/Introduction: Texture analysis quantifies the spatial arrangement and variation of voxel intensities within a region of interest, extracting high-order features, such as grey-level co-occurrence (GLCM), and morphological descriptors that reveal tissue heterogeneity invisible to the naked eye [1-3]. These features function as reproducible imaging biomarkers for lesion characterization, improving diagnosis, risk stratification, and treatment monitoring in oncology [1,3]. However, the sheer

number of available texture features necessitates a rigorous, systematic workflow to isolate those that are truly robust and reproducible [4, 5].The aim is to develop and validate a systematic workflow for deriving stable PET texture biomarkers, with the goal of enhancing diagnostic, prognostic, and monitoring tools in gynecological cancers. ***Materials and Methods:*** In this pilot study, eight patients underwent dynamic FDG-PET/MR over 30 minutes, divided into six 5-minute frames. For each patient, seven standard uptake value (SUV) images were generated and two VOI-strategies were compared: 1. Individualized VOI: a unique SUV42% contour per frame based on that frame's $SUV_{max.}$ 2. Averaged VOI: a single SUV42% contour from the entire 30-minute acquisition, applied identically to all frames. All images were resampled to isotropic 1×1×1 mm resolution using both Hamming-windowed-sinc and third-order B-spline interpolation. A total of 174 features per frame were extracted with SPAARC software under IBSI standards [6,7] and z-score normalized per patient. For each feature, the coefficient of variation (CV)across the six frames was computed and averaged across patients. Features were ranked by ascending CV, then selected iteratively if their absolute Pearson correlation with all previously chosen features was <0.7. Finally, temporal stability was assessed by Friedman's test ($\alpha = 0.05$), retaining features with $p > 0.05$. ***Results:*** Overall, the workflow revealed that the choice of VOI strategy and interpolation method significantly affected feature stability. When using individualized VOIs, Hamming interpolation produced 16 stable features, whereas B-spline interpolation yielded 15. In contrast, with averaged VOIs both Hamming and B-spline interpolators resulted in 11 stable features each. Across all VOI strategies and interpolators, the features consistently identified as robust biomarkers were ClusterShade(cm_clust_shade_3D_comb), Coarseness(ngt_coarseness_3D), Compactness(morph_com) and Kurtosis(stat_kurtfrom). ***Conclusion:*** This workflow identifies reproducible PET texture biomarkers. VOI definition strongly influences both the number and nature of stable features, while the choice of interpolation modulates their extraction. Individualized VOIs enable a broader set of parameters capturing both border and inner-texture heterogeneity; fixed VOIs produce a more concise, reproducible panel focused on internal texture. ***References:*** 1.Shur, J.D: Radiographics, 2021_2. EP-1071

Artificial intelligence for opportunistic detection of immune checkpoint inhibitor-related adverse events using [^{18}F]FDG PET/CT

C. Spielvogel*, L. Zisser, A. Lazarevic, D. Haberl, C. Eseroglou, M. Hacker, R. Calabretta;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Immune checkpoint inhibitors (ICIs) have transformed the treatment landscape for various cancers, including lung cancer, melanoma, and lymphoma. By blocking PD-1, PD-L1, and CTLA-4, ICIs unleash cytotoxic T cells to target tumor cells. However, they can cause immune-related adverse events (irAEs) by activating off-target immune responses. [^{18}F]FDG PET/CT is a promising tool for visualizing systemic immune activation, but manual assessment of organ-level inflammation is time-consuming and underlies inter-reader variability. This study explores the use of an automated artificial intelligence (AI)-based segmentation approach to detect organ-level changes in FDG uptake before and after ICI therapy, aiming to opportunistically identify irAEs. ***Materials and Methods:*** Patients with lung cancer, melanoma, or lymphoma who underwent [^{18}F]FDG PET/CT scans both before and after starting ICI therapy (PD-1, PD-L1, or CTLA-4 inhibitors) were included. An AI-driven segmentation model delineated organ boundaries on CT, which were eroded and transferred to PET for SUVmax and SUVmean quantification in irAE-related organs, including the thyroid, heart, pancreas, and liver. Lesion regions were excluded using a deep learning-based lesion segmentation model. Changes in organ uptake pre- vs. post-therapy were statistically analyzed and correlated with clinically reported irAEs. ***Results:*** A total of 64 patients were analyzed, with a median scan interval of 3.2 months. The thyroid showed significant FDG uptake increases post-ICI (ΔSUVmax median = 0.44, $p = 0.04$; ΔSUVmean = 0.22, $p = 0.08$). Elevated uptake occurred in 55% (SUVmax) and 53% (SUVmean) of patients. Among those with increased thyroid uptake, 29% developed thyroid-related irAEs, compared to only 3% of those with decreased uptake ($p = 0.008$). Patients with thyroid irAEs had markedly higher uptake changes (ΔSUVmax = 2.1; ΔSUVmean = 0.69). Hypothyroidism was the primary driver, significantly associated with increased thyroid SUVmax ($p = 0.002$) and SUVmean ($p = 0.03$), whereas hyperthyroidism showed weaker, non-significant trends. FDG uptake also rose in the myocardium, pancreas, and liver post-therapy, but without statistical significance ($p > 0.05$). ***Conclusion:*** AI-assisted analysis of [^{18}F]FDG PET/CT enables automated, opportunistic screening for irAEs in patients undergoing ICI therapy. AI-assessed thyroid FDG uptake, especially in hypothyroidism, is strongly associated with immune-related toxicity, suggesting its utility as a biomarker for early detection. This approach supports more proactive management of irAEs and may improve outcomes by guiding timely interventions.

EP-1072

Investigating AD and non-AD ^{18}F-flortaucipir distribution patterns in a memory clinic cohort

F. Piva[1]*, C. Boccalini*[2]*, N. Ashton*[3]*, H. Zetterberg*[3]*, K. Blennow*[3]*, G. B. Frisoni*[4]*, M. Veronese*[1]*, V. Garibotto*[4]*, D. E. Peretti*[2]*;*
[1]University of Padova, Padua, ITALY, [2]University of Geneva, Geneva, SWITZERLAND, [3]University of Gothenburg, Mölndal, SWEDEN, [4]Geneva University Hospitals, Geneva, SWITZERLAND.

Aim/Introduction: Neurodegenerative disorders may be characterized by distinct tauopathies, which result in different ^{18}F-flortaucipir tau PET topographic patterns. This study aimed to investigate in a memory clinic cohort whether ^{18}F-flortaucipir patterns could be used to differentiate between amyloid-positive and -negative forms of neurodegeneration, potentially eliminating the need for an amyloid-PET. ***Materials and Methods:*** A total of 81 subjects were included in this study: 40 with Alzheimer's disease characterized by both amyloid (A) and tau (T) accumulation (A+T+), 13 with suspected non-Alzheimer's pathology (SNAP: A-T+), and 28 without A or T abnormalities on PET (A-T-). Scaled subprofile modeling using principal component analysis (SSM/PCA) was applied to 18F-flortaucipir images to identify two disease patterns (DPs), representing A+ and A- neurodegeneration. Each subject's imaging data was then compared to these DPs, and the resulting similarity scores were used as inputs for three machine learning models: Support Vector Machine (SVM), Random Forest (RF), and Multi-Layer Perceptron (MLP) to predict amyloid status. Finally, Spearman correlation analyses were conducted to assess associations between similarity scores and plasma biomarker levels. ***Results:*** The two identified DPs exhibited distinct PET signatures consistent with current disease knowledge. All the machine learning models confirm the capacity of A+ DP to predict AD pathology, with MLP achieving the highest accuracy in groups discrimination (accuracy = 0.88), correctly classifying 38 out of 40 of A+T+ subjects. However, only 5 out of 13 A-T+ were correctly classified, highlighting the limited expressiveness of A- DP. Both A+ and A- DP scores are significantly correlated with plasma biomarkers, except for Ab_{42}/Ab_{40} and $p\text{-}tau_{231}$ plasma biomarkers with scores derived from the A- DP. ***Conclusion:*** SSM/PCA derived patterns on ^{18}F-flortaucipir-PET imaging provide information on

both amyloid and tau status, in favour of its use as first and possibly sole examination in the investigation of suspected AD. However, for non-AD cases, amyloid PET scans is still recommended.

EP-1073

A Non-Invasive Method for Measurement of Cerebral Glucose Transport Capacity and Metabolic Rate Using [^{18}F]FDG and a Pre-bolus Scan of the Heart

N. Hansen[1], *S. A. S. Kjeldsen*[1], *M. N. Lonsdale*[2], *I. L. Rasmussen*[2], *S. Fuglsang*[2], *C. S. Meyhoff*[3,4], *R. Boellaard*[5], *J. Rungby*[6,4], *N. J. Wewer Albrechtsen*[1,4], *L. Marner*[2,4,7];
[1]*Department of Clinical Biochemistry, Copenhagen University Hospital - Bispebjerg and Frederiksberg Hospital, Copenhagen, DENMARK,* [2]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital - Bispebjerg and Frederiksberg Hospital, Copenhagen, DENMARK,* [3]*Department of Anaesthesia and Intensive Care, Copenhagen University Hospital - Bispebjerg and Frederiksberg Hospital, Copenhagen, DENMARK,* [4]*Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK,* [5]*Department of Radiology and Nuclear Medicine, Amsterdam UMC, Amsterdam, NETHERLANDS,* [6]*Steno Diabetes Center Copenhagen, Herlev, DENMARK,* [7]*Department of Nuclear Medicine, Copenhagen University Hospital - Herlev Hospital, Herlev, DENMARK.*

Aim/Introduction: We aim at establishing a method for measuring cerebral glucose transfer capacity, T_{max}[1], and metabolic rate, CMR_{glc}, without the need for arterial sampling. Extending our previously presented non-invasive method for CMR_{glc}[2], which cannot measure T_{max} (as T_{max} is derived from the initial cerebral uptake K_1), we include a prebolus of [^{18}F]FDG and an additional scan of the heart for extracting the image-derived input function (IDIF). ***Materials and Methods:*** Six healthy subjects had a prebolus of 21 (range 16-26) MBq [^{18}F]FDG simultaneously with the initiation of a 10 min dynamic scan of the heart, followed by a 10 min static scan of the brain to assess [^{18}F]FDG uptake from the prebolus. Then, a second bolus of 188 (range 154-223) MBq was injected followed by a 40 min dynamic scan of the brain. Finally, a 5 min static heart scan covered the tail of the input function with the same VOI in the left ventricle for extraction of the IDIF. Both injections were performed with a power injector (1 mL/s) to ensure fast and reproducible boluses. Arterial sampling was performed continuously during the initial 10 min after the second injection, followed by manual samples every 5 min for plasma and whole-blood radioactivity concentrations to achieve the arterial input function (AIF). The IDIF was multiplied with the average plasma/whole-blood ratio. Kinetic modeling was performed for four bilateral regions using a four-parameter two-compartment model with fit of blood volume fraction. The time-activity curves were corrected for the residual activity from the prebolus injection in an iterative process assuming identical uptake during the two injections. K_1 and CMR_{glc} using IDIF vs. AIF were compared. ***Results:*** CMR_{glc} and K_1 estimates from IDIF demonstrated high correlation to values estimated from AIF with r^2=0.91 and r^2=0.86, respectively and with mean relative numeric differences of 7.0% and 8.2% but with a slightly higher CMR_{glc} values of 4.5% for IDIF (paired t-test, p=0.02). ***Conclusion:*** Our non-invasive method for robust estimation of CMR_{glc} and K_1 (to derive T_{max}) achieved acceptable bias compared with arterial sampling. The method is applicable to all scanner systems. Automated analyses are warranted for the labor-intensive iterative corrections for prebolus activity to allow for wide-spread use and voxel-wise analysis. ***References:*** [1]Gejl et al. 2017. Sci Reports 7:17490. [2]Henriksen et al. 2022. Neuroimage 253:119079.

EP-1074

Deep Learning-based attenuation correction of myocardial perfusion imaging studies

D. Apostolopoulos[1], *N. Papathanasiou*[1], *T. Spyridonidis*[1], *M. Spiliotopoulou*[1], *I. Apostolopoulos*[2];
[1]*University General Hospital of Patras, Patras, GREECE,* [2]*Department of Medical Physics, School of Medicine, University of Patras, Patras, GREECE.*

Aim/Introduction: Aim/Introduction CT-based attenuation correction (AC) improves the accuracy of myocardial perfusion imaging (MPI), mainly by increasing specificity. However, CT increases patients' irradiation, lengthens acquisition time and is not available in all gamma-camera systems. Deep learning (DL) models have been developed to predict AC from non-corrected (NAC) images. ***Materials and Methods:*** Materials and Methods The NAC and AC polar maps (PM) from 470 consecutive MPI SPECT/CT studies (in 320 males and 150 females with BMI 29.0 Kg/m^2±5.02) were used retrospectively to construct DL models for predicting AC from NAC PM. The hybrid system Hawkeye-4 (GE Healthcare) was employed in SPECT/CT acquisition. Seven hundred (700) AC-NAC PM pairs, in DICOM format, were retrieved from 230 stress-rest and 240 stress-only studies. The actual AC PM images served as the ground truth for the developed DL models. Patient-specific features (sex, chest perimeter at the mid-level of the heart and myocardial volume) were also taken into account for model creation and training. The developed models included variations of U-Net structures and attention-based convolutional neural networks. Finally, we applied the models prospectively in 155 PM pairs from 100 consecutive patients (70 males, 30 females) for validation. Chest perimeter was measured from CT images in the model-learning group and by a measuring tape in the validation group, whereas NAC myocardial volume was automatically calculated by the SPECT processing software. Model performance was assessed using structural similarity index (SSIM), mean absolute pixel value error (MAE), and peak signal-to-noise ratio (PSNR). In addition, calculated summed stress/rest/difference scores (SSS, SRS and SDS), as well as visual assessment by two Nuclear Medicine experts, were used to compare actual with predicted AC PM. ***Results:*** Results All models exhibited high performance metrics (MAE < 0.04 and SSIM > 0.96) in both learning and validation groups. SSS, SRS and SDS values were not different between actual and predicted AC PM ($p<0.05$). Experts' evaluation revealed visual discrepancies in many cases of the validation set (40-45% with different models), but these were minor, not affecting the final diagnosis. Substantial inconsistencies were observed in 1-2% of cases. The inclusion of patient-specific features improved model performance metrics by 5-10%. ***Conclusion:*** Conclusion Our findings suggest that DL-based AC estimation in MPI SPECT studies holds significant promise, with further improvement anticipated as more data are added in the model-learning group. The inclusion of patient-specific features in the model seems to increase the accuracy of predicted AC images.

EP-1075

Navigating complexity: effective workflow management for high throughput PET-CT imaging in a multi-tracer multi-machine theranostic nuclear medicine department.

T. Henry, *L. Ferreol, C. Balleyguier, D. Deandreis;*
Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: The integration of PET-CT imaging in oncology has revolutionized cancer diagnosis and management. However, the high demand for PET-CT imaging requires effective workflow management to ensure timely, efficient and secure patient care. This study aimed to describe the workflow strategies implemented at an oncological center to achieve high throughput of PET-CT imaging tailored to cancer patient care. ***Materials and Methods:***

We analyzed retrospective appointments data from January 2023 to April 2024, including examination dates, tracers' type, and referral committee. Incident reports were cross-referenced to identify operational disruptions. Interviews with the lead technologist and lead radiopharmacist were performed to thoroughly describe their organization, emphasizing the coordination among the two. ***Results:*** Our department conducted 14,649 PET-CT examinations over the study period, with FDG used in 90.4% of cases. Among FDG examinations, the breast committee accounted for 39.5%, followed by head and neck (10.4%) and skin (8.5%) committees. Analysis revealed cyclical patterns in activity, with regular dips coinciding with school holidays. A notable trend was observed with an increase in PSMA-like tracer usage and a corresponding decrease in choline-like tracers, reflecting evolving clinical guidelines. Sixty-one incidents were recorded, primarily occurring during morning startup procedures, resulting in 246 hours of lost operational time, significantly impacting daily PET-CT throughput (p=0.026). The nature of these incidents included equipment malfunctions and delays in radiopharmaceutical deliveries. To address these challenges, a three-tiered prioritization system for FDG examinations was established based on clinical urgency (urgent, rapid, programmed), with an overbooking system allowing scheduling of urgent cases beyond theoretical available slots. Three dedicated fast-track pathways were established for breast, gynecological, and lung cancers, providing rapid access to PET-CT for initial staging. A structured weekly schedule was implemented with specific days dedicated to different tracers, optimizing radiopharmacy resources. Implementing a dedicated technician solely for radiotracer injections improved communication between the injection area and scanning rooms, while staggered technician schedules optimized personnel coverage throughout the day. Additionally, a two-tier interpretation system was established, with dedicated physicians for same-day reporting and separate physicians analyzing non-urgent cases the following day without interruptions from clinical management tasks. ***Conclusion:*** Our study outlines a comprehensive approach to streamlining PET-CT services, from appointment scheduling to image interpretation. Implementing structured workflow management in PET-CT imaging can enhance operational efficiency, reduce delays, and improve patients' care and health workers' well-being in a high-volume oncology center.

EP-1076

Estimation of Relative Renal Function on DMSA Scans via Deep Regression

M. Abdi[1], *A. BELAID*[2], *Y. Ghedbane*[3], *S. YAHIAOUI*[2], *M. HABBACHE*[1], *Q. NAILI*[1];
[1]*Centre d'imagerie scintigraphique (CIS) Blida, Blida, ALGERIA,* [2]*Centre de Recherche sur L'Information Scientifique et Technique (CERIST), Algiers, ALGERIA,* [3]*Centre d'imagerie scintigraphique (CIS) Setif, Setif, ALGERIA.*

Aim/Introduction: Accurate estimation of relative renal function (RRF) is crucial for managing various renal disorders. Traditional methods can be time-consuming and variable according to region of interest drawing (ROI)[1]. This study aim to develop and evaluate a fully automated, image-based approach using deep learning regression to estimate RRF directly from static Dimercaptosuccinic Acid (DMSA) scintigraphy scans, bypassing manual ROI delineation. ***Materials and Methods:*** A retrospective dataset of 1116 static posterior DMSA scans, acquired using four different gamma cameras from patients with diverse pathologies, ages, and genders is used. Ectopic and fused kidneys are excluded (need for anterior scans). Ground truth RRF values are derived from consensus readings by two nuclear medicine physicians. The dataset is splited into training (0.8/0.2) and internal validation (IntVal) sets. To assess the model's generalizability, an external validation (ExtVal) set of 112 images is collected. A convolutional neural network (CNN) is developed for regression (predicts RRF percentages directly from image data). CNN performance is evaluated on the validation sets using Mean Absolute Error (MAE), the Pearson Correlation Coefficient (PCC) and the range of differences between predictions and ground truth. Gradient-weighted Class Activation Mapping (Grad-CAM) is employed for visual explanations. ***Results:*** The CNN demonstrates very promising results in estimating RRF from DMSA scans. The MAE is 3.45 and 3.79 on IntVal and ExtVal sets, respectively. The PCC is 0.98 and 0.95 on IntVal and ExtVal sets, respectively. The range of differences on ExtVal is [0.08%-15%], 3.80 +/- 2.89%, but did not exceed 8% in about 91% of the patients, which is at least similar to human reproducibility[1]. Visual inspection of the predicted RRF values against the ground truth shows a strong correlation. Visual analysis using Grad-CAM consistently highlights the regions corresponding to the left and right kidneys as the primary areas of the CNN's focus when estimating RRF. This suggests that the model learned to attend to the relevant anatomical structures for the prediction task. ***Conclusion:*** This study demonstrates the feasibility of deep learning regression for automated and accurate RRF estimation from DMSA scans (MAE: 3.45, Pearson's r: 0.98). The image-based approach offers a potentially faster and reproducible alternative for RRF assessment. Visual analysis using Grad-CAM confirms the model's focus on the kidneys, potentially increasing clinical trust in AI-driven RRF assessment. ***References:*** 1. Tondeur, Marianne, et al. "Inter-observer reproducibility of relative 99Tcm-DMSA uptake." Nuclear medicine communications 21.5 (2000): 449-453.

Aim/Introduction: This study compares five absorbed dose rate estimation methods to identify the most accurate approach for kidney and lumbar vertebra dosimetry in [^{177}Lu]Lu-DOTATATE therapy. ***Materials and Methods:*** CT images from day-1 SPECT/CT scans post-[^{177}Lu]Lu-DOTATATE injection in 18 patients were used to generate activity masks for kidneys and L1-L5 vertebrae using TotalSegmentator [1], assuming uniform activity concentrations (0.35 MBq/mL for kidneys, 0.034 MBq/mL for vertebrae) as ground-truth. SPECT was simulated using SIMIND [2] with a uniform activity distribution and noise, modelling a Siemens Intevo Bold system (9.5-mm crystal, MELP collimator, 9% energy resolution, 120 projections, 30s/projection, non-circular orbit, 256x256 matrix, 2.54-mm pixels, 10%-20%-10% energy windows around 208 keV). Images were reconstructed using PyTomography [3] (OSEM, 4 subsets, 20 iterations, attenuation correction, triple-energy-window scatter correction, resolution modelling, 2.4-mm voxels). Five absorbed dose rate estimation methods were evaluated using either activity masks ("mask") or SPECT images ("SPECT"), followed by: GATE [4] radiation transport simulations (5.2×10^8 decays) with CT-based materials, simulating 2 billion particles per patient ("GATE"); local energy deposition [5] with organ-specific density correction ("LED"), or GATE-derived ^{177}Lu voxel S-values with density correction ("VSV"): A (reference): mask+GATE; B: mask+LED; C: SPECT+GATE; D: SPECT+LED; E: SPECT+VSV. Partial volume correction for SPECT-based methods (C-E) used recovery coefficients derived from activity ratios of exact to enlarged VOIs. Relative errors in mean absorbed dose rate (vs. method A) were calculated per patient; group-level means and standard deviations were also computed. Dose rate-volume histograms (DVHs) were used for visual assessment. ***Results:*** In the kidneys, method

B showed the best agreement with the reference (0.0±0.5%), followed by C (-4.8±3.3%), D (-9.8±2.6%), and E (-11.3±3.8%). For vertebrae, B and C performed best, with relative errors ranging from -7.2±1.2% to -2.7±0.7% (L1 to L5) for B, and -8.3±20.23% to 5.7±7.8% for C. Methods D and E showed larger errors: -28.1±17.2% to -13.0±7.0% for D, and -30.5±15.4% to -14.3±7.7% for E. DVHs revealed greater deviations in methods D and E, while Monte Carlo-based methods (A and C) yielded more accurate and consistent dose rate distributions. ***Conclusion:*** While mask-based method B showed acceptable accuracy, SPECT-based Monte Carlo simulations (C) outperformed simplified methods such as LED (D) and voxel S-value (E), especially in the lumbar spine, where densities differ significantly from water. ***References:*** [1] Wasserthal etal. Monte Carlo bootstrapping to estimate statistical power for published tumor dose-response relationships in peptide receptor radionuclide therapy (PRRT)

T. Husevåg[1], *C. Stokke*[1,2], *M. Kvassheim*[1,2];
[1]*Oslo University Hospital, Oslo, NORWAY,* [2]*University of Oslo, Oslo, NORWAY.*

Aim/Introduction: We aimed to retrospectively estimate the statistical power of published PRRT tumour dose-response relationships using a Monte Carlo method bootstrap with Weibull extrapolation. ***Materials and Methods:*** 17 PRRT tumour dose-response relationships were extracted from figures or tables in [2-7] evaluating change in tumour volume/diameter (16) or chromogranin A levels (1), using Pearson correlation ρ.Bootstrapped subsamples were used to evaluate the rejection rate under the reported significance conditions repeated 1000 times for each sample size (i.e. a Monte-Carlo approach), estimating the statistical power until the study population size was reached. The bootstrapped sample size-power relationship was then extrapolated using the cumulative Weibull distribution (CWD) until the desired power was reached. If the reported relationship was far from significance [5,7] the TOST equivalence test [1] was used to evaluate the equivalence power for Δρ^2<0.25.The analysis was performed using in-house developed python-software [8]. ***Results:*** The CWD power extrapolation fit well for 15/17 relationships (R^2>0.95), yielding reasonable power estimates in relation to simulated sample sizes. Four relationships gave power estimates >95%, and the remaining 13 estimates ranged from 46% to 85%. While the dose-response relationship published in figure 2 by Ha et al. [4] was non-significant (p=0.06), the bootstrap power estimate was the lowest of all evaluated relationships (~45% power for 20 patients). A very stable CWD extrapolation (R^2=0.99) suggests the study might have benefited from increasing the sample size to e.g. 40 patients to raise the power to 90%. On the opposite end the relationship reported by Hebert et al. [2] could have reached the same power with about half the lesions, indicating large variability of statistical power between reported findings. Jahn et al. [7] reported a non-significant correlation with equivalence power of ~60%, indicating the need for increased sample. ***Conclusion:*** This approach enabled simple retrospective power assessments and suggested that most of the published PRRT tumour dose-response analyses would have benefitted from larger cohorts to reliably reduce the type II error probability. ***References:*** 1.Counsell A, Cribbie RA, Brit K Math & Statis. 2015;68(2):292-309. 2.Hebert K, et al., J Nucl Med. 2024;65(6):923-930. 3.Ilan E, et al. Age-Related Metabolic Changes in Japanese Healthy Controls undergoing [18F]-PET/CT Imaging

S. Gutschmayer[1], *M. Pires*[1], *T. Beyer*[1], *D. Ferrara*[1], *Z. Chen*[2], *Y. Xinzhu*[2], *J. Taki*[3], *S. Kinuya*[2], *L. K. S. Sundar*[1,4], *S. Takeda*[3], *H. Wakabayashi*[2];
[1]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, JAPAN,* [3]*PET Center, Kanazawa Advanced Medical Center, Kanazawa, JAPAN,* [4]*DIGIT-X Lab, Department of Radiology, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Metabolic aging involves varying physiological shifts across the human lifespan. Quantifying image readouts, such as energy-related metabolic activity and organ volumes, can be derived from [18F]FDG-PET/CT imaging to explore age-related systemic changes. Previous studies suggest that energy metabolism peaks in early life, plateaus in adulthood, and declines in older age [1]. This study characterizes organ-specific age-related metabolic shifts in healthy Japanese adults using FDG-PET/CT imaging. ***Materials and Methods:*** Whole-body PET/CT scans from 501 healthy Japanese subjects (351 males, BMI: 24 ± 3 kg/m^2; 150 females, BMI: 21 ± 3 kg/m^2) aged 22-89 (54 ± 11 years) were analysed. Automatic segmentation and quantification of organ-wise mean SUVlbm and volume were performed in eight organs (brain, liver, spleen, bone marrow, thyroid, subcutaneous fat, skeletal muscle, visceral fat) using MOOSE [2]. Linear correlation analysis was performed for each organ parameter versus age, with linear regression assessment (R^2) for no, sex, and BMI stratifications. Spearman correlation analyses were performed within age decades and two wider-age groups: 20-60 and >60 years. Correlations with $|\rho| \geq 0.45$ defined edges of undirected metabolic networks, linking organs with strong metabolic or morphological associations. ***Results:*** SUVlbm was not influenced by age; all regression models for all described groups yielded $R^2 < 0.3$, thus supporting previous findings of stable energy expenditure between 20-60 years [1]. However, network analysis revealed age-dependent shifts in inter-organ connectivity. In their 20s, participants showed SUVlbm-dominated networks (SUVlbm: 12 correlations, volume: 9 correlations). During the 30s, 40s, and 50s, volume-based correlations dominated while SUVlbm-related connections were reduced (30s: 17 SUVlbm vs. 34 volume; 40s: 6 vs. 15; 50s: 7 vs. 14). From the 60s onwards, SUVlbm connections became dominant again (60s: 8 SUVlbm vs. 10 volume; 70s: 17 vs. 18; 80s: 10 vs 9), indicating reappearing metabolic dependency. Similarly, in the age-grouped analyses, the 20-60 years group retained 6 SUVlbm and 14 volume correlations compared to 7 and 9 in subjects >60 years. ***Conclusion:*** FDG-PET/CT imaging reveals shifts in metabolic connectivity for healthy Japanese subjects across adulthood, mirroring known life-course metabolic phases. Given its ability to resolve organ-specific function and inter-organ connectivity, PET/CT is well-suited for investigating the systemic nature of metabolic aging and its physiological determinants. ***References:*** [1] Pontzer et al. Unravelling Amyotrophic Lateral Sclerosis FDG PET patterns using graph-based manifold partition

T. Zaharia[1,2], *J. Hong*[3], *R. Ni*[3], *A. Rominger*[3], *S. Hu*[4], *Y. Tang*[4], *K. Shi*[3];
[1]*Center of Artificial Intelligence in Medicine, University of Bern, Bern, SWITZERLAND,* [2]*ARTORG Center for Biomedical Engineering Research, University of Bern, Bern, SWITZERLAND,* [3]*Department of Nuclear Medicine, InselSpital, University of Bern, Bern, SWITZERLAND,* [4]*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA.*

Aim/Introduction: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder characterized by the progressive loss of motor neurons. The disease is progressing at a fast rate, leading to increased difficulty in day-to-day such as swallowing, salivation, writing etc. Our aim is to support diagnostic assessment by predicting disease progression and classifying patients into subtypes. To achieve this, we applied a novel unsupervised graph-based algorithm on FDGPET brain scans, to discover interconnected clusters correlating to clinical parameters. ***Materials and Methods:*** This study includes 126 clinically diagnosed ALS patients and 126 healthy controls, totalling 254 individuals with brain FDG-PET imaging [2]. In our cohort, there were 3 patients classified as suspected ALS, 39 as laboratory-supported, 23 as probable, and 26 as definite ALS cases, according to the Revised El Escorial Criteria. From the PET scans, we extracted SUVr values normalized to grey matter uptake for eight brain regions: Precentral gyrus, Frontal lobe, Supplementary Motor Area, Cerebellum, Vermis, Medulla Oblongata, Pons, and Midbrain. An unsupervised machine learning approach was used to cluster ALS patients into subtypes based on these regional uptake patterns. The algorithm applies a graph-based technique to infer a topology over the feature space, previously used in transcriptomics [3]. ***Results:*** The clustering algorithm, based on SUVr features, successfully differentiated ALS subgroups. The algorithm inferred a topology of 5 clusters. A statistically significant difference in disease progression rate was observed among clusters (Kruskal-Wallis test, $p < 0.05$). Furthermore, a subset of three clusters displayed strong differences in progression rate and significant difference in salivation score and Non-Motor Symptoms (Chi-squared test, $p < 0.05$). In this subset, we observe a correlation between increasing Putamen FDG-uptake and decreasing Supplementary Motor Area FDG-uptake for Progression Rate. ***Conclusion:*** We developed a data-driven pipeline to support ALS diagnosis and prognosis. By applying unsupervised clustering to brain FDG-PET data, we were able to infer disease subtypes, potentially aiding clinical decision-making and personalized care strategies ***References:*** [1] Eva L. FMEA (Failure Mode and Effects Analysis) for ^{177}Lu marked PSMA and DOTATATE/TOC therapies for risk treatment assessment

M. L. Belli[1], *M. Golinucci*[2], *G. M. Volpe*[3], *I. Marini*[4], *V. Di Iorio*[5], *F. Matteucci*[4], *E. Prati*[6], *M. T. Montella*[3], *A. Sarnelli*[1];
[1]*IRST - Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS - Medical Physics Unit, Meldola, ITALY,* [2]*IRST - Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS - Nurse Unit, Meldola, ITALY,* [3]*IRST - Istituto Romagnolo per lo Studio dei Tumori, Meldola, ITALY,* [4]*IRST - Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS - Nuclear Medicine Unit, Meldola, ITALY,* [5]*IRST - Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS - Oncology Pharmacy Unit, Meldola, ITALY,* [6]*IRST - Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" - IRST IRCCS - Healthcare Direction, Meldola, ITALY.*

Aim/Introduction: Radiometabolic ^{177}Lu based treatment is a complex process that involves different specialists. Due to his high complexity and to the potential serious risk of health damages for patients and healthcare professionals, a global analysis of the whole process would allow to identify the weak point and then improve clinical standards. Risk analysis also fulfil the requirement of 2013/59/EURATOM directive. We performed a FMEA (Failure Mode and Effects Analysis) analysis for ^{177}Lu therapies in order to identify the main critical points in the whole procedure. ***Materials and Methods:*** We divided the whole process of ^{177}Lu base therapies into main steps and identified all possible failure-modes. Each failure-mode was scored for severity (S), occurrence (O) and detectability (D), range:1-10. Based on the Risk Priority Number (RPN=SxOxD) all failures were ranked. Both in home marked or already and ready for injection radiopharmaceuticals were considered. Both ^{177}Lu-PSMA and ^{177}Lu-DOTATATE/TOC therapies were considered. ***Results:*** Failure mode with highest RPN score were: incorrect infusion supervision based on counts measurements; incorrect connection of catheters (vial-injection pump-patient); incorrect end of infusion; false negative of pregnancy test. Additionally, for home marked radiopharmaceuticals: incorrect selection of vial geometry calibration factor. ***Conclusion:*** The FMEA analysis allowed the identification of the main failure mode in ^{177}Lu treatment procedures. Based on the obtained results, strategies could be implemented in the clinical practice in order to further improve patient safety. The present results may help new implementation of ^{177}Lu base therapy in the prospective of increasing use of this kind of therapies.

EP-1082

ICSH Formulas for Normal Blood Volume: 30 Years Later, a Descriptive Population Study Comparing the Reference Cohort to Actual Patients Explored for Isotopic Blood Volume Determination

M. Ragot[1], *J. Dubois*[2], *L. Drevon*[3], *A. Salabert*[4], *L. Guiheneuc*[5], *C. Rouet*[6], *S. Mackowiak*[7], *Z. Mauduit*[8], *M. Jung*[1], *M. Tempier*[1], *P. Orhon*[1], *A. Revy*[1], *S. Levesque*[1];
[1]*Centre Jean Perrin, Clermont-Ferrand, FRANCE,* [2]*CHU de Montpellier, Montpellier, FRANCE,* [3]*Assistance Publique – Hôpitaux de Paris, St Louis, Paris, FRANCE,* [4]*CHU de Toulouse, Toulouse, FRANCE,* [5]*CHU de Nantes, Nantes, FRANCE,* [6]*CH Métropole Savoie, Chambery, FRANCE,* [7]*CHU d'Amiens, Amiens, FRANCE,* [8]*CHU de Grenoble, Grenoble, FRANCE.*

Aim/Introduction: Isotopic determination of red cell mass (RCM) and plasma volume (PV) is essential for the diagnosis of polycythaemia. Interpretation is based on the ratio of the measured value to a theoretical normal value, derived from formulae published by ICSH in 1995, using data collected between 1956 and 1969. They establish normal RCM and PV values according to body surface area (BSA), age and sex. Thirty years later, they are still used to conclude whether a value is pathological or not, but are they suitable for the current patient population? ***Materials and Methods:*** For the ICSH cohort, data were extracted from the six articles underlying the ICSH recommendations, according to the methodology outlined by Pearson et al.. For our cohort, consenting patients who underwent RCM and/or PV measurement between 2019 and March 2025 were retrospectively included. Statistical analyses were conducted on Microsoft Excel® and R®, using Wilcoxon tests. ***Results:*** 3215 patients were included from 8 hospitals, with a gender ratio of 4.47. For the determination of normal RCM, the ICSH cohort included 283 men, with a median age of 30 years, BSA of 1.90 m^2 and BMI of 23.0 kg/m^2. Our cohort included 2629 men with a median age of 61 years, BSA of 1.99 m^2 and BMI of 27.5 kg/m^2. Age, BSA and BMI differed significantly ($p<0.001$). 1385 (53%) patients were over 60 years-old, but only 3 subjects were over 60 in the ICSH cohort. 701 (27%) patients had a BSA higher than 2.1 m^2 and 687 (26%) were obese versus only 32 and 16 in the ICSH cohort. For women, the ICSH cohort included 171 subjects, with a median age of 30 years, BSA of 1.64 m^2 and BMI of 21.4 kg/m^2. Our cohort included 584 women with a median age of 63 years, BSA of 1.71 m^2 and BMI of 25.6 kg/m^2. Age, BSA and BMI differed significantly ($p<0.001$). The ICSH cohort included only 8 subjects over 60 years-old, whereas 311 (53%) patients were over 60. 152 (26%) patients were obese versus 12 subjects. These

differences in age, BSA and BMI were also significant for plasma volume cohorts. ***Conclusion:*** The formulae for determining normal RCM and PV were derived from a small cohort of predominantly young and normal-weight subjects. Our findings confirm the underrepresentation of elderly and overweight patients and raise concerns regarding the applicability and reliability of these formulae in current clinical practice.

EP-1083

Reproducibility study of tumor lesion features in [^{68}Ga] Ga-PSMA PET/CT images

M. Alfaiate[1,2], *C. Constantino*[1], *F. Oliveira*[1], *L. C. Silva*[1], *R. Vigário*[2], *D. C. Costa*[1];
[1]*Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*NOVA School of Science and Technology, Caparica, PORTUGAL.*

Aim/Introduction: This study aims to evaluate the reproducibility of radiomic features from lesions identified in consecutive [^{68}Ga] Ga-PSMA PET/CT images of prostate cancer patients. ***Materials and Methods:*** Fifty prostate cancer patients, for staging or restaging assessment, underwent two consecutive acquisitions on the same scanner (Philips GEMINI TF16) with a single injection of [^{68}Ga]Ga-PSMA. The time interval between the two scans did not exceed 40 minutes. On average, the first acquisition began 60 ± 12 minutes post-injection, followed by the second at 93 ± 11 minutes. Both acquisitions and reconstruction protocols were in accordance with EARL1 standards. All visible lesions suspected of malignancy were identified by an experienced nuclear medicine physician. Then, lesions identified on both acquisitions were semi-automatically segmented with a previously validated Bayesian classifier algorithm [1]. 106 radiomic features were extracted with "pyradiomics", an open-source python package in compliance with Image Biomarker Standardization Initiative (IBSI) [2]. The features were subdivided into 14 shape-based, 17 first-order, and 75 gray level (texture). For the statistical analysis, reproducibility was assessed with the intraclass correlation coefficient (ICC) as a measure of agreement. A significance level of 5% was set for inference. ***Results:*** A total of 236 [^{68}Ga]Ga-PSMA avid lesions were segmented. For the textural analysis, only 87 lesions were included, since the others were smaller than 64 voxels (4096 mm^3)—following IBSI guidelines. 79% of the shape-based features showed good reproducibility (0.75≤ICC<0.9). The remaining showed moderate reproducibility (0.4≤ICC<0.75). 65% of first-order features showed good or excellent (ICC≥0.9) reproducibility, whereas the rest showed moderate reproducibility. Gray level features had a wide variety of agreement results, 43% had good or excellent reproducibility, 55% had moderate reproducibility, and 3% had poor reproducibility (ICC<0.4). All ICC results were statistically significant. For features frequently used in clinical practice, such as maximum and mean standardized uptake value, and lesion volume (0.83≤ICC≤0.89), from the first to second acquisition, there was a median decrease of 6%, 3% and 4% respectively. The complete ICC results are available online (https://github.com/NM-Radiopharmacology/PSMA_FeaturesReproducibility). ***Conclusion:*** Overall, for [^{68}Ga]Ga-PSMA PET, shape and first-order features are more reproducible, i.e., less sensitive to real scenario conditions, such as time difference between acquisitions, patient positioning, and lesion segmentation, than gray level features. Furthermore, the latter are only feasible for large lesions. In this context, shape and first-order features should be prioritized for follow-up and predictive studies. ***References:*** [1] Constantino, et al. https://doi.org/10.1007/s10278-023-00823-y [2] Griethuysen, et al. https://doi.org/10.1158/0008-5472.CAN-17-0339

Structured Ground Truth Extraction from Robot-Assisted Radical Prostatectomy (RARP) Histopathology report to Support AI-Based Prostate Cancer Staging

J. Chaudhary, *A. K. Pandey, S. Kumar, S. Kaushal, P. D. Sharma, H. K. P, R. Kumar;*
All India Institute of Medical Sciences, AIIMS, New Delhi, New Delhi, INDIA.

Aim/Introduction: Artificial intelligence (AI) and machine learning (ML) are transforming nuclear medicine by enhancing diagnostic precision in oncologic imaging. Structured ground truth data are essential for training and validating AI/ML models. While histopathology is not traditionally part of nuclear medicine workflows, robotic-assisted radical prostatectomy (RARP) histopathology reports provide critical outcome data for Ga-68 PSMA PET/CT-based AI research in prostate cancer. To develop and validate a natural language processing (NLP) pipeline for extracting structured clinical parameters from RARP histopathology reports, enabling the creation of a ground truth dataset for future AI/ML model development in nuclear medicine. ***Materials and Methods:*** A rule-based NLP pipeline using regular expressions was developed to extract key parameters from 59 unstructured, scanned RARP histopathology reports: prostate size (3D dimensions), prostate weight, tumor size, seminal vesicle size, vas deferens length, and Gleason scores. Prostate volume was calculated using the ellipsoid formula. Manual validation was performed to assess extraction accuracy. Statistical correlations among parameters were evaluated using Pearson correlation. ***Results:*** The NLP pipeline achieved a sensitivity ranging from 72% to 100% and specificity between 79% and 100% across the 59 reports. Statistically significant correlations were found between prostate volume and both Gleason score and prostate weight ($p < 0.05$). The resulting structured dataset provides a reliable foundation for developing and validating AI/ML models using Ga-68 PSMA PET/CT imaging data. ***Conclusion:*** This study demonstrates a reproducible approach for generating structured ground truth data from histopathology reports, bridging the gap between imaging and outcomes. It supports AI/ML integration into prostate cancer imaging workflows and highlights the importance of data science in advancing precision diagnostics in nuclear medicine. Future work will involve applying this dataset in model development and clinical validation.

Potential of Large Language Models for Proofreading PET Reports

W. Roll[1], *L. Kober*[1], *D. Ventura*[1], *M. Masthoff*[1], *C. Backhaus*[1], *M. Schäfers*[1], *K. Rahbar*[1], *L. Plagwitz*[2], *P. Schindler*[1];
[1]*University Hospital Münster, Münster, GERMANY,* [2]*University of Münster, Münster, GERMANY.*

Aim/Introduction: The aim of this study was to investigate the ability of three large language models (LLMs), GPT-o1, DeepSeek R1-70b and Llama 3.3-70b, to detect common errors in anonymized PET/CT and PET/MRI reports. ***Materials and Methods:*** A retrospective dataset of 200 consecutive PET reports (100 correct, 100 with up to three artificially introduced errors each) was used. A total of 183 deliberately introduced errors were categorised as spelling & grammar, content or technical. Each report was presented to the three LLM with the same single prompt without subsequent modifications. The number of correctly identified errors and the time taken to complete each log were recorded. ***Results:*** Overall, GPT-o1 detected 84.2% (154/183) of the errors, significantly outperforming DeepSeek R1-70b (47.0%, 86/183) and Llama 3.3-70b (57.4%, 105/183; $p < 0.001$). GPT-o1 also showed

superior detection rates for spelling & grammar (76.8% vs. 25.3% vs. 38.9%) and technical (97.1% vs. 57.1% vs. 65.7%) errors. The detection of content errors did not differ significantly between the three models ($p = 0.406$). Reading time per report was significantly faster for GPT-o1 (28 ± 4 seconds), followed by Llama (48 ± 8 seconds) and DeepSeek (108 ± 29 seconds) ($p < 0.0001$). ***Conclusion:*** In PET/CT and PET/MRI reports GPT-o1 demonstrated the highest error detection rate of the LLMs evaluated. Future efforts to optimize and potentially fine-tune privacy-compliant open-source models might further improve their accuracy.

EP-1086

Artificial Intelligence as a New Research Ally? Performing AI-Assisted Systematic Literature Reviews in Nuclear Medicine

S. van Mossel[1,2], *M. Oude Wolcherink*[2], *R. de Feria Cardet*[3], *L. De Geus-Oei*[1,2,4], *D. Vriens*[5], *H. Koffijberg*[2], *S. Saing*[2,3];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*University of Technology Sydney, Sydney, AUSTRALIA,* [4]*Delft University of Technology, Delft, NETHERLANDS,* [5]*Radboud University Medical Center, Nijmegen, NETHERLANDS.*

Aim/Introduction: Systematic literature reviews (SLR) are fundamental for aggregating clinical evidence and identifying knowledge gaps, especially in nuclear medicine where randomised controlled trials are rare. The workload is increasing due to the growing number of articles to screen, while only about 1% of search results are relevant for data extraction. With an average completion time of over 15 months, SLRs may become outdated by the time they are published. The increasing workload reduces researchers' willingness to conduct SLRs and leads to overly narrow search strategies when prioritising time constraints over review quality. Artificial intelligence (AI) tools have been developed to reduce screening time, but their validation in nuclear medicine is lacking. To contribute to nuclear medicine domain-specific validation efforts, we assessed the performance of AI-assisted screening in a post hoc analysis of our published SLR [1]. ***Materials and Methods:*** From 2,398 unique articles identified on PubMed and Scopus, 57 were included for full-text review and 10 for data extraction. Titles, abstracts and inclusion decisions were reconstructed for AI-assisted screening with open-source ASReview Software (v1.2). Through simulation with Makita, an extension of ASReview Software, the number of relevant articles found using ASReview was compared to that found through the original full manual screening. Makita is a workflow generator for validation studies using the command line interface of ASReview. The software codes used to perform this analysis are available [2]. ***Results:*** Simulation results show the accuracy per number of articles screened. Using ASReview it took 600/2,398 articles to find all 57 articles included for full-text review and 250/2,398 articles to find all 10 articles included for data extraction: a saving of approximately 75% and 90% respectively. ***Conclusion:*** AI-assisted SLRs allow extended database searches with more generic search terms but without increasing reviewer workload, compared to full manual searching. However, AI tools are not yet established in PRISMA or Cochrane statements, indicating a need for more validation. This post hoc analysis contributes to the nuclear medicine domain-specific validation of AI tools and indicates that ASReview may be a valid and efficient tool for performing SLRs in our field. ***References:*** [1] van Mossel S, de Geus-Oei LF, et al. Deep Learning Reorientation for Myocardial Perfusion Imaging SPECT

T. Huxohl[1], *R. Borgschulze*[2];
[1]*Heart and Diabetes Center NRW, Bad Oeynhausen, GERMANY,* [2]*Bielefeld University, Bielefeld, GERMANY.*

Aim/Introduction: To facilitate the clinical interpretation of myocardial perfusion SPECT images and to create polar maps, transversal images are reoriented into standard planes. Manual reorientation is time consuming and operator dependent. Furthermore, routinely used automatic algorithms may fail if the myocardium is incomplete due to perfusion defects. Therefore, a deep learning approach inspired by [1] is implemented and its generalizability across different scanners is evaluated. ***Materials and Methods:*** A deep neural network was trained to predict reorientation parameters (three translation parameters and two rotation parameters). The dataset used consists of data from three scanners (450 Siemens Symbia Intevo SPECT/CT, 64 GE Discovery 530c and 47 Philips Cardio-MD), including a dedicated cardiac SPECT (GE Discovery), and was manually labeled. To assess generalizability, training was performed with multi-scanner data, with Symbia Intevo data only, and with Symbia Intevo data, but with unrealistic data augmentation [2]. ***Results:*** Multi-scanner training yielded correlation coefficients (Pearson R) of around R=0.98 for the translation parameters and R=0.92 for the rotation parameters. With single-scanner training, performance remains the same for translation parameters (R=0.98), while declining slightly for rotation parameters (R=0.81) when transferred to different scanners. Training with unrealistic data augmentation did not improve performance across scanners. ***Conclusion:*** It is possible to perform across multiple scanners, including dedicated cardiac scanners. Learning translation parameters works better than learning rotation parameters. Unrealistic data augmentation does not increase generalizability across scanners. ***References:*** [1] Duo Zhang et al. Development and Validation of an Artificial Intelligence Assistant for PET Phantom Analysis

T. Palchan Hazan[1], *J. A. Kennedy*[1,2], *T. Hazan*[3], *Z. Keidar*[1,2];
[1]*Rambam Health Care Campus, Haifa, ISRAEL,* [2]*Ruth and Bruce Rappaport Faculty of Medicine, Technion, Haifa, ISRAEL,* [3]*Technion, Haifa, ISRAEL.*

Aim/Introduction: Quality control in nuclear medicine imaging requires standardized phantom testing that requires an analysis process which is time-consuming and requires specialized expertise. This study evaluates large language models (LLMs) to: 1) generate automated analysis code, and 2) create an AI assistant for streamlined analysis through natural language interaction. This approach offers a method that is adaptable to various quality control procedures. ***Materials and Methods:*** We developed a two-phase approach utilizing Claude, an advanced LLM. In phase one, the LLM was prompted to create Python code for DICOM processing, and analysis specific to the American College of Radiology (ACR) PET phantom requirements, with all instructions provided in natural language. The resulting code implemented tools for loading DICOM, visualization, analyzing phantom slices, and generating reports. In phase two, we developed an AI assistant with a specialized system prompt that enabled it to utilize these

tools through conversational user interaction. The assistant guides users through the analysis workflow, executes the appropriate tools, and interprets results according to ACR criteria. We validated this approach by comparing the AI assistant's performance against established in-house automated algorithms refined over several years. We analyzed 68 ACR phantom studies from 2 different PET/CT systems available at Rambam Health Care Campus. ***Results:*** The LLM successfully generated all necessary code for the analysis toolkit based solely on natural language instructions, with minimal need for manual code adjustments (<5% of code blocks required modification). The AI assistant accurately executed the analysis workflow, correctly identifying the appropriate slices, placing ROIs, and calculating key metrics, including background uniformity and SUV ratios. Bland-Altman analysis demonstrated good agreement across all SUV measurements, with biases ranging from −0.10 to +0.08 g/mL and 95% limits of agreement spanning 0.05 to 0.69 g/mL. Complete concordance (100%) was observed between the AI assistant and the established method in pass/fail classifications. The natural language interface allowed technologists to complete phantom analysis with minimal training, reducing the average analysis time from 45 minutes (manual process) to a few minutes (AI-assisted). ***Conclusion:*** This study demonstrates the feasibility of using LLMs to create imaging analysis code and develop conversational AI assistants guiding users through complex phantom analysis. The approach offers significant advantages in flexibility, eliminating the need for extensive programming knowledge when implementing or modifying analysis workflows. The validated AI assistant generates standardized ACR reports for PET. Future work will extend this toolkit to include other phantom types including NEMA.

Monitoring Health with Whole-Body [18F]-FDG PET/CT

S. Gutschmayer[1], *D. Ferrara*[1], *B. K. Geist*[2], *Ö. Özer*[1,2], *J. Yu*[1,2], *M. Pires*[1], *I. Rausch*[1], *M. Hacker*[2], *L. K. S. Sundar*[1,3], *W. Langsteger*[2], *T. Beyer*[1];
[1]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [3]*DIGIT-X Lab, Department of Radiology, LMU Munich, Munich, GERMANY.*

Aim/Introduction: [18F]FDG-PET/CT is central to oncologic imaging, but publicly available datasets rarely represent healthy populations, limiting insight into normal physiology. To address this gap, we conducted a study in which healthy controls underwent test-retest [18F]FDG-PET/CT imaging to provide repeat measures and variances of normative values on whole-body metabolism. ***Materials and Methods:*** 50 Caucasian participants (26F/24M, 38 ± 14 years) were included. Each control underwent test and retest whole-body (WB) FDG-PET/CT imaging within 35 days. Scans were performed on a WB-PET/CT system following an injected dose of 100 MBq [18F]FDG and 63 min listmode acquisition. PET image reconstruction was done 58-63 min post-injection using OP-OSEM with TOF information, PSF correction, 4 iterations, 5 subsets, and all standard corrections applied. Of the 50 participants, 2 showed incidental early-stage malignancies and were excluded from the study. MOOSE [1] was used to extract the mean standardized uptake value (SUV), density as Hounsfield Units (HU), and volume of the heart, brain, lungs, kidneys, spleen, liver, pancreas, subcutaneous fat, visceral fat, and skeletal muscle (latter 3 at vertebrae 3L level). Repeatability of PET/CT readouts was evaluated at group and subject levels. For the group analysis, region-based population averages were compared using the relative %-difference and an unpaired Student's t-test. At the subject level, we computed the relative %-difference (Δ%) between test and retest scans for each participant and employed a paired Student's t-test to assess intra-subject repeatability. We used the organ readouts to establish cohort-specific normative values (CT and PET) and ranges for each organ. ***Results:*** Test/retest SUVs were consistent at the group level with Δ% < 6%. Subject-level variability remained low, except for visceral fat (Δ% = 11%) and skeletal muscle (Δ% = 5.5%, $p < 0.05$). Group-level HU was consistent at Δ% < 2%. Higher subject-level differences in the lungs, heart, and subcutaneous fat (<=8%) were likely due to motion and weight changes. Organ volumes showed the best repeatability with group-level variation of <3.5%. ***Conclusion:*** WB-[18F]FDG-PET/CT imaging yields reproducible organ readouts in a test-retest setting in healthy controls. The normative readouts can be used to compare patient readouts to and highlight organ-specific aberrations from the cohort norm by z-maps (organ readout differences normalised to the organ standard range). For future work, we aim to include non-imaging parameters such as wearable readouts and blood parameters in our analyses. ***References:*** [1] Sundar et al. Bridging the Gap between SPECT and PET using AI: Proof of concept on 99mTc-PSMA SPECT to 68Ga-PSMA PET synthesis

A. Lopez Montes[1], *L. Lopes*[1], *K. Hlongwa*[2], *M. Rivombo*[2], *O. Israel*[3], *A. Afshar-Oromieh*[1], *A. Rominger*[1], *S. More*[2], *K. Shi*[1];
[1]*University of Bern, Bern, SWITZERLAND,* [2]*Cape Town University, Cape Town, SOUTH AFRICA,* [3]*Technion Rappaport School of Medicine, Haifa, ISRAEL.*

Aim/Introduction: Advancements in SPECT instrumentation and tracer development poses it a viable alternative to PET imaging for several applications, particularly in resource-limited settings. However, differences in image quality and tracer uptake between SPECT and PET continue to hinder their integration under a unified framework, such as in joint clinical studies. To bridge this gap, enhancing diagnostic value for theranostics, improving patient management in patients without available PET and SPECT and enabling broader collaboration including participation from centers without PET, harmonization of the two modalities is essential. As a proof of concept, we focus on harmonizing ^{99m}Tc-PSMA SPECT with ^{68}Ga-PSMA PET for prostate cancer. ***Materials and Methods:*** 40 patients were scanned for staging prostate cancer using ^{68}Ga-PSMA PET and ^{99m}Tc-HYNIC-PSMA SPECT within a difference of 37.8 days. A ResUnet3D was trained to translate from SPECT to PET, learning the differences in uptake and image quality. Both PET and SPECT images were aligned prior to the training using a multimodal rigid registration approach. 35 of the patients were used in the training while the other 5 were used for the validation. For that, Total Segmentator was used, segmenting the main organs from the CT and the differences in organ-wise (kidneys, liver and prostate) uptake between the original SPECT and the generated PET harmonized from SPECT (harmonized-PET) were compared. Root Mean Squared Error (RMSE) between the harmonized and the original PET as well as between the original SPECT and the PET was reported for comparison. ***Results:*** The average RMSE between the harmonized-PET and the original one was 2.4±0.39 while the RMSE between the original SPECT and PET was 3.42±0.44 resulting in an improvement of 30%. On the other hand, the SSIM was improved from 0.71±0.07 to 0.80±0.03. Organ wise, the MSE between the harmonized-PET and the original PET was reduced in a 97% for liver and a 60% for the rest of the studied organs when compared with the ones between the original SPECT and the original PET. ***Conclusion:*** In this work, we have shown the feasibility of generating PET images representing the uptake of ^{68}Ga-PSMA from SPECT ^{99m}Tc-PSMA scans. On-going work is focused on increasing the number of patients for the training. Furthermore, the results can be generalized for different scanners and radiotracers. The results of this work will contribute to the harmonization between PET and SPECT bridging the gap between countries and institutions with different level of resources.

Explain Yourself! A Multi-Institutional PET/CT Reporters' Perspective on Explainable AI

C. Baskerville[1,2], *J. M. Y. Willaime*[2], *V. Prakash*[1,3,4], *T. Ali*[5], *S. Bhuva*[6], *G. Ellul*[7], *R. Frood*[8,9], *S. Kamat*[10], *S. Maitra*[3], *D. Rosewarne*[11], *A. Scarsbrook*[8,9], *P. D. Strouhal*[4], *A. Zarei*[8], *K. Wells*[1];
[1]*Centre for Vision, Speech and Signal Processing, The University of Surrey, Guildford, UNITED KINGDOM,* [2]*Mirada Medical Ltd., Oxford, UNITED KINGDOM,* [3]*Royal Surrey NHS Foundation Trust, Guildford, UNITED KINGDOM,* [4]*Alliance Medical Ltd., Warwick, UNITED KINGDOM,* [5]*The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UNITED KINGDOM,* [6]*Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM,* [7]*East Kent Hospitals University NHS Foundation Trust, Canterbury, UNITED KINGDOM,* [8]*Leeds Teaching Hospitals NHS Trust, Leeds, UNITED KINGDOM,* [9]*Faculty of Medicine and Health, University of Leeds, Leeds, UNITED KINGDOM,* [10]*King's College London NHS Foundation Trust, London, UNITED KINGDOM,* [11]*The Royal Wolverhampton NHS Trust, Wolverhampton, UNITED KINGDOM.*

Aim/Introduction: While artificial intelligence (AI) has the potential to dramatically improve clinical efficiency, broad adoption in Nuclear Medicine (NM) has yet to be realised due to hindrance by a lack of trust and understanding [1][2]. Explainable AI (XAI) could address these issues and facilitate human-in-the-loop oversight, a requirement of the EU AI Act for high-risk AI systems, yet controlled user testing is sparse [3][4]. This study examined task-specific XAI systems in NM using a novel hierarchical framework addressing the lack of standardised approaches to evaluation. ***Materials and Methods:*** This study proposes a 'Hierarchy of AI Interpretability', a framework evaluating interpretability needs across diverse stakeholder groups. This framework underpinned a multi-institutional study observing ten radiologists interacting with AI recommendations and explanations during tumour-node-metastasis (TNM) staging of lung cancer using [^{18}F] FDG PET-CT scans. Three interpretability levels were tested against standard 'black-box' systems spanning low-level Input Feature Attribution (IFA), High-Level Concepts (HLC) and Global Algorithmic Transparency (GAT). The study tested two hypotheses: (1) radiologist preference for adoption of an XAI clinical decision support system (CDSS) versus a black-box AI system, and (2) which XAI interpretability levels provide useful decision support for supporting/refuting AI recommendations. Analysis combined Likert scale data comparing explanation types with large language model (LLM)-assisted thematic analysis of qualitative feedback. ***Results:*** Sign tests confirmed radiologists were more likely to adopt AI-CDSS with interpretability than without (IFA: $p<0.005$; HLC: $p<0.005$; GAT: $p<0.05$). All interpretability levels provided useful information for evaluating AI recommendations (IFA: $p<0.005$; HLC: $p<0.005$; GAT: $p<0.01$). Thematic analysis revealed a key trade-off between explanation depth and usability. Preference along this continuum depended on perceived case difficulty: unambiguous cases required only visual confirmation with minimal detail, whilst complex cases shifted preference toward more detailed explanations despite longer interpretation time. ***Conclusion:*** The novel XAI hierarchical framework used in this study enabled initial evaluation of stakeholder considerations in PET-CT related AI. This task-based user study demonstrated radiologists' preference for XAI integration into decision support systems as compared to standard 'black-box' AI systems and provides useful information for validating AI recommendations. While these findings require validation in a larger prospective study, the explanation depth vs. usability trade-off supports the need for a CDSS with AI explanations configurable to individual case complexity. ***References:*** [1] M. Reimagining Administrative Workflows: ChatGPT o1 Optimizes ICD-10 Coding in Nuclear Medicine.

T. Ruhwedel*, J. Rogasch, P. Dahlke, C. Furth, C. Wetz, S. Shnayien, I. Schatka, H. Amthauer, N. Beetz;*
Charité Universitätsmedizin Berlin, Berlin, GERMANY.

Aim/Introduction: European physicians face significant workloads. In Germany alone, physicians spend an average of 3 hours per day on administrative tasks and frequently work ≥5 additional hours per week. Large Language Models (LLMs) such as ChatGPT o1 offer promising opportunities to automate and reduce this workload. The current version of the ICD-10 catalogue spans around 850 pages, making nuclear medicine reporting a robust test case of AI-assisted coding. We investigated whether ChatGPT o1 can accurately—and more rapidly—assign ICD-10 codes to PET/CT reports. ***Materials and Methods:*** 100 different fictious PET/CT reports were created based on standardized institutional text modules for PET/CT including contrast-enhanced diagnostic CT. Each report was assigned a single, most relevant ICD-10 code by two experienced nuclear medicine physicians who routinely code PET/CT exams. Coding of multiple reports at the same time was allowed. One physician used ChatGPT o1, while the other was limited to traditional search engines. Time was recorded in seconds, from the beginning of report review to entry of the ICD-10 code into a data table. Discrepancies were resolved via a blinded consensus process. Differences in error distribution across ICD-10 hierarchy levels were analyzed using four-field tables and the McNemar test. Time differences were assessed using the Wilcoxon signed-rank test. ***Results:*** At the first character of the ICD-10 code, the ChatGPT-assisted coder made 2 errors compared to 3 errors by the manual coder ($p = 1.0$). For the second and third characters, ChatGPT-based coding resulted in 3 errors versus 5 ($p = 0.727$). At the fourth and fifth characters, ChatGPT o1 significantly outperformed manual coding, with 6 errors versus 17 ($p = 0.035$). Overall, the ChatGPT-assisted coding resulted in 6 incorrect codes, whereas manual coding led to 18 ($p = 0.023$). Median coding time was 135 seconds (range 41 - 433 s) without ChatGPT and just 8 seconds (range 6 - 9 s) with it. The median time difference between both coders was 127 seconds (range 33 - 424 s; $p < 0.001$). ***Conclusion:*** ChatGPT o1 significantly improved both speed and accuracy in assigning ICD-10 codes to PET/CT reports. Higher accuracy of ICD-10 codes might reduce billing errors and insurance rejections, while saved time could be reallocated to patient care. Given the complexity of PET/CT reports, similar AI-based approaches could be extended to other imaging modalities such as diagnostic CT or MRI.

EP-1093

Short-Term Variation in Body Composition in Healthy Adult Volunteers Undergoing Long Axial Field-of-View [^{18}F]FDG-PET/CT

E. Sullivan[1], *G. Cook*[2,3], *A. Hammers*[2,3], *D. Ferrara*[4], *B. Geist*[5], *S. Gutschmayer*[4], *M. Hacker*[5], *M. Pires*[5], *J. Yu*[4,5], *L. Shiyam Sundar*[4], *T. Beyer*[4];
[1]*Department of Nutritional Sciences, Faculty of Life Science & Medicine, King's College London, London, UNITED KINGDOM,* [2]*School of Biomedical Engineering and Imaging Sciences, King's College London, London, UNITED KINGDOM,* [3]*King's College London and Guy's and St Thomas' PET Centre, St Thomas' Hospital, London, UNITED KINGDOM,* [4]*QIMP Team, Medical University of Vienna, Vienna, AUSTRIA,* [5]*Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Computed Tomography (CT) analysis at the L3 vertebra is the de facto gold standard for body composition research. Long Axial Field-of-View PET/CT enables relatively low-dose imaging in healthy volunteers, with added metabolic insights. This study aimed to establish reference data for physiologic intra-individual variation in [^{18}F]FDG-PET/CT parameters, against which to compare pathological aberrations. ***Materials and Methods:*** Fifty healthy Caucasian adults underwent whole body [^{18}F]FDG-PET/CT imaging with retest at 38±10 days. Two subjects with incidental findings of cancer were excluded. Body composition parameters (volume (mm3), CT attenuation (HU) and [^{18}F]FDG uptake (SUVbw) of skeletal muscle (SM), subcutaneous and visceral adipose tissue (SAT&VAT)) for the entire axial volume incorporating the L3 vertebra were evaluated using MOOSE software(1). Non-parametric tests were performed and Bonferroni adjustments for multiple testing were applied to X^2 tests. ***Results:*** Of 48 subjects included, 23 were male. Median [IQR] age was 32.5 [26-51] years. Median [IQR] body mass index (BMI) was 24.4 [21.8-25.8] kg/m^2. BMI (20-25kg/m^2) was present in 52% subjects with, BMI <20kg/m^2 in 13%, 25-20kg/m^2 in 31%, and >30kg/m^2 in 4%. Between test and retest, 60% of subjects remained weight stable (± 2%), with 23% of subjects gaining 2-5% and 13% losing 2-5% body weight. Inter-individual variations (volume gain or loss >2%) were present in 42% and 31% for SM, 52% and 40% for SAT and 36% and 52% for VAT, respectively. Degree of weight and SM volume changes were uncorrelated (rho=-0.056, p=0.705), whereas weight change was significantly correlated with SAT & VAT volume changes (rho=0.340, p=0.018; rho=0.346, p=0.016, respectively). There were no significant correlations between muscle, or adipose tissue SUVs, or baseline BMI and changes in body weight or tissue volume between scans, except for people with BMI <25kg/m^2 being more likely to gain 2-5% SAT volume and people with BMI >30kg/m^2 more likely to lose 2-5% SAT volume, compared to normal BMI individuals (50% vs. 8%, p=0.036; 100% vs. 8%, p<0.05, respectively). ***Conclusion:*** Significant (>2%) variation in weight and body composition were observed in healthy adults over a short interval. Weight did not fully reflect body composition changes, highlighting the role of imaging in distinguishing between physiologically important changes in body composition. Future studies should record illness and intentional/unintentional changes in weight, diet, activity or lifestyle factors in the weeks preceding scans, in order to accurately interpret metabolic variations. ***References:*** 1.Shiyam Sundar et al., DOI:10.2967/jnumed.122.264063.

EP-1094

Statistical Preprocessing of PET Radiomic Features: Normalisation, Outlier Filtering, and Correlation-Based Pruning for Robust Machine Learning Applications in a Hodgkin Lymphoma Cohort

S. Nikolovski*, G. Spirov, S. Tasevski, N. Manevska;*
University Institute of Positron- Emission Tomography, Skopje, NORTH MACEDONIA, THE REPUBLIC OF..

Aim/Introduction: Radiomic features extracted from positron-emission tomography/computed tomography (PET/CT) images provide quantitative characterisation of tumour phenotype but are highly sensitive to technical, biological, and imaging variability. Without systematic preprocessing, these features risk introducing instability and noise into predictive machine learning models. This study aimed to implement and evaluate a robust, multi-step preprocessing pipeline to improve data quality and model readiness in a classical Hodgkin lymphoma patient cohort, including distribution normalisation, outlier filtering, and correlation-based pruning of PET-derived radiomic features. ***Materials and Methods:*** A retrospective cohort of 104 patients with histopathologically confirmed classical Hodgkin lymphoma was analysed. Each patient underwent a pre-treatment [^{18}F] Fluoro-2-deoxy-2-D-glucose (FDG) PET/CT scan. Lymph nodes and lesions were automatically segmented from PET images using a convolutional neural network (CNN)-based segmentation tool, with all segmentations reviewed and confirmed by a certified nuclear medicine specialist. From the segmented structures, one representative lymph node per patient was selected for radiomic analysis. PET images were resampled to 4x4x4 mm^3 isotropic voxels and intensity discretised into 128 bins across a standardised uptake value (SUV) range of 0-40. A total of 131 radiomic features were extracted using the LIFEx software platform (v7.8.0) [1]. Features with skewness greater than 1 were subjected to logarithmic transformation. Outlier filtering was performed using the interquartile range (IQR) method, where values below Q1 – 1.5xIQR or above Q3 + 1.5xIQR were excluded at the patient level. Pearson correlation analysis with a threshold of $|r| > 0.9$ was used to identify and remove highly correlated features. ***Results:*** Log transformation was applied to 90 skewed features, successfully correcting 68.7% of their distributions. Outlier removal improved robustness without excluding features entirely. Correlation-based pruning reduced dimensionality from 131 to 27 uncorrelated, statistically normalised features. This refined subset will serve as input for future supervised machine learning models aimed at outcome prediction. ***Conclusion:*** A structured statistical preprocessing approach—comprising log transformation, outlier filtering, and correlation-based feature pruning—successfully improved the quality, stability, and usability of PET-derived radiomic features in a classical Hodgkin lymphoma cohort. This technical optimisation supports the development of more reproducible, interpretable, and generalisable machine learning models in PET-based oncology research. ***References:*** [1] Nioche C, Orlhac F, Boughdad S, et al. LIFEx: a freeware for radiomic feature calculation in multimodality imaging to accelerate advances in the characterisation of tumour heterogeneity. Cancer Research 2018;78(16):4786-4789.

EP-1095

Improved Imaging of Hemodynamics from Dynamic FDG PET-CT studies with Bolus Venous injection of the Tracer.

F. O'Sullivan*[1], Q. Wu[1], F. Gu[2], K. Shi[3], A. Rominger[3];*
[1]University College, Cork, IRELAND, [2]School of Mathematics and Physics, North China Electric Power University, Beijing, CHINA, [3]Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: High-resolution dynamic [18F]FDG PET-CT imaging following bolus injection has the potential to recover approximate quantitation of blood volume and flow. But standard intravenous tracer injection typically produces a high intensity signal on the venous pathway between the injection site (IS) and the first appearance of the arterial input (AIF) at the left ventricle (LV). Without adjustment, standard kinetic analysis of hemodynamics substantially overestimates flow and blood volume in the neighborhood of the IS-LV pathway. The work develops an algorithmic technique to correct time-course data for the IS-LV pathway artefacts and improve hemodynamic mapping. ***Materials and Methods:*** Data from a set of 25 dynamic PET-CT imaging studies on a Siemens Biograph scanner were used. All studies involved bolus intravenous injection of [18F]FDG into either the left or right arm [1]. The analysis approach adjusts all voxels with an early time-activity curve (eTAC) - eTACs are TACs where the peak intensity in the TAC occurs more than 1s before the peak intensity in the LV. eTACs are modelled using a semi-parametric form involving a multi-exponential first-pass pre-LV component, describing transit through the heart and a non-parametric, AIF-driven component, describing recirculation. Artefact suppression involves removal of the estimated first-pass pre-LV component from any eTAC voxels. The distribution of voxel-level blood volume in an ROI encompassing a neighbourhood of the IS-LV pathway on the injected arm and a similarly placed ROI on the non-injected arm were evaluated. Statistical deviations between the injected

and non-injected arm distributions were assessed before and after artefact suppression. In addition, the blood volume distributions over the non-injected arm before and after artefact suppression were compared. ***Results:*** Representative eTAC data were very well described by the 2-component modelling scheme - R^2-values are typically in excess of 95%. Removal of the fitted multi-exponential component produces adjusted data with minimal negative artefacts. Without incorporation of the non-parametric AIF-driven element, artefact-adjusted time-course data are grossly impacted by negative artefacts. Before artefact suppression, the percent difference between mean blood volumes over the IS-LV neighbourhood ROI was 50% to 500% higher that a comparable ROI over the non-inject arm; after artefact suppression differences is reduced to +/-15%. IS-LV artefact suppression is not found to distort blood volume patterns in the non-injected arm. ***Conclusion:*** The proposed technique improves the accuracy hemodynamic quantitation derived over the IS-LV neighbourhood in FDG-PET studies involving bolus venous injection of the tracer. ***References:*** Wu et al 2024, J Nucl Med;65(6):971-979.

Unsupervised Learning of Obesity-Associated Metabolic Patterns from Whole-Body ^{18}F-FDG PET/CT

R. JIANG[1,2,3], *X. Xie*[1,2], *M. Dong*[4], *Q. Sun*[4], *Z. Li*[4], *Y. Xiao*[5], *N. Ma*[4], *J. Li*[4], *H. Yang*[4], *X. Lin*[4], *H. Yan*[4], *H. Zheng*[1,2], *D. Liang*[1,2], *N. Zhang*[2], *C. C. Liu*[3], *Z. Hu*[1,2];
[1]*Research Center for Medical AI, Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA,* [2]*Key Laboratory of Biomedical Imaging Science and System, Chinese Academy of Sciences, State Key Laboratory of Biomedical Imaging Science and System, Shenzhen, CHINA,* [3]*Department of Data Science and Artificial Intelligence, The Hong Kong Polytechnic University, Hong Kong, CHINA,* [4]*Peking University Shenzhen Hospital, Shenzhen, CHINA,* [5]*Shenzhen Exit-Entry Frontier Inspection Station General Hospital, Shenzhen, CHINA.*

Aim/Introduction: Obesity is a major health concern linked to systemic metabolic imbalance and associated with various chronic diseases. Although prior work explored obesity from a metabolic network perspective [1], it relied on hand-crafted features based on limited data, personal observations, and subjective preferences. Such methods risk embedding bias and overlooking subtle patterns, leading to limited robustness and generalizability. This study introduces an unsupervised method to uncover obesity-related metabolic patterns without relying on manual priors. ***Materials and Methods:*** We introduce an unsupervised learning approach to uncover relationships between glucose metabolism and obesity from whole-body ^{18}F-FDG PET/CT data. A cohort of 1,160 subjects supports stable learning and broad applicability. We investigated obesity-related metabolic pathways using a systemic perspective. 576 normal-weight subjects [body mass index (BMI) < 24 kg/m^2, 50.07 ± 33.93 years, 302 men and 274 women] and 584 overweight or obese subjects [BMI ≥ 24 kg/m^2, 51.77 ± 36.23 years, 372 men and 212 women] underwent whole-body ^{18}F-FDG PET/CT imaging. We divided the cohort into BMI-based quantile groups and performed random sampling with replacement within each group. Organ-specific metabolic covariance networks were constructed based on the whole-body standardized uptake value, and an unsupervised deep-clustering framework was used to uncover latent features without human priors. Finally, class activation mapping and SHAP analysis were conducted to interpret the most influential network nodes and inter-organ connections. ***Results:*** The unsupervised deep clustering model achieved an ACC of 0.9925, NMI of 0.9898, and ARI metrics of 0.9842, indicating accurate group separation based on inter-organ metabolic connectivity patterns. CAM and SHAP analyses further revealed that the model prioritized metabolic interactions between liver-stomach, pancreas-liver, and duodenum-brain. ***Conclusion:*** Our unsupervised framework autonomously extracts inter-organ metabolic network signatures from whole-body PET/CT imaging data, without reliance on subjective priors. The high values of ACC, NMI, and ARI indicate that the clustering algorithm effectively identifies obesity-associated patterns within the inter-organ metabolic network. Additionally, a sufficiently large sample size strengthens the reliability and external validity of the network-derived findings. This study demonstrates the promise of unsupervised PET data mining in revealing metabolic insights for precision health. ***References:*** [1]W. Lu, Y. Duan, K. Li, Z. Cheng, and J. Body composition analysis of [18F]FDG-PET/CT images: The L3 vertebra region as a surrogate for whole-body quantification

M. Pires[1], *D. Ferrara*[1], *S. Gutschmayer*[1], *J. Yu*[2], *A. Frille*[3,4], *B. Geist*[2], *M. Hacker*[2], *S. Hesse*[3], *L. K. S. Sundar*[5], *T. Beyer*[1];

Aim/Introduction: [18F]FDG-PET/CT imaging is widely used for staging and restaging cancer patients. Beyond its diagnostic utility, it offers the potential to extract quantitative biomarkers such as imaging-derived body composition, which may aid in detecting cancer-associated metabolic alterations. However, whole-body (WB) segmentation of skeletal muscle (SKM), visceral adipose tissue (VAT), and subcutaneous adipose tissue (SAT) is highly time-consuming, limiting the development of deep-learning solutions for automated WB segmentation. Since the L3 vertebral region is an established surrogate for WB composition in radiology [1], we investigate whether automated L3-based tissue segmentation can accurately estimate the tissue volume, standardized uptake value (SUVbw), and CT density (CT_HU) of SKM, VAT, and SAT compared to WB manual segmentations. ***Materials and Methods:*** A retrospective cohort of 42 subjects (21 healthy controls, 21 lung cancer patients) who underwent WB FDG-PET/CT imaging was analysed. An experienced medical expert manually delineated WB volumes of SKM, VAT, and SAT. In addition, L3-level segmentations were generated using AI-based MOOSE [2]. Correlation between WB and L3 measurements was assessed using linear regression (r^2) for SUVbw, CT_HU, and tissue volume. ***Results:*** L3-derived imaging parameters strongly correlated with WB-derived parameters across several measurements. SKM, SUVbw, and CT_HU derived from L3 and WB segmentations showed excellent agreement (r^2 = 0.87 for both). However, the correlation of tissue volume of SKM was weak (r^2 = 0.25). For VAT, estimates for all readouts (SUVbw, CT_HU, and volume) correlated well between L3 and WB measurements (r^2 = 0.81, 0.80, and 0.88, respectively). For SAT, volume readings correlated well (r^2 = 0.88). However, correlations for SUVbw and CT_HU were only modest (r^2 = 0.66 and 0.77, respectively). ***Conclusion:*** The L3 region is an adequate surrogate for WB estimations of both SUVbw and CT_HU for SKM and SAT, as well as the volume of adipose tissues. ***References:*** [1] Anyene, I et al. Development of an Explanation-Supporting AI for Nuclear Medicine Procedures Using Open-Source LLMs and Retrieval-Augmented Generation Technologies

N. Imaizumi, *M. Sato, T. Kita, F. Sasaki, A. Yumoto, H. Daisaki; Gunma Prefectural College of Health Sciences, Maebashi, JAPAN.*

Aim/Introduction: We attempted to develop a conversational AI to explain nuclear medicine pretreatment procedures on behalf of the patient. In a previous study, a paid version of ChatGPT was used for the study, and 77.9% of the responses were rated as above average or excellent [1]. However, the large cost of using the paid version of LLM may prevent individual hospitals from taking advantage of it. Therefore, we evaluated the performance of an open-source LLM, and furthermore, we verified whether the performance of the open-source LLM can be comparable to the paid version by utilizing Retrieval Augmented Generation (RAG) technology. ***Materials and Methods:*** Four open-source LLMs (Gemma 2 9B Instruction Tuned, deepseek-ai/DeepSeek-R1, Llama-3-8B-8192, Qwen QwQ 32B (Preview) 128k) were evaluated in this study. In order to use RAG technology, we also used the Dify AI; a total of 8 conversational AIs were created with and without the RAG engine using the Dify AI. These models were asked what the pre-treatment was for bone scintigraphy, myocardial blood flow scintigraphy, cerebral blood flow scintigraphy, and PET, and their performance was evaluated at that time. ***Results:*** The accuracy of responses generated by the LLM-only conversational AI was 28.1%, while the integration of RAG significantly improved the accuracy to 65.6% (Wilcoxon signed-rank test, P = 0.019). ***Conclusion:*** Although further study is needed, the results suggest that even open-source LLMs may be able to develop a conversational AI to explain nuclear medicine pre-treatment. ***References:*** [1] Matsutomo, N., Fukami, M. & Yamamoto, T. Investigation of the Dosimetry Differences Between Pre-Therapy SPECT/CT and Post-Therapy PET/CT Scan in Selective Internal Radiation Therapy (SIRT)

E. Urwin[1,2], *D. Morgan*[1], *D. McGowan*[1], *L. Livieratos*[2]; [1]*Churchill Hospital, Oxford, UNITED KINGDOM,* [2]*King's College London, London, UNITED KINGDOM.*

Aim/Introduction: In SIRT 99mTc-MAA is used to plan the activity of microspheres required to deliver the prescribed dose. The success of SIRT relies on accurate dosimetry to optimise tumour absorbed dose while minimising liver toxicity. Previous work has shown a difference between the prescribed and delivered dose using 99mTc-MAA SPECT/CT and 90Y PET imaging respectively. [1] This retrospective study (24/HRA/3659) aims to quantify this difference and identify limitations in existing methodologies to improve dosimetry accuracy. ***Materials and Methods:*** Twenty patients who received SIRT were selected and the absorbed dose to the tumour, perfused (PNL) and whole normal liver (WNL) were calculated using a new Software and compared to results from a Partition Model in-house spreadsheet for validation. The difference between pre-therapy and post-therapy absorbed doses was calculated. The impact of SPECT/CT and PET/CT PVEs, interoperator variability, and post-therapy segmentation methods (deformable transformation, rigid transformation, and new VOIs) were investigated on the calculations of absorbed dose to volumes of interest (VOIs). ***Results:*** Validation of the new software showed good agreement with the in-house spreadsheet (mean deviations of 0.1%). When comparing pre- and post-therapy absorbed doses, there was overall correlation however large absolute differences were observed with absolute deviations up to 84.9Gy for tumours. Analysis of post-therapy volume segmentation methods showed no statistically significant difference however the difference in tumour absorbed dose between pre- and post-therapy varied up to 64Gy across the 3 methods . Recovery curve correction methods used to correct for PVEs significantly changed the pre- and post-therapy absorbed dose difference ($p<0.001$). No significant differences were found between operators on the pre-therapy absorbed doses however absorbed doses to the perfused and tumour VOIs varied largely (mean 59.2Gy and 78.0Gy respectively). ***Conclusion:*** The results from this study reveal good confidence in 99mTc-MAA SPECT/CT pre-therapy dosimetry for estimation of the absorbed dose to the normal liver in 90Y microspheres therapy. However, there are large tumour absorbed dose differences between pre- and post-therapy imaging suggesting opportunity for optimisation of tumour and liver dose. This arises from a variety of factors including a change in activity distribution, PVE, segmentation methods and inter-operator variability. ***References:*** Gnesin, S., et al., Partition Model-Based 99mTc-MAA SPECT/CT Predictive Dosimetry Compared with 90Y TOF PET/CT Posttreatment Dosimetry in Radioembolization of Hepatocellular Carcinoma: A Quantitative Agreement Comparison. Aim/Introduction: Using SPECT-CT renal dosimetry imaging (4, 24 and 72 hours post injection) from the OZM-067 ^{177}LU-DOTATATE trial (NCT02743741), this study aims to quantify the accuracy of single time point (STP) dosimetry at 72 hours and to investigate the impact of utilizing a site specific calibration factor to correct for the error, while improving harmonization among sites. ***Materials and Methods:*** A 3-parameter bi-exponential (3PBE) function was fitted as the reference fit using the area under the time activity curve for dose calculation. STP dosimetry calculation based on Hanscheid(2018) was performed using the 72 hour time point. A linear regression fit between STP and 3PBE for each site produced varying slopes suggesting that site specific calibration factors were required to prevent some sites being over or under-corrected. To investigate the feasibility of generating a site specific correction factor, in an effort to improve STP accuracy when using STP as a clinical dosimetry method, a simulation was done to determine a calibration factor for each site using a training set of the first 15 cycles (30 kidneys). This calibration was then applied to the rest of the patient data (testing set) from each site. The pre and post correction data were evaluated in terms of mean error when comparing STP and 3PBE dosimetry estimates. ***Results:*** SPECT-CT data (153 patients/492 cycles/955 kidneys) was utilized to generate

the renal dose for each injection using 3PBE dosimetry for the 4 trial sites (Table 1:Original Data). The linear regression fits between methods yielded slopes between 1.053 and 1.108 (Pearson correlation between 0.963 and 0.985), representing an average overestimation of between 0.287 and 0.524 Gy (9.32-11.33%) for the STP method relative to 3PBE. The training data set from each site was used to generate a site specific correction factor ranging from 1.071 to 1.120. Applying this factor to the testing data was able to substantially reduce the average error (Table 1:Corrected Data) at each site to between -0.078 and 0.028 Gy (-1.05-2.09%) while maintaining a high Pearson correlation (0.960-0.985). When pooling the testing data from all sites, the overall overestimation was reduced from 0.426±0.390 Gy (10.16±8.46%) to -0.046±0.358 Gy (-0.23±7.78%). ***Conclusion:*** STP dosimetry is highly correlated with 3PBE but over-predicts for most cases. Applying a site specific correction factor can help resolve this over-estimation without affecting the correlation, allowing less imaging per patient while maintaining accurate dosimetry comparable across different sites. ***References:*** Hänscheid, J Nucl Med. 2018

PBPK-Driven Digital Twinning in Radiopharmaceutical Therapies enabling Predictive Dosimetry from Dynamic Pre-Therapy PET Data

M. Sabouri*, A. Rafiei Sardouei, J. Fowler, O. Gharibi, H. Abdollahi, C. Uribe, A. Rahmim;*
University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: Absorbed dose calculations in radiopharmaceutical therapies (RPTs) rely on post-therapy SPECT data, while pre-therapy PET scans offer valuable pharmacokinetic information. We developed a computational framework using advanced Physiologically Based PharmacoKinetic (PBPK) modeling that simulates radiopharmaceutical distributions by solving a system containing >100 ordinary differential equations (ODEs). In this study, we use an inverse approach to estimate pharmacokinetic parameters from dynamic 18F-prostate specific membrane antigen (PSMA) PET data, thus creating digital twins for individual patients, from which 177Lu-PSMA SPECT time-activity curves (TACs) and absorbed doses can be predicted. ***Materials and Methods:*** A virtual cohort of 30 patients was generated using clinical pharmacokinetic distributions and simulated with a validated PBPK model to produce patient-specific 18F-PSMA PET TACs. The model, initialized randomly, was optimized using Adam (learning rate: 1×10^{-4}) to minimize MSE against dynamic PET data. Optimization occurred in two stages: 0-50 minutes for estimating receptor densities and blood flow, and up to 500 minutes for decay-based release rates. Early stopping was used for convergence. The predicted parameters were used to model 177Lu-PSMA biodistribution and time integrated activity curve (TIAC) was measured (directly related to absorbed doses). The accuracy of estimated parameters and TIACs were assessed using mean absolute percentage error (MAPE). Code is publicly available. ***Results:*** The accuracy of estimated parameters were assessed using MAPE and showed low errors for most receptor density (salivary glands (SG): 3.64%, kidneys: 1.13%, and tumors: 20.27%) and blood flow (SG: 1.19% and tumors: 4.60%) parameters, but higher deviations in release rate (SG: 117.97%, kidneys: 32.80%, and tumors: 1246.54%). For predictive dosimetry, SPECT-derived TIAC values demonstrated good agreement for kidneys (4.63%) and SG (16.58%), while tumors showed a higher discrepancy (120.18%), indicating potential challenges in accurately estimating tumor uptake. ***Conclusion:*** The proposed PBPK-based digital twinning involves solving an inverse problem to enable accurate prediction of pharmacokinetic parameters and absorbed doses for organs like kidneys and salivary glands using only PET data. Meanwhile, predicting tumor uptake remains a challenge, highlighting the need for improved modeling or data integration to reduce uncertainties in tumor dosimetry. At the same time, and importantly, focus on OARs is the key first step as toxicity limits will act as key constraints to ensure patients are not over- or under-treated. ***References:*** Fele-Paranj et al. PBRPK modeling of radiopharmaceutical therapies. EJNMMI Radiopharm Chem. 9, 6 (2024). https://doi.org/10.1186/s41181-023-00236-w

EP-1102

Radioimmunotherapy of Non-Hodgkin Lymphoma with Lilotomab Conjugated to Different Radionuclides: A Simulation Study

H. Ramsvik[1]*, J. Blakkisrud*[1]*, M. Kvassheim*[1,2]*, A. Løndalen*[3,4]*, C. Stokke*[1,5]*;*
[1]*Department of Physics and Computational Radiology, Oslo University Hospital, Oslo, NORWAY,* [2]*Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY,* [3]*Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY,* [4]*Division of Radiology and Nuclear Medicine, Innlandet Hospital Trust, Elverum, NORWAY,* [5]*Department of Physics, University of Oslo, Oslo, NORWAY.*

Aim/Introduction: The effect of a radionuclide therapy is dependent on the radionuclide. [^{177}Lu]Lu-lilotomab satetraxetan targets the CD37 antigen on B-cells and was investigated for relapsed indolent non-Hodgkin lymphoma patients in the phase 1/2a LYMRIT-37-01 trial. Using the uptake and biodistribution data of these patients, this work aims to simulate the absorbed dose from alternative radionuclides to the organs at risk. ***Materials and Methods:*** The biokinetics of whole body (3), red marrow (RM) (8), spleen (6), kidneys (6) and liver (6) for 10 patients treated with [^{177}Lu]Lu -lilotomab satetraxetan were estimated by SPECT/CT and planar imaging generally 0, 1, 4 and 7 days post-injection (day 4 and 7 for RM) [1]. The time activity curves (TACs) were normalized by patient weight and administered activity. Bi-exponential curves were fitted (mono-exponential for RM and whole body) and 1000 TACs were simulated by sampling from the fitted parameters. Coefficients were resampled for negative activity values and non-converging TACs. Absorbed doses to organs at risk were calculated for ^{177}Lu, ^{90}Y, ^{166}Ho, ^{225}Ac, ^{169}Er and ^{161}Tb, assuming equal biokinetics and local energy deposition. Redistribution of ^{225}Ac daughters was modelled according to the ICRP Publication 137,141, and 151 biokinetic models in Simbiology (MATLAB v2023b, MathWorks) by placing time-integrated activities in compartments: 'Kidneys', 'Liver1', 'Spleen', 'Trabecular marrow', and 'ST1', and free daughters in equilibrium at injection were put in 'Plasma'. ***Results:*** For the investigated patients, the median absorbed dose to RM was 2.1 mGy/MBq for the [^{177}Lu]Lu -lilotomab satetraxetan treatment. Simulated median absorbed doses to RM were 1.8, 2.3, 2.9, 6.6 and 515 mGy/MBq for ^{169}Er, ^{166}Ho,^{161}Tb, ^{90}Y and ^{225}Ac, respectively. For spleen, kidney and liver, all median absorbed doses were below 4.5 mGy/MBq, except for ^{225}Ac. Daughter redistribution increased the ^{225}Ac kidney absorbed dose by 2.5% and changed the absorbed dose to liver, spleen, and RM by less than 1%. Due to sparse early sampling for RM, a larger uncertainty is to be expected for this organ and would likely be more pronounced for radionuclides with shorter physical half-life. ***Conclusion:*** From the preliminary investigations, RM is the primary activity limiting organ regardless of radionuclide. Future work will focus on estimating absorbed doses to tumors to compare the therapeutic efficacy. This may contribute to inform the design of a new lilotomab-based radioimmunotherapy. ***References:*** [1] Stokke et. al EJNMMI 2018(45).

Prediction of tumor kinetics of [^{90}Y]Y-FAPI-46 using [^{68}Ga]Ga-FAPI-46 PET CT imaging

M. Watanabe[1,2]*, W. Jentzen*[2]*, D. Kersting*[2]*, K. Herrmann*[2]*, W. P. Fendler*[2]*, P. F. Costa*[2]*;*
[1]*Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University Hospital, Kyoto, JAPAN,* [2]*Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY.*

Aim/Introduction: Among many surface markers of cancer-associated fibroblasts, fibroblast activation protein (FAP) was shown to be upregulated in the stroma of more than 90% of epithelial carcinomas and sarcoma. FAP expression implicated in various cancer-related signaling pathways contributes to tumor progression, invasion, metastases, immunosuppression, and chemotherapy resistance. For this reason, radiolabeled FAP-targeting peptides, such as [^{90}Y]Y-FAP-inhibotor-46 (^{90}Y-FAPI-46) for radioligand therapy (RLT), have a growing impact for the treatment of various tumor entities, possibly leading to treatment response at acceptable side effects. Dosimetry can be used to predict tumor control and normal organ toxicity probability. The aim of this study is to investigate if lesion uptake (%), time-integrated activity coefficient (TIAC) and tumor absorbed dose (Gy/GBq) of patients receiving their first-cycle [^{90}Y]Y-FAPI-46 can be predicted by pretherapeutic [^{68}Ga]Ga-FAPI-46 (^{68}Ga-FAPI-46) PET/CT. ***Materials and Methods:*** Fourteen patients (five males and nine females) for restaging underwent [^{68}Ga]Ga-FAPI-46 PET/CT and serial ^{90}Y-FAPI-46 PET/CT within 3 months. There were 11, 1, 1 and 1 patients with solitary fibrous tumor, gastric cancer, prostate cancer and leiomyosarcoma, respectively. Tumor lesions were retrospectively semi-automatically segmented on each PET image. In this dosimetry model, the biological half-life of ^{68}Ga-FAPI-46 and ^{90}Y-FAPI-46 was assumed to be the same. Lesion's uptake (%), TIAC and tumor absorbed dose (Gy/GBq) were estimated and the difference and their correlation between ^{68}Ga-FAPI-46 and ^{90}Y-FAPI-46 PET/CT-derived values was analyzed. ***Results:*** As for the Bland-Altman analysis, mean % differences of lesions' uptake (%), TIAC (hr) and tumor absorbed dose (Gy/GBq) between each PET/CT were −34.36%, −15.77% and −15.78% with 95% of confidence interval of −119.70 to 50.95%, −100.40 to 68.89% and −100.40 to 68.81%, with Spearman's rho of 0.95, 0.93 and 0.76, respectively (p<0.0001 each). The TIACs (n=24) based on ^{68}Ga-FAPI-46 PET/CT and ^{90}Y-FAPI-46 PET/CT were 0.07 ± 0.14 hr (median: 0.03; range: 0.001 to 0.66) and 0.07 ± 0.13 hr (median: 0.04; range: 0.001 to 0.48), respectively. There was no statistically significant difference. ***Conclusion:*** The lesion's uptake, TIAC and tumor absorbed dose on ^{90}Y-FAPI-46 PET/CT and ^{68}Ga-FAPI-46 PET/CT were highly correlated. Although the differences of the lesion's uptake, TIAC and tumor absorbed dose calculated based on each PET modality were still large, ^{68}Ga-FAPI-46 PET/CT may have a potential to optimize the treatment plan of future FAP RLT candidates.

EP-1104

Dosimetry and safety of the PDGFRb PET tracer [^{68}Ga]Ga-DOTA-Cys-ATH001: first-in-human data in patients with liver fibrosis and healthy subjects

M. Lubberink[1], *T. G. Lohith*[2], *Z. Derdak*[2], *P. Wilkens*[2], *H. Wennbo*[2], *E. Palmer*[3,4], *A. Ramolli*[4], *B. Mitran*[5,6], *A. Abouyzayed*[5,6], *L. Johansson*[6], *F. Rorsman*[1,7], *J. Vessby*[1,7], *O. Eriksson*[1,5];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Takeda Pharmaceutical Company Limited, Cambridge, MA, UNITED STATES OF AMERICA,* [3]*Karolinska Institutet, Stockholm, SWEDEN,* [4]*Karolinska University Hospital, Stockholm, SWEDEN,* [5]*Antaros Tracer AB, Uppsala, SWEDEN,* [6]*Antaros Medical AB, Gothenburg, SWEDEN,* [7]*Uppsala University Hospital, Uppsala, SWEDEN.*

Aim/Introduction: Platelet Derived Growth Factor Receptor Beta (PDGFRb) is a general marker of pericytes and associated to virtually all fibrotic pathology and tissue remodeling. PDGFRb is strongly upregulated on activated hepatic stellate cells, the main source of extracellular matrix deposition in liver fibrosis (1). [^{68}Ga]Ga-DOTA-Cys-ATH001 is an Affibody molecule being developed as a PET tracer for non-invasive imaging of active liver fibrogenesis by quantification of PDGFRb (2). Here we present biodistribution and radiation dosimetry data from first-in-human PET trial NCT06562361. ***Materials and Methods:*** Radiation dosimetry of [^{68}Ga]Ga-DOTA-Cys-ATH001 was evaluated in healthy subjects (n=3) and patients with metabolic dysfunction-associated steatohepatitis (MASH) with elevated serum Pro-C3, a well-established fibrogenesis marker (n=3). Participants were administered 2.5 MBq/kg (<1µg/kg peptide mass) [^{68}Ga]Ga-DOTA-Cys-ATH001 intravenously, and imaged by a dynamic PET/MRI (Signa) abdominal scan, followed by whole body scans at 1, 2 and 3 h post-injection. All major organs and tissues (n=25) were segmented for biodistribution and time-activity curves (TACs) were uncorrected for decay. The area under the curve (AUC) of each TAC was calculated by rectangular integration. A single exponential fit to the last data point in the dynamic scan and the three whole-body scans was used to estimate the remainder of the AUC and extrapolating to infinity. The time-integrated activity (TIAC) was calculated as the AUC under each TAC and scaled to the reference organ weights in ICRP110 followed by division with the amount of injected activity. Absorbed dose coefficients and effective doses according to ICRP 103 were calculated using IDAC DOSE 2.1 (3). ***Results:*** The effective dose of [^{68}Ga]Ga-DOTA-Cys-ATH001 was 0.028 ± 0.002 mSv/MBq. The dose-limiting organ was the kidneys (0.463 ± 0.021 mGy/MBq in males and 0.339 ± 0.033 mGy/MBq in females). Administration of a target dose of 2 MBq/kg (circa 150 MBq in males) would result in an effective dose of 4.1 mSv and an absorbed dose to the kidneys of 69 mGy in males, with slightly lower doses in females. Thus, at this dose level, at least two annual administrations of [^{68}Ga]Ga-DOTA-Cys-ATH001 are feasible while conforming to relevant dosimetry safety guidelines. Subjects tolerated the tracer well with no adverse effects following tracer administration. ***Conclusion:*** [^{68}Ga]Ga-DOTA-Cys-ATH001 has an excellent dosimetry and safety profile that support further clinical development as a repeatable, non-invasive PET marker of active liver fibrogenesis. ***References:*** 1. Wong et al, J Clin Invest 1994; 2. Wegrzyniak et al, iScience 2024; 3. Andersson et al, EJNMMI Res 2017

EP-1105

Comparison of dosimetry in I-131 therapy for benign thyroid diseases using Marinelli and Hänscheid Methods

M. Mamach*, T. L. M. Felgenhauer, L. Geworski;*
Department for Medical Physics and Radiation Protection, Hannover, GERMANY.

Aim/Introduction: Radioiodine therapy with I-131 is an established treatment for benign thyroid conditions such as Graves' disease (GD) and autonomous adenoma (AA). Methods used for dosimetric planning are heterogenous in Europe. We evaluated key dosimetric parameters—maximum iodine uptake (IU_{max}), effective half-life (T_{eff}), and activity per dose (ApD)—comparing pre-therapy and in-therapy measurements using the Marinelli (MAR) and Hänscheid (HAN) methods [1,2]. ***Materials and Methods:*** Retrospective dosimetry was performed on 195 patients (70 GD, 125 AA). Each received 0.8-4.4 MBq I-131 pre-therapy, with uptake measured at 4h, 24h, and 7d using a gamma probe (NUVIA Instruments GmbH, Dülmen). During therapy, uptake was measured at 4h, 24h, 48h and 5-7d. T_{eff} and ApD were calculated via MAR and HAN. IU_{max} was derived from measurements. Paired t-tests were conducted using JMP (Student Edition 18, SAS Institute Inc., NC). ***Results:*** In AA patients, pre-therapy T_{eff} differed significantly (by 0.1 d, p<0.001, MAR 6.8±1.4 d, HAN 6.6±1.4 d) but not in-therapy (MAR 5.9±1.6 d, HAN 6.0±1.7 d). ApD differed by 0.5MBq/Gy in pre-therapy (p<0.001, MAR 3.5 ±2.5 MBq/Gy, HAN 3.0±2.2 MBq/Gy) and in-therapy (0.5MBq/Gy, p<0.001, MAR 3.5±3.4 MBq/Gy, HAN 3.0 ±2.6 MBq/Gy). T_{eff} was significantly larger pre-therapy (MAR by 0.9d, p<0.001, HAN by 0.7d, p<0.001). ApD and IU_{max} (pre-therapy 33±12 %, in-therapy 32±18 %) showed no significant difference.Significant differences in GD patients were observed in pre-therapy T_{eff} (0.06d, p<0.001), pre-therapy ApD (0.3MBq/Gy, p<0.001) and in-therapy ApD (0.3MBq/Gy, p<0.001). T_{eff} was larger pre-therapy (MAR by 0.5d, p<0.001, HAN by 0.4d, p=0.007) and ApD was underestimated by 0.2MBq/Gy pre-therapy for both methods with p<0.001). IU_{max} (pre-therapy 58±15 %, in-therapy 57±15 %) showed no significant difference. ***Conclusion:***

Significant differences exist between MAR and HAN, yet intra-method variability is higher. Overall, T_{eff} was overestimated in pre-therapy assessments possibly resulting in an under-treatment if not adjusted. Neither method demonstrated clear superiority, underscoring the need for further comparative analysis and potential standardization in radioiodine dosimetry. ***References:*** [1] L.D. PBPK model to predict [^{177}Lu]Lu-DOTA-TATE time-integrated activity with single-time-point [^{68}Ga]Ga-DOTA-TATE PET/CT imaging

V. Vasic[1], *J. Gustafsson*[2], *E. Yousefzadeh-Nowshahr*[1], *A. Beer*[1], *K. Sjögreen Gleisner*[2], *G. Glatting*[1];
[1]*Department of Nuclear Medicine, Ulm University Medical Centre, Ulm, GERMANY,* [2]*Medical Radiation Physics, Lund University, Lund, SWEDEN.*

Aim/Introduction: Estimating the time-activity curve (TAC) of [^{177}Lu]Lu-DOTA-TATE in organs at risk and neuroendocrine tumours (NETs) is an essential step toward individualising peptide receptor radionuclide therapy (PRRT), as it is an essential element in absorbed dose (AD) calculations. This study aims to predict the TAC of [^{177}Lu]Lu-DOTA-TATE from a [^{68}Ga]Ga-DOTA-TATE PET/CT image and population information used in a whole-body physiologically based pharmacokinetic (PBPK) model. ***Materials and Methods:*** Twelve patients with diagnosed NETs who underwent a diagnostic [^{68}Ga]Ga-DOTA-TATE PET/CT and PRRT using [^{177}Lu]Lu-DOTA-TATE were analysed. A PBPK model was implemented for [^{68}Ga]Ga-DOTA-TATE and [^{177}Lu]Lu-DOTA-TATE, including all organs and NETs [1]. Model parameters were based on literature values, direct patient-specific measurements, or estimated through a fitting procedure to measured [^{68}Ga]Ga-DOTA-TATE organ and tumour activities. Various error models were evaluated to estimate the uncertainties in the measured time-activity data. Reference TACs were determined using both [^{68}Ga]Ga-DOTA-TATE and [^{177}Lu]Lu-DOTA-TATE time-activity measurements, while predicted [^{177}Lu]Lu-DOTA-TATE TACs were estimated based solely on [^{68}Ga]Ga-DOTA-TATE PET/CT time-activity measurements. Time-integrated activities (TIAs) for several organs and tumours were calculated from predicted and reference TACs. The relative prediction error (RPE) and the mean absolute percentage error (MAPE) were calculated to assess the accuracy of the prediction. ***Results:*** The proportional data-based error model, which accounts for the different errors between organs and tumours, as well as between imaging modalities (PET/CT and planar + SPECT/CT), was the error model most supported by the data. The median errors for organs and tumours were $b_{T,Organ}$=6% and $b_{T,Tumour}$=39% for post-therapy SPECT/CT time-activity measurements, and $b_{D,Organ}$=35% and $b_{D,Tumour}$=27% for pre-therapy PET/CT time-activity measurements, respectively. In prediction assessment, the mean and standard deviation of RPE for TIAs were (-5 ± 51)%, (-4 ± 22)%, (-13 ± 40)%, and (-10 ± 21)% for tumours, kidneys, liver, and spleen, respectively. The MAPE values for tumours, kidneys, liver, and spleen were 43%, 18%, 31%, and 17%, respectively. ***Conclusion:*** The findings show that single-time-point [^{68}Ga]Ga-DOTA-TATE PET/CT imaging offers valuable prediction of TACs and TIAs in organs and tumours in [^{177}Lu]-DOTA-TATE-targeted therapy comparable to the results of Siebinga et. al. [2]. However, there is potential to improve prediction accuracy of tumours and liver. ***References:*** [1] Vasić V et al. Single-Time-Point Dosimetry using Nonlinear Mixed-Effects Modelling in Sparse [^{177}Lu]Lu-PSMA-617 Therapy Data

F. Ananda[1], *D. Hardiansyah*[1], *R. Ritawidya*[2], *A. J. Beer*[3], *N. Varmenot*[4], *L. Ferrer*[4], *G. Glatting*[3,5];
[1]*Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA,* [2]*Center for Research on Radioisotope, Radiopharmaceutical, and Biodistribution Technology, National Research and Innovation Agency (BRIN), Tangerang Selatan, INDONESIA,* [3]*Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [4]*Médecine Nucléaire, ICO René-Gauducheau, Saint-Herblain, FRANCE,* [5]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.*

Aim/Introduction: Single-time-point (STP) dosimetry for [^{177}Lu]Lu-PSMA-617 therapy using population-based model selection with nonlinear mixed-effects modeling (PBMS NLMEM) has recently emerged as a promising approach, offering improved objectivity and reproducibility in dose estimation[1]. However, its performance has not yet been evaluated in populations with sparse data—a common scenario in molecular radiotherapy due to practical limitations in data collection. Assessing the accuracy of PBMS NLMEM under such conditions is critical for its clinical adoption. Therefore, this study aims to evaluate the feasibility and accuracy of STP dosimetry using the PBMS NLMEM framework in patients undergoing [^{177}Lu]Lu-PSMA-617 therapy with sparse time-activity data. ***Materials and Methods:*** Renal biokinetic data of [^{177}Lu]Lu-PSMA-617 were collected from sixty-four mCRPC patients at (4.8 ± 0.9) h (N=60), (24.5 ± 1.5) h (N=6), (94.0 ± 6.6) h (N=16), and (128.5 ± 12.7) h (N=46) after intravenous administration. Thirteen sum-of-exponential functions (SOEF) were fitted to all-time-point (ATP) data using the NLMEM framework. Various combinations of fixed effects, random effects on uptake parameters, and strategies for handling intra-individual variability (either fixed to a reference value or estimated) were systematically evaluated. The optimal SOEF, selected through PBMS NLMEM, was then applied for STP dosimetry. The accuracy of STP-based time-integrated activity (sTIA) estimates was assessed against ATP-based references (rTIA) using relative deviations (RDs), root-mean-square errors (RMSEs), and mean absolute percentage errors (MAPEs). The performance of the PBMS NLMEM-based STP dosimetry was further compared with the STP method proposed by Hänscheid et al. [2] and a "no-time-point" approach. ***Results:*** Based on the PBMS NLMEM analysis, the function $f_{6a}(t)=A_1e^{(-(\lambda1+\lambda p)t)}+A_2e^{(-(\lambda2+\lambda p)t)}-A_3e^{(-(\lambda3+\lambda p)t)}-(A_1+A_2-A_3)e^{(-(\lambda bc+\lambda p)t)}$ with fixed λ_3 (fixed effect), and A_3 and λ_3 (random effect), with $\lambda_{bc}=\ln(2)/(1\ min)$ and $\lambda_p=\ln(2)/(6.64\ d)$, and fixed intra-individual variability, was selected as the optimal function for TIA estimation. STP dosimetry using the PBMS NLMEM at 24.5 h (RMSE: 19.2%; MAPE: 1.4%) and 94 h (RMSE: 11.1%; MAPE: 2.2%) outperformed Hänscheid's method (RMSE: 29%; MAPE: 3%) and (RMSE: 12%; MAPE: 3%) and the no-time-point approach (RMSE: 55%; MAPE: 33%). ***Conclusion:*** The PBMS NLMEM framework accurately estimates [^{177}Lu]Lu-PSMA-617 time-integrated activity from sparse biokinetic data, with optimal performance using a single SPECT/CT measurement at either 24 h or 94 h after administration. ***References:*** [1]D. A Novel Single-Time-Point Dosimetry Approach in ^{177}Lu-Labeled Somatostatin Analog Therapy: Feasibility and Clinical Validation

E. Farajzadeh[1], *M. Sadeghi*[2], *J. Aghamohammadi*[3], *M. Akbari*[1], *N. Habibi*[3], *M. Davarpanah*[3];
[1]*Secondary Standard Dosimetry Laboratory (SSDL), Pars Isotope Co., Karaj, IRAN, ISLAMIC REPUBLIC OF,* [2]*Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF,* [3]*Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Single time point dosimetry (STPD) for 177Lu-labeled somatostatin analog therapy offers a streamlined alternative to conventional multi-time point (MTP) protocols, however its accuracy and clinical applicability are still open to question. In this novel prospective study, a standardized correction-factor approach is introduced to STPD, designed to reduce measurement variability and improve the estimation of both organ and tumor-specific doses. This study aimed to determine whether this novel STPD method can provide reliable dosimetric data comparable to MTP measurements, while significantly reducing the imaging burden on patients. ***Materials and Methods:*** Twenty patients (mean age 59 ± 11 years; 13 males, 7 females) with progressive, metastatic neuroendocrine tumors were enrolled. All received a therapeutic injection of 177Lu-DOTA-peptide, followed by a single SPECT/CT scan 24±2 hours post-infusion. Time-activity data were corrected using patient-specific scaling factors from prior pharmacokinetic models. For validation, 10 patients underwent a standard MTP protocol (4, 24, 72, and 120 hours). Dose calculations were done with OLINDA/EXM (Version 2.0). Primary endpoints included accuracy of dose estimation (kidneys, liver, spleen, bone marrow, and index lesions) and potential impact on clinical decision-making. ***Results:*** The novel STPD method showed strong correlation with multi-time point dosimetry(MTPD) results (Spearman r=0.92, p<0.001). Median absolute differences in absorbed doses across organs ranged from 7% to 12%, indicating clinically acceptable agreement. The mean effective dose rate to bone marrow differed by ±9% compared to MTP data. In 18 of 20 patients (90%), STPD-based estimations did not alter treatment plans or raise safety concerns. Patients reported high satisfaction due to fewer scans and reduced hospital visits. ***Conclusion:*** These findings highlight the feasibility and clinical utility of a novel correction-factor STPD protocol in 177Lu-based radionuclide therapy. By maintaining dosimetric accuracy comparable to MTP analyses, this approach can optimize resource allocation, minimize patient burden, and facilitate broader implementation of personalized dosimetry in routine clinical practice. ***References:*** Madsen MT, Menda Y, O'Dorisio TM, O'Dorisio MS. Aim/Introduction: In Targeted Radionuclide Therapy (TRT), radiotracers are employed to selectively deliver radiation to tumor sites. However, systemic administration inevitably results in radiation exposure to healthy tissues, and treatment efficacy is closely tied to the dose actually absorbed by the tumor. Therefore, accurate and personalized dosimetry is critical to optimize therapeutic outcomes and minimize toxicity.To address this need, we propose the WIDMApp (Wearable Individual Dose Monitoring Apparatus) approach: a novel, real-time in vivo dosimetry system. It combines lightweight wearable particle detectors that continuously monitor photon emissions over several days, reconstructing Time Count Curves (TCCs), with a patient-specific Monte Carlo simulation—based on a single SPECT/CT scan—to model detector-organ geometry and compute organ-specific detection probabilities. An unfolding algorithm integrates these data to derive Time Activity Curves (TACs), allowing for organ-specific dose estimation.Until now, the WIDMApp approach has been validated through Monte Carlo simulations and phantom studies. This work presents the first feasibility study conducted on patients. ***Materials and Methods:*** The WIDMApp prototype consists of a 10-channel photon counter utilizing a lightweight (1.5×1.5 cm^2) p-terphenyl scintillator. The study was conducted on patients undergoing TRT with ^177Lu-DOTA at the IRCCS Regina Elena National Cancer Institute in Rome, where standard SPECT-based dosimetry was also performed.For this preliminary test, the detectors were not worn continuously but placed on the patient's body in a reproducible manner at multiple time points post-injection. Each acquisition session lasted approximately 30 minutes. ***Results:*** As a first-in-human feasibility study, the objective is not yet to validate the accuracy of WIDMApp-derived dosimetry against standard methods. Instead, the focus is on assessing the method's feasibility and potential. Specifically, we examine the correlation between organ activity as measured by standard SPECT and the TACs obtained via the WIDMApp system.Secondary goals include evaluating the impact of detector placement and quantity, assessing intra-patient variability, and estimating the acquisition time required for effective activity unfolding. ***Conclusion:*** The WIDMApp approach aims at revolutioning TRT efficacy by means of real-time, accurate and personalized dosimetry, using a wearable array of photons detectors and a SPECT/CT-based Monte Carlo simulation.After principle validation in Monte Carlo and phantom studies, the very first tests on patients are now ongoing, and will be presented in this contribution,providing preliminary insights into the clinical potential of this novel dosimetric approach.

Fast Patient-Specific Dosimetry for PRRT Using GPU-Accelerated Monte Carlo Simulation: A Comparative Study Between irtGPUMCD and GATE

H. Jozi[1,2], *R. Lefol*[1,2], *Y. Lemaréchal*[1,2,3], *J. M. Beauregard*[2,4,5], *P. Després*[1,2,3];
[1]*Département de physique, de génie physique et d'optique-Université Laval, Québec, QC, CANADA,* [2]*Centre de recherche du CHU de Québec-Université Laval, Québec, QC, CANADA,* [3]*Centre de recherche de l'Institut universitaire de cardiologie et de pneumologie de Québec-Université Laval, Québec, QC, CANADA,* [4]*Department of Radiology and Nuclear Medicine, and Cancer Research Centre-Université Laval, Québec, QC, CANADA,* [5]*Department of Medical Imaging, CHU de Québec-Université Laval, Québec, QC, CANADA.*

Aim/Introduction: Personalized dosimetry is critical for optimizing efficacy and minimizing toxicity in 177Lu-DOTATATE peptide receptor radiopharmaceutical therapy (PRRT) for neuroendocrine tumors (NETs). Voxel-based Monte Carlo (MC) methods remain the gold standard for internal dose calculation due to their accuracy in modeling radiation transport and tissue heterogeneity. GATE is a well-established MC toolkit but is computationally intensive, leading to long calculation times. To address this, irtGPUMCD, a GPU-accelerated MC engine derived from bGPUMCD, offers fast and accurate internal dosimetry. This study aims to benchmark and compare the performance of irtGPUMCD and GATE in generating voxel-level dose-rate maps from post-treatment

quantitative SPECT/CT images. ***Materials and Methods:*** Fifteen patients diagnosed with NETs were included in this study. Whole-body quantitative SPECT/CT images acquired at 72 hours post-administration 177Lu-DOTATATE(J3) — a clinically optimal time point for single-time-point dosimetry—were used as simulation input. Patient-specific activity and anatomical maps were imported into both GATE (v9.2) and irtGPUMCD to generate 3D voxel-level absorbed dose rate maps with associated uncertainty. For each patient, simulations were run with 5×10^9 primary particles. GATE simulations were executed on a CPU cluster using 100 parallel jobs (submitted through SLURM), while irtGPUMCD ran on a dedicated NVIDIA DGX A100 equipped with 8GPUs. Organ segmentation was performed using TotalSegmentator, which automatically delineated the kidneys, liver, spleen, and vertebra L3. The generated contours were subsequently processed to produce 3D binary organ masks. These masks were applied to the dose-rate maps from both codes, normalized to their respective maxima, to extract organ-specific dose distributions. Voxel-wise percentage differences were then computed across the entire patient volume and within each organ for global and regional comparison for two MC frameworks. ***Results:*** Under identical settings, GATE required 17 ± 1.5 hours per patient, while irtGPUMCD completed simulations in just 4.7 ± 0.1 seconds, including RTDOSE generation. Organ segmentation took 145 ± 3.2 seconds per patient for generating DICOM RTSTRUCT. The mean statistical uncertainty remained below 1% for both Monte Carlo codes across all four organs of interest (OOIs). Across the volume, 93% of voxels exhibited a percent dose difference below ±1%. Mean organ-level differences were 1.4 ± 0.8%, 2.4 ± 2.5%, 1.0 ± 0.3%, and 2.0 ± 1.0% for the kidneys, liver, vertebra_L3, and spleen, respectively, confirming strong global and regional consistency between irtGPUMCD and GATE. ***Conclusion:*** This study demonstrates that irtGPUMCD generates accurate patient-specific dose-rate maps with close agreement to GATE. Leveraging GPU acceleration, it significantly reduces computation time, suggesting high potential for clinical use in patient-specific PRRT dosimetry.

EP-1111

The Clinical Impact of Specific Activity and Precursor Mass content on Absorbed Doses to Tumours and Organs-at-risk for a novel PSMA targeting RLT

B. Fongenie[1], *N. Scott*[1], *A. Rinscheid*[2], *C. Lapa*[2], *J. Sykes*[3], *T. Mauch*[1], *D. Stevens*[1];
[1]*Blue Earth Therapeutics, Oxford, UNITED KINGDOM,* [2]*Augsburg University Hospital, Augsburg, GERMANY,* [3]*Blue Earth Diagnostics, Oxford, UNITED KINGDOM.*

Aim/Introduction: The pharmacokinetics (PK) of a radiopharmaceutical are a critical driver of safety and efficacy for radioligand therapy (RLT). It has been hypothesised that formulation properties of radiopharmaceuticals may affect absorbed doses in tumours and organs-at-risk. Despite ongoing clinical trials, a dearth of data exists in humans investigating this question. Here we analyse human data from two clinical settings across a range of specific activities and precursor masses for a novel PSMA-targeted RLT, ^{177}Lu-rhPSMA-10.1. Formulation properties, including the aforementioned, were recorded for all administrations and correlated with dosimetry results. ***Materials and Methods:*** 17 patients across two clinical experiences were included in this analysis. Given the range of activities administered (1.0GBq - 8.0GBq), activity normalized absorbed doses (D_{norm}) were calculated for each administration. These were correlated against formulation properties for each administration including specific activity and precursor mass. Linear regression and one-tailed ANOVA tests were performed. To avoid the impact of treatment response, linear regression for tumour dose was performed for all cycles and cycle 1 only. Precursor masses administered ranged from 89.5 to 667 µg. ***Results:*** Results suggest an inverse correlation between precursor mass and D_{norm}. Significant differences were observed using ANOVA testing between absorbed doses to kidneys in phase 1 patients administered ^{177}Lu-rhPSMA-10.1 manufactured at different sites (P-value<0.01) corresponding with significant differences in precursor mass. Given high interpatient variability, the effect on tumour doses was weaker. For linear regression, the R^2 for D_{norm} against precursor mass for tumour (cycle 1 only), kidney and salivary glands including Rinscheid data were 0.33, 0.63 and 0.55 respectively. Analyses of SUV_{peak} and SUV_{mean} of tumors in PSMA-PET screening scans could not explain these trends. Other properties showed weaker trends with lower R^2 values. ***Conclusion:*** An inverse correlation between precursor mass and D_{norm} was found. Although relative changes to D_{norm} were significant, absolute changes were small (e.g. for Kidney 0.3 - 0.6Gy/GBq). Conclusions from this data are limited by a small sample size, inter-patient variability in PK obscuring trends and a lack of administrations with extreme formulation properties. These results suggest it may be possible to identify an optimum formulation mass content maximizing therapeutic index. This may differ between alpha and beta labelled molecules, depending on predicted off-target toxicity. ***References:*** [1] - An Intrapatient Dosimetry Comparison of ^{177}Lu-rhPSMA-10.1 and ^{177}Lu-PSMA-I&T in Patients with Metastatic Castration-Resistant Prostate Cancer Andreas Rinscheid et al Journal of Nuclear Medicine Dec 2023, 64 (12) 1918-1924; DOI: 10.2967/jnumed.123.265970

Test-Retest Comparison of Total-Body ^{90}Y PET for Post-SIRT Dosimetry: Evaluating Scanner Performance Across Platforms

M. Santoro[1], *I. Gabucci*[1], *C. Macis*[1], *G. Della Gala*[1], *F. Bisello*[1], *F. Zagni*[1], *I. Brusa*[2], *A. Golemi*[2], *E. Lodi Rizzini*[3], *A. G. Morganti*[3,4], *S. Fanti*[2,5], *L. Strigari*[1];
[1]*Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Radiation Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [5]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY.*

Aim/Introduction: Selective Internal Radiation Therapy (SIRT) delivers ^{90}Y resin/glass microspheres to hepatocellular carcinoma (HCC) patients. Post-treatment PET/CT enables dose verification, but the low positron yield of ^{90}Y (0.0032%) might introduce variability and bias, particularly in small or low-activity regions, limiting the accurate assessment of heterogeneous dose distributions. Total-body (TB) PET/CT systems may offer improved performance, but comparative validation with digital scanners having a standard axial field of view (sAFOV) and algorithms available in the same clinical centre is essential. ***Materials and Methods:*** The ^{90}Y activity distribution derived from a TB PET/CT scanner was compared against a sAFOV digital PET/CT using a bayesian penalized likelihood reconstruction, currently adopted in our clinical practice. A NEMA phantom containing 2.97 ± 5% GBq of ^{90}Y (sphere-to-background ratio 7.8:1 across six spheres, 10-37 mm) underwent multiple acquisitions over 7 days for test-retest analysis. Eight HCC patients were imaged on both systems about 20 hours post-SIRT to evaluate cross-scanner consistency. Image quality metrics included contrast recovery (CR), background variability (BV), and CRBV index [1]. Absorbed dose estimates were compared using dose metrics and gamma index analysis. ***Results:*** The TB PET/CT scanner showed consistently higher CR and CRBV and lower BV across reconstruction algorithms compared to the sAFOV PET/CT. Phantom results demonstrated stable performance over time up to low activity levels. Patient scans revealed dose discrepancies up to 60% between scanners, with the TB system achieving greater CRBV in small lesions (<15 mm). Gamma index

analysis confirmed higher agreement at elevated dose levels (e.g., 94.62% at 312 Gy vs. 62.45% at 132 Gy), highlighting the impact of scanner sensitivity on dose distribution accuracy. ***Conclusion:*** The TB PET/CT scanner exhibits superior image quality and test-retest reliability for ^{90}Y PET, in both phantoms and HCC patients especially in small target volumes. While absorbed dose metrics were broadly similar across scanners in this cohort, the enhanced sensitivity of the TB system may provide more accurate dosimetry. Further validation against clinical outcomes such as tumor control and toxicity are ongoing in a prospective study of HCC patients. ***References:*** [1] Santoro M, Della Gala G, Paolani G, Zagni F, Civollani S, Strolin S, Strigari L. Whole-body single-time-point 177Lu-PSMA-617 lesions and bone marrow dosimetry at first cycle is significantly associated with biological and imaging outcomes

A. Dieudonne[1], *A. Terro*[2], *A. Dumouchel*[1], *S. Perret*[1], *A. Edet-Sanson*[1], *P. Vera*[1], *F. Di Fiore*[3], *L. Augusto-Pelegrin*[3], *P. Decazes*[2], *D. Tonnelet*[1];
[1]*Centre Henri Becquerel, Rouen, FRANCE,* [2]*University of Rouen Normandy, Rouen, FRANCE,* [3]*University Hospital of Rouen, Rouen, FRANCE.*

Aim/Introduction: This study investigates the relationship between whole-body lesions and bone-marrow dosimetry at first treatment cycle (C1) and biological and imaging outcomes in patients with metastatic castration-resistant prostate cancer (mCRPC) treated with 177Lu-PSMA-617. ***Materials and Methods:*** Patients were retrospectively included from January 2023 to May 2024. SPECT/CT imaging was conducted from vertex to mid-thigh using a VERITON-CT 200 scanner (Spectrum Dynamics, Haifa, Israel), from day 0 to days after infusion. Images were reconstructed using OSEM (4 subsets, 8 iterations) with attenuation and scatter corrections. To reduce uncertainty in single-time-point dosimetry, imaging delays between 20 and 120 hours were considered. Automated dosimetry was performed using SimpleDose(1): lesion and bone-marrow segmentation were performed using a nnU-Net framework, and absorbed doses were calculated via collapsed cone superposition (2). Time-integration coefficients were derived from Jackson et al. (3) for lesions and Kurth et al. (4) for bone-marrow. Response was evaluated using PSA50 (≥50% PSA reduction) and 18FDG or 68Ga-PSMA-11 PET/CT imaging, 6-8 weeks post-treatment. Blood counts were measured before and after therapy. Statistical analyses were conducted using one-tailed t-tests. ***Results:*** Thirty-one patients were analysed. Median age was 73 [IQR 8.5] years. Imaging time post-injection was 71 [22.6] hours. Baseline PSA level was 28.3 [IQR 125] ng/mL. Patients received a median of 4 treatment cycles (range: 2-6), with 7.01 [IQR 0.096] GBq/cycle. Median total lesions volume was 102 [IQR 191] mL. Nine out of 31 patients that responded to treatment had significantly higher lesion absorbed doses at C1 with 4.5 [IQR 8.4] Gy vs. 2.0 [IQR 3.3] Gy for non-responders (p=0.046). The absorbed dose associated with 50% response probability (D_{50}) was 5.0 Gy (95% CI: 3.7-6.9), and for 80% response (D_{80}), 7.8 Gy (95% CI: 6.0-10.0). Although no haematological toxicity was observed, the bone-marrow absorbed dose was positively associated with a >20% decrease in white blood cells: 0.13 [IQR 0.27] Gy vs. 0.047 [IQR 0.058] Gy (p=0.022) and a non-significant trend was observed for platelets (p=0.095). ***Conclusion:*** The absorbed dose to lesions and bone marrow after first infusion of 177Lu-PSMA-617 is associated with biological and imaging outcomes. These results also highlight the clinical value of automated dosimetry and single-time-point dosimetry for cohort studies. ***References:*** 1. Dieudonné A et al. EP-1115

Dosimetric comparison between^{177}Lu-PSMA-617 and^{177}Lu-PSMA I&T in patients with Metastatic Castration Resistant Prostate Cancer (mCRPC) using a ring-shaped CZT-based camera

L. D'Ambrosio*, F. Manna, C. Maisto, R. de Marino, A. Morisco, M. Aurilio, V. Porfidia, A. Prisco, R. De Migno, M. Raddi, F. De Lauro, F. Di Gennaro, S. Lastoria;*
National Cancer Institute IRCCS Pascale, Naples, ITALY.

Aim/Introduction: The most frequently used PSMA-targeting small-molecule inhibitors are DOTA-PSMA-617 (PSMA-617) and DOTAGA-PSMA I&T (PSMA I&T); DOTA and DOTAGA denote the cages enclosing the radionuclides and I&T denotes the radionuclide that yields both imaging and therapy. We present our dosimetric protocol to estimate organs at risk (OARs) and lesions absorbed dose during the first cycle in 10 PSMA-617 and 10 PSMA I&T patients using a CZT-SPECT imaging system ***Materials and Methods:*** Total-body SPECT-CT images, involving 5-6 consecutive bed positions (4-6 minutes/bed) were acquired at 2.5 h, 20 h, > 90 h pi using Veriton® camera (Spectrum Dynamics Medical). All SPECT images were obtained from the 113 keV (± 10%) energy peak and reconstructed with corrections for attenuation and scatter correction. The activity concentration in kidneys, parotid glands (PGs), submandibular glands (SMGs) and lesions was determined by Hermes software (Hermes Medical Solutions) and the absorbed dose was obtained using residence time and personalized organ masses as input data for the OLINDA 2.2 software. Sphere model of unit density was used for PGs and SMGs and lesions. Measurements with external probe at different time points were performed to estimate the activity within the body of the patient. The retention was modelled on a bi-exponential decay process with As and Al the constants of the short and long components and λs and λl the effective decay constants ***Results:*** Despite renal longer half-life of PSMA-617 (36.3 vs. 31.6 h), the renal dose was lower than PSMA I&T (0.29 vs. 0.61 Gy/GBq). Comparable doses to the PGs and SMGs (1.04 vs 0.87 and 0.90 vs 0.87 Gy/GBq) were measured. A large inter-patient variation in lesion kinetics and dosimetry occurred; mean absorbed doses for lesions were 5.6 (n=11) and 5.1 (n=20) Gy/GBq for PSMA-617 and PSMA I&T, respectively. The mean retention constants As and Al and mean effective half-lives of the short and long component were 0.49, 0.51 and 6.1 h, 77.5 h for PSMA-617 and 0.62, 0.38 and 6.0 h, 63.1 h for PSMA I&T ***Conclusion:*** Our data indicate that renal doses were higher for PSMA I&T, while comparable doses were measured for PGs, SMGs and lesions. PSMA I&T exhibits a faster whole-body clearance compared to PSMA-617. The use of CZT imaging system enables good quality images in shorter times than analogic cameras.

Aim/Introduction: RHN001, currently being investigated in the RHINO clinical trial, is a novel PSMA-targeting theranostic ligand

that can be radiolabelled with either ^{99m}Tc for imaging (RHN001-Dx) or ^{188}Re for therapy (RHN001-Tx), offering a generator-based alternative to PSMA radioligand therapy of patients with prostate cancer. Although ^{99m}Tc is widely accessible and cost-effective, its application in quantitative dosimetry has been limited to the performance of conventional NaI(Tl)-based SPECT systems. We evaluated the feasibility and accuracy of image-based dosimetry for ^{99m}Tc-labeled RHN001-Dx using a new-generation CZT SPECT/CT system in patients with PSMA-positive prostate cancer. ***Materials and Methods:*** Patients (n = 4) received an administered activity of 580.3 ± 86.7 MBq of RHN001-Dx. Quantitative SPECT/CT imaging was performed using the GE StarGuide CZT gamma camera at approximately 20 minutes, 2 hours, 4-6 hours, and 20-24 hours post-injection. SPECT/CT data were reconstructed using vendor-optimized parameters. Organs segmented for dosimetry included the kidneys, salivary glands, red marrow (L2-L4) estimation, and ICRP-103 whole-body effective doses. VOIs were drawn on low-dose CT and co-registered to quantitative SPECT at each time point to generate TACs. Residence times were calculated in QDOSE, and final dose estimates, including equivalent doses, were determined using OLINDA/EXM v2.2. ***Results:*** The kidneys received the highest doses (0.065 ± 0.003 mSv/MBq; median: 0.065[0.061-0.068] mSv/MBq; CV: 5.1%), followed by the salivary glands (0.036 ± 0.021 mSv/MBq; 0.032 [0.16-0.065] mSv/MBq; CV: 59.2%). Red marrow doses were lower (0.006 ± 0.001 mSv/MBq; 0.006 [0.005-0.007] mSv/MBq; CV: 13.4%), while the ICRP-103 whole-body effective doses averaged 0.008 ± 0.0007 mSv/MBq; 0.008 [0.007-0.009] mSv/MBq; CV: 10.0%. The kidneys showed the highest absolute doses, while the salivary glands demonstrated the highest inter-patient variability. The estimated effective whole-body dose ranged from 3.42 mSv-5.51 mSv, comparable in magnitude to reported values for [^{99m}Tc]Tc-PSMA I&S (3.11 mSv-4.23 mSv)[1], further supporting the dosimetric feasibility of RHN001-Dx. ***Conclusion:*** This study demonstrates the feasibility of quantitative image-based dosimetry using a CZT SPECT/CT system for RHN001-Dx. The observed dosimetric profiles are consistent with those of other ^{99m}Tc-labeled PSMA agents, reinforcing the safety and reliability of this RHN001-Dx. These results offer valuable dosimetric benchmarks for further clinical development of RHN001-Dx as part of a generator-based theranostic pair with ^{188}Re-labeled RHN001-Tx. ***References:*** 1. EP-1117

Estimation of long-term radiation toxicity risk to normal organs in radiopharmaceutical therapy.

P. McCormack[1], *Z. Mulyukov*[2], *D. Iu*[3], *F. Yang*[3];
[1]Novartis Pharmaceuticals, Manchester, UNITED KINGDOM, [2]Novartis Pharmaceuticals, Basel, SWITZERLAND, [3]Novartis Pharmaceuticals, Cambridge, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Currently accepted tolerance doses for long-term radiation toxicity are based on data from external beam radiation therapy (EBRT). These organ-specific thresholds are associated with toxicity probabilities over certain periods. The kidney limit for 23Gy implies a 5% probability of failure within 5 years. These EBRT-derived thresholds are adopted for radioligand therapy (RLT) but should be viewed as guidelines, since they are independent of the radioligand or patient population and do not account for the interindividual variability in organ absorbed doses. Additionally, these thresholds are defined for long-term toxicity, such as a 5% probability of an event occurring within 5 years, and do not consider survival rates of the treated patient population. Consequently, relying on EBRT tolerance thresholds to ensure RLT safety may lead to inaccurate assessments of toxicity risks. ***Materials and Methods:*** The proposed approach for evaluating the long-term toxicity risks is based on extrapolation of EBRT normal tissue complication probabilities (NTCP) to RLT using biological effective dose (BED). Toxicity risk is estimated as an expected value of NTCP over probability distribution of the BED for the organ at risk. The method is applied to kidney absorbed dose data from the Erasmus clinical study of ^{177}Lu-DOTATATE and compared to the clinical safety data. Simulations are conducted to assess impact of absorbed dose variability on the toxicity risk. Adjustment of maximum administered activity to match the same risk level in patient populations with different survival times is also discussed. ***Results:*** The mean kidney absorbed dose in the Erasmus clinical study (n=414) was 19±5 Gy. Despite 18.8% of patients exceeding 23Gy no treatment-related kidney failures were reported (follow-up of 78 months). Nephropathy risk estimated using EBRT NTCP for kidney absorbed dose was 5.6%, while the risk estimated with NTCP extrapolated using BED was 0.6%. The toxicity risk in treated population depends on the mean and the CV of absorbed dose. Simulations indicate with a 50% CV the 5% long-term risk is reached with mean kidney BED of 22Gy, whereas for 15% CV, same risk is reached at mean kidney BED of 32Gy. ***Conclusion:*** The interindividual variability of kidney dosimetry is a crucial factor to consider when understanding and predicting long-term kidney toxicity. The current absorbed dose threshold-based approach fail to account for this variability. The presented methodology aims to provide an estimation of population toxicity risk accounting for the probability distribution of organ BED and life expectancy of patients***:***

EP-1118

Application of post-reconstruction partial volume correction techniques for quantitative SPECT imaging of ^{225}Ac

G. Liubchenko[1], *G. Boening*[1], *M. Rumiantcev*[1], *M. Zacherl*[1], *G. T. Sheikh*[1], *S. Resch*[1], *R. A. Werner*[1,2], *S. I. Ziegler*[1,3], *A. Delker*[1];
[1]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY, [2]Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Sciences, Division of Nuclear Medicine and Molecular Imaging, Baltimore, MD, UNITED STATES OF AMERICA, [3]Clinic for Nuclear Medicine, Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: The extreme low-count regime for clinical ^{225}Ac-SPECT imaging poses a challenge to accurate quantitative SPECT imaging. Moreover, SPECT imaging suffers from partial volume effects (PVE), which can degrade quantification and lead to an underestimation of the absorbed dose estimates, especially in small lesions. The aim of this study was to investigate the impact of partial volume correction (PVC) techniques on post-therapeutic imaging of the three imageable energy windows (440, 218 and 78 keV) of ^{225}Ac. ***Materials and Methods:*** A phantom with three 3D-printed spheres (191, 100, 48 ml; foreground-to-background ratio of 8.1:1) was imaged on a Siemens Symbia Intevo T16 SPECT/CT system equipped with a HEGP collimator (16 projections per head, 128x128 pixel) to compare the impact of iterative Yang (IY)- and Richardson-Lucy (RL)-based PVC techniques, in terms of contrast-to-noise ratios (CNR) and recovery coefficients (RC). These PVC methods were also compared for a patient cohort with two SPECT/CT scans acquired (on the same imaging system as the phantom) 24 and 48 h post-injection following [^{225}Ac]Ac-PSMA-I&T therapy, to evaluate their impact on kidney and lesion dosimetry. IY-based PVC was applied to the kidneys, using the segmentations obtained from CT scans. RL-based PVC was applied to all of the lesions that were visible in the abdominal region. ***Results:*** In the phantom study, application of PVC techniques resulted in a clear increase in RC and CNR across all spheres and energy windows. The average RC increase across all spheres was 24±2% (RL) and 142±50% (IY) for 440 keV, 33±8% (RL) and 146±60% (IY) for 218 keV, and 13±2% (RL) and 98±30% (IY) for 78 keV. The average CNR increase was 10±8% (RL) and 262±130% (IY) for 440 keV, 40±10% (RL) and 274±130% (IY) for 218 keV, and 2±6% (RL) and 151±60%

(IY) for 78 keV. In the patient study, IY-based PVC increased kidney RBE-weighted absorbed doses by 172±54%, 157±45% and 146±47%, for 440, 218 and 78 keV energy windows, respectively. RL-based PVC increased lesion RBE-weighted absorbed doses by 34±6%, 29±8%, and 23±10%, for 440, 218 and 78 keV energy windows, respectively. ***Conclusion:*** The phantom and patient studies demonstrated that the use of PVC techniques substantially improved kidney (IY) and lesion (RL) quantification, highlighting their value for the post-reconstruction enhancement of ^{225}Ac SPECT images.

Bayesian individual fitting versus population fitting with non-linear mixed-effects modelling in single-time-point dosimetry: A comparative evaluation

I. Budiansah[1], *D. Hardiansyah*[1], *B. B. Patrianesha*[1,2], *S. M. B. Peters*[3], *S. Ardjo Pawiro*[1], *B. Privé*[3,4], *J. Nagarajah*[3,5], *M. W. Konijnenberg*[3,6], *A. Ambros J. Beer*[7], *G. Glatting*[7,8];
[1]Universitas Indonesia, Depok, INDONESIA, [2]Research Center for Safety, Metrology, and Nuclear Quality Technology, National Research and Innovation Agency (BRIN), Tangerang Selatan, INDONESIA, [3]Radboud University Medical Centre, Nijmegen, NETHERLANDS, [4]Department of Radiology and Nuclear Medicine, Erasmus Medical Centre, Rotterdam, NETHERLANDS, [5]Röntgeninstitut Düsseldorf, Düsseldorf, GERMANY, [6]Department of Radiation Oncology, Erasmus Medical Centre, Rotterdam, NETHERLANDS, [7]Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY, [8]Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.

Aim/Introduction: This study compares the performance of Bayesian individual fitting and Bayesian population fitting using non-linear mixed-effects modelling (NLMEM) in all-time-point (ATP) and single-time-point (STP) dosimetry. ***Materials and Methods:*** Renal biokinetic data of [^{177}Lu]Lu-PSMA-617 were collected from ten patients with low-volume metastatic hormone-sensitive prostate cancer (mHSPC) from a prospective clinical study at Radboud University Medical Centre (NCT03828838). Each patient received [^{177}Lu]Lu-PSMA-617 therapy, with an administered activity of (3.1±0.1) GBq. Five SPECT/CT scans were performed at: (2.3±0.5)h, (23.8±2.0)h, (47.7±2.2)h, (71.8±2.2)h, and (167.4±1.9) h after injection. The structural models employed in this study were based on previously published studies [1,2], The function for Bayesian individual fit was $f_{4a}(t)=A_1e^{-(\lambda1+\lambda phys)t}+A_2e^{-(\lambda2+\lambda phys)t}-(A_1 + A_2)e^{-(\lambda bc+\lambda phys)t}$, and for Bayesian NLMEM $f_{6a}(t)=A_1e^{-(\lambda1+\lambda phys)t}+A_2e^{-(\lambda2+\lambda phys)t}-A_3e^{-(\lambda3+\lambda phys)t}-(A_1 + A_2 - A_3)e^{-(\lambda bc+\lambda phys)t}$. Goodness-of-fit criteria were visual inspection, relative standard errors (RSEs) of fitted parameters < 0.5, and absolute values of the off-diagonal elements of the correlation matrix < 0.8. The reference time-integrated activity coefficients (rTIACs) were derived from the structural model with the highest Akaike weight. Leave-one-out fitting was performed in ATP dosimetry to obtain Bayesian information for both methods separately: the mean and standard deviation of individual parameters for Bayesian individual fitting and the fixed-effect, random-effects, and covariance matrix of population parameters for Bayesian NLMEM fitting. These parameters were subsequently applied as prior information to fit STP data in STP dosimetry. Root-mean-square-error (RMSE) was used to determine the optimal time point for STP dosimetry, defined as the time point with the lowest RMSE. TIACs precision was expressed as the RSE: the ratio of the standard error to the estimated TIAC. ***Results:*** Both Bayesian individual and Bayesian NLMEM fitting met the predefined goodness-of-fit criteria in ATP dosimetry. Model comparison using Akaike weights selected $f_{6a}(t)$ as the reference function. Hence, the rTIACs were derived from Bayesian NLMEM. In ATP dosimetry, TIACs were similar between methods (maximum absolute relative deviation 1.1%) with precisions of 1.8[0.1, 4.7]% (individual) and 2.3[2.2, 2.6]% (NLMEM). In STP dosimetry, the optimal time point was (47.7±2.2)h after injection for Bayesian individual (RMSE: (8.2±1.7)%) and (23.8±2.0)h after injection for Bayesian NLMEM (RMSE: (6.2±2.0)%). sTIACs precision was similar: 8.3[6.1, 9.7]% vs. 7.3[8.6, 9.4]%. ***Conclusion:*** In ATP fitting, both methods yielded comparable TIACs with high precision. In STP dosimetry, each method identified a different optimal time point, with Bayesian NLMEM showing lower RMSE, suggesting reduced sensitivity to outliers. ***References:*** 1.Hardiansyah et al., J Nucl Med, 20242.Patrianesha et al., Physica Medica, 2025

EP-1120

Impact of Temporal Sampling and Software Tools on Dosimetry in Radioligand Therapy

S. Peric[1], *M. Avanzo*[1], *A. Drigo*[1], *C. Avigo*[1], *G. Pirrone*[1], *L. Barresi*[1], *G. Fanetti*[2], *E. Borsatti*[3], *A. Dassie*[1];
[1]Medical Physics Department, Centro di Riferimento Oncologico di Aviano, IRCCS, Aviano, ITALY, [2]Radiation Oncology Department, Centro di Riferimento Oncologico di Aviano, IRCCS, Aviano, ITALY, [3]Nuclear Medicine Department, Centro di Riferimento Oncologico di Aviano, IRCCS, Aviano, ITALY.

Aim/Introduction: Dosimetry in radioligand therapy is based on Time Activity Curve (TAC) assessment and Time Integrated Activity (TIA) calculation. The estimation of TIA depends on the measurement time points and its uncertainty is often overlooked. Accurate assessment of TIA uncertainty is essential to balance therapeutic efficacy and organ protection. The purpose of this work was to evaluate the impact of different software and time point combinations in calculated TAC and TIA. ***Materials and Methods:*** This retrospective study included four patients with somatostatin receptor positive gastroenteropancreatic neuroendocrine tumors, treated with Lutetium-177 DOTATATE between February and December 2024. The dosimetric evaluation focused on right, left kidney and target. SPECT-CT imaging was performed at four time points (TPs), during the first and fourth therapy cycles (TP-1 4h±1h, TP-2 24h±2h, TP-3 48h±2h, and TP-4 168h±30h). TACs were modeled using best-fitting mono- and bi-exponential functions. Uncertainty of calcualted TIA were estimated by combining uncertainties associated with measurements and fitting procedure. The analysis was performed with two commercial software tools: OLINDA and MIM SurePlan, and a custom routine developed in MATLAB. Goodness-of-fit metrics Squared Error (SE), R^2 were used to evaluate TAC models, and Akaike Information Criterion (AIC) was used for selection of models in MIM and MATLAB. TIAs were also calculated using fewer TP, and their relative differences against the baseline 4-points TIA were evaluated. ***Results:*** Metrics for goodness of fit were generally high for baseline with SE = (0.000120 ± 0.0040), R^2 = (0.998 ± 0.016) for OLINDA, AIC = (2.22 ± 48.0), R^2 = (1.00 ± 0.059) for MIM SurePlan, and AIC = (–33.0 ± 59.0), R^2 = (0.996 ± 0.019) for MATLAB. After reducing points, TP-234 yielded the most accurate results across all software according to the median and standard deviation of the TIA relative difference: OLINDA: 0.06 ± 1.59, MIM SurePlan: 0.02 ± 0.11, MATLAB: -0.09 ± 0.20. Among the two-point combinations, TP-24 provided the most robust performance, with relative differences of OLINDA: 0.07 ± 0.26, MIM SurePlan: -0.08 ± 0.12, MATLAB: -0.04 ± 0.19. Error analysis proved critical to assess result reliability. Kruskal-Wallis test results confirmed no statistically significant differences in TIA among software at the 0.05 significance level. ***Conclusion:*** The study confirms that dosimetry can be performed with reduced number of time points. Moreover, multiple software platforms can be reliably used for TIA estimation. Despite the small sample, the findings provide a useful basis for refining clinical workflows. Further validation in larger populations are essential next steps.

EP-1121

GPU-Accelerated Monte Carlo Dosimetry for Yttrium-90 and Holmium-166 Radioembolization: Validation of Torch MC Against Geant4 in Heterogeneous Anatomies

O. Kwon[1], *J. Grudzinski*[1,2], *B. Bednarz*[1,2], *P. Wickre*[2];
[1]University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, [2]Voximetry, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Monte Carlo (MC) dosimetry is critical for optimizing Yttrium-90 (Y-90) and Holmium-166 (Ho-166) radioembolization therapies, addressing limitations of traditional methods in modeling patient-specific anatomy and radiation transport. Studies confirm MC's superiority in predicting absorbed doses, improving tumor control while reducing toxicity risks, especially in the lung. Advanced MC-based personalized dosimetry enables more effective and safer treatment planning for liver cancer therapies. ***Materials and Methods:*** Torch MC was validated against Geant4 for Y-90 and Ho-166 dosimetry using the ICRP 110 adult male phantom. Three validation approaches were employed: (1) Monoenergetic testing compared Torch's GPU-accelerated δ-scattering and Geant4's physics models, evaluating voxel-level absorbed doses against established S-values. (2) Spectral validations utilized ICRP 107 and IAEA decay spectra-based simulations, assessing Torch's per-decay sampling accuracy relative to Geant4. (3) Patient-specific evaluations were performed using clinical male patient data (128^3 voxels), comparing Torch's GPU-based calculations (RTX 3070 GPU, <5 minutes runtime) to Geant4's CPU-based simulations (~5 hours runtime). Agreement was quantitatively assessed, particularly at heterogeneous regions (e.g., liver-lung interfaces). ***Results:*** Monoenergetic validation demonstrated excellent agreement, with voxel-level dose distribution deviations of 0.12% for beta emissions and 3.36% for gamma emissions within Y-90 and Ho-166 energy ranges. S-value calculations for critical source-target pairs aligned closely, validating Torch's physics models for therapeutic radionuclides. In spectral validation tests, Torch MC and Geant4 showed deviations with using ICRP 107 and IAEA spectra, 0.20% and 1.65% for liver and -2.60% and -3.45% for lung regions, respectively. Particularly for Ho-166's low-energy gamma emissions (32-81 keV), where tissue interface effects were accurately resolved. Patient-specific evaluations verified robust dose agreement in heterogeneous anatomical regions, including liver-lung interfaces, yielding organ-level S-value differences of Y-90 and Ho-166 with 1.05% and -3.88% in liver and 5.43% and 1.81% in lung regions, respectively, supporting Torch's clinical reliability. ***Conclusion:*** This study demonstrated that Torch MC achieves comparable accuracy to Geant4 in Y-90 and Ho-166 dosimetry, with <3.36% deviations in monoenergetic comparisons, <3.45% in spectral validations, and <5.43% in patient-specific organ-level S-value assessments. The GPU-accelerated framework reduced computation times, enhancing clinical applicability. These results validate Torch's potential for personalized radioembolization treatment planning, particularly in anatomically heterogeneous regions such as liver-lung interfaces. Future work should expand validation to multicenter patient cohorts and explore real-time adaptive dosing strategies**.** ***References:*** S. Agostinelli et al., NuclInstrumMeth. (2003). J. Allison et al., IEEETransNuclSci. (2006). J. Allison et al., NuclInstrumMeth. (2016). A. Besemer et al., CancerBiotherRadiopharm. (2018). A. Capotosti et al., ApplSci. (2024).

One-Minute 360° CZT SPECT Enables Reliable Organ Dosimetry for ^{90}Y-SIRT Planning

Z. Mansouri*, Y. Salimi, N. Bianchetto Wolf, I. Mainta, V. Garibotto, H. Zaidi;*
Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: The aim of this work was to establish the optimal scan time for ^{90}Y-selective internal radiation therapy (SIRT) planning with pretreatment ^{99m}Tc-MAA SPECT using 360°cadmium-zinc-telluride (CZT) solid-state detector technology. ***Materials and Methods:*** Twenty patients (12 Male, 8 Female; BMI range, 21.3-30.4 kg/m^2) underwent a pretreatment ^{99m}Tc-MAA SPECT, each with a 6-min/bed (average 4 beds) acquisition on a 360° CZT SPECT camera following the injection of an average ± SD of 125.5 ± 40.2 MBq. All images were reconstructed from list-mode raw data to obtain scan durations of 1 min/bed, 2 min/bed, etc., up to a maximum of 6 min/bed. For each of the scan durations, organ and multi-compartment voxel-level dosimetry was conducted using the local energy deposition method. The dosimetric results of the short duration scans were compared to those of the full duration (6min/ bed) serving as standard of reference using quantitative metrics, including region- and voxel-level absolute error (RAE, %), mean absolute error (MAE, Gy) and gamma evaluation with the criteria of 2.46 mm distance to agreement and 5% dose difference. ***Results:*** The voxel-level RAE decreased from 78.4% with 1 min/bed acquisition to 23.2% at 5 min/bed, respectively. Lesion and whole normal liver (WNL) RAEs were less than 1% for all acquisition times, with the highest being 0.53% for the 1-minute per bed scan, with corresponding MAE of less than 0.09 Gy. Gamma analysis showed that lesion pass rates increased from 41.2% at 1 min/bed to 88.3% at 5 min/bed, while WNL pass rates improved from 87.2% to 99.33%. ***Conclusion:*** Shorter scan times can significantly enhance patient comfort, reduce motion-related artifacts, and improve clinical workflow efficiency only without sacrificing the reliability of treatment planning dosimetry. In this study, we attempted to find an optimized scan time according to organ- and voxel-level metrics. The results showed that 1 min/bed acquisition using 360° CZT SPECT enables clinically acceptable organ-level dosimetry for ^{90}Y-SIRT planning. In contrast, for voxel-level dosimetry, this time reduction may not provide accurate dose maps evaluated by both voxel error and relevant gamma pass rates.

EP-1123

Motion corrected PET compared to static PET in post ^{90}Y resin TARE imaging: Potential towards improved ^{90}Y dosimetry

M. W. M. van Wijk*, C. D. E. Van Speybroek, M. G. J. de Bakker, J. Roosen, M. J. R. Janssen, S. M. B. Peters, J. F. W. Nijsen;*
Department of Medical Imaging, Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim/Introduction: A dose-response relationship is well established in transarterial radioembolization (TARE), highlighting the importance of accurate pre- and post-treatment dosimetry. Current yttrium-90 (^{90}Y) imaging methods remain limited by factors such as motion artefacts, which may compromise assessment of microsphere distribution, especially at the lesion level. One approach that may improve image quality and treatment evaluation is motion corrected PET. In this study, motion corrected ^{90}Y PET reconstructions are compared to standard static ^{90}Y PET, with the aim of exploring their potential contribution to more precise dosimetry. ***Materials and Methods:*** Patients planned for standard clinical treatment using ^{90}Y resin TARE were eligible to participate in this study. They were scanned using a reflector block to track their breathing. In addition to the standard static reconstructions, a motion corrected ^{90}Y PET was reconstructed. Anatomical manual segmentation and thresholding was performed to evaluate the count differences and the spill out between static and motion corrected PET. Manual segmentation was performed using low dose CT and arterial enhanced CT or MRI as a reference. Thresholding was performed using Otsu's method on the PET signal. The tumour to normal (T/N) ratio was determined using the mean counts in the tumour and the whole liver. ***Results:*** From November 2024 to April 2025, PET scans from six patients that received ^{90}Y resin TARE were reconstructed both static and motion corrected. Three patients were analysed so far, which received 1.37, 1.91 and 2.40 GBq of ^{90}Y resin microspheres, respectively. Treated lesions had a volume of 174, 146 and 13 mL on CT. Thresholding resulted in a mean treated volume of 122, 144 and 25 mL for thresholding static ^{90}Y PET, and 113, 136 and 14 mL for gated ^{90}Y PET. The spillout differences could also be appreciated visually. T/N ratio was 49, 11 and 12 for static yttrium PET and 46, 11 and 11 for motion corrected ^{90}Y PET respectively. Inclusion

and additional analysis is ongoing. ***Conclusion:*** This study aims to evaluate the added value of motion corrected ^{90}Y PET on ^{90}Y TARE dosimetry. Preliminary analysis shows a difference between the estimated treated volume of motion corrected compared to static reconstructions indicating reduced spillout, due to reduced respiratory motion artefacts. Future findings among more patients and a more extensive analysis including DVHs of the tumours might give more insight in the influence and added value of motion corrected ^{90}Y PET on ^{90}Y dosimetry.

Gastro-intestinal LuPSMA scintigraphy uptake patterns and dosimetry in patients with metastatic prostate cancer treated with LuPSMA: a single center retrospective study

V. Ludwig[1], *Z. Ells*[1], *C. Meyer*[1], *L. M. Unterrainer*[1,2], *P. G. Maliha*[1,3,4], *T. Grogan*[1], *M. Dahlbom*[1], *J. Czernin*[1], *J. Calais*[1];
[1]UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]LMU Klinikum München, Munich, GERMANY, [3]Centre Hospitalier de l'Université de Montréal Centre de Recherche, Université de Montréal, Montréal, Montreal, QC, CANADA, [4]Centre Hospitalier de l'Université de Montréal, Montreal, QC, CANADA.

Aim/Introduction: Gastrointestinal (GI) adverse events are common after [^{177}Lu]Lu-PSMA radioligand therapy (RLT) in metastatic prostate cancer, including nausea (35%), vomiting (19%), constipation (20%), and diarrhea (19%)[1]. LuPSMA planar scintigraphy and SPECT imaging allow visualization of GI biodistribution post-therapy. This study investigates correlations between GI uptake patterns over time and absorbed dose estimates in bowel segments, and their relationship to GI adverse events. ***Materials and Methods:*** A retrospective analysis was performed on 43 patients from the Phase 2 RESIST-PC trial (NCT03042312). GI symptoms before and after the first [^{177}Lu]Lu-PSMA-617 cycle were documented. Scintigraphy included planar imaging at +4h, +24h, +48h, +72h, and +96-168h, and SPECT/CT at +24h. A camera-specific calibration factor was applied. OSEM reconstruction (48 iterations, 1 subset, no filtering) with scatter and attenuation correction was done using MIM SPECTRA. Absorbed dose estimates were derived from hybrid planar + SPECT/CT data using MIM SurePlan (7.3.5). Three readers scored anterior planar images visually using a 0-4 uptake scale (0: no uptake; 4: ≥3× liver/syringe). The GI tract was divided into six segments: duodenum (D), small bowel (SB), ascending (AC), transverse (TC), descending colon (DC), and rectosigmoid (RS). Segments were manually contoured on CT at +24h, and time-integrated activity curves were fit using trapezoidal integration. ***Results:*** New GI symptoms occurred in 24/43 patients (56%): constipation (21%), nausea (28%), diarrhea (19%), vomiting (7%), soft stool (5%), and gas (2%). High duodenal uptake at 24h and 72h correlated most with symptom development (AUC 0.73 and 0.63). Uptake elsewhere showed weaker predictive value (AUC 0.50-0.54 per time; 0.53-0.60 per location). Inter-reader agreement was moderate (Fleiss' Kappa 0.272, ICC 0.508). In the first 7 patients with dosimetry data processed and available, the median (range) absorbed to the small bowel, ascending colon, transverse colon, descending colon and rectosigmoid were 1.21 (0.70-1.81), 1.49 (0.95-2.85), 1.59 (0.29-9.75), 1.63 (0.26-8.97) and 0.92 (0.20-5.69). ***Conclusion:*** In this series of 24 patients, the [^{177}Lu]Lu-PSMA GI uptake patterns did not correlate with development of new GI symptoms after first cycle of RLT. ***References:*** Sartor O, de Bono J, Chi KN, et al. Feasibility of single-time-point dosimetry application in ^{177}Lu -DOTATATE/DOTATOC-treated pediatric neuroblastoma

X. Sun[1], *F. Zheng*[1], *X. Sun*[2];
[1]Department of Nuclear Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA, [2]Department of Nuclear Medicine, Shandong Cancer Hospital and Institute, Jinan, CHINA.

Aim/Introduction: ^{177}Lu-DOTATATE/DOTATOC peptide receptor radionuclide therapy (PRRT) has demonstrated potential for treating pediatric neuroblastoma (NB)[1], and in clinical practice can be measured dosimetry by multi-time-point dosimetry (MTP)[2]. However, the high workload and limited patient compliance associated with MTP restrict its application. Consequently, single-time-point dosimetry (STP) approaches have emerged as a promising alternative[3,4], though their effectiveness in pediatric populations has not been thoroughly investigated. This study aimed to assess the dosimetric determination of ^{177}Lu-DOTATATE/DOTATOC in pediatric neuroblastoma patients to determine whether STP could serve as a viable replacement for MTP. ***Materials and Methods:*** A total of 24 pediatric NB patients who received 1-2 cycles of ^{177}Lu-DOTATATE or ^{177}Lu-DOTATOC underwent dosimetric measurement of lesions and critical organs using the 96 h single-time point dosimetry (STP_H) method proposed by Hänscheid et al[4]. The results were compared with those obtained from standard MTP. ***Results:*** In patients treated with ^{177}Lu-DOTATATE, the mean relative deviation absolute values of the STP_H-calculated absorbed dose from MTP were <10% for lesions, kidneys, bone marrow, liver, and spleen, with Pearson's correlation coefficients of 0.99, 0.93, 0.97, 0.84, and 0.84, respectively. In patients treated with ^{177}Lu-DOTATOC, the mean relative deviation absolute values for kidneys, spleen, and bone marrow were <10%, with Pearson's correlation coefficients of 0.97, 0.77, 0.35, 0.48, and 0.93 for lesions, kidneys, bone marrow, liver, and spleen, respectively. ***Conclusion:*** The findings confirm that the 96 h STP_H method can reliably replace MTP for dosimetric assessment in pediatric NB patients treated with ^{177}Lu-DOTATATE and performed well in renal dosimetry for ^{177}Lu-DOTATOC therapy. ***References:*** [1] Fathpour G, Jafari E, Hashemi A, et al. EP-1126

Fast and reliable response evaluation of [^{177}Lu]Lu-PSMA-I&T therapy using between-cycle [^{177}Lu]Lu-SPECT/CT scanning

V. Nuttens, *D. Ooms, M. Koole;*
AZORG, Aalst, BELGIUM.

Aim/Introduction: Post-therapy SPECT/CT imaging is gaining importance for assessing total tumor volume (TTV) and total lesion activity (TLA) as early prognostic biomarkers of treatment response during [^{177}Lu]Lu-PSMA-I&T therapy. This study compares

the interobserver agreement of an optimized semi-automatic segmentation method to a manual approach for longitudinal assessment of TTV and TLA using post-therapy SPECT/CT scans. ***Materials and Methods:*** Six patients underwent four cycles of [^{177}Lu]Lu-PSMA-I&T therapy, with post-therapy SPECT/CT scans acquired 19 ± 1.5 hours after each cycle using a 3D CZT system. For the manual method, lesions were visually identified and delineated using an edge detection method. The semi-automatic approach applied global SUV thresholds from 2 to 10, followed by manual removal of physiological uptake. For all (3) expert readers, segmentation times were recorded and reliability between observers was assessed using the intraclass correlation coefficient (ICC(2, 1)) for TTV and TLA and Fleiss' kappa score (kF) for therapy response evaluation based on between-cycle TTV and TLA changes. In addition, TTV and TLA correlations between the manual and semi-automatic method were evaluated for each SUV threshold as well as the different types of errors between manual and semi-automatic identification of disease progression. ***Results:*** Manual segmentations took 6.8 minutes per SPECT/CT, while semi-automatic segmentations were performed in less than 1 minute, regardless of SUV threshold. For the manual segmentations, an ICC(2, 1) = .57 was obtained for TTV and a kF = .38 for TTV-based response evaluation. TLA and TLA-based response evaluation showed a higher interobserver agreement of ICC(2, 1) = .92 and kF = .73 respectively for the manual segmentations. For the semi-automatic segmentations, TTV and TLA and TTV- and TLA-based response evaluation showed perfect interobserver agreement except for an SUV threshold of 2 and 3 (kF = .91). An SUV threshold of 8 showed the highest correlation and agreement with manual TLA and TLA-based response evaluation, with one non-responder misclassified as a responder compared to two non-responders misclassified as a responder for an SUV threshold of 3. ***Conclusion:*** A manual TLA-based response assessment demonstrated much higher interobserver agreement than manual TTV-based response evaluation. Meanwhile, a threshold-based semi-automatic segmentation approach is fast and reliable for assessing TTV and TLA changes longitudinally. An SUV threshold of 8 showed the highest correlation with manual TLA and TLA-based response evaluation, making it the recommended approach for clinical follow-up of [177Lu]Lu-PSMA-I&T patients with [177Lu]Lu-SPECT. ***References:*** [1] 10.1007/s00259-023-06536-2 [2] 10.2967/jnumed.122.264677 [3] 10.2967/jnumed.122.264398

Aim/Introduction: Accurate dosimetry is essential for optimizing the safety and efficacy of transarterial radioembolization (TARE) in liver tumor treatment. This study compares predosimetric absorbed dose (pre-AD) values, calculated using the Partition Model-Based Method (PMBM) from ^{99m}Tc-MAA SPECT/CT, with postdosimetric absorbed dose (post-AD) values, derived from voxel-based analyses of post-treatment ^{90}Y-SPECT/CT, in patients treated with resin microspheres. ***Materials and Methods:*** This retrospective study included 76 consecutive patients treated with TARE using resin microspheres between 2023 and 2024. All patients underwent pre-treatment ^{18}F-FDG PET/CT and ^{99m}Tc-MAA SPECT/CT, followed by post-treatment ^{90}Y-SPECT/CT. Viable metabolic tumor and perfused volumes were calculated from ^{99m}Tc-MAA SPECT/CT, guided by recent ^{18}F-FDG PET/CT. ^{99m}Tc-MAA SPECT/CT images were analyzed in conjunction with ^{18}F-FDG PET/CT images. Multiple regions of interest were delineated across various slices, and their mean values were calculated, tumor-to-normal tissue (T/N) ratios, lung shunt percentages, and other relevant parameters were determined and entered into an Excel-based template for the Partition Model-Based Method (PMBM) to compute predicted absorbed dose values. Following treatment, personalized postdosimetric absorbed dose values were calculated using voxel-based NUKDOS software from ^{90}Y-SPECT/CT images. These values were compared across all cases for the perfused tumor, whole healthy liver, and both lung parenchyma. ***Results:*** Significant differences were observed between pre-AD and post-AD values for perfused tumor, whole healthy liver, and lung parenchyma ($p<0.001$; Table-1). Correlation analyses revealed a very strong correlation for lung parenchyma ($r=0.954$, $p<0.001$), a strong correlation for perfused tumor ($r=0.722$, $p<0.001$), and a moderate correlation for whole healthy liver ($r=0.59$, $p<0.001$). Notably, pre-AD values for healthy liver and perfused tumor were higher than post-AD values in 78% (n=59/76) and 76% (n=58/76) of cases, respectively. ***Conclusion:*** Accurate dosimetry is critical for assessing toxicity risks (healthy liver and lung parenchyma) and therapeutic efficacy (perfused tumor) in TARE, particularly for repeated treatments. This study revealed a moderate correlation between predosimetric absorbed dose (pre-AD) values, calculated using the Partition Model-Based Method (PMBM), and voxel-based postdosimetric absorbed dose (post-AD) values derived from post-treatment 90Y-SPECT/CT images, particularly for the whole healthy liver. Notably, in approximately 75% of cases, pre-AD values for both perfused tumor and whole healthy liver exceeded post-AD values. These findings suggest that PMBM may overestimate doses, potentially limiting its reliability for pre-treatment assessment of treatment efficacy and toxicity risks.

Estimation of Renal Time-Integrated Activity of [^{177}Lu]Lu-PSMA-I&T Using Single-Time-Point [^{68}Ga]Ga-PSMA-HBED-CC PET/CT and Physiologically-Based Pharmacokinetic and Population-Based Pharmacokinetic Modeling

D. Hardiansyah[1], *A. Riana*[1], *E. Yousefzadeh-Nowshahr*[2], *A. Allmann*[3], *A. J. Beer*[2], *M. Eiber*[3], *G. Glatting*[2];
[1]*Universitas Indonesia, Depok, INDONESIA,* [2]*Ulm University, Ulm, GERMANY,* [3]*Technische Universität München, Munich, GERMANY.*

Aim/Introduction: Minimising imaging sessions in molecular radiotherapy can reduce patient burden and streamline clinical workflows. Recent approaches integrating population pharmacokinetics with non-linear mixed-effects modelling (NLMEM) and physiologically based pharmacokinetic (PBPK) models offer a promising framework for accurate dosimetry using only single-time-point (STP) data. This study investigates the feasibility and accuracy of estimating time-integrated activity (TIA) for [^{177}Lu]Lu-PSMA-I&T therapy using pre-therapeutic [^{68}Ga]Ga-PSMA-HBED-CC PET/CT data within a PBPK-NLMEM framework. ***Materials and Methods:*** Thirteen patients with metastatic prostate cancer underwent [^{68}Ga]Ga-PSMA-HBED-CC PET/CT imaging before receiving [^{177}Lu]Lu-PSMA-I&T therapy. PET/CT was performed at approximately (0.9 ± 0.1) h after injection ((115 ± 16) MBq, (1.6 ± 0.3) nmol). Post-therapeutic planar whole-body scintigraphy data were acquired at multiple time points: (1.1 ± 0.7) h, (20.7 ± 2.3) h, and (163.8 ± 2.0) h post-injection, with additional measurements available for selected patients. A PBPK model [1] was fitted to the full biokinetic dataset to compute reference TIAs (rTIAs) for the kidneys, tumors, and whole body. STP-derived TIAs (sTIAs) were estimated by refitting model parameters to PET data from one patient at a time using the jackknife approach, with remaining patient data informing the population-level model. Relative deviations (RDs) between sTIA and rTIA were assessed. To improve the accuracy of tumor sTIA estimation, a functional relationship between tumor receptor density and the ratio of rTIA to sTIA was derived from the PBPK model. This relationship was then used to predict individual sTIA values in each patient using

a leave-one-out cross-validation approach. ***Results:*** Renal sTIA values derived from a single PET/CT measurement at (0.9 ± 0.1) h after injection closely matched rTIA estimates, with a mean RD of 5% ± 12%. In contrast, tumor and whole-body estimates showed a larger variability: Tumor 1 (44% ± 156%), tumor 2 (75% ± 270%), and whole body (-8% ± 27%). Utilising the relationship of tumor receptor density and the ratio of rTIA to sTIA markedly improved individual tumor sTIA estimation, reducing RDs to -1% ± 31% and 0% ± 44% for tumors 1 and 2, respectively. ***Conclusion:*** Accurate renal TIA estimation is achievable from a single PET/CT scan acquired approximately one hour after injection. While tumour and whole-body predictions showed higher variability, incorporating receptor density significantly improved tumour dosimetry. These findings underscore the potential of combining STP imaging with PBPK-NLMEM approaches to enable simplified yet reliable dosimetry in [^{177}Lu]Lu-PSMA-I&T therapy. ***References:*** Kletting P, Schuchardt C, Kulkarni HR, et al. PLoS One. 2016;11:e0162303.

Few-Time-Points Non-Linear Mixed-Effects Dosimetry: Accuracy and Precision of [^{177}Lu]Lu-PSMA-617 in Kidneys

A. Hakim[1], *D. Hardiansyah*[1,2], *E. Yousefzadeh-Nowshahr*[2,3], *U. Nemer*[4], *R. Ritawidya*[1,5], *F. Kind*[4], *A. J. Beer*[3], *P. T. Meyer*[4], *G. Glatting*[2,3], *M. Mix*[4];
[1]*Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA,* [2]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [3]*Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [4]*Department of Nuclear Medicine, Medical Center – University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [5]*Research Center for Radioisotope, Radiopharmaceutical, and Biodosimetry Technology, National Research and Innovation Agency (BRIN), Tangerang Selatan, INDONESIA.*

Aim/Introduction: This study aims to evaluate the accuracy and precision of few-time-points (FTP) calculations of time-integrated activity (TIA) in kidneys for [^{177}Lu]Lu-PSMA-617 by applying non-linear mixed-effects (NLME) modeling. ***Materials and Methods:*** Biokinetic data from the kidneys of 63 patients with metastatic castration-resistant prostate cancer undergoing their first treatment cycle with [^{177}Lu]Lu-PSMA-617 were analyzed. SPECT/CT imaging measurements were conducted at five time points (TP): TP1 = (1.8±0.8)h, TP2 = (18.7±0.9)h, TP3 = (42.6±1.0) h, TP4 = (66.3±0.9)h, and TP5 = (160.3±24.2)h after injection. A four-exponentials function incorporating six adjustable parameters: $f(t)=A_1e^{-(\lambda1+\lambda p)t}+A_2e^{-(\lambda2+\lambda p)t}-A_3e^{-(\lambda3+\lambda p)t}-(A_1+A_2-A_3)e^{-(\lambda bc+\lambda p)t}$ with $\lambda p=\ln(2)/(6.6443\ d)$ and $\lambda bc=\ln(2)/(1\ min)$ identified as the best model for the data [1] was used in this study. Reference time-integrated activities (rTIAs) were obtained by fitting the four-exponentials function parameters to all-time-point (ATP) data within the NLME framework. Estimated time-integrated activities (eTIAs) were computed by fitting FTP data, comprising combinations of one, two, three, and four time points from the biokinetic dataset. The accuracy of FTP-NLME-derived eTIAs was evaluated through root-mean-square errors (RMSEs) and mean-absolute-percentage errors (MAPEs) associated with the relative deviation between eTIAs and rTIAs. The precision of individual rTIAs and eTIAs derived from each FTP-NLME combination was assessed by analyzing the coefficient of variation (CV) and their standard deviation of the TIAs. ***Results:*** RMSEs and MAPEs for each optimal TP combination were (11.0±1.7)% and (7.2±1.7)% for TP3, (6.5±1.1)% and (4.8±0.9)% for TP25, (3.9±0.7)% and (2.3±0.7)% for TP135, and (1.4±0.6)% and (0.9±0.6)% for TP1235. The %CV values of individual TIAs were (17.0±5.3)% for TP3, (8.5±2.3)% for TP25, (6.3±1.1)% for TP135, (5.1±0.7)% for TP1235, and (4.4±0.7)% for ATP. ***Conclusion:*** The accuracy and precision of various FTP methodologies were evaluated, enabling the determination of the optimal number of measurements required based on the desired accuracy and precision. This study demonstrates that using TP3 in STP, 2TP, 3TP, or 4TP results in greater accuracy and precision compared to other TPs in calculating individual TIAs for [^{177}Lu]Lu-PSMA-617 therapy. ***References:*** [1] Hardiansyah, D., Yousefzadeh-Nowshahr, E., Kind, F., Beer, A. Assessing the Feasibility of Early Post-Treatment Dosimetry in 166Ho Radioembolization

A. Didonna[1,2], *G. Muti*[2], *C. Romano*[2], *S. Capitanio*[2], *C. Carbonini*[2], *C. Rossetti*[2], *P. E. Colombo*[2];
[1]*Università degli Studi di Milano, Milano, ITALY,* [2]*ASST Grande Ospedale Metropolitano Niguarda, Milano, ITALY.*

Aim/Introduction: 166Ho radioembolization is a radiotherapy in which radioactive 166Ho-microspheres are administered through a microcatheter directly into the tumor. Using the γ-emission at 80.6keV, the 166Ho-microspheres distribution can be imaged with SPECT/CT for dosimetry in pre-treatment and post-treatment phases. This study explores the feasibility of post-treatment dosimetry one day after patient treatment, assessing potential high count rate's influence on quantitative accuracy. Different calibration-VOIs, tumor-VOIs and voxel-dosimetry calculation methods are considered. ***Materials and Methods:*** A cohort of four patients was treated using holmium spheres with injected activities in the range 1GBq-6GBq. A SPECT/CT scanner was used to perform a first acquisition at the patient's discharge, 24-hours post-injection, and a second acquisition 4-5 days post-injection, following vendor's guidelines. A triple energy-window method was employed for scatter correction, with a main window around 80.6keV (15%-width) and two scatter windows (71.69keV, 90.32keV; 8%-photopeak-width). A calibration factor based on the injected activity and the counts in four calibration VOIs (2-cm-superiorly-extended-liver, 2%-maximum-threshold, 10%-maximum-threshold, liver-and-lungs-union) was calculated. The tumor-VOI was obtained as the co-registered pre-treatment and as the post-treatment-maximum-threshold-VOI matching the tumor volume. The dedicated vendor's dosimetry software was used for dose-point-kernel and local-dose-deposition reconstructions. Average doses in the liver, lungs and tumor were registered. ***Results:*** The average doses computed using the 2%-maximum-threshold, 2-cm-superiorly-extended-liver and liver-and-lungs-union VOIs for calibration show good agreement, while the 10%-maximum-threshold (used in the pre-treatment phase) overestimates the doses. The consistency of the measured count rates at varying activities with the paralyzable-dead-time model and the variation of calibration factors based on acquisition-time activity indicate that dead-time leads to a progressive count loss with increasing activity. The computed average doses in the liver and lungs are compatible $|D_(4/5days)/D_24h-1|<0.1$. The tumor average dose ratio is consistently less than 1 with co-registration, while for post-treatment maximum-thresholding the outcomes vary. The dose-point-kernel and local-dose-deposition methods provide comparable results ($|D_ldm/D_dpk-1|<0.11$). ***Conclusion:*** The study suggests the feasibility of 24-hours post-injection dosimetry in the liver and lungs, despite count rate saturation evident in count rate and calibration factor measurements.

EP-1131

Is 1D Whole-Body Dosimetry Still Worth It? A Pilot Study on Red Marrow Dose Estimation in [^{177}Lu]Lu-DOTATATE Therapy

T. Kracmerova[1,2], *J. O. Zmek*[1], *D. Prchalova*[1], *S. Buresova*[1], *A. Kenova*[1], *T. Rehacek*[1];
[1]*Motol University Hospital, Prague, CZECH REPUBLIC,* [2]*Military University Hospital, Prague, CZECH REPUBLIC.*

Aim/Introduction: As the number of patients treated with [^{177}Lu]Lu-DOTATATE (Lutathera®) increases, so does the need for personalized dosimetry. However, standard protocols are often time consuming and resource intensive. This pilot study evaluates the relationship between whole-body absorbed dose and mean absorbed dose to red bone marrow (RBM) using a simplified, non-

invasive. Based on dose rate monitoring and SPECT/CT imaging, we aim to develop a clinically feasible approach for individualised treatment planning. ***Materials and Methods:*** This retrospective pilot study included 14 patients (8 female, 6 male, mean age 64 years, range 40-77) who underwent [^{177}Lu]Lu-DOTATATE therapy with a total of 54 administrations. Each patient received 3-4 cycles of 7.4 GBq (range 4209-7534 MBq); in two cases, the fourth cycle was cancelled due to clinical deterioration. Patients were selected on the basis of on high whole-body doses in the first cycle (>0.5 Gy), suggesting cumulative absorbed doses of >2 Gy.Whole-body dosimetry was estimated using the DOMOS dose rate monitoring system (Nuvia a.s.) with collimated NaI detectors placed ~2.5 m above the patient. Each patient had at least seven time point measurements per cycle, including a late time point at 168 h post-administration. Data were fitted with a bi-exponential model; S-values were taken from OLINDA v1.0. Quantitative abdominal SPECT/CT images were acquired using Siemens Symbia Intevo Excel. During the first cycle, scans were acquired at 6, 24, 48 and 168 hours; during subsequent cycles included only a 24 hour scan. Liver, spleen, kidneys, and vertebrae (L2-L4) were segmented using Siemens syngo.via. Data were fitted with a mono-exponential model; S-values were taken from IDAC-Dose 2.1. ***Results:*** The mean whole-body dose was 0.72 Gy (101 mGy/GBq), range 0.19-2.36 Gy. The estimated RBM dose from SPECT was 0.24 Gy (33 mGy/GBq), range 0.071-0.652 Gy. Mean organ absorbed doses were 8.71 Gy (liver), 3.42 Gy (spleen), and 3.28 Gy (kidneys). The whole-body dose overestimated RBM dose by >53% on average. No significant correlation was found between whole-body dose and RBM dose ($r = -0.30$, $p = 0.0355$), nor between tumour liver uptake and whole-body dose ($r = 0.50$, $p = 0.00018$). ***Conclusion:*** Whole-body dosimetry alone is not suitable for accurate RBM dose estimation. It consistently overestimates RBM dose by more than 50%. This study supports the need for simplified 3D dosimetry using SPECT/CT. Larger studies (≥300 administrations) in patients with lower tumour uptake are needed to validate this approach and promote wider clinical adoption.

Monte Carlo Calculation Of Patient Effective Dose For ^{18}F-FDG PET Examinations

M. Baker;
Clatterbridge Cancer Centre, Liverpool, UNITED KINGDOM.

Aim/Introduction: Patient dosimetry for internal emitters is typically based upon standardised phantoms. Whilst these phantoms have improved in their ability to reflect typical patient anatomy, there is often little option to adjust the phantom to match bespoke patients. This work utilised real patient anatomy as well as Monte Carlo modelling and up-to-date biokinetic data to determine the effective dose for eighty patients weighing between 40 kg and 142 kg to determine the effect of patient size on the estimated effective dose. ***Materials and Methods:*** Clinical, single time-point images for 80 whole-body patients were retrospectively collected from two PET-CT scanners at Clatterbridge Cancer Centre. The images were contoured using AI-assisted technology to produce masked images for each source organ. GATE Monte Carlo software was used to simulate the absorbed dose distribution from each masked image to determine bespoke S-values for each patient. Cumulated activity was included from both ICRP 128 and Kamp et al (2023) to calculate the absorbed dose to each organ for each patient, allowing the effective dose for each patient to be estimated. ***Results:*** The effective dose per unit administered activity was found to be lower when using ICRP 103 tissue weighting factors and cumulated activity from Kamp et al (2023) than currently proposed in ICRP 128, with an average factor of 1.58E-02 mSv/MBq for patients in the range of 65 kg to 75 kg. There was a decrease in dose factor of approximately 20% between the smallest and largest patients within the cohort. ***Conclusion:*** Using bespoke S-values derived using real clinical data, and the most up-to-date biokinetic data and tissue weighting factors, the effective dose per unit of administered activity was determined to decrease as patient mass increased. Updated estimates of cumulated activity are now available, and should be coupled with the most recent tissue weighting factors to ensure that calculations are accurate and relevant. Total effective doses may be considerably lower than those initial proposed by ICRP 128. ***References:*** ICRP. (2015). Dosimetry of Organs at Risk of Patients Treated with [^{177}Lu]Lu-PSMA Suggests Margins for Dose Escalation

M. Almeida[1,2,3], *L. C. Silva*[1], *M. Costa*[1], *R. Parafita*[1], *F. Oliveira*[1], *Â. Silva*[1], *J. M. Sampaio*[2,3], *P. Ferreira*[1], *D. Costa*[1];
[1]*Champalimaud Foundation, Nuclear Medicine-Radiopharmacology, Lisboa, PORTUGAL,* [2]*Faculdade de Ciências da Universidade de Lisboa, Lisboa, PORTUGAL,* [3]*Laboratório de Instrumentação e Física Experimental de Partículas, Lisboa, PORTUGAL.*

Aim/Introduction: Personalized voxel-wise dosimetry of patients undergoing [^{177}Lu]Lu-PSMA therapy is paramount to help assess the effectiveness of treatment and tissue toxicity and may allow for the optimization of the activity injected into each patient. This study estimates the absorbed dose distributions in organs at risk (OAR) in patients with metastatic castration-resistant prostate cancer undergoing [^{177}Lu]Lu-PSMA therapy. ***Materials and Methods:*** Fourteen patients undergoing [^{177}Lu]Lu-PSMA therapy between December 2023 and February 2025 in our institution were included, for a total of 48 treatment cycles. For all treatment cycles, the prescribed activity was 7400 MBq. After each cycle, single-photon emission computed tomography (SPECT) images were acquired at three time points (4h, 24h, and 4-7 days) post-injection. A single CT acquisition per cycle was used for photon attenuation correction during SPECT reconstruction. OAR (left and right kidneys, liver, and spleen) segmentation was performed automatically on the CT images and validated by a nuclear medicine physician. The absorbed dose rate distributions were computed by convolution of the activity with the dose-voxel kernel. The time-integration was based on the best fit (mono-exponential or bi-exponential) of the time-activity curve of each OAR. The OpenDose3D and TotalSegmentator extensions of the open-source 3D-Slicer software were used. ***Results:*** The average activity of [^{177}Lu]Lu-PSMA injected per patient and cycle was 6861±214 MBq (range: 6253-7223 MBq). The mean absorbed dose in each cycle was 2.2±1.0 Gy (range: 0.2-4.9 Gy) for the right kidney; 2.7±1.6 Gy (range: 0.5-9.6 Gy) for the left kidney; 0.6±0.3 Gy (range: 0.2-1.2 Gy) for the liver; and 0.4±0.2 Gy (range: 0.1-1.1 Gy) for the spleen. The mean absorbed dose per injected activity was 0.33±0.15 Gy/GBq (range: 0.03-0.72 Gy/GBq) for the right kidney; 0.39±0.24 Gy/GBq (range: 0.09-1.39 Gy/GBq) for the left kidney; 0.09±0.04 Gy/GBq (range: 0.03-0.19 Gy/GBq) for the liver; and 0.06±0.03 Gy/GBq (range: 0.02-0.17 Gy/GBq) for the spleen. ***Conclusion:*** The mean absorbed doses in OAR are in line with those reported in the literature. Considering the commonly accepted restriction of the absorbed dose in the kidneys (23 Gy) as the most critical, the activity to be injected per treatment could be slightly higher, assuming 4 to 6 cycles per treatment. These results show that, in terms of OAR dosimetry, there is room for better tailoring the activity to be injected into each patient per cycle, as well as the number of cycles.

EP-1134

Personalized dosimetry in ^{188}Re-SIRT using gafchromic film derived conversion factor- A comparison of mono-compartmental method with commercial tools

S. Chopra, *A. S. Oinam, G. Singh, K. Kaur, S. R. Shovan, B. R. Mittal, J. Shukla;*
Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Personalized dosimetry in radiopharmaceutical therapy enhances accuracy over generic approaches, though absorbed dose (AD) estimates can vary with methodology. While Monte Carlo Simulation (MCS) is highly accurate but resource-intensive, gafchromic film offers a simpler, cost-effective alternative with good agreement for β-AD. We developed a high-resolution Gafchromic film dosimetry approach using a custom PMMA phantom for ^{188}Re. A Dosimetric Volume Unit (DVU), representing the irradiated volume from isotropic point source emission, was defined, and a corresponding conversion factor (J/GBq) was derived. This factor was used to calculate patient-specific ADs via a mono-compartmental model in ^{188}Re-SIRT. Results were compared with dose estimates generated by OLINDA/EXM® V2.0, MIRDcalc, and QThera.AI.. ***Materials and Methods:*** A tissue-equivalent PMMA phantom with a central cavity for EBT3 Gafchromic film placement was designed to enable high-resolution dosimetry of ^{188}Re. Optical density readings from films exposed to varying ^{188}Re activities were used to quantify AD relative to radioactivity. Percentage depth dose (PDD) curves were generated using 25 µCi of ^{188}Re, providing AD estimates at 0.275 mm depth intervals across the entire beta range. The resulting dose fall-off profile defined a DVU, from which a conversion factor (J/GBq) was calculated and applied for personalized AD estimation in 15 ^{188}Re SIRT patients using a mono-compartmental model. These results were compared with dosimetric outputs from three widely used software tools. ***Results:*** A perfect linear relationship ($R^2 = 1$) was found between AD and radioactivity. For a homogeneous distribution, 1 µCi of ^{188}Re delivered 3.6 Gy/mm^3 during the first half-life and a total of 7.3 Gy/mm^3 over ten half-lives, with a maximum tissue penetration of 3.7 mm. The estimated DVU dimensions were $4.7 \times 4.7 \times 7.4$ mm^3, and the conversion factor was determined to be 34 J/GBq. Among 15 patients, the median AD using the mono-compartmental model was 81.9 ± 41.3 Gy, comparable to QThera.AI estimates (92.7 ± 53.4 Gy; p = 0.215). MIRDcalc yielded significantly lower values (51.8 ± 18.1 Gy; p = 0.026), while OLINDA/EXM® V2.0 produced the lowest ADs (12.0 ± 14.5 Gy; p = 0.000). ***Conclusion:*** The conversion factor derived from Gafchromic film showed strong agreement with QThera.AI estimates, validating its utility for accurate, empirical AD calculations in ^{188}Re-SIRT, similar to established ^{90}Y dosimetry methods. Considering the high cost of commercial softwares, this cost-effective method presents a viable alternative, potentially enabling wider adoption of personalized dosimetry, especially in resource-constrained settings.

Mathematical evaluation of therapeutic index as a function of radionuclide half-life in radiopharmaceutical therapy

J. Hesterman, *B. Schuller, K. Orcutt, J. Babich, J. Hoppin;*
Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA.

Aim/Introduction: In radiopharmaceutical therapy (RPT), therapeutic index (TI), defined as the ratio of tumor-to-normal tissue dose, is critical for treatment optimization. TI may be expressed using either absorbed dose (AD) or biologically effective dose (BED). Radionuclide selection is another fundamental aspect of RPT design. This analysis evaluates theoretical tumor-to-kidney (T:K) AD and BED ratios as functions of radionuclide half-life. ***Materials and Methods:*** Tumor and kidney kinetics were modeled using mono-exponential time-activity curves with initial amplitudes $A_{0,T}$ and $A_{0,K}$ and biological half-times $t_{b,T}$ and $t_{b,K}$. Biological kinetics were constant across radionuclides. Dose estimates assumed self-absorbed beta and alpha emissions, dose factors from ICRP 107, and complete daughter decay at deposition sites. Closed-form and empirical analyses assessed T:K AD ratios across radionuclide half-lives (t_r). Due to complexity, BED calculations focused empirically on radionuclides 212Pb and 225Ac. Initial standardized uptake values (SUV_0) were 8 (tumor) and 4 (kidney). Biological half-times were evaluated in two scenarios: short (tumor 30h, kidney 10h) and long (tumor 300h and kidney 100h, reflective of PSMA and SSTR RPTs). Repair half-times and radiosensitivity parameters (alpha/beta ratios) were literature-derived. ***Results:*** The analytical solution for the T:K AD ratio is $T{:}K(t_r) = [A_{0,T} * (t_{b,T} * t_r) * (t_{b,K} + t_r)] / [A_{0,K} * (t_{b,K} * t_r) * (t_{b,T} + t_r)]$. This ratio monotonically increases with radionuclide half-time when tumor biological half-time exceeds kidney biological half-time. BED analyses showed similar behavior, with both tumor and kidney BED higher than AD, yet relative increases were comparable, minimally altering T:K ratios.For typical administered activities (185 MBq for 212Pb, 7.5 MBq for 225Ac), absolute tumor AD and BED were higher for short-lived radionuclides when tumor biological half-times were short (e.g., tumor AD for $t_{b,T}$ = 30h; 212Pb = 4.9 Gy and 225Ac = 2.3 Gy). Conversely, longer-lived radionuclides delivered greater doses at long biological half-times (e.g., tumor AD for for $t_{b,T}$ = 300h; 212Pb = 6.4 Gy and 225Ac = 11.6 Gy). Across all scenarios, T:K AD and BED ratios consistently favored longer-lived radionuclides. ***Conclusion:*** Modeling demonstrates enhanced therapeutic indices with increasing radionuclide half-life, independent of tumor and normal tissue biological kinetics. Illustrating this point, 225Ac therapeutic indices exceeded those of 212Pb across all scenarios for which tumor biological half-time exceeds kidney biological half-time. A higher therapeutic index allows more flexibility in dosing without risking patient safety. ***References:*** PMID: 19285593, 15653658, 1846045, 3620815

EP-1136

First Cycle Dosimetry as a Prediction Metric of ^{177}Lu-PSMA Therapy Outcomes

A. Al-Balushi, *N. Al-Maymani, T. Al-Raii, S. Kheruka, H. Al-Saidi;*
Sultan Qaboos Comprehensive Cancer Care & Research Center - University Medical City, Muscat, OMAN.

Aim/Introduction: The objective of this study was to evaluate the relationship between first cycle absorbed doses delivered to organs-at-risk and therapeutic outcomes, aiming to identify dosimetric patterns predictive of treatment efficacy and safety. ***Materials and Methods:*** The study was conducted on five male patients at SQCCCRC, each receiving standard doses (7.4GBq) of ^{177}Lu-PSMA per cycle. Quantitative SPECT/CT imaging was performed post therapy at 3-4 and 24-48 hours post administration. Absorbed dose calculations were conducted using the MIRD formalism, with S-values derived from the ICRP 110 adult male phantom adjusted for individual patient organ masses [1]. Mean absorbed doses for kidneys and salivary glands were analyzed and correlated with therapeutic response and observed side effects. ***Results:*** Our results categorize patients into two groups according to the absorbed doses delivered to the kidneys and salivary glands. Three patients who received higher kidney doses (0.36-0.64 Gy/GBq) but lower salivary gland doses (0.01-0.02 Gy/GBq) completed six treatment cycles without experiencing significant side effects. Conversely, two patients who had higher salivary gland doses (0.14-0.46 Gy/GBq) and lower kidney doses (0.15-0.24 Gy/GBq) discontinued therapy after the second cycle due to disease progression. These patients developed mild to moderate xerostomia at cumulative salivary gland doses ranging from 3 to 6 Gy and were subsequently prescribed artificial saliva sprays. ***Conclusion:*** Our findings demonstrate a clear correlation between first-cycle absorbed doses to organs-at-risk

and therapeutic outcomes. Increased radionuclide retention in the salivary glands correlated with reduced treatment efficacy and xerostomia. Conversely, patients who responded well to the treatment received safely higher doses to the kidneys. Therefore, first-cycle dosimetry is crucial for identifying patterns that enhance treatment precision and promote outcomes. ***References:*** [1] International Commission on Radiological Protection. Patient-Specific Dose Assessment in Whole-Body CT Imaging during PET-CT Procedures

P. Sheikhzadeh[1], *M. Asami*[1], *M. Shahrbabki Mofrad*[1], *N. Kasraie*[2]; [1]*Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*UT Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA.*

Aim/Introduction: The increasing use of PET-CT imaging in clinical practice has raised concerns regarding radiation exposure from the CT component, particularly during whole-body scans. This study aims to evaluate and compare patient-specific organ doses and effective dose (ED) using two established methods: Dose Length Product (DLP) conversion and the NCICT dosimetry software. ***Materials and Methods:*** A retrospective analysis was conducted on 500 patients (226 men, 274 women) who underwent whole-body PET-CT scans. Effective dose was calculated using two approaches: (1) multiplying DLP values by a standard conversion factor (0.015 mSv/mGy·cm), and (2) using the NCICT software, which employs Monte Carlo simulations for organ dose estimation. Gender- and age-based differences in ED and organ doses were examined. ***Results:*** The average DLP was 516.4 ± 200 mGy·cm. The corresponding ED was 7.76 ± 3.01 mSv via the DLP method and 6.82 ± 2.56 mSv using NCICT. Organ dose analysis revealed the thyroid received the highest radiation exposure, followed by the kidneys in females and testes in males. While the DLP method slightly overestimated ED in females, NCICT provided more individualized estimates by accounting for anatomical variability. A significant age-dependent variation in ED was also observed, with differing trends between genders. ***Conclusion:*** Whole-body CT in PET-CT imaging results in measurable organ and effective doses, with substantial variability influenced by patient age, sex, and anatomical characteristics. Using patient-specific dosimetry methods like NCICT provides more accurate ED estimates than generalized DLP conversion factors. These findings support the necessity of tailored imaging protocols and dose optimization strategies in routine clinical practice to ensure diagnostic quality while minimizing unnecessary radiation exposure. ***References:*** Malekhedayat M, Stewart C, Chu PW, Wang Y, Kasraie N, Franc B, Smith-Bindman R. Patient-Specific Internal Dose Calculation Based on 68Ga-Citrate PET Images: Validation of a Monte Carlo Approach and Comparison to Conventional Analytical Method

S. Asidkar[1], *S. Yavari*[1], *M. Abbasi*[1], *M. Jahanbin*[1], *A. Parach*[2], *P. Sheikhzadeh*[1]; [1]*Tehran university of medical science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Regional Medical Physics Service, Belfast Health & Social Care Trust, Belfast, UNITED KINGDOM.*

Aim/Introduction: This study aims to establish patient-specific dosimetry for Gallium-68 (^68Ga) citrate using Monte Carlo simulations (GATE v.9.1), focusing on its role in enhancing diagnostic accuracy and refining imaging protocols in nuclear medicine. To validate its reliability for clinical applications, the Monte Carlo method will be compared with TLD-based dosimetry. Furthermore, the validated Monte Carlo results will serve as a benchmark to evaluate discrepancies and practicality in general dosimetry methods, determining their suitability for routine clinical use. ***Materials and Methods:*** Patient-specific dosimetry was conducted using PET/CT images following intravenous injection of ^68Ga-citrate. The voxelized phantom and source were derived from CT and PET images, respectively. Simulations were performed using GATE v.9.1 with a runtime of 1 second to calculate dose distributions. Organ activity and absorbed doses were estimated using IDAC-DOSE2-1 and OLINDA/EXM tools. Dosimetry results from GATE simulations were compared with those obtained from general methods. Additionally, the GATE code was validated by comparing its results with TLD measurements. ***Results:*** Two dosimeters were positioned around the NEMA phantom to measure the absorbed dose, which varied between 0.22 msv and 1.02 msv. Dose calculations performed using GATE simulations ranged between 0.25 msv and 1.0 msv. A comparative analysis was conducted to verify the accuracy of GATE against phantom-based methods. Mean doses for several organs were evaluated using Monte Carlo simulations and phantom-based approaches. The results revealed that the highest dose was delivered to the spleen, and the largest discrepancy was also observed in the spleen. Discrepancies between organs ranged from 0.06 to 2.86, indicating significant variations in the outcomes of the applied methods. ***Conclusion:*** This study validated GATE-based Monte Carlo simulation by comparing with TLD measurements, showing strong agreement and confirming the accuracy of the MC method. This approach proved suitable for dosimetric calculations of various radiopharmaceuticals in both diagnostic and therapeutic applications. Patient-specific dosimetry results were compared with phantom-based methods, revealing significant discrepancies in some cases and underscoring the superior accuracy of MC simulations for internal dosimetry.

Automated Hybrid Dosimetry for Precise [^{177}Lu]Lu-DOTATATE Peptide Receptor Radionuclide Therapy

Z. Dong[1], *X. Jin*[2], *X. Meng*[2], *J. Yu*[2], *Z. Xie*[3]; [1]*National Biomedical Imaging Center, College of Future Technology, Peking University, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Peking University Cancer Hospital, Beijing, CHINA,* [3]*Institute of Medical Technology, Peking University Health Science Center, Peking University, Beijing, CHINA.*

Aim/Introduction: Personalized dosimetry is essential in [^{177}Lu]Lu-DOTATATE peptide receptor radionuclide therapy (PRRT), particularly for patients with neuroendocrine neoplasms (NENs)[1-2]. While SPECT/CT imaging offers detailed 3D dose distribution, its routine clinical implementation limited. Conversely, planar scintigraphy lacks the spatial resolution needed for robust organ-level dosimetry. To address this trade-off, we proposed a fully automated hybrid dosimetry protocol combining single-time-point (STP) SPECT/CT with serial planar scintigraphy. ***Materials and Methods:*** Eight patients with NENs and liver metastases undergoing [^{177}Lu]Lu-DOTATATE therapy were enrolled. Imaging was performed using both planar and SPECT/CT imaging at Days 0, 1, 2, and 5-7 post-therapy. To address the 2D overlap limitations inherent in planar imaging, we calculated overlap correction factors (OCFs) derived from 3D activity distributions obtained via SPECT and organ masks automatically segmented using TotalSegmentator[3] on baseline CT images. Next, time-integrated activity (TIA) at the organ-level was estimated by fitting serial planar data and scaling these values to the injected dose for consistency. For voxel-level dosimetry, STP SPECT images were scaled voxel-wise using the organ-specific TIA values, generating 3D TIA maps. These maps were then used as input for Monte Carlo simulations (GATE) to compute absorbed dose distributions.

Multi-time-point (MTP) SPECT/CT-based dosimetry was used as the reference standard for validation. ***Results:*** Our proposed method demonstrated close agreement with MTP dosimetry. The liver showed the highest accuracy, with a mean absolute relative error (MARE) of 9.64% ± 7.33% across all patients. The right kidney (MARE: 17.29% ± 9.77%) showed slightly higher errors than the left kidney (MARE: 15.38% ± 9.98%). ***Conclusion:*** This hybrid dosimetry approach effectively balances accuracy and clinical feasibility. In PRRT for NENs, liver dose estimates were highly reliable, while kidney and the other organs with rapid tracer kinetics susceptible to STP errors. ***References:*** 1. Maccauro M, et al. Feasibility of single-time-point dosimetry in Lu-177-based cocktail radiopharmaceutical therapy

W. Peng[1,2], *Y. Liu*[2], *Y. Chen*[1], *G. Mok*[2];
[1]*Department of Nuclear Medicine, Affiliated Hospital of Southwest Medical University, Luzhou, Sichuan, China, Luzhou, CHINA,* [2]*Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Macau SAR, MACAO.*

Aim/Introduction: Single-time-point (STP) dosimetry is clinically desirable for personalized dosimetry in radiopharmaceutical therapy. However, its feasibility in the cocktail radiopharmaceutical therapy, i.e., administrating 2 pharmaceuticals with the same isotope to the patients consecutively in this study, remains to be validated. We aim to investigate the feasibility of STP dosimetry in multiple cocktail radiopharmaceutical therapy regimens for treating bone metastases in patients with various primary tumors. ***Materials and Methods:*** We retrospectively analyzed 15 patients under the standard ^{177}Lu-PSMA-617 therapy (n=5, 200~235 mCi, prostate cancer), and cocktail therapies with various ^{177}Lu-labeled pharmaceuticals, including ^{177}Lu-DOTA-ibandronic acid (^{177}Lu-DOTA-IBA)+^{177}Lu-FAP-2286 (n=3, 30+150~170 mCi, lung cancer, breast cancer, colon cancer), ^{177}Lu-DOTA-IBA+^{177}Lu-DOTATATE (n=3, 30+160~170 mCi, small bowel neuroendocrine neoplasms, carotid aneurysm, adrenal pheochromocytoma), and ^{177}Lu-DOTA-IBA+^{177}Lu-PSMA-617 (n=4, 30+150 mCi, prostate cancer). All patients underwent sequential quantitative SPECT/CT images at a minimum of 3 time points, i.e., ~2 to ~168 h post-injection. Standard full-time-point (FTP) dosimetry and STP dosimetry (1) were performed using the MIM Dosimetry Software. The median absolute error (MedAE) of STP dosimetry was calculated in comparison to FTP dosimetry for the kidneys, liver, spleen, bone marrow, and selected tumors (n=41 in 15 patients). ***Results:*** For ^{177}Lu-DOTA-IBA+^{177}Lu-FAP-2286, the lowest MedAE of STP dosimetry was observed at 48 h for kidneys (10.05%), liver (15.48%), spleen (11.44%), bone marrow (21.34%), and tumors (6.70%). For ^{177}Lu-DOTA-IBA+^{177}Lu-DOTATATE, the lowest MedAE was obtained at 72 h for kidneys (26.73%), liver (16.27%), spleen (19.13%), bone marrow (17.37%) and tumors (10.45%). For ^{177}Lu-DOTA-IBA+^{177}Lu-PSMA-617, the lowest MedAE of STP dosimetry for kidney was observed at 72 h for liver (13.36%) and spleen (15.79%), and at 48 h for bone marrow (23.54%) and tumors (9.52%). For the standard ^{177}Lu-PSMA-617 therapy, the lowest MedAE was observed at 72 h for kidneys (8.93%) and bone marrow (5.17%), at 168 h for liver (22.76 %), and at 24 h for spleen (21.63%). ***Conclusion:*** In general, 48-72 h post-injection was found to be the most reliable window for STP dosimetry across most regions-of-interest in different cocktail treatments assessed, with error<30%. ***References:*** 1. Hänscheid H et al. Dose Mapping After Endoradiotherapy with 177Lu-DOTATATE/DOTATOC by a Single Measurement After 4 Days. J Nucl Med. 2018;59(1):75-81.

A Comparison of ^{90}Y-SPECT/CT and ^{90}Y-PET/CT Imaging in Voxel-Based Dosimetry for TARE with Resin ^{90}Y-Microspheres

Z. Balaban Genc[1], *A. Eroglu*[1], *S. Beykan Schürrle*[2], *O. Erez*[1], *S. Cetin*[1], *N. Schürrle*[2], *E. Arık*[1], *E. Soydemir*[1], *T. Erdil*[1], *T. Ones*[1];
[1]*Marmara University, School of Medicine, Istanbul, TÜRKIYE,* [2]*Oncosia Scientific GmbH, Durrwangen, GERMANY.*

Aim/Introduction: Transarterial radioembolization (TARE) is a targeted radiotherapy technique for liver tumors, delivering radioactive microspheres intra-arterially to selectively irradiate tumor-feeding vascular structures. Accurate dosimetry is critical for optimizing treatment planning and managing toxicity risks. This study compares post-treatment dosimetric values derived from ^{90}Y-SPECT/CT and ^{90}Y-PET/CT imaging in TARE using resin ^{90}Y-microspheres. ***Materials and Methods:*** This retrospective study included 21 consecutive patients treated with TARE using resin microspheres between 2023 and 2024. Absorbed doses (in Gray, Gy) were calculated using the voxel-based NUKDOS software for whole liver (including tumor), perfused tumor, perfused healthy liver, and whole healthy liver, based on post-treatment ^{90}Y-SPECT/CT and ^{90}Y-PET/CT images. Dosimetric values were compared statistically. ***Results:*** A very high correlation was observed between dosimetric calculations from both imaging modalities ($p<0.001$). No significant differences were found in absorbed doses for the whole liver (including tumor) ($p=0.249$) or perfused healthy liver ($p=0.204$). However, absorbed doses for the perfused tumor were significantly higher with ^{90}Y-PET/CT ($p=0.001$). For the whole healthy liver, a significant difference was noted ($p=0.007$), though median values were comparable (20.62±13.63 Gy vs. 17.95±12.17 Gy). ***Conclusion:*** Few studies have directly compared post-treatment ^{90}Y-SPECT/CT and ^{90}Y-PET/CT using voxel-based dosimetry. This pilot study demonstrates a very strong correlation between dosimetric values from both modalities. Notably, ^{90}Y-PET/CT yielded higher absorbed doses for the perfused tumor, a key factor in treatment efficacy. Absorbed doses for the whole healthy liver, critical for toxicity assessment, were similar despite statistical differences. Given the high correlation, both imaging modalities appear suitable for dosimetric studies. However, prospective, multicenter studies with larger cohorts are needed to validate these findings.

EP-1142

Effects of imaging time points on precision in absorbed dose to the kidneys in patients with neuroendocrine tumours receiving ^{177}Lu-DOTATATE therapy

M. Sandström, *E. Ilan, M. Lubberink;*
Uppsala University Hospital / Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Fractionated molecular radiotherapy with ^{177}Lu-DOTATATE is an effective treatment option for patients with generalized neuroendocrine tumors. Calculating the absorbed doses (AD) to solid organs has been suggested to optimize the treatment, by allowing as many treatment cycles as possible without exceeding absorbed dose limits to organs at risk. The precision of the calculated AD depends on how well the activity concentrations are determined and the selection of timepoints when the activity concentrations are determined. The current aim was to study the precision dependence on the imaging

timepoints. ***Materials and Methods:*** Time-activity curves for both right and left kidneys were used from one randomized patient out of the 1150 patients treated with ^{177}Lu-DOTATATE at Uppsala University Hospital. Based on the measured time-activity curve, a normal distribution with a standard deviation of 10% was added to create new measurement points. This was repeated to create 65000 sets of datapoints using random numbers in MatLab. Six sampling schemes with different timepoints were used, with timepoints between 24 h and 168 h. Two commonly used temporal sampling schemes are presented here: 24h, 96h and 168h (scheme 1) and 24h, 48h and 72h (scheme 2). A single exponential curve was then fitted to the datapoints of all 65000 sets, from this the percentage deviation from the absorbed dose and effective half-life was calculated for all sets individually and the median, 5% and 95% percentiles were determined. ***Results:*** For scheme 1, the median (5% percentile - 95% percentile) of the percentage deviation for the AD in the right and left kidney was 0.1 (-15.5 - 20.9) and 0.2 (-10.2 - 10.8), respectively. For scheme 2, the corresponding numbers were 0.0 (-28.4 - 64.7) and 1.0 (-13.5 -29.7). The percentage deviation of the effective half-life for scheme 1 was 0.0 (-15.8 - 21.2) for the right kidney and 0.1 (-15.5 - 20.9) for the left kidney. For scheme 2, the corresponding numbers were 0.1 (-29.0 - 66.1) and 0.0 (-28.4 -64.7). The precision in AD and effective half-life was much better when the time between the first and last measurement point was as long as possible. This effect was much more pronounced for the effective half-life than for the AD. ***Conclusion:*** The results of this study indicate that a long time between the first and the last imaging timepoint is beneficial for the precision in absorbed dose calculations.

Aim/Introduction: This is a post hoc analysis of the prospective bi-centric randomized phase II trial: RESIST-PC. The efficacy and safety profile of variable injection activities (6.0 vs. 7.4 GBq) of 177Lu-PSMA-617 in patients with progressive metastatic castration-resistant prostate cancer (mCRPC) were evaluated. Here we report the FDA-required absorbed dose (AD) estimates to organs and tumors, which were obtained with a hybrid method (planar + SPECT imaging). ***Materials and Methods:*** Patients were treated with either 6.0 or 7.4 GBq of 177Lu-PSMA-617. In both groups, whole body planar scintigraphy images were acquired after the first cycle at 4, 24, 48, and 72h with an optional timepoint after 168h. Patients also underwent quantitative SPECT/CT 24h after treatment. Image and dose analysis were performed leveraging a hybrid 2D/3D dosimetry protocol. ADs were calculated for the kidneys, salivary glands, and liver. Representative lesions were included based on visible uptake at all imaging timepoints. Lesions were segmented semi-automatically on SPECT images and propagated to the registered planar image series with manual adjustments. Relative time-activity curves were derived from counts in the serial planar scans, and scaled by the quantitative SPECT activity. The scaled activity measurements were fit exponentially, then convolved with a 177Lu dose kernel to yield AD estimates. ***Results:*** A total of 48/64 patients treated between 07/2017 and 07/2018 had complete imaging datasets (n=16 received 6.0 GBq, n=32 received 7.4 GBq). The mean kidney, submandibular gland, parotid gland, and liver ADs among the whole cohort (and 6.0 vs. 7.4 GBq arms) were: 0.29±0.11 (0.32±0.14 vs. 0.28±0.09), 0.23±0.18 (0.29±0.26 vs. 0.20±0.12), 0.26±0.15 (0.30±0.22 vs. 0.24±0.10), and 0.11±0.09 (0.11±0.08 vs. 0.11±0.09) Gy/GBq, respectively. The difference in organ AD between administered activities was not statistically significant.302 lesions were included (median=7 per patient). The mean AD in bone lesions (n=251) was 1.94±1.83 and 1.63±1.96 Gy/GBq for 6.0 (n=107) and 7.4 (n=144) GBq groups, respectively [ns]. The mean AD in lymph node lesions (n=32) was 6.03±3.81 and 1.67±2.00 Gy/GBq for 6.0 (n=12) and 7.4 (n=20) GBq groups, respectively [p=0.01]. The mean AD in liver lesions (n=19) was 2.96±2.64 Gy/GBq (only applicable for 7.4 GBq cohort). ***Conclusion:*** AD in 48 patients with mCRPC treated with 177Lu-PSMA-617 were estimated using a hybrid imaging methodology, yielding organ doses within tolerable ranges, while tumor ADs varied widely both on the inter- and intra- patient level. There was no significant AD difference between the 6.0 and 7.4 GBq groups.

Comparison of ultra-fast Monte Carlo (MC) dosimetry calculations with standard method in Y-90 post-therapy PET/CT studies

K. Knesaurek[1], *J. Grudzinski*[2];
[1]*Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA,* [2]*Voximetry, Inc, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: The aim of this study is to compare ultra-fast Monte Carlo (MC) dosimetry calculations with the standard method in post-therapy Y-90 PET/CT studies. ***Materials and Methods:*** A locally developed MC dosimetry program was run on a laptop equipped with an NVIDIA GeForce RTX 3070 GPU, featuring 5120 cores, CUDA compute capability 8.6, 8.0 GB RAM, and a GPU clock speed of 1.560 GHz. In a typical case, MC dose computation was completed in 68.0 seconds, achieving an uncertainty goal of 0.99% over 200 iterations. The results of the ultra-fast MC calculations were compared with the standard local deposition method (LDM) previously used in our Y-90 post-therapy PET/CT dosimetry studies [1]. The comparison focused exclusively on mean doses within the liver, specifically the liver tumor and normal liver tissue. Lung and tissue interference regions were excluded from analysis. ***Results:*** Comparison across six cases demonstrated strong correlation (r^2 = 0.99) between the two methods. LDM values were slightly higher for both tumor (T) and normal tissue (NT) measurements. Tumor dose values ranged from 413-1451 Gy for MC and 465-1738 Gy for LDM. Normal tissue values ranged from 11-76 Gy for MC and 12-82 Gy for LDM. The mean percent difference between LDM and MC values was 14% for T and 6% for NT. The percent difference range was 9-20% for T and 1-8% for NT. ***Conclusion:*** Ultra-fast MC dosimetry yields mean dose estimates comparable to those of the standard LDM approach. These findings support the feasibility of employing full, rapid MC dosimetry in clinical radiation therapy. ***References:*** 1. Knešaurek K. Comparison of post-therapy Y-90 PET/CT dosimetry methods in liver therapy with Y-90 microspheres. World J Nucl Med. 2020;19:359-65.

Aim/Introduction: Radioembolization with yttrium-90 (^{90}Y) or holmium-166 (^{166}Ho) microspheres is an established procedure for treatment of primary and secondary liver tumours. Retrospective studies have shown promising results correlating increased tumour-absorbed dose to better overall survival and tumour response [1]. Accurate PET or SPECT dosimetry is imperative for precise therapeutic delivery [2]. However, respiratory-induced hepatic displacement (8-25 mm during shallow breathing) can cause motion artifacts. This is characterized by partial volume and spill-in/spill-out effects, potentially leading to erroneous dose assessments [3-6]. This study aims to evaluate and quantify the impact of respiratory motion on ^{90}Y-PET-based dosimetry using a moving liver phantom. ***Materials and Methods:*** A liver-mimicking agarose gel phantom was created, with a non-radioactive outer shell and a radioactive background containing three tumour-mimicking spheres (diameters: 30, 40, 60 mm) filled with 271 kBq/mL (corrected for acquisition time) of ^{90}Y resin microspheres (4.5:1 sphere-to-background concentration ratio ($S:BG_{ratio}$)). The largest sphere contained a non-radioactive necrotic core (diameter: 30 mm). The phantom was placed on a respiratory motion system with adjustable motion parameters, set to mimic a shallow breathing pattern [7]. The setup was scanned on a Siemens PET/CT system, employing their reflector block-based respiratory motion correction. Additionally, the phantom was scanned with the respiratory motion system turned off for optimal imaging. Images were reconstructed with and without motion correction. In all configurations, counts inside the spheres and radioactive background were determined by delineating the known dimensions of the spheres and background on the CT images. To perform dosimetric analysis and compare the acquired data, the mean absorbed dose and dose volume histograms will be computed. ***Results:*** PET-based results for the phantom showed $S:BG_{ratio}$ of 2.32, 3.24, 3.01 for each sphere with motion correction, and 2.57, 3.11, 3.04 without motion correction. Optimal imaging showed $S:BG_{ratio}$ of 2.83, 3.17, 2.94. The $S:BG_{ratio}$ of the non-radioactive necrotic core was 2.33, 2.62 and 1.71 with motion correction, without motion correction, and with optimal imaging, respectively. Analysis is still ongoing and detailed results will be shared at the congress. ***Conclusion:*** This study investigates the impact of respiratory motion on dosimetry in ^{90}Y radioembolization in a phantom model and will evaluate the performance of a clinically available motion correction tool. It will further quantify the impact of both respiratory motion and motion correction. ***References:*** [1] Hermann e.a., 2020. [2]Elschot, e.a., 2011. [3]Keall e.a., 2006. Bridging diagnosis and dosimetry: investigating the predictive role for ^{68}Ga-DOTATOC PET/CT in ^{177}Lu-DOTATATE PRRT

C. Ingraito[1,2], *A. Monaci*[3], *M. Cuomo*[1], *G. Argiroffi*[1], *M. Kirienko*[1], *A. Lorenzoni*[1], *F. Rubino*[1], *C. Chiesa*[1], *M. Maccauro*[1];
[1]*Nuclear Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY,* [2]*Post Graduate Specialisation School for Medical Physics, Università degli Studi di Milano, Milan, ITALY,* [3]*Post Graduate Specialisation School for Nuclear Medicine, Università degli Studi di Firenze, Firenze, ITALY.*

Aim/Introduction: Lesion dosimetry after the first administration of ^{177}Lu DOTATATE was predictive of PFS [1]. This retrospective study explores whether pre-treatment ^{68}Ga-DOTATOC PET/CT, typically used for patient selection, could provide an even earlier prediction of post-therapy dosimetry values. ***Materials and Methods:*** We assessed correlations between 8 PET-derived parameters and 5 post-therapy Absorbed Dose (AD) values across over 300 lesions. Patients had PET scans and lab tests within six months prior to treatment. After the first ^{177}Lu cycle, two SPECT/CT dosimetric scans were acquired (20, 162 hours post-injection). Lesions and Organs-At-Risk (OARs) were segmented on PET using a semi-automatic gradient and a fully automated method, then adapted to SPECTs after image registration. Statistical comparisons employed Bland-Altman analysis (bias B, standard deviation SD) and Spearman's correlation (r coefficient). Machine Learning (ML) approach, incorporating VOI statistics and biomarkers, was explored for predictive modelling. ***Results:*** Of the 40 correlations analysed, a strong association ($p<10^{-4}$) emerged between the PET-derived Somatostatin Receptor-Expressing Tumour Volume and the post-treatment Time-Integrated Activity Coefficient (τ) (r=0.78). Correlation improved after stratification on Ki-67 index (r_{G1}=0.89, r_{G2}=0.76). A linear regression model was used to estimate τ, enabling AD calculation via MIRD formalism. Across all tumours, Bland-Altman yielded B=-38%, SD=63%. Stratified analysis and improved parabolic interpolation enhanced precision: G1 tumours showed B=5.82%, SD=51.8%; G2 had B=-0.62%, SD=69%. The ML approach is under refinement to further improve predictive reliability. ***Conclusion:*** The linear model prediction of τ over volume was overly simplistic, yielding unacceptable AD dispersion due to intrinsic differences between PET and SPECT (acquisition time: 1h vs 20h, somatostatin-analog ligand: TOC vs TATE, kidney protection: absent/present). The ML model in development may bridge these gaps, boosting predictive accuracy. ***References:*** [1]: Maccauro M, Cuomo M, Bauckneht M, Bagnalasta M, Mazzaglia S, Scalorbi F, Argiroffi G, Kirienko M, Lorenzoni A, Aliberti G, Pusceddu S, Giuseppina C, Matteo GE, Seregni E, Chiesa C. The LUTADOSE trial: tumour dosimetry after the first administration predicts progression free survival in gastro-entero-pancreatic neuroendocrine tumours (GEP NETs) patients treated with [177Lu] Lu-DOTATATE. EP-1147

Correlation between absorbed dose, SUVmax and Krenning Score after Peptide Receptor Radionuclide Therapy (PRRT) treatment in neuroendocrine tumors

A. Barrera Cerpa*, M. Ribelles Segura, A. Fernández Iglesias, L. Paruta Araez, C. Villaprado Meza, K. Sanabria Ramírez, P. Boya Román, I. Blanco Saiz, F. Lozada Delgado, Á. Rosero Enríquez, D. Gómez Sánchez, E. Anda Apiñaniz, R. Vera García, E. Goñi Gironés; Hospital Universitario de Navarra, Navarra, SPAIN.*

Aim/Introduction: Our aim was to evaluate the relationship between the tumor-absorbed dose (TAD) and physiological standardized uptake values (SUVs) estimated from [177Lu]Lu-DOTA-TATE SPECT/CT, as well as their association with Krenning scores (K-scores) derived from planar imaging. ***Materials and Methods:*** This analysis was conducted on patients with advanced well-differentiated NETs grades 1-3 who underwent [177Lu] Lu-DOTA-TATE (7.4 GBq per cycle). Target lesions were selected based on the RECIST 1.1 criteria. Parameters and dosimetry were performed at two time points, 1st and 4th cycles post-therapy. Statistical analyses such as Kruskal-Wallis and Wilcoxon were conducted to investigate correlations. Written consent was taken from all the patients. ***Results:*** A total of 16 patients (50% females), mean age of 62.25 ± 10 years with 62 lesions, including primary tumour sites and metastases. Lesions were designated as K-score IV (n=40), K-score III (n=4), K-score II (n=17), K-score I (n=1) in the 1st cycle and as K-score IV (n=18), K-score III (n=17), K-score II (n=22), K-score I (n=5) in the 4th cycle. The median SUVmax for all lesions in the 1st cycle was 9.5 (IQR: 4.4-20.1) and in 4th cycle was 6.6 (IQR: 3.4-18.7). The differences were significative (p=0.012). Statistically significant changes of SUVmax among K-score groups were observed in the 1st and 4th cycle (p<0.005). There was a trend of greater SUVs values with higher K-score (p>0.005). The median total absorbed dose by all lesions in the 1st cycle was 14.3 Gy (IQR: 6.8-24.2) and in the 4th cycle was 9.1 Gy (IQR: 4.7-15.2). The differences were significative (p 0,01). There was also a trend of greater TAD with higher K-score (p>0.005). There is a clear trend

toward higher TAD in the first cycle with an a lower absorbed in the 4ths cycle (cut of 40% decrease p <0.05). ***Conclusion:*** Our findings suggest a positive correlation between Krenning score, SUVmax, and TAD. They also provide further evidence supporting the TAD in the first cycle as a potential predictive biomarker in the context of precision medicine.

EP-1148

Outcome-Driven Timing Optimization of Single Time Point Dosimetry for PSMA-Directed Radiopharmaceutical Therapy

J. Hu[1], *R. Seifert*[1], *C. Vinicius Gomes*[1], *Y. Chen*[1], *W. Jutidamrongphan*[1], *M. Amon*[2], *J. Wang*[1], *S. Xue*[1], *A. Afshar-Ormiehali*[1], *A. Rominger*[1], *K. Shi*[1];
[1]*Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland, Bern, SWITZERLAND,* [2]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland, Bern, SWITZERLAND.*

Aim/Introduction: Single-time-point (STP) dosimetry emerges as a simplified alternative to Multiple-time-points (MTP) dosimetry standards. The development of STP is based on reference to MTP, nevertheless, MTP may introduce biases due to undersampling and population-based assumptions, which may hamper its ability in STP optimization. This study proposes the optimization of STP directly based on treatment outcomes and focuses on the optimal selection of time points for STP. ***Materials and Methods:*** Data from 51 mCRPC patients treated with [^{177}Lu]Lu-PSMA-617 RPT were retrospectively analyzed. SPECT/CTs were acquired at time points from 1 to 3 days p.i. Transient treatment-emergent adverse events (TEAEs) and long-term PSA decline rates were monitored following CTCAE v5.0 and PCWG3. Mean absorbed doses ($STPD_{tox}$ and $MTPD_{tox}$) and cumulative doses ($STPD_{response}$ and $MTPD_{response}$) were computed for organs-at-risk and whole-body tumors, respectively. ***Results:*** Bone marrow dosimetry from $STPD_{tox}$ correlated significantly with anaemia grading (reduction of hemoglobin amount), peaking on 3-day p.i. (Spearman's $\rho = 0.46$, $p_{adj} < 0.001$), aligning with $MTPD_{tox}$ (Spearman's $\rho = 0.43$, $p < 0.001$). Williams' F-test confirmed that $STPD_{tox}$ and $MTPD_{tox}$ were equivalently correlated with anaemia grades. For PSA response assessment, both $MTPD_{response}$ and $STPD_{response}$ showed no significant difference in correlation with PSA decline rate on 1-day p.i. (Spearman's $\rho = -0.34$, $p_{adj} < 0.001$) and 2-day p.i. (Spearman's $\rho = -0.33$,$p_{adj} < 0.001$). ***Conclusion:*** Findings suggest that Hänscheid-based STP dosimetry on 2-days p.i. is identified as a practical alternative for outcome-driven timing, linking marrow dosimetry to hematologic toxicity and tumor dosimetry to PSA decline rate, thus supporting its potential for streamlined clinical application.

EP-1149

Correlation Between Tumor-Absorbed Radiation Dose and Tumor Volume Reduction in Sarcoma Patients Treated With [^{177}Lu]Lu-FAP-2286

R. Nami[1], *M. Nasiri*[2], *S. Banihashemian*[3], *A. Abolhosseini Shahrnoy*[1], *G. Divband*[4], *M. Akbari*[3];
[1]*Parsisotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Cellular & Molecular Biology, School of Biology, Damghan University, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Cancer Research Center, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Khatam PET-CT Center, Khatam-al-Anbia Hospital, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: This study aimed to assess whether the absorbed dose of a [^{177}Lu]Lu-FAP-2286, correlates with the reduction in primary and metastatic lesions volume in patients with advanced sarcoma. ***Materials and Methods:*** Ten patients with histologically confirmed metastatic sarcoma were treated with [^{177}Lu]Lu-FAP-2286 . Based on the treatment response, the patients were divided into two groups: one with a significant reduction in tumor size (n=4) (Group 1) and the other with an increase in the initial tumor size (n=6) (Group 2). Dosimetry was performed for each patient, using MIRDCALC method, after six cycle of [^{177}Lu]Lu-FAP-2286 therapy, to quantify the tumor-absorbed radiation dose. The correlation between absorbed dose/ml and tumor volume reduction was evaluated in primary and metastatic lesions using Spearman's correlation test. A linear regression model was also applied to assess dose-response trends. ***Results:*** Preliminary analyses revealed that, the initial tumor volume in Group 2, before and after treatment, (1672.4±510.2 and 2118.7±680.7 respectively) was significantly larger than that in Group 1 (243.4±35.2 and 160.7±11.7 respectively) (P=0.038 and P=0.035 respectively). Additionally, the total absorbed dose in Group 2 was significantly higher than that in Group 1 (381,226.4 ± 28,112.9 vs. 528,335.8 ± 64,422.4 mGy respectively, and P<0.05). Interestingly, the absorbed dose/ml in Group 1 was higher than that in Group 2 (1617.7 ± 118.2 vs. 498.3 ± 146.2 mGy respectively, $P < 0.001$). Further analyses showed moderate positive correlation between the primary tumor absorbed dose (Dose/ml) but not total absorbed dose, and percentage tumor volume changes (31.7 ± 5.05% vs. -20.2 ± 5.2%, $P < 0.001$), as determined by Spearman's correlation ($\rho = 0.90$, $P < 0.001$). These findings suggest that higher absorbed doses/ml are associated with greater primary tumor shrinkage. Similarly, linear regression analysis demonstrated a statistically significant association between the absorbed dose/ml and percentage tumor volume reduction ($R^2 = 0.41$, $P < 0.001$).Interestingly, for metastatic lesions (n=14 in each group), the total absorbed dose (314,819.5±63,090.9 in group 1 vs 250,769.8±88,619.1 in group 2) was significantly correlated with the percentage reduction in tumor size (Spearman's $\rho = -0.42$, $P = 0.045$), whereas no such correlation was observed for dose/ml. However, linear regression did not reveal a significant linear relationship between the total absorbed dose and percentage reduction in tumor volume for metastatic lesions ($P = 0.2$). No treatment-related grade 3 or 4 toxicities were observed during the study. ***Conclusion:*** These findings suggest that the absorbed dose of [^{177}Lu]Lu-FAP-2286 is positively associated with tumor volume reduction in sarcoma patients. This supports the potential for personalized radiopharmaceutical therapy based on patient-specific dosimetry. Further studies with larger cohorts are warranted to validate these results.

EP-1150

Single time point approaches for salivary gland dosimetry and correlation with PET follow-up

A. Noto[1], *X. Shen*[1], *M. Zacherl*[1], *M. Rumiantcev*[1], *G. Liubchenko*[1], *G. Böning*[1], *R. Werner*[1,2], *G. Sheikh*[1], *A. Delker*[1], *S. Resch*[1];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Sciences, Division of Nuclear Medicine and Molecular Imaging, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Salivary glands are primary organs-at-risk in Lu-177-PSMA-treated prostate cancer patients due to the high incidence of xerostomia. Previous studies have shown that PET/CT uptake correlates with absorbed dose and predicts toxicity when using multi-time-point (MTP) dosimetry. This study assessed whether single-time-point (STP) dosimetry after the first therapy cycle can replace MTP dosimetry to reduce clinical workload, and whether the PET-dose correlation remains valid. ***Materials and Methods:*** The submandibular (SG) and parotid (PG) glands of 10 patients with metastatic castration-resistant prostate cancer were included. Three patients received six cycles of Lu-177-PSMA-I&T, and seven underwent four cycles. MTP dosimetry with SPECT/CT acquisitions at 24, 48 and 72 h after injection and mono-exponential time-activity curve fitting served as reference. STP dosimetry for cycle two and onward was performed using SPECT/CT imaging at 24 or 48 h and two different approaches. In the first, the effective half-life was derived from the patient-specific first cycle MTP dosimetry. In the second approach, it was determined using a population-based effective half-life including

all cycles and patients except the one under investigation (leave-one-out method). Mean absolute deviations from the reference absorbed dose values were determined. The correlation between STP absorbed dose and SUV mean values from the second F-18-PSMA-1007 PET (performed prior to the third cycle) was evaluated. ***Results:*** No significant differences were observed between the effective half-lives of different cycles ($p > 0.08$). STP dosimetry at 24 and 48 h showed comparable performance, with 48 h showing slightly better accuracy. For the patient-specific method, the mean deviations for cycles two to six were 10.1±8.3%, 10.±8.6%, 13.7±10.7%, 15.1±9.2%, and 7.4±4.0%. For the population-based method, the mean deviations were 10.6±8.6%, 9.4±9.1%, 14.0±14.0%, 14.0±9.3%, and 9.6±6.6%. The percentage of glands with deviations below 10% was 55.8% for the patient-specific and 57.2% for the population-based method. A strong correlation was found between uptake in the second PET and absorbed dose in the third cycle for both methods, with results similar to those obtained from MTP dosimetry: for the patient-specific method, SGs $r = 0.66$, $p < 0.01$ and PGs $r = 0.61$, $p < 0.01$; for the population-based method, SGs $r = 0.67$, $p < 0.01$ and PGs $r = 0.59$, $p < 0.01$. ***Conclusion:*** Both STP dosimetry approaches may serve as suitable alternatives to MTP dosimetry for assessing salivary gland absorbed doses, and the predictive value of PSMA-PET imaging remains valid for salivary gland toxicity assessment.

EP-1151

Patient-Specific Dosimetry of ^{177}Lu-FAPI-2286 in Peptide Receptor Radionuclide Therapy Using GATE Monte Carlo Simulations: A Pilot Study

S. Shafiee Dastgerdi[1], *L. Hassanzadeh*[2], *G. Divband*[3], *H. Sharifi*[4];
[1]University of Isfahan, Isfahan, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, School of Medicine, Rajaie Cardiovascular, Medical & Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Nuclear Medicine, Jam Hospital,, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Molecular Imaging, Faculty of Advanced Technologies in Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The advent of integrated functional-anatomical imaging modalities such as PET/CT and SPECT/CT has significantly enhanced the accuracy of patient-specific dosimetry in radionuclide therapy over the past decade. 177Lu, with a half-life of 6.7 days, is increasingly utilized in peptide receptor radionuclide therapy (PRRT). Precise quantification of radiation doses to tumors and critical organs. Particularly the kidneys, is essential to optimize therapeutic efficacy and minimize toxicity [1]. ***Materials and Methods:*** The GATE v9.4.1 MC simulations toolkit was used in the present study to produce dosimetric data. The Dose Actor was utilized for dose calculation, and was attached to the CT images with Edep and UncertaintyEdep enabled. This allowed the storage of deposited energy and the statistical uncertainty in the 3D dose map. Each simulation utilized 2.4×10^9 primary particles to ensure high accuracy. Serial planar scintigraphy at 3, 48, and 72 hours post-injection, alongside SPECT/CT at 72 hours, provided time-activity data for dose estimation. Absorbed doses to kidneys and tumors were calculated as Gy/GBq for the first treatment cycle. ***Results:*** No acute adverse events were observed following 177Lu-FAPI-2286 administration.Mean absorbed kidneys dose after treatment for the four patients was 0.89 ± 0.20 Gy/GBq. The results of tumor doses varied for different pathologies: Two female patients aged 35 and 36 years with triple-negative and HER2-positive breast cancer (47 lesions) received 6.3 ± 2.5 Gy/GBq, while two patients (1 male) aged 40 and 47 years with synovial sarcoma and recurrent dermatofibrosarcoma protuberans (11 lesions) received 3.91 ± 1.82 Gy/GBq. ***Conclusion:*** The pilot study demonstrates the feasibility and clinical value of GATE based patient-specific dosimetry in 177Lu-FAPI-2286 PRRT. Accurate dosimetry enables individualized treatment planning, potentially improving therapeutic outcomes and minimizing kidneys toxicity. Further studies with larger cohorts are warranted to validate these preliminary findings and refine dose-response relationships in targeted radionuclide therapies. ***References:*** [1] Stamouli, I., Nanos, T ., Chatzipapas, K., Papadimitroulas, P., Zoglopitou, L., -A., Kalathas, T., Katsakiori, P. Personalized ^{177}Lu-FAPI-2286 Peptide Receptor Radionuclide Therapy Dosimetry in a Metastatic Rectal Cancer Patient: A Simulation Study

H. Sharifi[1], *L. Hassanzadeh*[2], *G. Divband*[3], *S. Shafiee Dastgerdi*[4];
[1]Department of Molecular Imaging, Faculty of Advanced Technologies in Medicine, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, School of Medicine, Rajaie Cardiovascular, Medical & Research Center, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Nuclear Medicine, Jam Hospital, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Faculty of physics, University of Isfahan, Isfahan, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Accurate patient-specific internal dosimetry remains a critical challenge in nuclear medicine. In metastatic rectal cancer, where conventional treatments often fail in advanced stages, personalized dosimetry for ^{177}Lu-FAPI-2286 is vital to optimize therapeutic efficacy while minimizing toxicity. ***Materials and Methods:*** The absorbed dose calculations for this study were based on the Geant4 (GEometry ANd Tracking) Application for Tomographic Emission (GATE) MC toolkit (v9.4). All simulations applied the "standard model" in GATE for electromagnetic processes, which is effective and validated over an energy range of 1 keV-100 TeV. The absorbed dose per organ was calculated, and the deposited energy per voxel was stored using the "dose actor" tool in GATE. The dose actor builds three-dimensional images of the deposited energy in a given volume with a specified voxel resolution. The dose actor takes into account the total energy and the interaction probability of the particles, as well as the density of each voxel. The CT and SPECT images were used as attenuation maps and activity distribution of patient phantom respectively. Hence the CT and SPECT images have been registered by 3D Slicer software to achieve the same matrix and pixel sizes using the module "Resize Image (BRAINS)". Simulations used 2.4×10^9 primaries to ensure statistical accuracy. The study included a 60-year-old male with metastatic rectal cancer undergoing ^{177}Lu-FAPI-2286 therapy. To evaluate the biodistribution and absorbed doses, serial planar scintigraphy was performed at 3, 48, and 72 hours post-injection. Additionally, SPECT/CT imaging was conducted at three days post-injection to determine cumulative activity in tumors and organs. ***Results:*** The patient received an average administered activity of 6.31 GBq over two cycles, constrained by a kidney dose tolerance of 23 Gy. Calculated mean absorbed doses to he kidneys were 0.612 ± 0.0005 Gy/GBq (cycle 1) and 0.544 ± 0.0005 Gy/GBq (cycle 2). Metastatic lesions in bilateral pulmonary nodules, retroperitoneal, and left common iliac lymph nodes showed mean absorbed doses of 5.16 ± 0.003 Gy/GBq (range 0.30 - 7.19 Gy/GBq) in cycle 1 and 3.45 ± 0.005 Gy/GBq (range 0.12 - 5.82 Gy/GBq) in cycle 2. ***Conclusion:*** ^{177}Lu-FAPI-2286 therapy is a promising and well-tolerated option for metastatic rectal cancer. Implementing personalized dosimetry is essential to maximize therapeutic response and safety, supporting tailored treatment planning in targeted radionuclide therapy.

Accuracy, Efficiency and Clinical Validation of GATE and GAMOS-based Monte Carlo dosimetry framework for 99mTc Radiopharmaceutical

A. Alshehri[1,2];
[1]Najran University, Najran, SAUDI ARABIA, [2]Radiology sciences department | Collage of applied medical science | Najran University, Najran, SAUDI ARABIA.

Aim/Introduction: Accurate estimation of absorbed doses from radiopharmaceuticals in human organs relies on computational simulations due to the impracticality of direct measurement. This study employed GATE and GAMOS Monte Carlo codes to simulate

99mTc radiation dose distributions in the Zubal anthropomorphic phantom, focusing on cardiac perfusion imaging protocols. ***Materials and Methods:*** This study employs Monte Carlo simulation frameworks, GATE (Geant4 Application for Tomographic Emission) and GAMOS (GEANT4-Based Architecture for Medicine-Oriented Simulations), to model radiopharmaceutical dosimetry using the Medical Internal Radiation Dose (MIRD) methodology. A Zubal anthropomorphic phantom was simulated in both codes to calculate self-absorbed fractions (SAF), S-values, and mean organ doses for 99mTc, with cumulative heart activity integrated into target organ dose assessments. Activity distributions were analyzed at injection and 60 minutes post-injection (cardiac rest phase) to validate against established clinical data. ***Results:*** GATE leveraged its Geant4-based physics engine for detailed particle transport, while GAMOS prioritized computational efficiency through optimized geometry parameterization. Results demonstrated strong agreement between the codes, with GATE predicting pancreas (21%), gallbladder (18%), and kidneys (16%) as high-dose organs, and GAMOS yielding marginally lower values (20%, 17%, and 15%, respectively). Both frameworks identified comparable trends: pancreas > gallbladder > kidneys > spleen > heart/liver, aligning with prior studies. However, GATE exhibited superior precision due to advanced physics modeling, whereas GAMOS achieved30% faster computation times. ***Conclusion:*** This dual-code approach highlights the trade-offs between accuracy and efficiency in dosimetry, offering a validated framework for optimizing radiopharmaceutical dosing across varying post injection periods. The study underscores GATE's utility for high-precision clinical applications and GAMOS's suitability for rapid prototyping, collectively advancing personalized nuclear medicine therapies. ***References:*** Alessandra Boschi, Licia Uccelli, Lorenza Marvelli, Corrado Cittanti, Melchiore Giganti, and Petra Martini. EP-1154

The effect of glucocorticoids on radioiodine-131 bio-kinetics in patients suffering from Graves' Disease

C. Happel*, B. Bockisch, D. Groener;*
University Medical Center Frankfurt; Clinic for Radiology and Nuclear Medicine; Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Radioiodine therapy (RIT) of Graves' disease (GD) may stimulate the development of Graves' Ophthalmopathy (GO) or exacerbate a pre-existing subclinical GO. Therefore, international guidelines recommend the administration of additional glucocorticoid medication for patients undergoing a RIT with pre-existing GO. Therefore, the aim of this retrospective analysis was to quantify the influence of protective glucocorticoid medication on intra-therapeutic effective half-life of ^{131}I during RIT of patients suffering from GD. ***Materials and Methods:*** 211 patients with GD who underwent RIT without any additional thyroid medication were analysed retrospectively. These patients were subdivided into two subgroups. Group A: 35 patients with concomitant EO and protective glucocorticoid medication; Group B: 176 patients without EO and additional glucocorticoid medication. Effective half-life was determined pre- and intra-therapeutically and compared statistically between the groups. ***Results:*** In the glucocorticoid group the mean effective half-life was 5.69 d in RIUT and 5.47 d during RIT ($p > 0.05$). A comparable result was obtained in group B (5.75 d in RIUT and 5.46 d during RIT; ($p > 0.05$)). The comparison of the two subgroups did not show a significant relation ($p = 0.79$). Therefore, intrathyroidal effective half-life is not significantly influenced by glucocorticoid medication. ***Conclusion:*** Current studies found the mineralocorticoid potency of Prednisolone to possibly decrease intra-thyroidal EHL. In the presented study those results could not be verified. This might be due to the use of Methylprednisolon instead of Prednisolon. The reason for the reduced intrathyroidal EHL may therefore be the diuretic effect of prednisolone.

EP-1155

Evaluation of different methods for determining the intra-renal effective half-life during ^{177}Lu-PSMA-617 Radioligand Therapy

C. Happel*, B. Bockisch, K. Klimek, D. Groener;*
University Medical Center Frankfurt; Clinic for Radiology and Nuclear Medicine; Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: In Radioligand therapy (RLT) with ^{177}Lu-PSMA the kidneys are the primary organ at risk. Prerequisites for renal dosimetry are absolute quantification of the intra-renal activity and determination of the intra-renal effective half-life (IREHL) of the radiopharmaceutical. For absolute quantification of intra-renal activity at least one SPECT/CT-acquisition is necessary. EHL can be determined using a VOI-analysis of sequential SPECT-acquisitions (Method A), a ROI-analysis of the dorsal views (Method B) or the geometric-mean of conjugated views from sequential scintigraphic whole-body images (WB) (Method C). Aim of this study was to evaluate the aforementioned methods for calculating EHL comparatively. ***Materials and Methods:*** Scintigraphic data of 30 consecutive patients who underwent RLT with ^{177}Lu-PSMA-617 were evaluated retrospectively. Mean age of the patients was 73±6.9a. Mean administered activity was 7.8±1.1GBq. Abdominal SPECT-images and conjugated WB were obtained 24, 48, and 72h after administration (AnyScan-Mediso; SPECT: 64steps; 15s/step; scan-speed (WB) 20cm/min). IREHL was calculated for each patient using a mono-exponential fit to the time-activity-curve using methods A, B, and C. ***Results:*** Mean EHL calculated from Method A was 30.2±6.8h for the left (lk) and 30.6±7.2h for the right kidney (rk), which is consistent with Sarnelli et al. (39.2 ± 21 h) [1]. The ROI-analysis of Method B yielded mean IREHL of 45.8±30h (lk) and 40.9±20h (rk). The ROI-analysis of Method C yielded mean IREHL of 70±68h (lk) and 52.2±37h (rk). To assess the accuracy of the different methods of calculation, the determination-coefficient was calculated for each analysis. Median R2 was 0.992 (lk) and 0.993 (rk) (A), 0.986 and 0.988 (B) and 0.941 and 0.971 for Method C. ***Conclusion:*** The analysis revealed significant deviations between IREHL determined by Method B and C compared to the IREHL determined with Method A. These significant differences and the high fluctuation ranges in the evaluation of the WB result primarily from the often temporally altered superimposition by intestine, other organs such as spleen and liver, and in some cases from the superimposition by metastases. The deviations and the evaluation of the determination-coefficient show that a correct determination of the IREHL via ROI analysis of WB (method B and C) is not possible due to patient-specific differences in the superimposition. The determination must therefore necessarily be carried out via a VOI evaluation of several sequential SPECT images (method A).

EP-1156

Thyroid dosimetry in two common ^{123}I-based neurological studies: a retrospective study

W. Morton, *R. Feathers, J. Freeman, P. Bartholomew; South Tyneside and Sunderland NHS Foundation Trust, Sunderland, UNITED KINGDOM.*

Aim/Introduction: Radioiodine-based radiopharmaceuticals are commonly used in diagnostic nuclear medicine neurological studies. To reduce dose to the thyroid it is common practice to administer stable iodide to the patient prior to injection of the radiopharmaceutical as a thyroid prophylaxis. The aim of this study was to measure the absorbed dose to the thyroid in patients injected with ^{123}I-Ioflupane and ^{123}I-meta-iodobenzylguanidine (MIBG) where the thyroid was not blocked with prophylaxis. ***Materials and Methods:*** A cohort of 80 patients were included in this retrospective study; 39 patients undergoing ^{123}I-Ioflupane SPECT and 41 patients undergoing planar cardiac ^{123}I-MIBG. In the group of patients undergoing ^{123}I-Ioflupane study, 9 received thyroid blocking prophylaxis (120 mg potassium iodide) and the remaining 30 did not; of the 41 patients undergoing cardiac ^{123}I-MIBG, 12 received thyroid prophylaxis and 29 did not. In addition to standard clinical imaging all patients underwent planar scintigraphy of the thyroid. The measured counts in the thyroid were used to calculate the activity of radioiodine in the thyroid using the known sensitivity of the gamma camera to ^{123}I. Calculated cumulative activity in the thyroid was then used to work out the thyroid-thyroid absorbed dose, $D(r_{thy}\text{-}r_{thy})$, following standardised MIRD methodology. ***Results:*** Mean $D(r_{thy}\text{-}r_{thy})$ calculated for the four sub-cohorts of patients in this study were calculated as: ^{123}I-Ioflupane (185 MBq) with prophylaxis 0.0 mGy, ^{123}I-Ioflupane (185 MBq) no prophylaxis 10.8 mGy; ^{123}I-MIBG (370 MBq) with prophylaxis 4.7 mGy, ^{123}I-MIBG (370 MBq) no prophylaxis 17.5 mGy. The range of measured thyroid uptake activity in each patient sub-cohort followed a log(normal) distribution, as expected. ***Conclusion:*** In the UK, national clinical guidelines recommend blocking the thyroid in non-thyroidal radioiodine diagnostic studies where the absorbed dose to the thyroid is >50 mGy. No patient within this study received a thyroid dose greater than this value (maximum 42.2 mGy). We believe these findings could contribute to the justification for not blocking the thyroid in ^{123}I-based neurological studies in cases where administration of the prophylaxis is contraindicated (for example, iodine hypersensitivity or sub-clinical hyper/hypothyroidism). ***References:*** Bochet, L.G. 1999, 40:62S-101S. Evaluation of Voxel-Based Dosimetry Using Different Calculation Algorithms in 177Lu-PRRT

M. Masubuchi[1,2], *K. Miwa*[2,3], *N. Miyaji*[3], *T. Yamao*[3], *N. Akiya*[2], *K. Wachi*[2], *S. Kimura*[3], *K. Furuya*[1], *T. Nakamura*[1], *Z. Wu*[1], *A. Iwasaka*[1], *S. Hashimoto*[1], *Y. Hirano*[1];
[1]*Department of Radiology, University of Tsukuba Hospital, Tsukuba, JAPAN,* [2]*Department of Radiological Sciences, Graduate School of Health Sciences, Fukushima Medical University, Fukushima, JAPAN,* [3]*Department of Radiological Sciences, School of Health Sciences, Fukushima Medical University, Fukushima, JAPAN.*

Aim/Introduction: Voxel-based dosimetry is essential in targeted radionuclide therapy (TRT), allowing the estimation of absorbed dose distributions based on serial SPECT/CT imaging. Differences in calculation algorithms can lead to discrepancies in absorbed dose estimates. The present study aimed to evaluate the performance of five voxel-based absorbed dose calculation methods by comparing them with the ground truth absorbed dose (Gy) derived from pharmacokinetic modeling. ***Materials and Methods:*** Ground truth absorbed dose (Gy) was generated using a pharmacokinetic model for 177Lu-DOTATATE with the anthropomorphic ICRP 110 phantom. A 3D-printed phantom (MRT Dosimetry Project) was imaged at six time points (1, 4, 24, 40, 72, and 144 hours post-injection) using SPECT/CT. Volumes of interest (VOIs) were defined for the liver, spleen, kidneys, and tumor. Absorbed doses were calculated using five algorithms: (1) Full Monte Carlo (FMC) using RT-PHITS (EGS5-based, JAEA), (2) Semi Monte Carlo (SMC) using Voxel Dosimetry (Hermes, based on PENELOPE), and three algorithms implemented in OpenDose3D via 3D Slicer—Local Energy Deposition (LED), convolution-based voxel S values (CONV), and full Monte Carlo using GEANT4. Estimated doses were compared to the ground truth, and percent deviations were calculated for each VOI. ***Results:*** Ground truth absorbed dose (Gy) were: liver 1.7, spleen 5.4, right kidney 3.6, left kidney 3.6, tumor 28.1. RT-PHITS, a full Monte Carlo method, showed the highest accuracy for all organs: liver (2.9Gy 72.11%), spleen (5.3Gy -1.71%), right kidney (4.1Gy 12.53%), left kidney (3.9Gy 9.17%), tumor (27.8Gy -1.15%). The spleen and tumor showed high accuracy with deviations within ±2%. Notably, liver doses were consistently overestimated across all software, likely due to the presence of lesions in the liver region. ***Conclusion:*** Algorithm selection influences the accuracy of voxel-based dosimetry in 177Lu-PRRT. RT-PHITS, using the Full Monte Carlo method, provided the highest overall accuracy for all organs. Caution should be exercised when estimating doses in organs containing lesions, as these may lead to over estimation. ***References:*** Kenta Miwa, et al. Feasibility of individual dosimetry using RT-PHITS for patients with SPECT/CT imaging after ^{177}Lu-DOTATATE peptide receptor radionuclide therapy, Phys Eng Sci Med, 2025, in press.

EP-1158

Computational and Nuclear Data Evaluation of an Emerging Therapeutic Copper Radioisotope for Imaging and Dosimetry

M. Mehrabi;
Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The therapeutic application of beta-emitting radiopharmaceuticals has seen remarkable progress in recent years, particularly in the treatment of neuroendocrine tumors, prostate cancer, and other malignancies. Among emerging candidates, copper-67 ($t_{1/2}$ = 2.6 days) has attracted increasing attention due to its favorable decay characteristics and its chemical compatibility with copper-64, a positron-emitting isotope widely used in diagnostic imaging. ***Materials and Methods:*** This study investigates the imaging and dosimetric characteristics of copper-67 through simulation-driven analysis, leveraging nuclear decay data from IAEA and ICRP databases. Photon emission probabilities, energy spectra, and internal dose coefficients were extracted to model its performance in clinical imaging scenarios. Monte Carlo simulations were used to model photon transport and estimate recovery coefficients (RCs) within a standard anthropomorphic chest phantom, enabling direct comparison with ^{99m}Tc, ^{177}Lu, and ^{64}Cu under identical imaging conditions. ***Results:*** Analysis of nuclear data confirmed the dominant gamma emission at 184.6 keV with a yield of approximately 48.7%, which, in combination with medium-energy collimators, was found optimal for SPECT imaging. Simulated images showed comparable quality to those of ^{177}Lu, with recovery coefficients supporting quantitative accuracy. Dosimetric evaluation using standardized S-values indicated therapeutic beta emissions with a mean energy of 141 keV per decay, suitable for mid-range tissue penetration. ***Conclusion:*** By incorporating nuclear decay and dosimetric data, this study demonstrates the imaging viability and therapeutic potential of copper-67. The findings support its role as a dual-function radionuclide for theranostic applications. Given its favorable physical and radiological properties, copper-67 holds significant promise for future clinical applications, and further investigations into its therapeutic efficacy are strongly encouraged.

Avidination for RadionuclideTHerapy in Nonpalpable Breast Cancer (ARTHE): Dosimetry of a New Locoregional Approach

A. Sarnelli[1], *M. Cremonesi*[2], *E. D'Andrea*[3], *M. Sansovini*[1], *V. Di Iorio*[1], *M. Monti*[1], *P. Sanna*[4], *M. Amadori*[4], *A. Curcio*[4], *P. Possanzini*[4], *I. Grassi*[1], *P. Caroli*[1], *I. Marini*[1], *S. Nicolini*[1], *M. Belli*[1], *V. Mautone*[1], *E. Scarpi*[1], *L. Fabbri*[1], *A. Miserocchi*[1], *G. Paganelli*[5], *F. Falcini*[4], *F. Matteucci*[1];
[1]*Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori", Meldola, ITALY,* [2]*Istututo Europeo di Oncologia, Milano, ITALY,* [3]*Azienda Ospedaliero-Universitaria Policlinico Umberto I, Roma, ITALY,* [4]*AUSL Romagna, Forli, ITALY,* [5]*Istituto Oncologico Romagnolo, Forli, ITALY.*

Aim/Introduction: "Avidination for RadionuclideTHerapy in Nonpalpable Breast Cancer (ARTHE)" is an innovative nuclear medicine approach for the management of early breast cancer. Few days after a Vacuum Assisted Breast Biopsy (VABB), in the presence of cancer, avidin is injected under ultrasound guidance into the VABB cavity followed by an injection of Biotin-DOTA-90Y. The goal in terms of absorbed dose prescription is to deliver about 200 Gy to the residual microscopic disease into the target volume surrounding the VABB cavity. This phase-I study investigates three activity levels of 90Y Dota-biotin and evaluates side effects and biodistribution of avidin-biotin-DOTA-90Y after loco-regional injection. ***Materials and Methods:*** The empty cavity volume resulting after the VABB procedure ranges between 1 and 1.7 ml and the radioactive solution is meant to be injected within such a cavity. Three activity levels are investigated: 28, 57 and 126 MBq. A standard scintigrafic whole-body image and a PET image are acquired at 1-3 h p.i to exclude the possibility of wash-out from the lesion site and to perform dosimetry, respectively. In a cohort of 18 patients, serial PET images are acquired at different time points. A dedicated software is used to segment the region of interest, to quantify the activity inside the target region. A MonteCarlo (MC) simulation of the dose profile inside and outside the cavities is performed to evaluate the dose in the tissues surrounding the cavity, where residual microscopic disease is generally still present. The adsorbed dose is estimated at different distances (1-3 mm) from the cavity edge with and without diffusion. PET images are processed in order to generate individualized input source and geometry files for dose computation with the MC approach. ***Results:*** We simulate the dose profiles for various cavity geometries and volumes. The three levels of activity investigated result in a 200 Gy absorbed dose at the edge of the cavity. The dose strongly decreases as a function of the distance, sparing the healthy tissues. Thanks to the cross-fire effect and the range of beta particles, the diffusion guarantees higher doses to the microscopic disease surrounding the VAAB cavity than without diffusion. ***Conclusion:*** The dose strongly depends on the assumption made on the cavity volume and on the distance from the injection site. The outcome also depends on the operator's experience. Further investigations are needed to correlate the absorbed dose with the clinical follow-up and the anatopathological results.

EP-1160

Optimizing CD44v6-Targeted Radioimmunotherapy: A Retrospective Red Marrow Dosimetry Comparison of ^{186}Re, ^{177}Lu, and ^{161}Tb

J. Hemmingsson[1], *M. Nestor*[2], *A. Lundgren Mortensen*[3], *F. Y. Frejd*[4], *P. Bernhardt*[1];
[1]*University of Gothenburg - Sahlgrenska Academy, Gothenburg, SWEDEN,* [2]*Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala, SWEDEN,* [3]*Department of Molecular Medicine and Surgery, Karolinska Institutet, Gothenburg, SWEDEN* [4]*Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: CD44v6-targeted radioimmunotherapy (RIT) has emerged as a promising treatment for several cancers with limited therapeutic alternatives. The slow clearance of full-sized antibodies from the bloodstream promotes tumor uptake but also increase radiation exposures to risk organs, such as to the radiosensitive red marrow. While emerging therapies tend to favor medium- to short-range electron emitters like 177-lutetium or 161-terbium, clinical studies have evaluated bivatuzumab (BIWA 4), labelled with the long range beta emitter 186-rhenium, demonstrating tumor response and acceptable tolerability (1, 2). The aim of this study is to retrospectively estimate the red marrow absorbed dose for ^{186}Re, ^{177}Lu, and ^{161}Tb using published clinical data, and compare these estimates with previously reported values. ***Materials and Methods:*** Multiple time-point data on activity concentrations in serum (n=20) and bone marrow aspirate (n=9) from the two clinical trials with ^{186}Re-BIWA 4 was used as input for a compartment model. The model assumes no specific uptake in the red marrow, which is supported by the data where activity concentrations in the bone marrow supernatant is, on average, 4 times higher than for the cell pellet. After correcting for the differing physical half-lives, radionuclide-specific biodistributions were generated for ^{186}Re, ^{177}Lu, and ^{161}Tb. Red marrow absorbed doses were estimated using blood-based and aspiration-based dosimetry methods, in addition to the blood-based approach used in the original study, which was applied only for ^{186}Re. ***Results:*** The blood-based method, assuming equivalence between plasma and extracellular red marrow activity concentrations, resulted in skeletal-averaged absorbed doses to red marrow of 0.37, 0.22, and 0.34 Gy/GBq for ^{186}Re, ^{177}Lu, and ^{161}Tb, respectively. Although calculated differently, switching to supernatant activity concentrations from bone marrow aspirate produced similar estimates: 0.33, 0.21, and 0.31 Gy/GBq. Combining our serum biodistribution data for ^{186}Re with the original dosimetry approach yielded red marrow doses of 0.61 and 0.47 Gy/GBq for males and females, respectively, values closely matching the originally reported 0.64 and 0.49 Gy/GBq. ***Conclusion:*** For CD44v6-targeted RIT, the blood-based methodology produces red marrow absorbed dose estimates comparable to those from bone marrow aspirate. These estimates are crucial for guiding the optimization of radionuclide therapies by informing the selection of radionuclides and activity levels that balance therapeutic efficacy with haematological safety. As such, accurate red marrow dosimetry plays a central role in the development of safer and more effective RIT strategies. ***References:*** 1.Börjesson PK et al. Deep Longitudinal Immunophenotyping of Immune Cells in Patients with Metastatic Castration-Resistant Prostate Cancer Treated with ^{212}Pb-based PSMA-Targeted Alpha Therapy

A. Soderholm[1], *A. Karmann*[1], *A. Hansen*[2], *S. Sandhu*[3], *C. Sweeney*[4], *L. Leveque-El Mouttie*[5], *D. Wyld*[6], *M. Baronet*[1], *N. Esteban*[1], *M. Crumbaker*[1], *L. Skingley*[1], *T. Kryza*[1], *P. Santoro*[1], *G. Li*[1], *S. Puttick*[1], *S. Shakti*[1], *S. Rose*[1];
[1]*AdvanCell Pty Ltd, Sydney, AUSTRALIA,* [2]*Princess Alexandra Hospital, Brisbane, AUSTRALIA,* [3]*Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,* [4]*University of Adelaide, Adelaide, AUSTRALIA,* [5]*Translational Research Institute, Brisbane, AUSTRALIA,* [6]*Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA.*

Aim/Introduction: Radioligand therapies (RLT) represents a promising modality for cancer treatment. However, the effects of

RLT on immune cell populations and the potential for immune biomarkers to predict treatment responses and optimise treatment are not yet understood. This research aims to design and validate a full-spectrum flow cytometry panel for the detection of immune cell populations in blood samples from patients with metastatic castration-resistant prostate cancer (mCRPC) who received ^{212}Pb-based PSMA-targeted RLT, ^{212}Pb-ADVC001, in the TheraPb study (NCT05720130). Following panel validation, immune cell populations will be characterised to identify potential immune biomarkers that may predict treatment response and guide the selection of novel therapeutic combinations for future studies. ***Materials and Methods:*** A 32-color flow cytometry panel was developed for deep immunophenotyping of the major immune cell subsets present in the peripheral blood of mCRPC patients using a 5-laser full-spectrum cytometer (Cytek Biosciences). Markers and gating strategies to identify immune populations including CD4 T cells, CD8 T cells, regulatory T cells, gamma-delta T cells, NKT-like cells, B cells, NK cells, macrophages, monocytes, and dendritic cells were optimised. The panel allows for further characterisation of each cell type using activation and differentiation markers, enabling identification of 35 distinct immune subpopulations. The Cytek Panel Builder and AI-guided SpectroPanel tool were used for fluorescent tag assignment, assessment of panel complexity, and selection of commercially available antibodies. Cryopreserved peripheral blood mononuclear cells (PBMCs) from patients receiving ^{212}Pb-ADVC001 in the TheraPb trial were used to validate the panel before analysing temporal changes in PBMC populations longitudinally. ***Results:*** A novel flow cytometry panel has been developed to study immune cell populations in patients with mCRPC treated with ^{212}Pb-ADVC001. Clear resolution of all immune populations was achieved, with the gating strategy reliably identifying 35 distinct immune subpopulations. Fluorescence spillover and spectral overlap were minimal. The assay effectively monitors PBMC changes in both fresh and cryopreserved samples. ***Conclusion:*** We present a novel flow cytometry panel specially tailored to phenotype immune cell populations in patients treated with ^{212}Pb-ADVC001. The panel has potential to provide valuable insights into the adaptive immune response in subjects treated with targeted alpha therapies. The presented approach may also be beneficial in predicting response and optimising dosing schedules, enabling biomarker driven adaptive dosing regimens. Results from preliminary analyses showing changes in immune cell populations elicited by ^{212}Pb-ADVC001 during treatment will be presented.

EP-1162

Optimizing Radiopharmaceutical Dosage in Pediatric SPECT-CT

M. Weymeskirch, *F. Hubele, O. Allegrini, J. Salvadori, C. Porot;*
Institut de Cancérologie Strasbourg Europe (ICANS), Strasbourg, FRANCE.

Aim/Introduction: The European Association of Nuclear Medicine (EANM) pediatric dosage card provides essential guidance for adjusting radiopharmaceutical (RP) activity according to patient weight and RP type. However, certain clinical situations fall outside established standards, in which explicit recommendations are lacking, particularly for high-weight children and adolescents, or less common procedures. This study aims to evaluate how these gaps are addressed in clinical practice and to identify areas in need of clarification or standardization. ***Materials and Methods:*** This retrospective study included 451 pediatric SPECT-CT (single-photon emission computed tomography/computed tomography) scans performed between January 2023 and December 2024 at the nuclear medicine department. Data on patient age, weight, RP type, and administered activity were collected using Pharma Manager®. When applicable, administered activities were compared to the EANM dosage card (version 2016). Special attention was paid to cases not covered by standard recommendations. A multidisciplinary team reviewed these scenarios to propose protocol improvements. ***Results:*** Pediatric SPECT-CT examinations represent approximately 2.5% of annual nuclear medicine procedures at the department. Most procedures, including bone scintigraphy (HDP), static renal imaging (DMSA), and dynamic renal imaging (MAG3) were compliant with EANM dosage card guidelines. However, several gaps in standardization were noted:Patients over 68 kg (13 examinations): The dosage card provides no pediatric guidance for this group. Adjustments were made using capped pediatric protocols or adult dosages, based on clinical judgment and required image quality.Uncommon procedures: For gastric emptying studies (7 examinations), no official dosage card recommendations exist. Dosing decisions were guided by EANM publications, published case studies, or expert consensus. ***Conclusion:*** Our findings highlight the limitations of the current EANM dosage card in certain pediatric scenarios. Local adaptation and multidisciplinary decision-making remain essential for managing high-weight young patients and rare procedures. We recommend extending the EANM dosage card to include patients up to 100 kg and to incorporate less common pediatric procedures such as Meckel scintigraphy and gastric emptying studies. These updates would contribute to greater harmonization, reduce variability in clinical interpretation, and enhance the safety and consistency of pediatric nuclear medicine across institutions.

Improving the target design for enriched Iridium-192 production for brachytherapy

S. Kashi, *A. Nourouzi, M. Dehghan, A. Naserbegi, M. Behzadi, M. Mehrabi, M. Asadian;*
Advanced Technologies Company of Iran, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Iridium-192 is a significant radioactive isotope utilized in the medical field, particularly in brachytherapy. It is produced through (n,γ) reactions in a nuclear reactor under neutron flux. Ir-192 decays by emitting beta and gamma particles, with maximum energies of 0.672 MeV and 0.604 MeV, respectively. Ir-192 is effective for treating tumors in various organs, including the breast, tongue, prostate, and brain, due to its relatively low energy gamma emission (0.412 MeV), allowing for precise targeting. The design of targets for the production of Ir-192 is influenced by the specific activity of the isotope, which depends on the enriched isotope, density and geometric dimensions of the target. ***Materials and Methods:*** In this study, enriched Ir-191 was produced to 99% in the form of IrF6 through a gas separation process. Following the separation, the Ir-191 was converted into powdered Ir, which was then shaped into or wire lengths of 0.6 x 3.5 mm, achieving a purity of 99.9%. The density of the disks was measured, resulting in a range of 14-23 g/cm^3, as confirmed by experimental results. The specific activity of Ir-192 was evaluated using the Monte Carlo method with the MCNP-2.6 code under the thermal flux of 7.0E+13 n/cm^2. ***Results:*** The results indicated that reducing the density and thickness of the target significantly increased the specific activity of Ir-192. Experiments showed that lower density targets yielded higher specific activity, which corroborated the computational findings. The optimal design parameters for the production of Ir-192 were

identified, demonstrating how modifications in target geometry and composition can enhance yield and effectiveness. The calculation results for densities between14 and 23 g/cm^3, show specific activities of 1200 to 970 ci/g. So by reducing the density, higher specific activities are obtained. ***Conclusion:*** The findings confirm that adjustments in target density can lead to increased specific activity, making Ir-192 more effective for brachytherapy. Considering the self-shielding effect and high absorption cross-section, the specific activity of Ir-192 depends on the density of the target. ***References:*** IAEA-TECDOC-1340. Manual for reactor produced radioisotopes. January 2003

EP-1164

Innovative cation-exchange strategies towards cost-effective terbium/gadolinium separations

A. Moiseeva[1], *P. V. Grundler*[1], *Z. Gao*[2], *J. W. Engle*[2], *N. P. van der Meulen*[1];
[1]*Paul Scherrer Institute, Villigen PSI, SWITZERLAND,* [2]*University of Wisconsin–Madison, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Lanthanide separation is challenging due to the similar chemical properties and atomic radii of these elements. However, the emergence of radiolanthanides in nuclear medicine has motivated pursuit of robust, reliable, fast, and cost-efficient separation methods. In this work, a commercial cation exchange resin was studied to determine its potential for isolating no-carrier-added terbium from gadolinium target. Terbium radioisotopes could cover the whole spectrum of nuclear medicine since there are positron and photon emitters ideally suited for diagnosis, and β$^-$-/Auger- and α-emitters used for therapy, thus expanding significantly the field opened by ^{177}Lu and currently a standard in targeted radionuclide therapy. ***Materials and Methods:*** AG MP-50 macroporous cation exchange resin was evaluated by means of bench experiments. Distribution coefficients for gadolinium, terbium, and dysprosium were measured. Chromatographic columns (10 mm × 150-180 mm) containing AG MP-50 resin (NH_4^+ form) were loaded with 10-50 µg of terbium and dysprosium (from ICP analytical standards) and with up to 115 mg of natural gadolinium oxide dissolved in 1 mL 8-10 M HNO_3. Elution was performed with α-hydroxyisobutyric acid (α-HIBA), and collected fractions were analyzed by ICP-OES. ***Results:*** According to the distribution coefficients, the most optimal concentration of the α-HIBA eluent was 0.13 M (pH 4.5), where the calculated Tb/Gd separation factor (S_F) was determined at 3.3. For dynamic experiments, dissolution, saturation, loading, and rinsing steps were optimized to achieve the efficient separation of 10 µg of terbium from up to 50 mg of gadolinium with $S_F > 10^5$, confirmed by ICP-OES analysis. The yield of terbium in this case was higher than 99 %. The volume of the purified terbium fraction is ~ 45-50 mL, which allows the collection of terbium fraction to be controlled, e.g., for implementation in a hot cell. ***Conclusion:*** A method to separate terbium from gadolinium oxide material was developed using a commercially available cation exchange resin. The technique produced results promising for ^{155}Tb and ^{161}Tb production (1, 2). It has been effective using trace terbium activities and will be applied to higher activities soon. ***References:*** 1. Favaretto, C., Talip, Z., Borgna, F., et al. (2021). EP-1165

High efficiency isolation of theranostic terbium radioisotopes from gadolinium with cation exchange chromatography

Z. Gao[1], *E. Aluicio-Sarduy*[1], *A. N. Moiseeva*[2], *T. E. Barnhart*[1], *N. P. van der Meulen*[2,3], *J. W. Engle*[1,4];
[1]*University of Wisconsin – Department of Medical Physics, Madison, WI, UNITED STATES OF AMERICA,* [2]*PSI Center for Life Sciences - Center for Radiopharmaceutical Sciences, Villigen, SWITZERLAND,* [3]*PSI Center of Nuclear Engineering and Sciences - Laboratory of Radiochemistry, Villigen, SWITZERLAND,* [4]*University of Wisconsin - Department of Radiology, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: Terbium radioisotopes are interesting for theranostic nuclear medicine [1]. Their purification from accelerator and reactor feedstock materials is challenging, as for the entire lanthanide series' similar fundamental chemistries [2]. In this study, Aminex 50W-X4 and -X6 resins were investigated for their ability to efficiently isolate no-carrier-added (n.c.a.) terbium radioisotopes from macroscopic quantities of gadolinium. ***Materials and Methods:*** Distribution coefficients (K_d) were measured to identify the most suitable candidate from two sulfonic-acid-based resins for dynamic (column) experiments. Both resins were tested using dissolved $^{nat}Gd_2O_3$ and terbium ICP standard or cyclotron-irradiated $^{nat}Gd_2O_3$. Columns containing resin (10x143mm, NH_4^+ form) were loaded with gadolinium and terbium in HNO_3 media and eluted with 0.13 M α-HIBA solution adjusted to pH 4.5 with NH_4OAc. Fractions collected from experiments with stable isotopes were analyzed by ICP-OES. Sequential proton and deuteron irradiations of pressed pellets of $^{nat}Gd_2O_3$ produced, among others, ^{156g}Tb ($t_{1/2}$ = 5.35d, 100% EC, 67% 534.29keV γ) and ^{159}Gd ($t_{1/2}$ = 18.479h, 100% , 11.78% 363.543keV γ) for tracer experiments. Eluent fractions were analyzed with HPGe. ***Results:*** K_d measurements indicated that both resins have potential for Gd/Tb separation. In dynamic experiments, resolution between gadolinium and terbium improved with decreasing HNO_3 concentrations in load solutions and at lower flow rates. Targets were dissolved in 6mL 1.3M HNO_3 and loaded at 0.5mL·min^{-1}. In these optimized conditions, 50W-X6 resin experiments recovered more than 99.99% of terbium from 40mg gadolinium (Tb/Gd $S_F > 10^5$) and 99.97% of ^{156}Tb from 40mg irradiated $^{nat}Gd_2O_3$ (Tb/Gd $S_F > 10^5$). 50W-X4 results were less promising. The limit of detection of gadolinium by ICP-OES was 0.01ppm. ***Conclusion:*** Aminex 50W-X6 shows potential for efficient isolation of terbium radioisotopes from gadolinium targets. The method can be used to isolate reactor-produced ^{161}Tb (β$^-$) and charged-particle produced ^{152}Tb (β$^+$) and ^{155}Tb (γ) radioisotopes. ***References:*** [1] DOI: 10.1007/s00259-013-2563-z [2] DOI: 10.1016/j.nucmedbio.2023.108389

Aim/Introduction: Tb161 is an emerging radionuclide for therapeutic applications. It emits low-energy beta particles as well as conversion electrons and Auger electrons. Tb161 in no-carrier-added (n.c.a.) quality is produced by thermal neutron capture on enriched Gd-160 targets, followed by decay of short-lived Gd161 to Tb161 and a radiochemical Gd/Tb separation. Yields and radionuclidic purity of the produced Tb161 depend directly on the quality of the target material, i.e. its enrichment level and chemical purity, and on the irradiation conditions. ***Materials and Methods:*** Activation calculations and test irradiations of different enriched Gd-160 targets have been performed for different neutron flux conditions at different research reactors: RHF operated by ILL Grenoble, MARIA operated by NCBJ Swiérk, BRR operated by HUN-REN EK-CER Budapest and TRIGA RC-1 operated by ENEA Casaccia. ***Results:*** The measured Tb161 yields scale roughly proportionally to the thermal neutron flux, indicating that "product burnup" of Tb161 by subsequent neutron captures is not a limiting factor. The residual content of Gd157 and Gd155 in enriched Gd160 determines the magnitude of neutron self-shielding in larger targets and hence may limit the scale-up of production. Tb159 as chemical impurity and Gd158 as isotopic impurity in a Gd-160 target would lead to reduced molar activity of the produced Tb161 and admixture of traces of longer-lived Tb160. Therefore, highly enriched and chemically pure Gd160 targets are required to produce Tb161 in true n.c.a. quality. ***Conclusion:*** Based on the nuclear physics properties that are decisive for this production path, high-purity n.c.a. Tb161 could be produced at a comparable scale and roughly similar costs as n.c.a. Lu177, but the availability of highly enriched Gd-160 target material remains a prerequisite. ***References:*** This project has received funding from the European Union under grant agreement No 101061230 (SECURE), from the European Union's Horizon 2020 research and innovation programme under grant agreement No 101008571 (PRISMAP) and from the French Institut National du Cancer under grant agreement No INCA_16111 (PLBIO21-243). Part of the isotopes used in this research were supplied by the U.S. Department of Energy Isotope Program, managed by the Office of Isotope R&D and Production.

Preparation of Large-Area 203Tl Targets for Medical Radionuclide Production

J. Chen, *Z. Liu;*
Peking University, Beijing, CHINA.

Aim/Introduction: High-purity thallium-203 (^{203}Tl) targets are critical precursors for cyclotron-based production of diagnostic radionuclides such as ^{201}Tl and ^{203}Pb. To enhance production yield, advanced target designs with inclined geometries and minimized beam-target angles are employed to distribute high beam power over larger areas, improving heat dissipation. However, achieving uniform electrodeposition of Tl on large or irregularly shaped substrates remains a significant challenge. ***Materials and Methods:*** A thallium nitrate ($TlNO_3$) solution was prepared in deionized water as the plating bath, supplemented with , ethylenediaminetetraacetic acid (EDTA), and the surfactant BRIJ-35 (to reduce overpotential). Silver sheets served as substrates for circular (φ10 mm) or rectangular (14 mm × 150 mm) electroplating. The bath pH was maintained at 8-9.5 using NaOH or H_2SO_4. Electrodeposition was performed under square-wave voltage (1~10 Hz) with a magnetic stirrer (300 rpm), a maximum current density of 15 mA/cm^2, and controlled bias (forward: 10 mA/cm^2, reverse: 2~3 mA/cm^2). Post-plating, targets were rinsed with water/ethanol, dried, and evaluated for thickness uniformity, material recovery, and mechanical stability. ***Results:*** The optimized protocol achieved a uniform Tl deposit of 1023 mg/cm^2 on φ10 mm circular areas. For irregular geometries, a 14 mm × 150 mm rectangular substrate exhibited a homogeneous thickness of 415 mg/cm^2. EDTA ensured stable Tl^+ solubility, while BRIJ-35 mitigated localized overpotential, enabling smooth deposition. Hydrazine hydrate effectively suppressed prevents Tl^+ oxidation to Tl^{3+} at the anode. The square-wave voltage strategy enhanced adhesion and thickness control, critical for high-power irradiation. ***Conclusion:*** A reproducible electroplating method was developed for large-area ^{203}Tl targets, addressing challenges in uniformity, adhesion, and scalability. By integrating alternating current and optimized bath chemistry, this approach enables robust fabrication of high-thickness Tl coatings suitable for cyclotron irradiation, advancing the production efficiency of medical radionuclides.

EP-1168

Cyclotron-Based ^{64}Cu Production from ^{64}Ni: MCNPX Simulation and theoretical Validation

Z. Karimi, *H. Azizakram, A. Abolhosseini Shahrnoy;*
Parsisotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,

Aim/Introduction: ^{64}Cu is a versatile radionuclide widely used in positron emission tomography (PET) and targeted radionuclide therapy due to its favorable decay properties (β^+, β^-, half-life: 12.7 hours). This study investigates the production and optimization of ^{64}Cu via the ^{64}Ni(p,n)^{64}Cu reaction in a low-energy cyclotron, focusing on simulation-based yield predictions. A key challenge to successful radiolabeling in medical applications is minimizing impurities from competing reaction channels while maintaining high activity. ***Materials and Methods:*** The production process was simulated using the Monte Carlo code MCNPX, with reaction cross-sections calculated from the ENDF/B-VII library. Enriched 64Ni (99.53%) target was designed using SRIM code, optimizing geometry based on stopping power calculations to match experimental setups of a CYCLON30 cyclotron. Proton energies (6 - 13 MeV) were evaluated to maximize the ^{64}Ni(p,n)^{64}Cu cross-section while minimizing impurities. According to the ^{64}Ni(p,n)^{64}Cu excitation function, the highest yield of this nuclear reaction is expected at 11.66 MeV incident proton beam energy, with good efficacy in the 6-13 MeV range, thus avoiding the opening of unwanted channels, resulting in isotopes from competitive nuclear reactions. The target was irradiated at a beam current of 20 µA for 4 hours. The thick target yield was estimated using excitation functions and stopping power data. ***Results:*** Simulations showed optimal ^{64}Cu production at 6-13 MeV proton energy, balancing high cross-section (≈800 mb) and low impurity levels. For 4-hour irradiations with 20 µA current, theoretical activities at end of bombardment (EOB) were 277 ± 13.9 mCi and the simulation result of 236 ± 20.1 mCi. The thickness of target material to satisfy the energy range of 6-13 MeV evaluated is 600 µm. simulation results agreed with theoretical predictions within acceptable deviation, confirming model reliability. ***Conclusion:*** This study validates MCNPX-based simulations to evaluate and optimize ^{64}Cu production in low-energy cyclotrons. These findings inform future strategies for enhancing medical radionuclide production. ***References:*** 1. Baruta, S., Leonte, R., Cocioaba, D., Craciun, L., Ur, C. A., & Niculae, D. (2022). EP-1169

Development of a New Solid-State ^{229}Th/^{225}Ac Generator Design

E. Yalcintas Bethune, *A. Cosby, A. Younes, C. Dunckley, J. Larrabee, J. Camacaro, P. de Roos, R. Sumner, S. Tanzey, Q. Pham, L. Lilley;*
TerraPower, Bellevue, WA, UNITED STATES OF AMERICA.

Aim/Introduction: In this work, we present on-going research to develop a single stage bulk separation of ^{225}Ac from its parent, ^{229}Th. ^{225}Ac ($t_{1/2}$ = 9.92 days) is a unique isotope within the

envelope of medically relevant radioisotopes; as an alpha emitter (4 alpha emissions per ^{225}Ac) it is among the few contending actinides for radiopharmaceutical applications, specifically for the development of targeted alpha therapeutics. The most direct and radio-isotopically pure route to obtain ^{225}Ac is from the routine harvest of its long-lived parent ^{229}Th ($t_{1/2}$ = 7932 y) that naturally decays to ^{225}Ac via ^{225}Ra. The high activity of ^{229}Th and its progeny presents unique challenges for large sized generators, such as: (i.) degradation of organic resins; (ii.) buildup of pressure (from water radiolysis) creating operational challenges for solution-based generators; (iii.) exposure of high dose to the materials and equipment used for storage and process. ***Materials and Methods:*** The proposed separation is based on solubility phenomena where tetravalent ^{229}Th forms a solid $ThO_2.xH_2O$(s) in equilibrium with its solubility product. Trivalent actinides are not chemically hydrolyzed at pH <6 thus, we expect ^{225}Ac to be soluble under the same conditions. The difference between Th and Ac oxide solubilities provides the basis for a single-stage bulk separation. A proof-of-concept experiment confirmed the feasibility of this generator system. ***Results:*** . ^{225}Ac is harvested from 1 mg ^{229}Th with 100% yield based on HPGe data. The ^{225}Ac/^{225}Ra separation is achieved through extraction chromatography using a UTEVA resin, followed by DGA resin and prefilter resins. The final ^{225}Ac product has been analyzed by analytical methods, including HPGe and iTLC, to confirm that the ^{225}Ac yield is as expected, there is no ^{229}Th nor ^{225}Ra breakthrough, and 98.9% radiolabeling yield is achieved. The yield and purity profile of this generator design will be presented. ***Conclusion:*** The ability to utilize fixed, solid state ^{229}Th generators provides a valuable tool in increasing the stable supply of clinical grade ^{225}Ac to radiopharmaceutical drug development, with the goal of supporting widespread treatment of cancer patients via ^{225}Ac based targeted alpha therapy.

EP-1170

Investigation of ^{161}Tb radionuclide production for therapy application via neutron induced reaction

H. Azizakram, *Z. Karimi;*
Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: ^{161}Tb has gained recognition as a promising radionuclide in nuclear medicine specially in targeted radionuclide therapy (TRT) due to its favorable decay characteristics. The aim of this study was to investigate the production and optimization of ^{161}Tb via indirect neutron induced reaction, ^{160}Gd(n,γ)^{161}Gd→(3.66 min, β^-)^{161}Tb in Tehran Research Reactor (TRR). This study focused on simulation and theoretical activity investigation at the end of bombardment (EOB). ***Materials and Methods:*** The TRR was simulated via MCNPX and the bulk of target were designed in central part of TRR's core. The enriched target of $^{160}Gd_2O_3$ (98%) were irradiated via thermal neutron flux of 4×10^{13} n.cm^{-2}.s^{-1}. Various target weight of 10 mg, 50 mg and 100 mg were selected. The irradiation time was determined to be 3 and 4 times of the ^{161}Tb half-time (6.89 days) to optimize the production process. The use of an enriched $^{160}Gd_2O_3$ target material is essential to minimizing the generation of impurities and optimizing its suitability for medical applications. After irradiation, the neutron distribution function and cross section of ^{160}Gd(n,γ)^{161}Gd reaction were calculated via MCNPX code and ENDF/B-VII library and compared with the theoretical activity. ***Results:*** Simulation of ^{161}Tb production via the ^{160}Gd(n,γ)^{161}Gd→^{161}Tb reaction in the TRR were conducted using MCNPX. The target of $^{160}Gd_2O_3$ (98%) was positioned in central part of reactor core with thermal neutron flux of 4×10^{13} n·cm^{-2}·s^{-1}. The simulation and theoretical activities at the EOB were calculated. At 20.67 days of irradiation, the theoretical activities for 10 mg, 50 mg, and 100 mg targets were 0.786, 3.93 and 7.86 GBq, respectively, while the corresponding simulated activities were 0.731, 3.68 and 7.21 GBq. For the extended irradiation period of 27.56 days, theoretical activities increased to 0.842, 4.21 and 8.42 GBq for the respective target masses, with simulated activities showing comparable results at 0.782, 3.91 and 7.92 GBq. In All cases, the activity increased as a result of the increased target mass and prolonged irradiation time. ***Conclusion:*** This study demonstrates the potential of simulation-based approaches for predicting ^{161}Tb production, highlighting the need for higher neutron flux to achieve clinically relevant activity levels. ***References:*** 1. Ensuring Radionuclidic and Chemical purity of Actinium-225 from Thorium-229 generator

J. Camacaro, *C. P. Dunckley, P. de Roos, Q. Pham, R. Sumner, S. Tanzey, A. L. Lakes, E. Yalcintas Bethune, L. M. Lilley, A. Younes;*
TerraPower Isotopes, Bellevue, WA, UNITED STATES OF AMERICA.

Aim/Introduction: ^{225}Ac is currently being utilized in clinical trials (Phases I - III) evaluating targeted alpha therapy in cancer treatments. Several production methods are being investigated in the industry to enable large-scale production of ^{225}Ac. This work examines ^{225}Ac produced from ^{229}Th generators. Given the stringent quality control requirements expected for radiopharmaceutical, harvesting ^{225}Ac from ^{229}Th generators demands precise and reliable analytical methods to assess ^{225}Ac purity. This is done by observing, or eliminating the possible presence of, any parent radionuclides (^{229}Th and/or ^{225}Ra), and other potential contaminants (e.g., trace metals) while minimizing time and labor costs. ***Materials and Methods:*** In this work, we disclose the measurement techniques employed, with an emphasis on instrumentation selection, method conditions, detection limits, and the strategy used to optimize the radionuclidic and chemical purity measurements. Additionally, we present our method for calibrating the gamma detectors using a counting geometry directly on the detector surface, accounting for summing effects to ensure accurate quantification. ***Results:*** Our results demonstrate that radionuclidic purity exceeding 99.7% could be measured using a combination of alpha and gamma spectroscopy in a timely manner. Metallic impurities were assessed via a triple quadrupole Inductively Coupled Plasma Mass Spectrometry (ICP-MS), where the use of various reactive gases effectively mitigated polyatomic interferences, enhancing the precision and reliability of the results. Final product attributes were confirmed through radiolabeling with DOTA (1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid) as a chelator commonly used for targeted alpha therapeutics, achieving radiolabeling yields greater than 95%. ***Conclusion:*** Together, these methodologies offer a comprehensive and reliable analytical framework of ^{225}Ac. This work supports the advancement of ^{225}Ac for targeted alpha therapy and contributes to the development of scalable quality control processes for radiopharmaceutical production.

EP-1172

Critical Control Points study in the production process of Mo-99/Tc-99m generators in Ezeiza Atomic Centre

D. Camporotondi*;*
Comisión Nacional de Energía Atómica, Buenos Aires, ARGENTINA.

Aim/Introduction: This work focuses on identifying Critical Control Points (CCP) within the process of producing Mo-99/Tc-99m generators in the Radioisotopes Production Plant of Ezeiza Atomic Centre (CNEA-Argentina). Tc-99m radiopharmaceuticals are still the major diagnostic tools in clinical nuclear medicine worldwide. Complying with regulations set by regulatory entities such as the Nuclear Regulatory Authority (ARN) and the National

Administration of Drugs, Foods and Medical Technology (ANMAT) is mandatory to ensure quality of manufactured products and safety of patients. Generator production is a complex process that involves multiple steps and requires proper management of quality risks. ***Materials and Methods:*** In this study, we carried out an in-depth analysis of the complete process from the obtention of sodium molybdate solution (fission Mo-99), to the assembly of all generator components, including quality controls required to comply European Pharmacopoeia standards. Flow-charts, Ishikawa diagrams and FMEA analysis tools were applied to each step of production process, to organize data and structure risk management to evaluate the potential failure modes throughout the whole process. The Risk Priority Number (RPN) is calculated by multiplying the severity, occurrence, and detection of each failure mode identified. Afterward, Hazard analysis and critical control points (HACCP) tool was applied to establish critical limits, monitor the CCPs and determine corrective actions to be taken. ***Results:*** Data analysis showed 10 CCPs related to physical, biological and chemical risks, leading to the suggestion of the modification of the process. As a result, the RPN were reduced for 2 CCPs, lowering the probability of occurrence and also excluding them from being considered as CCP. Those related to the skills and attention of workers will be constantly monitored to ensure the prevention of errors. ***Conclusion:*** This work provides a complete understanding of the process and sets solid foundations for effective preventative measures throughput the generators manufacturing procedures. ***References:*** ANMAT, "Guía Para La Evaluación De Solicitudes De Preparaciones Radiofarmacéuticas."ANMAT, "Guía de buenas prácticas de fabricación para elaboradores, importadores/exportadores de medicamentos de uso humano.," pp. 31-41, 2023.

EP-1173

Production and separation of ^{64}Cu and ^{161}Tb in a Nuclear Reactor to Support Hospital Research: A TRIGA Mark II Experience

L. Canziani[1], *G. Grosso*[1], *A. Gandini*[1], *A. Salvini*[1], *G. Pepe*[2];
[1]*Laboratory of Applied Nuclear Energy - Università di Pavia, Pavia, ITALY,* [2]*Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY.*

Aim/Introduction: The use of Isotopes ^{64}Cu and ^{161}Tb, Auger and β- emitters, is increasingly recognized. ^{161}Tb shares physical and chemical similarities with ^{177}Lu, offering potential for targeted cancer therapy. Similarly, ^{64}Cu is a versatile theranostic radionuclide, combining PET imaging with potential therapeutic applications. The production of ^{64}Cu typically occurs in medical cyclotrons while ^{161}Tb is produced from the irradiation of ^{160}Gd using a nuclear reactor, through n,γ reaction. However, separating these isotopes from the target materials is challenging due to their complex chemistry and the need for high radiochemical purity. ***Materials and Methods:*** In this study, various metallic samples, including zinc, copper, and zinc oxide, were irradiated in the TRIGA Mark II nuclear reactor at 250 kW. After irradiation, the samples were dissolved in HCl, and separation of ^{64}Cu from zinc was achieved using two DOWEX 1X8 resin columns with sequential elution in decreasing HCl concentrations. To reduce the HCl molarity, a TK201 resin column was used, yielding a final solution suitable for radiolabeling. For ^{161}Tb production, enriched ^{160}Gd targets were irradiated under the same conditions. Separation of ^{161}Tb was performed using LN3 ion exchange resin with αHIBA as the eluent, followed by further purification using a cation exchange resin. The radionuclidic purity was evaluated with High-Purity Germanium (HPGe) detector. ***Results:*** Among the irradiated samples, metallic copper yielded the highest activity but produced a carrier-added product. Metallic zinc, however, was preferred due to its higher yield and more efficient nuclear reaction. ^{64}Cu was successfully separated. The radiochemical purity of ^{64}Cu was >99%, with no ^{65}Zn contamination confirmed by gamma spectroscopy. The purification process achieved a decontamination factor of 1000 with the first column and an additional 100 with the second column. For ^{161}Tb, a 15 mg sample of enriched $^{160}Gd_2O_3$ was irradiated for 3 hours, resulting in 10^6 Bq of ^{161}Tb. The purification process demonstrated a decontamination factor of ~1000, though minor Gd contamination was still present. ***Conclusion:*** Low-power reactors are effective in the production of medical radionuclides like ^{64}Cu and ^{161}Tb for research applications and provide valuable educational opportunities, offering a platform for optimizing production techniques and enhancing communication and multidiscplinarity. Their role in advancing nuclear medicine and supporting research in hospitals is essential, despite a minor option in large-scale medical radioisotope production. Future research will focus on improving yield and efficiency, potentially through the use of larger sample masses and enriched targets.

EP-1174

Small-scall production of ^{161}Tb

D. Pawlak*, M. Żółtowska, I. Cieszykowska, P. Saganowski, A. Filiks, R. Mikołajczak;*
National Centre for Nuclear Research, Radioisotope Centre POLATOM, Otwock, POLAND.

Aim/Introduction: Terbium-161 ($T_{1/2}$ = 6.95 d) emits low-energy β^--particles (E_{β^-mean} 154 keV) and γ-radiation (E_γ = 48.9 keV (17.0%); 74.6 keV (10.2%)), similar to the decay properties of lutetium-177. It also emits conversion and Auger electrons, and is believed to be more effective in therapy than Lu-177 [1]. Small-scale production of Tb-161 in the ^{160}Gd(n,γ)^{161}Tb nuclear reaction was explored. ***Materials and Methods:*** Targets (mass of 8.4 - 11.8 mg) of gadolinium oxide enriched to 97.5% in Gd-160 were irradiated in the Maria research reactor in a neutron flux of $1x10^{14}$ $ns^{-1}cm^{-2}$ for 198-216 hours. Extraction chromatography was performed on LN2 resin (Triskem) to elute Tb-161 with 0.45 M HNO_3. In the next step, the Tb-161 solution was concentrated on DGA resin (Triskem) and eluted as a chloride with 0.05M HCl. Radionuclidic purity of the [^{161}Tb]$TbCl_3$ solution was determined by gamma spectrometry with an HPGe detector and chemical purity by the ICP-OES. The radiolabelling of DOTATATE served as the apparent molar activity test. ***Results:*** Terbium-161 was obtained with radioactivity from 0.74 to 0.95 GBq/mg Gd, calculated at the end of activation. The separation resulted in a high recovery of Tb-161, over 95%. The long-lived Tb-160 was the only radionuclide impurity identified and measured at the level of 0.005%. The content of metallic impurities was not more than 0.1 µg/mL, and the content of Gd was about 5 µg/mL. Despite that, the labelling yield of DOTATATE was over 99% for an apparent molar activity of 150 MBq/nmol. Importantly, when irradiating target material with a higher content of Tb-159 (0.08%), the apparent molar activity was around 50 MBq/nmol, and the content of Tb-160 was at the level of 0.3%. ***Conclusion:*** We have demonstrated an efficient ^{161}Tb production based on thermal neutron irradiation of ^{160}Gd in a nuclear reactor, followed by the two-step separation of ^{161}Tb using extraction chromatography. The enrichment of the target material in Gd-160 and its isotopic composition are crucial for the quality of the final product. ***References:*** [1] Müller, C., van der Meulen, N.P. & Schibli, R. cGMP-complaint implementation of high-yield automated [18F]FAPI-74 production with optimized quality control

W. Storms[1], *S. Celen*[2], *J. Maes*[2], *K. Serdons*[2], *K. Goffin*[2], *T. De Groot*[2], *L. Trump*[3], *C. Warnier*[3], *T. Gendron*[4], *R. Gerardy*[3], *K. Van Laere*[2], *C. M. Deroose*[2], *J. Kleynhans*[1], *F. Cleeren*[1];
[1]*Radiopharmaceutical Research, Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven, BELGIUM,* [2]*Nuclear Medicine, University Hospital Leuven, Leuven, BELGIUM,* [3]*Trasis, Ans, BELGIUM,* [4]*University of Liège, Liège, BELGIUM.*

Aim/Introduction: Fibroblast activation protein inhibitor (FAPI)-based positron emission tomography (PET) radiopharmaceuticals have emerged as promising tools for targeting cancer-associated fibroblasts (CAFs), a key component of the tumour stroma. Among these, [^{18}F]AlF-FAPI-74, labelled with fluorine-18 via the Al^{18}F-method [1,2], provides advantages such as feasibility for centralised production and a longer half-life compared to ^{68}Ga-labeled FAPI derivatives. Here, we present a high-yield, automated cGMP-compliant production of [^{18}F]AlF-FAPI-74 with optimized quality control methods, using an isocratic radio-HPLC method with enhanced fluorine-18 recovery compared to a standard acidic method [3]. ***Materials and Methods:*** [^{18}F]AlF-FAPI-74 was produced on an automated cassette-based module using a specific FAPI-74 sequence, cassette and reagents. Synthesis started with transfer of [^{18}F]F$^-$ (89.7±1.8 GBq), followed by Al^{18}F chelation & purification on C18-cartridge. An isocratic radio-HPLC method (ammonium acetate 0.05M, pH 5.5, and acetonitrile 91:9 v/v; C18 silica column; 0.8 mL/min) was evaluated for specificity, precision, linearity, LOQ/LOD, and recoveries of [^{18}F]F$^-$, [^{18}F]AlF, and [^{18}F]AlF-FAPI-74. To compare, recovery of [^{18}F]F$^-$/[^{18}F]AlF was also measured using a standard acidic HPLC method (gradient, water + 0.1% TFA/acetonitrile). Finally, the optimized radio-HPLC system was used to perform (radio-)chemical stability studies of [^{18}F]AlF-FAPI-74 (2.02 GBq/mL) in formulation buffer at room temperature for up to 10 hours post synthesis. ***Results:*** The GMP-compliant production of [^{18}F]AlF-FAPI-74 has been validated through three production runs. In a synthesis of 30 minutes, [^{18}F]AlF-FAPI-74 was obtained with a final batch activity of 36.3 ± 7.4 GBq (up to 42.5 GBq) and a decay-corrected radiochemical yield of 50.0 ± 10.3%. The calculated apparent molar activity was 1125 ± 311 GBq/µmol. All analytical methods were successfully validated. Importantly, by using the new HPLC method, an excellent recovery (>95%) of [^{18}F]F$^-$, [^{18}F]AlF and [^{18}F]AlF-FAPI-74 was observed. In contrast, while the recovery of [^{18}F]AlF and [^{18}F]AlF-FAPI-74 was above 95% for the acidic radio-HPLC system, only a recovery of 59 ± 20% was observed for [^{18}F]F$^-$, which might result in an overestimation of the radiochemical purity. [^{18}F]AlF-FAPI-74 was stable (>95% RCP) up to 10 hours after synthesis. ***Conclusion:*** This study demonstrates the successful development and validation of a high-yield, automated, and GMP-compliant production method for [^{18}F]AlF-FAPI-74, offering a robust platform for centralized radiopharmaceutical production. We recommend using a mobile phase with pH > 5 for silica-based C18 columns for quality control of ^{18}F-labelled radiopharmaceuticals. ***References:*** [1] Clinical Nuclear Medicine 44, 452-8 (2019) [2] J Nuc Med 62, 201-7 (2021) [3] J Pharm Biomed Anal 111, 209-14. EP-1176

A new fluorine-18 radiolabelled inhibitor of TRPC6 receptor for PET imaging of glioblastoma.

M. Iannone[1], *C. Papotto*[2], *S. Stucchi*[1,2], *E. Turolla*[1,2], *E. Vino*[1], *S. Todde*[1,2];
[1]*Tecnomed Foundation - University of Milan Bicocca, Monza, ITALY,* [2]*School of Medicine and Surgery - University of Milan Bicocca, Monza, ITALY.*

Aim/Introduction: TRPC6 is a Ca^{2+} permeable non-selective cation channel, member of a large family of transmembrane receptor potential canonical channels (TRPCs) and appears to be highly expressed in the lungs, placenta, ovary and spleen. Several studies have suggested that this channel is likely to play a role in glioblastoma multiforme (GBM) growth and development at different levels by regulating cellular metabolism, controlling cell proliferation, promoting angiogenesis, triggering the migration and invasion during glioma progression. Interestingly, inhibition of TRPC6 has shown to reduce tumour volume in subcutaneous mouse model of xenografted human tumours and increased mean survival in intracranial model mice. U251, U87 and T98G cells also show high TRPC6 expressions, which suggests that this receptor might potentially be a new target for imaging and therapy of human glioma. Here we report an automated procedure for the radiolabelling with fluorine-18 via nucleophilic substitution (S_N2) of a new TRPC6 inhibitor. ***Materials and Methods:*** Precursor and non-radioactive standards were purchased, radiolabelling procedures have been performed using a commercially available automated radiosynthesis system (GE-TRACERlab Fx-F_N). ***Results:*** The candidate molecular structure for fluorine-18 radiolabelling was selected following a careful evaluation of a series of compounds, either previously published or currently under patent, based on its affinity for hTRPC6 (IC_{50} = 0.7 nM), favourable BBB permeability (LogP = 2.01), good TRPC6/TRPC3 selectivity and the presence of a fluorine atom in a suitable position that allow for fluorine-18 radiolabelling without altering the original structure of the molecule. Fluorine-18 was successfully introduced via a standard nucleophilic substitution (S_N2) reaction on a tosylated precursor by heating at 100°C, followed by deprotection. The final fluorine-18 radiolabelled TRPC6 inhibitor was purified via semi-preparative HPLC and obtained in ready-to-inject formulation of 10% ethanol in physiologic solution (non-decay corrected RCY = 10.5 ± 2.5%, radiochemical purity > 95%, A_m = 43.3 ± 15.5 GBq/µmol, n = 10, total radiosynthesis time: 78 minutes). The radiosynthetic process was fully automated, and the compound stability was proved up to 4 hours, with no evidence of radiolysis. Cellular uptake studies in U251 GBM cells and HEK293 (no TRPC6 expressing) are currently in progress and also PET imaging preclinical studies on rodents are then planned. ***Conclusion:*** In conclusion, we have implemented a fully automated method for the radiolabelling with fluorine-18 of TRPC6 inhibitor for GBM PET imaging in high radiochemical yields and purity. Finally, cellular uptake studies and in vivo biodistribution will be conducted.

EP-1177

A radiopharmacist's guide to gallium: Implementing ^{68}Ga kit labeling in Your Radiopharmacy

A. Mihelcic, *B. Hudomalj;*
Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: ^{68}Ga is increasingly used in PET imaging, e.g. of neuroendocrine tumors with somatostatin analogs ([^{68}Ga]Ga-DOTATOC/DOTATATE) and prostate cancer with PSMA ligands. It plays a key role in theranostics, paired with ^{177}Lu-labeled agents, and in the development of new ^{68}Ga compounds. Growing demand and regulatory needs have driven automated ^{68}Ga radiopharmaceutical production. The availability of ^{68}Ga labeling kits and ^{68}Ge/^{68}Ga generators—requiring minimal equipment—supports wider adoption. This work outlines key considerations

for radiopharmacies upgrading from ^{99m}Tc to ^{68}Ga kit-based radiolabeling [1]. ***Materials and Methods:*** A careful review of ^{68}Ga kits SMPCs, ^{68}Ge/^{68}Ga generator, Current Good Radiopharmacy Practice [2] and EANM guideline on the validation of analytical methods for radiopharmaceuticals [3] was conducted with the aim of correct professional implementation of ^{68}Ga kit-based radiolabeling. ***Results:*** Regulatory-compliant use of new isotopes was ensured by a radiation protection expert, with radiopharmacist input on radiation exposure documentation. Following submission of marketing authorisation documents for the ^{68}Ge/^{68}Ga generator and ^{68}Ga kits, our radiopharmacy planned upgrades. A personnel of four (minimum two) was deemed sufficient, and internal/external training was completed. Existing premises were suitable for ^{68}Ga work. Of two existing LAF chambers in separate clean rooms, the one with adequate shielding was assigned to ^{68}Ga preparations, the other to remaining isotopes. Radiation protection equipment was enhanced (PET syringe/vial shields, generator shielding, automatic elution system), along with QC instrumentation (radio-TLC scanner for radiochemical purity, well counter for ^{68}Ge breakthrough, pH meter for buffer calibration). QA documents for ^{68}Ga procedures were developed and approved, covering standard operating procedures (SOPs) for purchase and material control of all starting materials, product preparation and QC, equipment use, and maintenance. Our work suggests qualification protocols for radioscanner and well counter (calibration, stability, linearity/range, repeatability). ^{68}Ga waste management followed existing protocols for other isotopes as its short half-life presented fewer challenges. ***Conclusion:*** Our approach to ^{68}Ga kit-based radiopharmaceutical production has established reliable SOPs. This work outlines essential radiopharmacy upgrades to support others in setting up ^{68}Ga production. Ongoing experience drives further process optimization. ***References:*** 1. Lepareur N. EP-1178

Feasibility and comparative evaluation of a candidate hydroxyethyl starch-based sedimentation agent for (^{99m}Tc)Tc-HMPAOautologous white blood cellslabelling

A. Deschavannes*, T. Pitaud-Renaud, A. Clotagatide, C. Rioufol, M. Piquemal;*
Hospices Civils de Lyon, Lyon, FRANCE.

Aim/Introduction: Labelling of autologous white blood cells (WBCs) with technetium-99m hexamethylpropyleneamine oxime ((^{99m}Tc)Tc-HMPAO) is a well-established nuclear medicine procedure for the detection of infections and inflammatory conditions. This process requires the separation of leukocytes from whole blood, typically achieved by red blood cell (RBC) sedimentation. PLASMION, a hydroxyethyl starch-based solution initially developed as a plasma volume expander, is widely used for this purpose. However, due to its impending discontinuation, the identification of an alternative with equivalent performance is necessary. HETASEP, another hydroxyethyl starch solution commonly used in cellular hematology, may represent a viable substitute. This study aimed to assess the feasibility of using HETASEP as a sedimentation agent for WBC labelling with (^{99m}Tc)Tc-HMPAO and to compare its performance with that of PLASMION. ***Materials and Methods:*** Experiments were performed using peripheral blood from healthy donors. For each donor, two parallel preparations were carried out: one with 15 mL of PLASMION, the other with 10 mL of HETASEP as the sedimentation agent. Apart from this difference, both preparations followed the same standard (^{99m}Tc)Tc-HMPAO labelling protocol. Key parameters were evaluated: macroscopic appearance of the WBC-rich layer after sedimentation, clarity and homogeneity of the final suspension before reinjection, and WBC viability assessed using the Trypan blue exclusion test. The RBC-to-WBC ratio was assessed by optical microscopy and confirmed by flow cytometry. Radiolabelling efficiency was calculated by measuring the percentage of radioactivity bound to the WBC pellet at the end of the procedure. ***Results:*** Three comparative tests were performed. The sedimentations were visually effective for both PLASMION and HETASEP. Leukocyte viability was 98.5% ± 1.2 with PLASMION and 97.8% ± 1.4 with HETASEP. The RBC-to-WBC ratio was 1.15 ± 0.03 for PLASMION and 1.25 ± 0.05 for HETASEP. Radiolabelling yields were 72.3% ± 4.5 with PLASMION and 70.1% ± 3.8 with HETASEP. Final suspensions were visually suitable for clinical use in all cases. ***Conclusion:*** This preliminary study suggests that HETASEP is a feasible and effective alternative to PLASMION for RBC sedimentation in (^{99m}Tc)Tc-HMPAO WBC labelling. It preserves WBC viability, ensures proper separation, and allows efficient radiolabelling. These promising results support further evaluation of HETASEP in a larger clinical setting.

EP-1179

Synthesis and Validation of [^{68}Ga]Ga-DOTA-Siglec-9 for Non-invasive PET Imaging

S. Migliari*[1], A. Guercio[1], A. Gagliardi[1], S. Bruno[2], M. Scarlattei[1], G. Baldari[1], A. Roivainen[3], S. Forsback[3], L. Ruffini[1];*
[1]Nuclear Medicine Division, Azienda Ospedaliero-Universitaria of Parma, Parma, ITALY, [2]Food and Drug Department, University of Parma, Parma, ITALY, [3]Radiopharmaceutical Chemistry Laboratory, Turku PET Centre, University of Turku, Finland, Turku, FINLAND.

Aim/Introduction: Siglec-9, a member of the Siglec family of receptors, has significant clinical implications due to its role in modulating immune cell trafficking and inflammation. This receptor is predominantly expressed on immune cells, such as neutrophils, monocytes, and dendritic cells, which are central players in immunity. Siglec-9 binds to sialic acid residues on glycoproteins, present on endothelial cells, and this interaction is critical in regulating immune responses during inflammation and tissue injury. Its interaction with VAP-1, a key endothelial adhesion molecule, is of particular interest for therapeutic development, especially in the context of chronic inflammatory diseases, autoimmune disorders, and cancer [1-4]. In this regard, recent studies have demonstrated that the Gallium-68-labeled Siglec-9 motif conjugated with 1,4,7,10-tetraazacyclododecane-N,N′,N″,N‴-tetraacetic acid ([^{68}Ga]Ga-DOTA-Siglec-9) can be effectively used for PET imaging of these disorders. The aim was to establish a new automated radiolabelling method for the radiopharmaceutical [^{68}Ga]Ga-DOTA-Siglec-9. ***Materials and Methods:*** The synthesis was fully automated, with real-time monitoring of reaction parameters such as time, temperature, and radioactivity. Gallium-68 was eluted from a GMP-certified 68Ge/68Ga generator using HCl, then purified on a cation exchange (SCX) cartridge and eluted with NaCl. The eluate was added to a reaction vial containing DOTA-Siglec-9 in HEPES buffer and incubated at 65°C for 6 minutes. After labelling, the crude product was purified on a C18 RP cartridge and eluted with ethanol/water. The final product was diluted with PBS and sterilized through a 0.2µm filter. The synthesis efficiency and release criteria were evaluated following the Ph. Eur. guidelines for all final products including radiochemical yield (RY), radiochemical purity (RCP), detection of free gallium (via Radio-UV-HPLC), gallium colloids (via Radio-TLC), molar activity (Am), chemical purity, pH, and LAL test. After optimizing the method, the entire process was validated through three consecutive syntheses, with stability monitored over time. ***Results:*** [^{68}Ga]Ga-DOTA-Siglec-9

was obtained with RY (55.04%), RCP (99.48%) and Am (23.15GBq/µmol). The process validation confirmed optimal mean values of RY, RCP and Am (56.16%, 99.40%, 20.26GBq/µmol). The stability of [^{68}Ga]Ga-DOTA-Siglec-9 was assessed at RT over a 3-hour period, yielding satisfactory results for its RCP (mean value 99.29%), appearance, pH and sterility. ***Conclusion:*** [^{68}Ga]Ga-DOTA-Siglec-9 was successfully synthesized in compliance with Ph. Eur. standards and is now ready for clinical application. ***References:*** [1] Viitanen R, et al. J Nucl Med. 2021 Apr;62(4):577-583. [2] Brzezicka KA, et al. Mol Aspects Med. 2023 Apr;90:101140. EP-1180

Content analysis of deviation reports in the in-house manufacture of PET radiopharmaceuticals

S. Forsback[1], *R. V. Kivelä*[2], *A. M. Juppo*[3];
[1]*University of Turku, Turku, FINLAND,* [2]*Hospital Pharmacy, Turku University Hospital, Turku, FINLAND,* [3]*University of Helsinki, Faculty of Pharmacy, Division of Pharmaceutical Chemistry and Technology, Helsinki, FINLAND.*

Aim/Introduction: In order to decrease the rejection rate of the batches of in-house manufactured PET radiopharmaceuticals in the Radiopharmaceutical Chemistry Laboratory at Turku PET Centre (TPC), a qualitative content analysis of the deviation reports was performed. ***Materials and Methods:*** Inductive content analysis as described by Elo and Kyngäs [1] on deviation reports documented during 2019-2023 at TPC was performed. All together 427 deviation reports were analysed and classified. Another person performing random check improved the reliability of the classification. In this study, technical faults were selected for further observation. ***Results:*** The deviations were classified according the root cause to four categories: technical faults, failing methods, problem with materials and human errors. Technical faults and human errors were further classified to several subcategories. Most of the deviations, more than 50 %, were classified as technical faults (n=216). Second largest category was human errors (n=166). Failing methods (n=36) and problems with materials (n=9) were quite rare causes for a deviation. The most frequent cause for a technical fault at TPC was faults in synthesis devices (n=142) and more precisely faults during the transfer of gas or liquid (n=85). In the category of technical faults in synthesis devices, in 88 cases (62 %) a batch of a radiopharmaceutical was rejected. ***Conclusion:*** Profound content analysis of the deviations generated in the production of PET radiopharmaceuticals during five-year period at TPC offers versatile means to develop the quality and robustness the manufacturing process of the radiopharmaceuticals. We have already utilised our findings by creating more precise instructions for the preventive maintenance of the synthesis devices. In future, we are going to use the results of this content analysis in the improvement of all our operations in the production of PET radiopharmaceuticals. ***References:*** 1. Elo S, Kyngäs H. The qualitative content analysis process. J Adv Nurs. 2008;62(1):107-115.

EP-1181

Improvement of the ^{177}Lu-PSMA$^{I\&T}$ Labelling Method for Clinical Production

P. Bohn*, A. Coussirou, M. Six, A. Salles, F. Basuyau, A. Edet-Sanson, P. Vera, D. Tonnelet;*
Centre Henri Becquerel, Rouen, FRANCE.

Aim/Introduction: At the Henri Becquerel Center, Rouen, Normandy, we have performed since January 2024 30 ^{177}Lu-PSMA$^{I\&T}$ labelling for patients with metastatic castration resistant prostate cancer and non-eligible in France to ^{177}Lu-PSMA^{617} following a method validated by the French Drug Agency (ANSM). An issue occurred in February 2025 with a shortage of one of the excipients which is absolutely necessary to prepare the pharmaceutical product. The method had to be modified to continue treating our patients. The aim of this abstract is to explain this modified method. ***Materials and Methods:*** The initial validated method is fully automated using a Luna synthesizer from Elysia-Raytest. Briefly, PSMA$^{I\&T}$ (115 µg) is diluted in an ascorbate buffer (160 mg sodium ascorbate and 40 mg ascorbic acid in 2 ml water for injection) and heated up to 85 °C in presence of 9 GBq of lutetium-177 chloride (GMP) for 20 minutes. After cooling, the resultant solution is filtered and diluted in saline and subjected to quality control. Due to its shortage, we replaced the ascorbate buffer by a commercial drug (Laroscorbine® 1g/5ml) which only contains ascorbic acid and sodium hydroxide. Of note, ascorbic acid had already been studied at various pH and concentration to stabilize DOTA and DOTAGA metallic complex in 2003 [1]. ***Results:*** We performed 3 validation batches with this new method with a yield > 95%, RCP assessed by HPLC > 97% and by TLC > 99%, endotoxins < 0.5 EU/ml, pH = 6. Sterility assays were conform and compound stability was > 3 days. The injectable solution is clear and colorless. Compared to the previous method, we only obtain a higher pH. (6 instead of 4.5). With this new method, the excipient (with a controlled bioburden) does not need to be dissolved, and a simple sampling from a sterile registered drug is sufficient as an excipient. ***Conclusion:*** The new method does not affect the quality of the final product but is easier, and cheaper. The French Drug Agency has approved this new procedure and we were able to treat our patients with no additional delay. In March 2025, there was still an ascorbate buffer shortage and 6 additional injections using this new method were performed, greatly benefiting the patients. ***References:*** [1] Ascorbic Acid: Useful as a Buffer Agent and Radiolytic Stabilizer for Metalloradiopharmaceuticals. EP-1182

Compassionate Use of [^{68}Ga]Ga-NODAGA[40Lys]-Exendin-4: Validation of an Automated Synthesis in a Sodium Acetate Buffer

M. Ragot*, M. Jung, P. Orhon, A. Revy, S. Levesque, M. Tempier;*
Centre Jean Perrin, Clermont-Ferrand, FRANCE.

Aim/Introduction: [^{68}Ga]Ga-NODAGA-Exendin-4 PET imaging has shown great promises for localization of benign insulinoma, being both highly specific and sensitive. In France, compassionate use of [^{68}Ga]Ga-NODAGA-Exendin-4 is allowed by current regulations. However, as it requires small-scale in situ radiolabeling, it is subject to prior authorization, following the submission and expertise of an Investigational Medicinal Product Dossier (IMPD). Herein, we present an automated radiosynthesis method, employing sodium acetate buffer for the first time at clinical scale. ***Materials and Methods:*** Radiosynthesis is automated on a synthesizer, using single-use cassettes and a GMP grade ^{68}Ge/^{68}Ga generator. Radiolabeling of the peptide takes place at 100°C for 15 min, with sodium acetate buffer (a non-toxic buffer approved for human use with no dose limit), ascorbic acid and previously purified gallium eluate. After purification, the final product is formulated in ethanol and NaCl 0.9% by passing through a 0.22 µm sterilizing filter. Three batches were produced and controlled in order to validate the synthesis. Appearance, checked by visual inspection, must be clear and limpid. pH, determined by indicator paper, must be between 4 and 8. Radiochemical identity and purity (RPC) are determined by radio-HPLC and thin layer chromatography (TLC). RPC must be greater than 90%, with less than 3% free gallium. Radionuclidic identity is assessed by gamma spectrometry and radionuclidic purity (RNP) by gamma counting after 48h. Endotoxins are researched by kinetic-chromogenic test and a sterility test is performed after liberation. Stability is assessed at room temperature, over a 2-hour period. ***Results:*** An average

activity of 343 MBq was obtained in 36 min, for a 31-week-old generator, resulting in a decay-corrected yield of 48%. The automated synthesis was found to be compliant with all quality control requirements. RCP was 97.0 ± 0.2%, with less than 1% free gallium for all batches. The solution was limpid and had a pH of 6. RNP was conform, with 0.37 ppm of ^{68}Ge. The final product was confirmed to be sterile, with no detectable endotoxins (< 2.5 EU/mL). It remained stable for 2 hours, with no increase in free gallium and no significant variation in volume activity, indicating the absence of adsorption. ***Conclusion:*** This radiolabeling method enables the rapid synthesis of [^{68}Ga]Ga-NODAGA-Exendin-4 in sodium acetate. The final activity and purity levels are compatible with clinical use, for small-scale productions by radiopharmacies. Authorization was obtained from the French regulatory authorities, allowing for the imaging of our first patient in March 2025.

EP-1183

Stability Evaluation of I-131 Radiolabeled Ferulic and Caffeic Acids: Effects of Storage Conditions and Stabilizing Agents

M. Radovic, *M. Peric, D. Stankovic, A. Vukadinovic, S. Vranjes-Djuric, D. Jankovic, M. Mirkovic;*
„VINCA" Institute of Nuclear Sciences - National Institute of the Republic of Serbia, University of Belgrade, Belgrade, SERBIA.

Aim/Introduction: Radiolabeling ferulic acid (FA) and caffeic acid (CA) with I-131 can provide valuable insights into their pharmacokinetics, metabolism, tissue distribution, and antioxidant activity. However, the process involves challenges related to the stability of the radiolabel bioactive compounds, the reactivity of the phenolic groups, and the potential for metabolism-induced alterations. This study aimed to radiolabel FA and CA with iodine-131 (^{131}I) in high radiolabeling yield, and to investigate the factors affecting their stability. ***Materials and Methods:*** Radiolabeling was performed using Chloramine-T as oxidizing agent, with optimized parameters including pH 6, oxidizing agent content (50 µg), the amount of bioactive compounds (200 µg), and reaction time (30 min). Stability studies evaluated the effects of storage conditions (refrigeration at 2-8 °C), the addition of ascorbic acid as a stabilizer, and solution dilution on the integrity of the labeled compounds. ***Results:*** High radiolabeling yields were achieved, with 95.5% for ^{131}I-ferulic acid and 78.3% for ^{131}I-caffeic acid. After 72 hours at room temperature, the labeling yield of both compounds dropped to below 25%. Dilution improved the stability of ^{131}I-ferulic acid but had no significant effect on ^{131}I-caffeic acid. The addition of ascorbic acid after radiolabeling effectively minimized oxidative degradation, improving the radiochemical purity of both complexes (98.2% for ^{131}I-ferulic acid and 85.6 % for ^{131}I-caffeic acid). Post-labeling storage at 2-8°C of radiolabeled compounds with ascorbic acid added, demonstrating higher long-term stability for ^{131}I-ferulic acid (95.1%), in comparison to ^{131}I-caffeic acid (38.3%) after 72 h. A comparative analysis between ^{131}I-ferulic acid and ^{131}I-caffeic acid revealed differences in labeling efficiency and stability profiles. While both compounds showed potential as radiolabeled bioactive agents, ^{131}I-ferulic acid demonstrated higher stability under investigated conditions. ***Conclusion:*** The addition of ascorbic acid and storage at lower temperatures enhances the stability of these compounds, making them suitable for applications in pharmacology, toxicology, and metabolic research.

EP-1184

Optimization of Automated Synthesis of [^{18}F]AlF-NOTA-FAPI-4 for Clinical Radiopharmacy Applications

L. Pires[1,2], *K. Zirbesegger*[2], *J. Giglio*[2], *J. Gambini*[2], *P. Duarte*[2], *V. Cardoso*[1], *S. Fernandes*[1], *E. Savio*[2];
[1]*Universidade Federal de Minas Gerais, Belo Horizonte, BRAZIL,* [2]*Centro Uruguayo de Imagenología Molecular, Montevideo, URUGUAY.*

Aim/Introduction: Fibroblast activation protein (FAP) is overexpressed in cancer-associated fibroblasts, making it a promising target for tumor imaging. While [^{68}Ga]NOTA-FAPI-4 is widely used, [^{18}F$^-$] fluoride offers advantages such as greater availability, longer half-life, and higher spatial resolution. The [^{18}F]AlF-NOTA strategy enables ^{18}F$^-$ coordination via an aluminum-based intermediate, providing a viable alternative for indirect radiolabeling peptides. This study aimed to optimize the production of [^{18}F]AlF-NOTA-FAPI-4 using automated synthesis modules, based on a systematic investigation of labeling parameters initially conducted at the bench scale. ***Materials and Methods:*** ^{18}F$^-$ was produced on GenTrace (GE) or PETrace (GE) cyclotrons and purified through QMA plus light cartridges (Sep-Pak, Waters). Bench-scale optimization evaluated the influence of $AlCl_3$ (Sigma) (0,01M) volume (1-8 µL), NOTA-FAPI-4 (MedKoo) mass (15-100 µg), heating time (5-15 min), and temperature (22 °C vs. 100 °C). Analytical conditions for determining radiochemical purity (RCP) by High-performance liquid chromatography (HPLC, Shimadzu) were developed using Phenomenex (Cat.N°00G-3148-E0), Macherey-Nagel (Cat.N°760008.48), Agilent (Cat.N°93999-902) columns, testing different mobile phases (Trifluoroacetic acid [TFA] 0,1% in water; phosphate 10 and 100mM; water) and elution gradients with TFA 0.1% in acetonitrile. Optimal labeling parameters were then applied to automated Synthra RNPlus and Tracerlab FN-FX modules, scaling up the process to 37GBq of ^{18}F$^-$ activity, 100µg of peptide, 6,5µL of $AlCl_3$ (0,01M) and heating at 100°C for 10 minutes, followed by purification on a C18 cartridge (Sep-Pak, Waters). The final formulation was prepared with 10% ethanol in physiological saline containing ascorbate buffer. ***Results:*** The most effective RCP method was achieved using the Agilent column, phosphate buffer (100 mM; pH 5.9), and acetonitrile with 0,1% TFA, using the following gradient: 0-100% B (0-10 min) | 100% B (10-15 min), flow 1mL/min, gamma and UV detection (254nm). In bench experiments, optimal yields (18.03%±1.55; n=3) were obtained using 15 µg of peptide, 2 µL of $AlCl_3$ (0,01M), heating at 100 °C for 10 minutes, and activities between 185-555MBq. When these conditions were translated to the automated synthesizers, average radiochemical yields increased to 25.9% ±5.08 (n=3). The HPLC analysis showed no ^{18}F$^-$ peak, so 7,65GBq ± 1,60 (n=3) of [^{18}F]AlF-NOTA-FAPI-4 was achieved for clinical use. ***Conclusion:*** [^{18}F]AlF-NOTA-FAPI-4 labeling under optimized conditions demonstrates high potential for clinical-scale GMP production using automated synthesis platforms. This approach supports broader Positrons Emission Tomography imaging access with radiopharmaceuticals targeting FAP since reproducibility, efficiency, and scalability were verified. Based on these results, our group is enabled to contribute to the advancement of personalized oncology diagnostics.

EP-1185

Towards clinical implementation of radiolabeled orally inhaled drug products: preliminary feasibility study using a Next Generation Cascade Impactor and [^{18}F] radiopharmaceuticals

J. Wolfert[1], *M. Konijnenberg*[1], *S. P. J. M. Tsai*[1], *I. van de Merwe*[1], *N. H. Hendrikse*[1], *L. Ruijgrok*[1], *T. A. Mulders*[1], *B. R. Lavon*[2], *F. A. Verburg*[1], *E. de Blois*[1];
[1]*Erasmus MC, Rotterdam, NETHERLANDS,* [2]*FLUIDDA NV, Kontich, BELGIUM.*

Aim/Introduction: Orally inhaled drug products (OIDPs), including pressurized metered dose inhalers (PMDIs), are essential in the treatment of respiratory diseases. As the demand for generic alternatives increases, computational fluid dynamics modelling has emerged as a promising approach for predicting deposition patterns as part of demonstrating bioequivalence. PET-imaging of radioactive OIDPs offers the potential for high-resolution visualization of pulmonary drug deposition as a basis of model validation. To ensure that the aerodynamic particle size distribution (APSD) of the PET-radiopharmaceuticals reflects that

of the drug, validation is essential. Analytical techniques such as a Next Generation Cascade Impactor (NGI) in combination with UPLC-UV and gammacounting can be used.[1] Furthermore, the use and inhalation of radioactive OIDPs generate challenges in terms of internal and external radiation. The aim of this study is to evaluate the technical feasibility of addition and analysis of PET-radiopharmaceuticals to OIDPs while ensuring safety for clinical application. ***Materials and Methods:*** A UPLC-UV method was developed to quantify beclomethasone dipropionate (BDP), fluticasone propionate (FP), and budesonide. To assess feasibility, an NGI was used in combination with a nebulizer. The PET-radiopharmaceuticals [^{18}F]FDG and [^{18}F]F-NaF were tested to quantify APSD and mean mass aerodynamic diameter (MMAD). A combination of each corticosteroid and a PET-radiopharmaceutical was used and NGI-stages were analyzed using UPLC-UV and gammacounting. Dosimetric estimates for lungs were calculated per inhaled pMDI dose using the pharmacokinetic models of technegas, pertechnate and F-18/[^{18}F] FDG of ICRP128. Additional dose calculations were performed for external radiation exposure expected during patient handling and activation of radioactive OIDPs, including to the eye lens, hands and face. Calculations were based on a total activity of 1000MBq per pMDI and 100MBq/inhalation. ***Results:*** The NGI setup in combination with UPLC-UV and gammacounter showed to be successful for the measurement of the APSD of BDP, FP, Budesonide in combination with [^{18}F]FDG or [^{18}F]F-NaF. The APSDs of the drugs and their respective radiopharmaceutical showed similar output and MMADs. Dosimetric calculations resulted in an effective dose of 0.044 mSv/MBq for inhalation, with an estimated external dose of 1 mSv (Hp 0.07; skin) and 0.25 mSv (Hp 3; eye lens) during handling of the device with 1000 MBq F-18. ***Conclusion:*** Results support the feasibility of using NGI-based methods to analyze radioactive OIDPs. The ability to quantify PET radiopharmaceutical in combination with used drug lays the groundwork for scaling up to clinical use of radioactive pMDI formulations. ***References:*** [1] Dolovich et al. Radiolabeling Methods.

EP-1186

Taking radioimmunoconjugate manufacturing to the next level: a universal cassette-based process for the Lu-177 radiolabeling of mAbs

C. Vanasschen, *A. Dubart, J. Masset, E. Duray, M. Hawotte, S. Degueldre, C. Warnier;*
Trasis, Ans, BELGIUM.

Aim/Introduction: Chemistry, Manufacturing and Control (CMC) is a central topic in nuclear medicine and radiopharmacy. While managing the automated radiosynthesis of small molecules/peptides with various isotopes has been the core of radiopharmacy in the past 20 years, radiolabeling and purification of radioimmunoconjugates bring new challenges to the field : recent breakthroughs on the development of diagnostic and therapeutic radioimmunoconjugates at the clinical level now urgently call for equivalent progress at the CMC level. We herein report the development of a fully automated process for the production of [177Lu]-labelled antibodies. ***Materials and Methods:*** Lu-177 was supplied in 0.04M HCl (75µL to 2mL, 40 GBq/mL). The disposable cassettes were equipped with Centripure 50 size-exclusion cartridges as well as with a device ensuring quasi-quantitative transfer of [177Lu]Cl3 to the reactor. Process development was performed using Trastuzumab-DOTAGA as model compound: CAR values ranged between 0.7 and 4.0 while the DOTAGA concentration in the radiolabeling medium was normalized to ensure comparable experimental results. The automated process was developed on the miniAllinOne synthesis module. ***Results:*** A buffer formulation was designed to bring the [177Lu]Cl3 adequate pH, irrespective of the amount of HCl in the [177Lu]Cl3 vial (75µL to 2mL). Manual experiments were carried out to optimize the DOTAGA concentration in the labeling medium as well as the amount of activity/DOTAGA ratio to maximize radiochemical conversions within 1h at 37°C. Those conditions were transferred to a fully automated fluidic process on miniAllinOne, including (i) [177Lu]Cl3 transfer (metal-free, >92% recovery), (ii) buffer and bioconjugate transfer, (iii) radiolabeling, (iv) conditioning of the SE cartridge, (v) purification on the SE cartridge and (vi) final product formulation. The resulting process yielded [177Lu]Trastuzumab with >70% RCY (n.d.c) in ≈ 90 minutes starting from 8 - 80 GBq, with radiochemical purities >95%. ***Conclusion:*** We report the development of a process and consumables for the automated radiosynthesis of [177Lu] radioimmunoconjugates on the miniAllinOne. The process is compatible with any mAb-DOTA(GA) conjugate or commercial [177Lu]Cl3 source and accommodates activity levels up to 80 GBq, yielding up to 10 patient doses of [177Lu]mAb. This approach significantly enhances radiation protection and improves batch-to-batch reproducibility and robustness. Current efforts focus on demonstrating the compatibility of this process with a range of therapeutic and diagnostic radioisotopes such as Ac-225, Tb-161 and Cu-67/67. The objective is to fully leverage the potential of a universal radiosynthesis process in accelerating the transition from development to clinical production of radioimmunoconjugates.

EP-1187

Optimization of 4-[^{18}F]fluoro-1-naphthol ([^{18}F]4FN) production and quality controls

M. Riondato[1,2], *J. Martinelli*[2], *R. Guelfo*[3], *L. Palio*[4], *C. Marini*[5], *G. Sambuceti*[2];
[1]*IRCCS Policlinic Hospital of Genoa, Genoa, ITALY,* [2]*Dept. Health Sciences, University of Genoa, Genoa, ITALY,* [3]*Dept. Chemistry and Chemical Technologies, University of Genoa, Genoa, ITALY,* [4]*Dept. of Science and Technological Innovation University of Piemonte Orientale, Alessandria, ITALY,* [5]*Institute of Molecular Biomimaging and Physiology (IBFM), National Research Council (CNR), Milan, ITALY.*

Aim/Introduction: [^{18}F]4FN is as a promising tool in positron emission tomography (PET) imaging, offering enhanced specificity for the detection of inflammatory and immune responses compared to traditional agents, such as [^{18}F]FDG. Its potential extends to the early detection of immune-related adverse events and prognostic imaging in the context of cancer immunotherapy, where timely insights into the immune system's behavior can significantly inform clinical decision-making. Ongoing research aims to validate the clinical utility of [^{18}F]4FN, with studies indicating that its application could enhance diagnostic accuracy, monitor therapeutic responses, and ultimately contribute to the tailored management of diseases characterized by dysregulated immune activity. We aimed at the development of [^{18}F]4FN, via automated radiosynthesis on a commercially available module and the implementation of methods fulfilling all acceptance criteria well suited for the routine quality controls before release for clinical use. ***Materials and Methods:*** The Boc-protected pinacol boronic ester precursor on the 1-4 substituted naphthol scaffold was first synthesized. [^{18}F]Fluorine was produced using an Eclypse HP cyclotron (Siemens, Germany). The radiolabelling protocol was developed on a AllInOne36 synthesizer platform (Trasis, Belgium) able to carry out Cu-mediated 18F-fluorodeboronation, including deprotection and semipreparative purification before reformulation. For the routine use the quality control of radiopharmaceuticals was validated according to the ICH Q2 (R1) "Validation of Analytical Procedures". ***Results:*** The procedures were optimized at low radioactivity in terms of solvents, catalysts, amount of precursor and time. The best results were obtained by reacting 15 mg pinacol boronates, 27 mg of $Cu(OTf)_2(Py)_4$ using 1,3-dimethyl-2-imidazolidinone (DMI) as solvent. Starting from the Boc-protected pinacol boronic ester precursor, our optimized protocol allowed to obtain ca. 30-70 MBq of the target compound from 180-350 MBq of starting [^{18}F]fluoride, with approximately 20% ndc. Although the tests carried out so far are at low radioactivity

ranges, the results are promising obtaining [^{18}F]4FN with a high radiochemical purity (>99%) and with significant higher yield compared to the data reported in the literature (6% ndc). QCs were validated with special attention to HPLC method (for e.g., specificity, linearity, and accuracy) optimizing absorbance of reference compounds and developing both isocratic and gradient methods. ***Conclusion:*** We have optimized the Cu-mediated deborylative fluorination method to prepare the [^{18}F]-labeled aryl compound [^{18}F]4FN in a reliable and consistent way with high chemical and radiochemical purity, suitable for in vitro and in vivo experiments, in about 90 min including validated CQs. ***References:*** F. Pisaneschi et al., Nature Biotechnology volume 40, 965- 2022

Independent verification of activity determination for radiopharmaceutical preparations

K. Baete[1,2], *L. Mihailescu*[3], *W. Deckers*[1], *C. Terwinghe*[1], *R. Aarts*[3], *W. Claeys*[2], *J. Kleynhans*[2], *C. M. Deroose*[1,2];
[1]*UZ Leuven, Leuven, BELGIUM,* [2]*KU Leuven, Leuven, BELGIUM,*
[3]*Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM.*

Aim/Introduction: In nuclear medicine (NM), specialized equipment is required for the preparation, activity determination, dispensing, and administration of radionuclides for diagnostic and therapeutic use. The traceability and accuracy of measured activity is important for imaging and treatment optimization. Unfortunately, manufacturers of activity meters often do not provide the information needed to assess the device accuracy and traceability. This should be independently verified during acceptance testing. Our department installed a shielded isolator for the synthesis and dispensing of diagnostic and therapeutic radiopharmaceuticals (Phaedra Combo, Comecer S.p.A., Italy). We calibrated and verified the accuracy of the built-in activity meters for specific radionuclides and recipients. ***Materials and Methods:*** The isolator contains two activity meters: a re-entrant well-type ionisation chamber (VIK-202, Comecer) for measuring activity in recipients during radiopharmaceutical preparation, and a pass-through chamber (DVK-103, Comecer) for measuring activity of the end-product in a vial. We verified the accuracy of both activity meters using traceable reference sources (^{57}Co, ^{60}Co, ^{133}Ba, and ^{137}Cs) and compared the response to other devices using ^{99m}Tc. We assessed the response for a variety of calibration settings using reference sources and compared that to other devices. The Fidelis secondary standard radionuclide calibrator of the Belgian Nuclear Research Centre (SCK CEN), traceable to a designated metrological institute, was used to calibrate the activity meters for ^{68}Ga, ^{89}Zr, and ^{177}Lu using a standardized source geometry. ***Results:*** Initial testing showed reassuring results for the re-entrant well-type ionisation chamber. However, the pass-through chamber showed a deviation of 18% for the accuracy with a ^{57}Co reference source. It appeared that the recipient holder and its automated positioning system was not taken into account during manufacturing calibration. Adjustment of the electrometer settings was necessary and required the determination of new calibration factors. We established new factors for ^{68}Ga, ^{89}Zr, and ^{177}Lu using the Fidelis secondary standard radionuclide calibrator. The pass-through chamber required additional calibration for specific recipients with ^{177}Lu and the accuracy is significantly influenced by the volume of the radiopharmaceutical solution in the recipient. ***Conclusion:*** Traceable calibration and independent verification of the accuracy of activity determination in NM is essential. We analysed the accuracy of activity determination for a shielded isolator and required significant adjustments of factory based calibration settings. We recommend the involvement of a national metrological service for independent verification of activity determination in NM applications.

EP-1189

Feedback of [^{68}Ga]Ga-FAPI-46 radiosynthesis for clinical applications

C. Provost, *C. Schmitt, M. Steffann, B. Irumva, M. Delion, J. Fouque, O. Madar;*
Institut Curie, Saint Cloud, FRANCE.

Aim/Introduction: The radiopharmaceutical [^{68}Ga]Ga-FAPI-46 is a promising agent for PET imaging targeting fibroblast activation protein (FAP) in oncology and fibrotic diseases. It offers advantages over traditional tracers, particularly in cancers with low [^{18}F] FDG uptake. A Good Manufacturing Practice (GMP) automated radiosynthesis process has been developed to ensure high radiochemical yields (RCY) and compliance with pharmaceutical injectable grade. This study reports on our 1-year experience of [^{68}Ga]Ga-FAPI-46 (Sofie) radiosynthesis on an EasyOne® synthesizer (Trasis). ***Materials and Methods:*** We conducted a retrospective review of 96 productions and quality controls between March 2024 and March 2025. Six people are certified for production and Quality Control (QC) of [^{68}Ga]Ga-FAPI-46. An EasyOne® synthesizer with cassette and reagent kit and 2 Galliapharm® (Eckert & Ziegler) generators were used to produce this radiopharmaceutical. The production lasts 30 minutes with 1 hour of preparation before running the production process. QC includes: solution appearance, pH, ascorbate, period, radiochemical purity (RCP) by radio-Ultra High Performance Liquid Chromotography (r-UHPLC) and radio Thin Layer Chromatography (r-TLC), chemical purity by UHPLC-UV, filter integrity, endotoxin and sterility. The QC is completed within approximately 45 minutes. The [^{68}Ga]Ga-FAPI-46 procedure requires, at least 2 different people for the production and the QC and a radiopharmacist for the pharmaceutical release. ***Results:*** Out of 85 compliant productions, 32 % were sent to our nuclear medicine department at Paris site and 68 % at Saint-Cloud site. One hundred doses were dispensed for 59 patients. The mean final activity was 667 ± 155 MBq (min-max : 315 - 973 MBq) in 10 mL. The mean activity yield (AY) was 65 ± 3 % (56 - 70 %), the mean of RCP was 98.8 ± 0.6 % (97.2 - 99.9 %) evaluated by r-TLC and 99.3 ± 0.4 % (98.0 - 99.9 %) by r-UHPLC. The mean of chemical purity was 3.2 ± 0.5 µg/mL (1.9 - 4.8 µg/mL) for FAPI precursor+[^{68}Ga]Ga-FAPI-46 and 1.5 ± 0.4 µg/mL for the unkown impurity (0.8 - 2.9 µg/mL). A total of 5 productions encountered failure due to human error. Details are sum up in table 1. ***Conclusion:*** The robustness of this particular GMP process was demonstrated in routine clinical use. Only five production were not released due to human errors. The optimization of the process is a challenging task. A structured organization with effective communication between radiopharmacy and nuclear medicine is essential to ensure the successful management of short half-life radionuclide production.

EP-1190

GMP Standardized Automated Synthesis and Quality Control of [^{68}Ga]Ga-PSMA-11, [^{68}Ga]Ga-FAPI-04, [^{68}Ga]Ga-DOTA-NOC and [^{68}Ga]Ga-PentixaFor for Clinical PET Imaging

M. Zhang*;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: The striking diffusion and the exciting prospects of ^{68}Ga radiopharmaceuticals require a comprehensively and correctly implemented quality assurance system to guarantee reliable and validated production processes, and ensure that the quality and safety of ^{68}Ga radiopharmaceuticals are sufficient to satisfy the intended use. The present work aims to establish standardize automatic synthesis protocols for [^{68}Ga]Ga-PSMA-11, [^{68}Ga]Ga-FAPI-04, [^{68}Ga]Ga-DOTA-NOC and [^{68}Ga]Ga-PentixaFor, and build quality control systems for these ^{68}Ga radiopharmaceuticals for clinical PET imaging. ***Materials and Methods:*** The automated production of ^{68}Ga-PSMA-11, [^{68}Ga]Ga-FAPI-04, [^{68}Ga]Ga-DOTA-NOC and [^{68}Ga]Ga-PentixaFor using the ITM gallium-68 generator

eluate was implemented in an iQS Fluidic Labeling Module. Decay-corrected radiochemical yield (RCY) and residue rates on C18 cartridge, filter and waste were evaluated for each batch of production. Assessments of appearance, pH, radiochemical identity and radiochemical purity (RCP) were performed instantly before product releasing, while other tests like endotoxin and sterile examinations etc. were evaluated retrospectively. ***Results:*** The time for the labelling synthesis and quality control was approximately 25 min. The GMP compliant automated production of [^{68}Ga]Ga-PSMA-11, [^{68}Ga]Ga-FAPI-04, [^{68}Ga]Ga-DOTA-NOC and [^{68}Ga]Ga-PentixaFor were reproducibly with high RCYs of 87.76 ± 3.61%, 78.44 ± 3.83%, 71.30 ± 4.40% and 77.05 ± 3.67%, respectively. The RCP of the four ^{68}Ga radiopharmaceuticals were all greater than 95%. Predefined acceptance criteria were met for all other tests like the sterility, endotoxins level, radionuclidic purity, residual solvent content etc. ***Conclusion:*** The standardized automatic synthesis protocols for the labelling of [^{68}Ga]Ga-PSMA-11, [^{68}Ga]Ga-FAPI-04, [^{68}Ga]Ga-DOTA-NOC and [^{68}Ga]Ga-PentixaFor were demonstrated to be reliable and reproducible, with high RCY and RCP. The final product solutions were safe and suitable, passing full acceptance criteria of radiopharmaceuticals for clinical use. The comprehensive and integrated framework we established for production and quality control of ^{68}Ga pharmaceuticals was proved to be solid and reliable.

EP-1191

Automated Radiosynthesis and Quality Control of [^{68}Ga]Ga-DOTA-NOC for Clinical PET Imaging

M. Zhang;
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: This study was carried out to optimize the radiosynthesis of [^{68}Ga]Ga-DOTA-NOC using an iQS Fluidic Labeling Module and the quality control (QC) checks were performed before being used as a clinical product. ***Materials and Methods:*** The automated production of [^{68}Ga]Ga-DOTA-NOC using the ITM gallium-68 generator eluate was implemented in an iQS Fluidic Labeling Module. To optimize the production of [^{68}Ga]Ga-DOTA-NOC, different methods focus on the mass of the precursor in the labeling reaction, and the ethanol concentration of the eluent as well as the volume of the eluent during the elution process of C18 cartridge was employed. The decay-corrected radiochemical yield (RCY) and residue rates on C18 cartridge, filter and waste were evaluated for each batch of production. Assessments of appearance, pH, radiochemical identity and radiochemical purity (RCP) were performed instantly before product releasing, while other tests like endotoxin and sterile examinations etc. were evaluated retrospectively. ***Results:*** The radiochemical yields (RCYs) of methods A-D were 71.24%, 72.86%, 76.35% and 82.98%. There was an extremely significant difference of RCYs between methods C and D, and significant difference of RCYs between methods A and C, while there was no significant difference of RCYs between methods A and B as well as B and C, which suggesting that 30 µg of the precursor was not enough for the labeling reaction and increasing the volume of ethanol eluent instead of increasing the ethanol concentration of the eluent can improve the RCY. As for the residual rates on C18 cartridge, there was no significant difference among methods A, B and C, while there was an extremely significant difference between methods C and D, which suggesting that there was amount of radioactive colloid generated in methods A-C, which was significantly decreased as the precursor mass increased to 50 µg. With the increasing of ethanol concentration of eluent, the residue rate on filter decreased significantly. There was no significant difference of residue rates of waste among methods A, B, C and D. The RCP of each batch of [^{68}Ga]Ga- DOTA-NOC was greater than 95%. Predefined acceptance criteria were met for all other tests like the sterility, endotoxins level, radionuclidic purity, residual solvent content etc. ***Conclusion:*** The optimized automatic synthesis protocol for the labelling of [^{68}Ga]Ga-DOTA-NOC was demonstrated to be reliable and reproducible, with high RCY and RCP. The final product solutions were safe and suitable, passing full acceptance criteria of radiopharmaceuticals for clinical use.

EP-1192

Automated Radiosynthesis and Quality Control of [^{68}Ga]Ga-PentixaFor for Clinical PET Imaging

M. Zhang;
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: Chemokine receptor CXCR4 is overexpressed in more than 27 different human tumors that make it a promising target in oncology. [^{68}Ga]Ga-PentixaFor is the most promising PETtracer for CXCR4 receptor imaging; hence, the present study was carried out to optimize the radiosynthesis of [^{68}Ga]Ga-PentixaFor using an iQS Fluidic Labeling Module and the quality control (QC) checks were performed before being used as a clinical product. ***Materials and Methods:*** The automated production of [^{68}Ga]Ga-PentixaFor using the ITM gallium-68 generator eluate was implemented in an iQS Fluidic Labeling Module. To optimize the production of [^{68}Ga]Ga-PentixaFor, different methods focus on the mass of the precursor in the labeling reaction, and the ethanol concentration of the eluent as well as the volume of the eluent during the elution process of C18 cartridge was employed. The decay-corrected radiochemical yield (RCY) and residue rates on C18 cartridge, filter and waste were evaluated for each batch of production. Assessments of appearance, pH, radiochemical identity and radiochemical purity (RCP) were performed instantly before product releasing, while other tests like endotoxin and sterile examinations etc. were evaluated retrospectively. ***Results:*** The radiochemical yields (RCYs) of methods A-D were 78.17%, 76.41%, 82.40% and 83.13%. There was extremely significant difference of RCYs between methods B and C, while there was no significant difference of RCYs between methods A and B as well as Cand D, which suggesting that 30 µg of the precursor was enough for the labeling reaction and increasing the volume of ethanol eluent instead of increasing the ethanol concentration of the eluent can improve the RCY. The reason behind this was that increasing the volume of ethanol eluent can significantly reduce the radioactivity residual on C18 cartridge and filter membrane. The RCP of each batch of [^{68}Ga]Ga-PentixaFor was greater than 95%. Predefined acceptance criteria were met for all other tests like the sterility, endotoxins level, radionuclidic purity, residual solvent content etc. ***Conclusion:*** The optimized automatic synthesis protocol for the labelling of [^{68}Ga]Ga-PentixaFor was demonstrated to be reliable and reproducible, with high RCY and RCP. The final product solutions were safe and suitable, passing full acceptance criteria of radiopharmaceuticals for clinical use.

EP-1193

Liquid target production of Gallium-68 by a low energy medical cyclotron, post-bombardment purification and radiosynthetic yield of Gallium-68 DOTATATE as compared with Ge68/Ga68 generator

J. Cheung, *N. Ng, K. Liu, P. Lee, C. Ho;*
Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.

Aim/Introduction: We were able to produce Gallium-68 chloride via ^{68}Zn(p, n)^{68}Ga reaction by a low-energy (12 MeV) on-site cyclotron installed with a liquid target. Our aim was to adapt a published purification protocol, which was initially designed for an automated module, to a home-made, manual disposable purification setup. Using the same labelling module, we attempted to produce Gallium-68 DOTATATE by modifying the labelling conditions originally used for Ge68/Ga68 generator, and compared the amount of activity and percentage yield between them. ***Materials and Methods:*** The CYPRIS™ HM-12S (Sumitomo

Heavy Industry, Ltd.) was installed with a Gallim-68 liquid target, loaded with [^{68}Zn]Zn(NO_3)$_2$ (66mg/mL) solution in dilute HNO_3 (0.178M). Target bombardment current was 40 µA for 60 minutes to produce crude Gallium-68 chloride solution. This was purified manually by following a published protocol adopted in GE FASTlab. Our disposable setup was composed of a ZR cartridge, a TK200 cartridge, four 3-way valves, two addition lines and three extension sets. The purified product was added in the ITM iQS labelling module prefilled with DOTATATE precursor dissolved in sodium acetate buffer. Attempts were made to vary the amount of DOTATATE precursor (25 to 100 µg) and the concentration of sodium acetate buffer (0.25 to 1.50 M) in order to derive the optimal conditions for radiolabelling. ***Results:*** The manual purification of cyclotron-produced Gallium-68 chloride yielded an average decay-corrected recovery of 55.64% (n=3), which meets the quality control standards specified in the European Pharmacopeia monographs, whereby Gallium-66 and 67 contents present should be less than the products obtained from higher energy cyclotrons. By systematically adjusting 2 different variables (amount of DOTATATE precursor and sodium acetate buffer concentration), we found the optimal conditions which are using 100 µg DOTATATE dissolved in 0.425M acetate buffer to react with purified Gallium-68 chloride at 105°C for 10 minutes. Gallium-68 DOTATATE was then successfully synthesized in the labelling module, attaining a radiochemical purity exceeding 95% by HPLC analysis and an average yield of 74.70% (EOP, n=3). ***Conclusion:*** Crude Gallium-68 chloride could be successfully produced, purified and labelled by the above proposed setup and purification procedures to give a favourable recovery rate and radiopharmaceutical yield. With the above optimal setup and conditions, we were able to synthesize Gallium-68 DOTATATE on demand with our on-site low-energy cyclotron modified with a liquid targetry, which is comparable in activity and yield to those conventionally obtained from a Ge68/Ga68 generator and labelling module.

EP-1195

Transfer Of The [^{18}F]FMPEP-d_2 From a Fixed-line Device To a Disposable Cassette System

E. Kerminen[1], *N. Rajala*[1], *A. K. Kirjavainen*[1,2];
[1]*Turku PET Centre, Turku, FINLAND,* [2]*Department of Chemistry, University of Turku, Turku, FINLAND.*

Aim/Introduction: [^{18}F]FMPEP-d_2 is a PET tracer targeting cannabinoid receptor CB_1. It has promising properties such as high brain uptake[1], high specific binding[1] and it has been used for imaging CB_1 expression in subjects with alcohol abuse[2] and neurological disorders such as Parkinson's disease[3]. Previously, [^{18}F]FMPEP-d_2 has been labelled with good radiochemical yield (RCY) and reasonable synthesis time by a method utilising a fixed-line device.[4] However, the procedure is difficult to adapt to other facilities and this limits the wide spread use of [^{18}F]FMPEP-d_2. Herein, is described a previously reported method transferred to a cassette based module. ***Materials and Methods:*** [^{18}F]FMPEP-d_2 was synthesised using Trasis AllInOne (AIO) module adapting the synthesis method published by Lahdenpohja et al.[4] The synthesis included 1) azeotropic distillation 2) formation of [^{18}F]CD_2BrF 3) Gas Chromatographic (GC) purification of [^{18}F]CD_2BrF 4) [^{18}F]fluoroalkylation of the phenolic precursor 5) HPLC purification and 6) formulation. The GC purification of [^{18}F]CD_2BrF was applied to the cassette based synthesis utilising an external heater compatible with AIO and an in-house GC column filled with porous polymer absorbent. ***Results:*** The synthesis of [^{18}F]FMPEP-d_2 was completed in 75 minutes with RCY of 8.0 ± 0.1 % radiochemical purity (RCP) of > 99 % and molar activity of ≥ 480 GBq/µmol (decay corrected to SOS) with full automation. The yield of [^{18}F]FMPEP-d_2 was 700 ± 10 MBq at EOS. ***Conclusion:*** [^{18}F]FMPEP-d_2 was successfully synthesised on Trasis AIO with high RCP and a RCY suitable for clinical applications. Although the synthesis requires a GC purification with an external heater, this simple set-up can be easily utilised in facilities worldwide. The synthesis is applicable to a GMP environment and the simplicity of the cassette-based approach increases the reproducibility of the synthesis. Although, the results are sufficient, optimisation is still ongoing with the expectation of improved results. ***References:*** (1) Reubi, J. C.; Waser, B. Eur. J. Nucl. Med. Mol. Residual solvents analysis on fully automated quality control system - Method validation and comparability with compendial methods (Ph Eur & USP)

X. Franci*, S. Leloux, N. Godeau, Y. Zandona, N. Verbrugge;*
Trasis, Ans, BELGIUM.

Aim/Introduction: With the increasing number of different PET radiotracers that commercial radiopharmacies are required to deliver nearly simultaneously on a daily basis, quality control (QC) of radioactive drugs is becoming a limiting factor. Among the ten other analyses, the QC1 system performs the residual solvents test automatically. The system uses a gas chromatography (GC) method that diverges in various technical aspects from the Ph Eur and USP monographs, while maintaining the same analytical principles. As it is an alternative GC method, there is a need to validate the method and demonstrate its comparability with compendial methods. This study outlines the strategy and results obtained for the GC method validation and comparability versus Ph Eur and USP on the QC1 from Trasis, using the FDG case. ***Materials and Methods:*** A standard qualified QC1 Core was used for the study. To facilitate automation and miniaturization, the GC system employs a dedicated headspace device for sample/reference standards preparation, a 10m WAX column, and a thermal conductivity detector. The GC method for determining ethanol, acetonitrile, and acetone was validated according to ICHQ2(R2) guidelines, considering specificity, linearity, precision, accuracy, and range as validation criteria. For comparison purposes, a conventional GC system (Thermoscientific GC Trace 1600/Triplus 500 HS with flame ionization detector (FID)) was used, following the the Ph Eur and USP compendial methods. ***Results:*** The method validation results demonstrated that the QC1 method is suitable for the residual solvent analysis of FDG, particularly for the identification and quantification of acetone, ethanol, and acetonitrile within the limits defined by the Ph Eur and USP monographs. The method validation study met acceptance criteria for specificity (Rs > 3 for all peaks, matrix-independent, asymetry factors between 0.95 and 1.04), linearity (R^2 > 0.99), accuracy (recovery [95-105%]), and precision (RSD < 3.0%) according to ICHQ2(R2) guidelines. Additionally, robustness regarding the temperature of the headspace and gas sample volume was confirmed. Comparative data generated on both systems (QC1 and classical GC) showed that the QC1 method is as effective as the pharmacopeia methods. ***Conclusion:*** This study demonstrates that the GC method implemented on the QC1 is appropriate for the residual solvent quality control analysis of FDG, particularly for the identification and quantification of acetone, ethanol, and acetonitrile within the limits defined by the Ph Eur and USP. The method was validated, and its equivalence to the pharmacopeial methods was confirmed by statistical analysis following Ph Eur 5.27 guideline.

EP-1197

Radio-TLC Linearity in the Range of Concentrations Used

C. Piedelobo Vaquero*, E. Dobra Neacsu, L. Cebollada Cameo, G. Rubio Fernández, J. Pérez Iruela;*
Servicio de Radiofarmacia. Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: The aim is to verify that our radio-TLC measures linearly within the range of concentrations we use on a daily basis. ***Materials and Methods:*** Whatman 3 strips (1 cm wide, 10 cm long) were used and one drop with a 25G 5/8" (0.5x16mm) needle was applied in a 1ml syringe. The samples were measured by the radiochromatograph. Our method was validated according to the EANM and ICH Q2(R1) guidelines. Linearity, limit of quantification (LOQ) and range were calculated for this purpose. For the linearity, a 10 cm strip was divided into 5 equal portions. A drop, with half of the concentration of the previous one, was placed in the centre of each part. It was measured twice by the radiochromatograph. A regression line of the concentration versus the corrected area in counts per second (cps) was obtained. In the EANM guideline several methods to determine the limit of quantification were suggested. In our case, it was determined both, visually and by the signal/noise method. The limit of quantification was stipulated when the signal/noise ratio was 10:1. Visually, it was checked by the loss of linearity. The lower limit of the range was obtained from the limit of quantification, and the upper limit, from the data provided by the radio-TLC supplier. ***Results:*** The linearity was calculated by plotting the concentrations in MBq/ml against the corrected area cps, a linear regression line was obtained with a correlation coefficient of 0.9965. For the LOQ the signal/noise ratio was 10:1 when the concentration was 3 MBq/ml. This was confirmed by visual inspection of the regression line, where a loss of linearity was observed at that concentration. The range was stablished taken into account the lower limit as the limit of quantification (3 MBq/ml), and the upper limit was determined by the manufacturer as 200,000 cps, which was equivalent to 1667.5 MBq/ml. ***Conclusion:*** Knowing the concentrations handled in our radiopharmacy, it can be said that the radio-TLC measures reliably within the concentration range used. ***References:*** ICH Q2(R1). Validation of Analytical Procedures - ICH Quality GuidelinesGillings, N., Todde, S., Behe, M. et al. EANM guideline on the validation of analytical methods for radiopharmaceuticals. EP-1198

Determine Radiochemical Purity of [^{99m}Tc]Tc-Nanocolloids in an Analytical Method with Accuracy, Precision and Specificity

C. Piedelobo Vaquero*, E. Dobra Neacsu, G. Rubio Fernández, L. Cebollada Cameo, P. Ortega Cuadrado, M. Rodríguez Gómez, J. Pérez Iruela;*
Servicio de Radiofarmacia. Hospital Universitario Ramón y Cajal., Madrid, SPAIN.

Aim/Introduction: The aim of this study is to verify whether our analytical method is capable of detecting and quantifying a 5% impurity, from a [^{99m}Tc]Tc-Nanocolloids sample, with accuracy, precision, and selectivity. This forms part of the validation of an analytical method. ***Materials and Methods:*** Materials: For our validation method we have used Whatman 3 strips (1cm wide and 9cm long) as the solid phase and acetone as the mobile phase. The development of it took 8 cm. For the reference method, Silica gel 60 strips (1cm wide, 11cm long) were used and for the mobile phase, acetone. The development, in this case, took 10 cm. In both cases, one drop with a 25G 5/8" (0.5x16mm) needle in a 1ml syringe was applied at 0.5cm from the base and the samples were analysed by radio-TLC. Methods: The albumin nanocolloids accuracy, to which we added 3 known concentrations of the impurity [^{99m}Tc]TcO_4^- , was analysed using radio-TLC. Our results were compared to those obtained using the method described in the technical data sheet. Six samples, with the same impurity concentration, were measured for precision and the operation was performed by two different operators for intermediate precision. For [^{99m}Tc]Tc-nanocolloids, the impurity to be detected was only [^{99m}Tc]TcO_4^-, so it can be calculated by the resolution between the two peaks. The precision, limit of quantification and range were confirmed in a previous research following the ICH Q2 and EANM guidelines. ***Results:*** Accuracy results show recovery percentages within the range of 98.52% to 101.77%, depending on the concentration measured. For precision, the average of 6 samples was 5.29%, the standard deviation was 0.24 and the coefficient of variation (CV) was 4.47%. The intermediate precision was also calculated, obtaining an average between the two operators of 5.47%, standard deviation of 0.26 and CV of 4.71%. The specificity, according to the resolution between the two peaks, was 4.85. ***Conclusion:*** It can be stated that our method is capable of detecting the 5% impurity with precision, accuracy, and specificity and because of that it could replace the technical data sheet method. ***References:*** ICH Q2(R1). Validation of Analytical Procedures - ICH Quality Guidelines. Gillings, N., Todde, S., Behe, M. et al. EANM guideline on the validation of analytical methods for radiopharmaceuticals. EP-1199

Towards Advanced Imaging of Cardiac Amyloidosis: Reassessing Aprotinin with ^{64}Cu Radiolabeling

L. Canziani[1]*, G. Manfrinato*[1]*, A. Gandini*[2]*, G. Pepe*[1]*;*
[1]*Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY,*
[2]*Laboratory of Applied Nuclear Energy - Università di Pavia, Pavia, ITALY.*

Aim/Introduction: Recent advances in therapies for amyloid cardiomyopathy rise a renewed interest in improving its diagnosis, particularly through nuclear imaging. MRI, echocardiography, and bone scintigraphy enhanced our understanding of the disease, no single diagnostic tool currently offers early detection, differential diagnosis, and treatment monitoring in one. In the 1990s, ^{99m}Tc-aprotinin appeared as a promising tracer for cardiac amyloidosis scintigraphy, but safety concerns lead to its withdrawal and even after its re-approval, the shortage of raw materials limited further evaluations in clinical studies The recent availability of new isotopes like ^{64}Cu, aprotinin may regain its relevance as a radiopharmaceutical vector. However, radiolabeling with ^{64}Cu presents technical challenges. To address these challenges, we are investigating laser-assisted techniques to improve labeling efficiency and potentially revive aprotinin-based imaging in modern nuclear medicine. ***Materials and Methods:*** A solution of 100 MBq of ^{64}Cu was added to 2450 KUI of aprotinin in acetate buffer (pH 5). Labeling was tested under three conditions: room temperature, heating at 75°C for 15 minutes, and irradiation with a 7 W, 450 nm blue laser for 15 minutes. Laser exposure was performed in a shielded setup with real-time temperature monitoring. Radiolabeling yield was assessed by ITLC using ITLC-SG and 0.1 M tribasic citrate as the mobile phase. ***Results:*** The labeling yield (LY) of [^{64}Cu]Cu-aprotinin was 0% in Vial-1 (room temperature), 30% in Vial-2 (heat method), and >46% in Vial-3 (laser method). In Vial-3, the temperature only increased slightly, reaching 38°C during irradiation. The LY remained stable after 12 hours of incubation. However, when a [^{64}Cu] carrier-added source was used, the LY rapidly dropped to 0%, even for both the heat and laser methods. ***Conclusion:*** Our study demonstrates that both laser-assisted and heat-based approaches for ^{64}Cu labeling of aprotinin show potential for cardiac amyloidosis imaging, with the highest labeling efficiency (>46%) for the laser method. Notably, the use of a carrier-added ^{64}Cu source significantly reduced labeling efficiency, highlighting the importance of using non-carrier-added radionuclides. Although heat-based labeling is effective, it poses a risk of compromising protein structure and altering biological function, making laser labeling the more favorable method. Moreover, ^{64}Cu-labeled aprotinin wpuld apply for PET/CT imaging offering superior diagnostic accuracy

compared to early scintigraphis studiesThese findings are preliminary, and further refinement of reaction conditions could lead to improved outcomes.

Aim/Introduction: The advent of theranostics has seen the ^{68}Ga/^{177}Lu radionuclide pair being utilised for peptide receptor radionuclide imaging and therapy. However, application of this nuclide pair is limited to hospitals with suitable PET scanners and ^{177}Lu supply is limited. An alternative is offered by the well-known ^{99m}Tc/^{188}Re-combination - a highly cost-effective potential theranostic pair that provides generator-based on-demand radiopharmaceuticals. With RHN001-Dx/-Tx we are currently investigating a PSMA targeting ^{99m}Tc/^{188}Re-labeled theranostic in a phase-I/II clinical trial (Rhino trial). A method for preparation of ^{188}Re-labeled RHN001-Tx has been reported before. The aim of the current work was an optimization of the existing ^{188}Re-labelling process for RHN001 providing a GMP compliant routine production of the study drug RHN001-Tx. ***Materials and Methods:*** [^{188}Re]$NaReO_4$ obtained from a ^{188}W/^{188}Re-generator in 0.9% NaCl as eluent. A Sep-Pak Alumina N cartridge was used for removal of remaining ^{188}W-breakthrough. Labelling was conducted with 95 µg RHN001 precursor and 4 ml $NaReO_4$ solution (6-14 GBq) in presence of 12 mg $SnCl_2$ and a mixture of ascorbic acid and sodium citrate as auxiliaries. The starting pH at a range of 2.0-3.5 and the labelling was conducted at 96 °C for variable times. Subsequently, the crude product was neutralized to pH 6.5-7.5 by adding 0.5 M sodium phosphate solution and incubated for a further 10 min at 96°C. The crude product was purified and reformulated by cartridge extraction using standard Sep-Pak tC18 plus light cartridge. The radiolabeled product was then eluted with 1 ml 70% ethanol via a 0.22 µm filter and diluted with the formulation buffer containing a mixture of gentisic acid, sodium ascorbate and sodium acetate. ***Results:*** RHN001-Tx was produced in radiochemical yields of 90 % ± 1% (n = 3) and high radiochemical purities above 95%. Reaction time was an item of optimization and could be reduced to 15 min. Shelf-life was proven for up to 6 hours post-production (RCP still 95% ± 2%, n = 3). All other quality control items met the typical requirements for radiopharmaceuticals (e.g., Eur. Ph.). ***Conclusion:*** The ^{188}Re-labeling of the study drug RHN001-Tx was successfully optimized and scaled up for the preparation of therapeutic doses in the range of 4-5.5 GBq with proven shelf-life of up to 6 hours. Further scale up to even higher doses is currently under investigation. In summary, RHN001-Tx is now available as fully GMP compliant material for application within Rhino trial.

EP-1201

Process Validation of [^{18}F]Fluoroestradiol and [^{18}F] PSMA-1007 Production on next-gen Automated Module following Regulatory-Compliant Transition Requirements

M. B. Silveira, *E. Cortez, A. F. Castro, C. L. S. Costa, L. T. C. Nascimento;
Center for the Development of Nuclear Technology (CDTN/CNEN), Belo Horizonte, BRAZIL.*

Aim/Introduction: The radiopharmaceuticals [^{18}F]Fluoroestradiol and [^{18}F]PSMA-1007 are crucial for oncology diagnostics of high-incidence breast and prostate malignancies, respectively. Enhancing global access to these agents requires optimizing synthesis processes while maintaining quality and safety. This study evaluates the transition from TracerLab MX-FDG to FastLab-2 automated synthesis modules to produce [^{18}F]Fluoroestradiol and [^{18}F]PSMA-1007, considering Good Manufacturing Practices (GMP) requirements, process validation (critical parameters and in-process controls), and operational scalability for high-demand clinical environments. ***Materials and Methods:*** Validation studies were performed using GE Healthcare's TracerLab MX-FDG and FastLab-2 synthesis modules. Three consecutive batches of each radiopharmaceutical were manufactured under GMP-controlled conditions. Quality attributes assessed included radiochemical purity/identity, radionuclide purity/identity, pH, sterility, endotoxins, residual solvents, and TBA presence. In-process controls included synthesis yield and sterile filter integrity (bubble point test), with data analyzed for batch-to-batch consistency in alignment with specifications. ***Results:*** The FastLab-2 module demonstrated enhanced performance in [^{18}F]Fluoroestradiol (25-27% yield) and [^{18}F]PSMA-1007 (20-30% yield) production, showing significantly improved reproducibility compared to the TracerLab MX-FDG system (15%-19% and 19%-22%, respectively). For process controls, starting with an initial activity of 560 GBq of ^{18}F, the End of Synthesis (EOS) yielded 150 GBq of [^{18}F]Fluoroestradiol and 160 GBq of [^{18}F]PSMA-1007 using Fastlab-2. Quality control analyses confirmed all batches met the specifications, with radiochemical purity (HPLC) consistently for [^{18}F]Fluoroestradiol (>95%) and [^{18}F] PSMA-1007 (>91%). Sterile filter integrity (bubble point pressure of 57-62 psi) exceeded acceptance criteria (>50 psi) for both systems. The enhancements of FastLab-2 significantly reduced manual intervention, deviations, and contamination risks. In contrast, the TracerLab MX-FDG displayed greater inconsistencies, which were attributed to flat-bottom reactor and the absence of active cooling. Comprehensive quality assurance documentation was completed, including change control records, similarity studies, risk analysis reports, and full validation protocols. ***Conclusion:*** The FastLab-2 integrates key technological advancements, including enhanced valve actuators, a conical reservoir, streamlined cassette installation, precise nitrogen control, and computerized system quality management. Validation studies confirmed full GMP compliance, particularly in in-process controls (synthesis yield, filter integrity) and quality assurance parameters, providing confidence in its regulatory compliance. The operational efficiency, regulatory compliance, and batch-to-batch consistency position the FastLab-2 as a reproducible solution for high-demand environments, highlighting its advantages in clinical-scale production. Transitioning to the FastLab-2 module significantly enhanced productivity and reliable distribution of [^{18}F]Fluoroestradiol and [^{18}F]PSMA-1007.

Imaging of Widespread Manifestations of Erdheim-Chester Disease with Ga-68 FAPI PET/CT and F-18 FDG PET/CT

C. Turkan[1], *Ö. Karadağ*[2], *Y. Büyükaşık*[3], *M. Tuncel*[1];
[1]*Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Hacettepe University Department of Internal Medicine, Divison of Rheumatology, Ankara, TÜRKIYE,* [3]*Hacettepe University Department of Internal Medicine, Divison of Hematology, Ankara, TÜRKIYE.*

Aim/Introduction: Erdheim-Chester disease (ECD) is a rare form of non-Langerhans cell histiocytic neoplasm characterized by multisystem involvement of foamy histiocytes and fibrosis. Diagnosing ECD is often challenging due to the rarity of the disease. A baseline whole-body F-18 FDG PET/CT is recommended in all cases to aid in diagnosis and to define the extent of the disease. Ga-68 FAPI is a promising agent for imaging fibrotic

processes in various organs. Current literature on the role of Ga-68 FAPI PET/CT in the diagnosis of ECD is scarce. Therefore, we would like to present a case with extensive manifestations of ECD imaged using both F-18 FDG and Ga-68 FAPI. ***Materials and Methods:*** A patient with an orbital and renal biopsy suspicious for ECD is imaged within one week using Ga-68 FAPI PET/CT and F-18 FDG PET/CT. ***Results:*** A 66-year-old man was admitted to hospital with flank pain and eye swelling. Following his initial imaging, renal and orbital biopsies were performed. The biopsy results were suspicious for ECD and IgG4-related disease. After consultation with rheumatology, the patient underwent Ga-68 FAPI PET/CT and F-18 FDG PET/CT scans. Both Ga-68 FAPI and F-18 FDG PET/CT revealed an extensive disease burden within the orbits, paranasal sinuses, periaortic soft tissues (coated aorta), right atrium (atrial pseudotumour), and retroperitoneum (hairy kidney sign), mesentery, and long bones. Ga-68 FAPI uptake was more pronounced than F-18 FDG uptake at all mentioned sites. In the central nervous system, Ga-68 FAPI PET/CT showed dural and cavernous sinus involvement that was not observed on F-18 FDG PET/CT. The patient was diagnosed with ECD based on imaging findings showing the classic sites of the disease and a re-evaluation of the existing biopsy results. ***Conclusion:*** Ga-68 FAPI PET/CT is a promising imaging modality for the diagnosis and accurate identification of disease burden in ECD and can be used in conjunction with F-18 FDG PET/CT. Our case demonstrates one of the most extensive disease burdens, clearly demonstrated by Ga-68 FAPI PET/CT.

EP-1203

Pitfall in ^{18}F-FDG PET/CT: Muscular Uptake Does Not Always Mean Inadequate Preparation - A Case Report of Antisynthetase Syndrome

V. Heringer, *E. Lima, T. Alves, C. Torricelli, N. Silva, G. Barbosa, E. Etchebehere;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Antisynthetase syndrome is a heterogeneous group of autoimmune disorders, most commonly presenting with the triad of myositis, arthropathy, and interstitial lung involvement[1]. The condition is characterized by the presence of autoantibodies directed against aminoacyl-tRNA synthetases. The precise role of those antibodies in disease pathogenesis remains unknown, posing challenges to the development of targeted therapeutic approaches[2]. ***Materials and Methods:*** A 47-year-old white male presented with a one-year history of symptoms, including periorbital edema, symmetric polyarthralgia of the hands and wrists with brief morning stiffness, Gottron's papules, interstitial lung disease, and myositis with proximal lower limb weakness, elevated creatine phosphokinase (CPK), and electromyography findings consistent with myopathy. Laboratory evaluation revealed a reactive antinuclear antibody (ANA) at 1/320 with a homogeneous nuclear pattern; positive anti-Jo-1 and C-reactive protein (CRP). Because of refractory muscle involvement, combined therapy with rituximab, mycophenolate, and intravenous immunoglobulin was required. Due to persistent low-grade fever and nonspecific signs of inflammatory activity (with no apparent infectious or neoplastic focus) it was recommended to perform ^{18}F-FDG PET/CT. ***Results:*** The PET/CT images demonstrated diffuse hypermetabolism in the musculature without significant tomographic abnormalities (SUV = 8.3 - right lower limb), suggesting diffuse inflammatory myopathy with no detectable infectious or neoplastic sites. ***Conclusion:*** This case highlights the importance of correlating clinical data with imaging findings, whether this information is obtained from the patient in person through questionnaires on the day of image scan or accessed from medical records in a hospital setting. Notably, some clinical conditions are rare, and the patient may not be aware of them. Limited literature is available on the findings of ^{18}F-FDG PET/CT in antisynthetase syndrome. In conclusion, diffuse systemic muscular inflammation was detected on ^{18}F-FDG PET/CT, and it may be useful in evaluating and monitoring the degree of inflammatory activity, showing that muscular uptake does not always mean inadequate preparation. ***References:*** 1. 1) Nazerani-Zemann T, et al. Nuklearmedizin. 2023. 2. 2) Patel P, et al. Int J Mol Sci. 2024. 3. 3) Jain TK, et al. Rev Esp Med Nucl Imagen Mol. 2016.

EP-1204

Incidental Detection of Hemorrhagic Stroke with Luxury Perfusion on a 99mTc-MDP Bone Scan in a Breast Cancer Patient: A Case of Hidden Neurological Sequelae

A. Akhter, *S. Sharmin, S. Islam;*
Institute of Nuclear Medicine and Allied Sciences (INMAS) Dhaka, BAEC, Dhaka, BANGLADESH.

Aim/Introduction: Neurological symptoms in cancer patients, such as cognitive decline, fatigue, and mood disturbances, are often attributed to psychological stress or treatment-related effects, potentially masking serious underlying pathology. We present a compelling case of a 67-year-old woman with breast cancer who was referred for a routine whole-body bone scan as part of metastatic surveillance. The scan incidentally revealed findings consistent with a subacute hemorrhagic stroke with luxury perfusion, highlighting the value of hybrid SPECT/CT in detecting subtle neurological abnormalities that can directly influence clinical decision-making. ***Materials and Methods:*** The patient, a breast cancer survivor post-surgery and chemotherapy state, presented with generalized weakness, poor responsiveness, and altered mental status for two weeks. She underwent a 99mTc-MDP bone scan for metastatic surveillance, 3 hours after the intravenous injection of 20 mCi of 99mTc-MDP. Hybrid SPECT/CT was performed to localize an incidental finding of increased radiotracer uptake in the left temporo-parietal region observed on the planar scan. Two days later, an MRI of the brain was conducted for further evaluation. ***Results:*** Planar bone scan revealed focal increased radiotracer uptake in the left temporo-parietal skull region, which was further localized by SPECT/CT to a large irregular hypodense area in the brain parenchyma, suggesting a cerebrovascular ischemic event rather than bone or brain metastasis. MRI of brain performed two days later showed a large area of altered signal intensity in the left temporo-parietal cortex extending into the posterior periventricular region. The lesion demonstrated T1 hypointensity, T2 hyperintensity, partial diffusion restriction, minimal GRE blooming, and significant post-contrast enhancement, consistent with a subacute hemorrhagic infarct with luxury perfusion. Additional findings included dilated ventricles, generalized brain atrophy, and deep white matter ischemic changes. The 99mTc-MDP uptake in the stroke was attributed to blood-brain barrier breakdown, inflammatory changes, calcium deposition, and ischemic tissue mineralization. This incidental finding led to the diagnosis of a silent hemorrhagic stroke. Clinical evaluation revealed mild anemia with normal serum electrolytes, excluding metabolic abnormalities. Based on the imaging findings, the patient was referred for conservative neurological care. ***Conclusion:*** This case underscores the importance of incidental findings in routine nuclear imaging for oncology patients. The detection of a silent hemorrhagic stroke on a 99mTc-MDP planar bone scan highlights the need for thorough evaluation of subtle neurological symptoms through hybrid SPECT/CT, prompting accurate diagnosis, guiding management, and improving patient outcomes.

EP-1205

From Prostate to Pulmonary Malignancy: A Case of Incidental Lung Adenocarcinoma detected by PSMA PET/CT with a significant impact on clinical management

D. Barbosa, *J. Ferro, H. Duarte, D. Silva, N. Vasconcelos, R. Marão, I. Sampaio;*
IPO, Oporto, PORTUGAL.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) Positron Emission Tomography/Computed Tomography (PET/CT) is an established modality for imaging prostate cancer patients. However, PSMA uptake has also been observed in non-prostate malignancies, a fact that is crucial to recognise in order to avoid misdiagnosis. Expression of PSMA in non-prostatic tumours, including lung adenocarcinoma, is increasingly recognised and correlates with endothelial PSMA expression in tumour-associated neovasculature. Incidental detection of lung cancer on PET-PSMA has been reported in about 2% of scans. We present a case where [68Ga]Ga-PSMA-11 PET/CT identified a primary lung cancer, significantly impacting patient management. ***Materials and Methods:*** A 69-year-old male patient diagnosed with prostate cancer underwent radical prostatectomy and bilateral lymphadenectomy. Pathological analysis revealed an adenocarcinoma Gleason score 7 (3+4), cT2N0M0 R0 (initial PSA: 8.2ng/mL). After a 5-year surveillance period, biochemical recurrence had occurred (PSA: 0.240ng/mL), and a [68Ga]Ga-PSMA-11 PET/CT scan was requested. ***Results:*** [68Ga]Ga-PSMA-11 PET/CT did not show locoregional recurrence; however, it revealed an intense PSMA-avid pleuropulmonary densification in the right upper lobe (SUVmax: 5.55), suggesting a primary cancer. This finding prompted further investigation. A contrast-enhanced CT scan revealed a 2.5 cm subpleural nodule in the right lung, and a CT-guided biopsy was subsequently performed. Histopathological analysis revealed lung adenocarcinoma, TTF-1 positive, with PD-L1 expression at 95% and a KRAS G12C mutation. Staging was completed with a brain magnetic resonance imaging (which showed no abnormalities) and a [18F]fluoro-2-deoxy-D-glucose PET/CT, which reported the known malignant neoplasm of the right lung (possibly with carcinomatous lymphangitis) and metastasis to mediastinal-hilar and right axillary lymph nodes and to the right pleura. Despite the persistence of PSA values up to 0.327ng/mL, the identification of primary lung cancer led to a modification of the patient's treatment plan. The salvage radiotherapy that had been planned for the recurrence of prostate cancer was postponed, and the patient was initiated on first-line palliative immunotherapy with pembrolizumab. ***Conclusion:*** This case underscores the diagnostic challenges associated with PSMA-PET/CT imaging, highlighting its ability to detect unsuspected primary malignancies other than prostate cancer. A meticulous evaluation of atypical PSMA-avid lesions is crucial to avoid misinterpretation, directly influencing patient outcomes by enabling prompt diagnosis and management of secondary primary tumours.

EP-1206

Renal Cell Carcinoma Masquerading as a Cervical Paravertebral Abscess: A Rare Case Report

C. S*, L. Goriparti, C. Bal, S. L.S., J. Krishna;*
All India Institue of Medical Science, New Delhi, INDIA.

Aim/Introduction: Renal cell carcinoma, accounts for over 90% of adult renal tumors. Nearly 50% of RCCs are found incidentally and often presents asymptomatically or with nonspecific symptoms. We report a rare case of RCC initially mimicking a cervical paravertebral abscess, highlighting the role of FDG PET/CT in diagnosing occult malignancy. ***Materials and Methods:*** Patient was instructed to avoid strenuous activity for 24 hours and fasted for atleast 8 hours before the scan. Blood glucose levels before the FDG administration was 106 mg/dl. 8 mCi (296 MBq) of ^{18}F-FDG was injected intravenously in right upper limb. PET/CT was acquired from the level of vertex to mid thigh, 60 minutes post injection. ***Results:*** An 80-year-old female presented with progressive left upper limb weakness (power 2/5) and lower neck pain. She also noticed a discharging sinus on the posterior aspect of neck, which is inactive at the time of acquisition of PET/CT. There are no symptoms suggesting renal involvement like hematuria, flank pain or a palpable flank mass. On Inspection - Single sinus opening (~0.5 cm) on neck at C4-C7 level with no active discharge. On Palpation, Tenderness present. No palpable mass. Neurological Examination: Motor: Left upper limb: Power-2/5 (shoulder abduction, elbow flexion), 3/5 (hand grip, finger extension). Right upper limb & bilateral lower limbs-Normal power (5/5). Reflexes-Biceps/Jerk: Left - diminished, right - normal. MRI revealed a 5.6 × 3.5 cm left paravertebral lobulated heterogeneous septate T2 weighted mass, suspected as an abscess/collection - possibly Koch. Despite 2 months of antibiotics, symptoms persisted.FDG PET/CT demonstrated: 1. Metabolically active lytic destructive lesion with large soft tissue component noted involving pre and paravertebral region of C4 to C7 vertebrae, measuring 5.9x 6.6x 5.3 cm with intraspinal extension. 2. Metabolically active large lobulated exophytic soft tissue mass with areas of internal necrosis noted arising from lower pole of right kidney measuring 9.6x 9.8x 6.5 cm, involving renal sinus and encasing IVC medially. ***Conclusion:*** This case underscores RCC's potential for atypical metastasis and the diagnostic utility of FDG PET/CT in occult malignancies. The absence of classic renal symptoms and initial abscess-like presentation delayed diagnosis, emphasizing the need for heightened suspicion in refractory structural lesions. PET/CT not only identified the primary tumor but also guided definitive management, showcasing its pivotal role in complex oncologic evaluations. ***References:*** Pandey J, Syed W. Renal Cancer. 2024 Oct 4. In: StatPearls [Internet]. Treasure Island (FL): StatPearls Publishing; 2025 Jan-. PMID: 32644401.

EP-1207

FDG PET/CT in Disseminated Cryptococcosis Mimicking Malignancy with Chest Wall Infiltration and Rib Destruction: A Rare Case of Fungal Pseudotumor

A. Mahalik*, A. Roy, N. Kundu, K. Jain, G. Lalitha, J. Krishna P., V. R. Singh, R. Kumar;*
All India Institute of Medical sciences, New Delhi, INDIA.

Aim/Introduction: Disseminated cryptococcosis is a rare but serious fungal infection, particularly in immunocompromised individuals. While MRI and CT are standard imaging tools, the role of ^{18}F-FDG PET/CT in evaluating the extent of infection and response to therapy is still emerging. Cryptococcal infections presenting with thoracic mass-like lesions that mimic malignancy and invade the chest wall are exceptionally uncommon. ***Materials and Methods:*** A 56-year-old male with a history of disseminated cryptococcosis (diagnosed August 2022) and on Voriconazole therapy underwent FDG PET/CT for assessment of residual disease on July, 2024. PET/CT revealed a heterogeneously FDG-avid pleural-based mass in the right upper lobe (8.1 x 7.5 x 9.3 cm), causing lytic destruction of the right 1st and 2nd ribs. The mass extended into the right supraclavicular, axillary, and anterior chest wall regions, involving right pectoralis and serratus anterior muscles. Additional FDG-avid nodules were noted in both lungs and right supraclavicular lymph nodes. Previously noted adrenal gland lesions had resolved. Interval imaging showed a significant reduction in disease burden compared to the prior scan. ***Results:*** This case illustrates the value of ^{18}F-FDG PET/CT in: 1. Identifying fungal infections mimicking aggressive malignancies. 2. Detecting rare sites of involvement such as ribs and skeletal muscles. 3. Monitoring therapeutic response to antifungal therapy over time. Chest wall invasion and rib destruction are exceedingly rare manifestations of cryptococcosis, more typically associated with neoplastic disease. The comprehensive metabolic assessment offered by PET/CT provided critical insights into disease behavior and therapeutic response. ***Conclusion:*** This case highlights a rare presentation of disseminated cryptococcosis involving chest wall structures and ribs, masquerading as malignancy. FDG PET/CT

proved instrumental in mapping disease extent and evaluating treatment response, underscoring its diagnostic and prognostic value in complex fungal infections.

EP-1208

A Rare Metastatic Journey: From Lower Limb to Heart in Cutaneous Squamous Cell Carcinoma Revealed by ^{18}F-FDG PET/CT

A. Akhter[1], *S. Sharmin*[1], *A. Haque*[2], *T. Hasan*[1], *S. Biswas*[1];
[1]*Institute of Nuclear Medicine and Allied Sciences (INMAS) Dhaka, BAEC, Dhaka, BANGLADESH,* [2]*Dhaka Medical College Hospital, Dhaka, BANGLADESH.*

Aim/Introduction: Squamous cell carcinoma (SCC) is a common malignancy typically involving local invasion and lymphatic spread. Hematogenous dissemination may occur in advanced stages, yet cardiac metastasis remains rare and is often diagnosed post-mortem. We present a unique case of cutaneous SCC originating from the right lower extremity, with rare metastatic spread to the heart, identified by ^{18}F-FDG PET/CT. ***Materials and Methods:*** A 32-year-old male presented with a long-standing ulcerated lesion on the right lower leg following trauma and was diagnosed with invasive, well-differentiated SCC in October 2022. He underwent multiple resections over two years for recurrent inguinal masses. A large lobulated lesion (13.3 × 10.8 × 6.1 cm) in the right groin encased major vessels and led to a right hindquarter amputation in April 2024. Histopathology confirmed metastatic SCC. The patient did not receive chemotherapy or radiotherapy due to negligence. A ^{18}F-FDG PET/CT scan was performed for systemic staging. ***Results:*** ^{18}F-FDG PET/CT showed multiple hypermetabolic lesions with central necrosis in the right inguinal region, groin, and lower abdominal wall (SUV max up to 17.8). A mildly FDG-avid pulmonary nodule (SUV max 2.0) suggested lung metastasis. Critically, a hypermetabolic soft tissue lesion (31.5 × 24 mm; SUV max 9.0) was identified in the interventricular septum of the heart near the apex, suggesting cardiac metastasis. Echocardiography confirmed a soft tissue mass arising from the right ventricle and adjacent apex, extending into the interventricular septum, with preserved LV ejection fraction (66%). No abnormal FDG uptake was noted in the liver, spleen, or bones. Based on these findings, systemic palliative chemotherapy with paclitaxel and carboplatin was initiated. ***Conclusion:*** This case illustrates an exceptionally rare cardiac metastasis from cutaneous SCC. Cardiac involvement is uncommon even in advanced disease and often asymptomatic. ^{18}F-FDG PET/CT was critical in identifying this unexpected metastatic site. The absence of systemic therapy may have allowed unchecked disease progression. This report emphasizes the importance of comprehensive imaging in aggressive or recurrent SCC cases, including cardiac evaluation, to guide clinical decision-making and improve patient outcomes.

EP-1209

Functional Tumor Heterogeneity Revealed by Discordant 18F FDG and 18F FES PET/CT in ER-Positive Breast Cancer: A Case of Imaging-Guided Insight into Endocrine Resistance

A. Mahalik*, N. Kundu, A. Roy, M. Tripathi, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: 18F-FES PET/CT is used to evaluate in vivo estrogen receptor (ER) expression and is increasingly being adopted to guide therapeutic decisions in ER-positive breast cancer. However, discrepancies between FDG and FES uptake, especially in the absence of histological confirmation, present a clinical challenge. ***Materials and Methods:*** A known case of ER-positive invasive ductal carcinoma, post-modified radical mastectomy, chemotherapy, and radiotherapy, underwent metastatic workup with ^{18}F-FDG PET/CT on 09.04.2022. FDG PET/CT revealed metabolically active lesions in the sternum and sacrum. However, on 18F-FES PET/CT performed on 05.05.2022, these lesions did not show any significant tracer uptake. Despite the discordant imaging findings and lack of biopsy confirmation of ER heterogeneity in these sites, the patient was continued on fulvestrant and palbociclib. On follow-up ^{18}F-FDG PET/CT dated 21.01.2023, there was appearance of new hepatic and osseous lesions suggestive of disease progression. ***Results:*** This case illustrates the role of functional imaging in uncovering tumor heterogeneity in ER-positive breast cancer. Discordant uptake between FDG and FES PET/CT suggests spatial variation in estrogen receptor expression—a hallmark of tumor heterogeneity. Such heterogeneity may influence treatment response and prognosis. The absence of FES uptake in FDG-avid lesions could reflect receptor downregulation or clonal evolution towards a more aggressive phenotype. This functional mismatch underscores the importance of integrating molecular imaging into clinical decision-making, especially when biopsy is not feasible. ***Conclusion:*** FES PET/CT offers vital insights into tumor biology by visualizing receptor expression heterogeneity. Discordance with FDG PET/CT should raise suspicion for subclonal receptor-negative populations contributing to endocrine resistance. Early identification of such heterogeneity can guide tailored treatment strategies and avoid delayed escalation of therapy. This case reinforces the evolving role of molecular imaging as a non-invasive biomarker for tumor heterogeneity in breast cancer.

EP-1210

Targeting the rare: ^{18}F-FDG PET/CT in pediatric bilateral orbital Rosai-Dorfman disease

K. Jain*, A. Mahalik, N. Kundu, J. Choudhary, S. Singh, V. R. Singh, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Rosai-Dorfman disease (RDD) is a rare, non-Langerhans cell histiocytic disorder that typically presents with massive cervical lymphadenopathy. Extra-nodal involvement is less common, and isolated bilateral orbital disease is particularly rare. We report a pediatric case with longstanding bilateral proptosis ultimately diagnosed as orbital RDD, with metabolic characterization and therapeutic monitoring via ^{18}F-FDG PET/CT. ***Materials and Methods:*** A male patient presented with progressive bilateral proptosis since the age of 6. At 16 years of age, MRI orbit and brain revealed bilateral intraorbital masses. An orbital biopsy was performed, and histopathology confirmed RDD, characterized by emperipolesis and S100 positivity. Patient underwent baseline and post therapy ^{18}F-FDG PET/CT according to our department protocol. Two experienced nuclear medicine physicians reviewed the scans done at the time of initial staging and post induction chemotherapy. ***Results:*** The baseline ^{18}F-FDG PET/CT demonstrated intense FDG uptake in bilateral intra-orbital lesions with bilateral cervical lymph nodal involvement, consistent with metabolically active nodal and extra-nodal RDD. The patient was initiated on systemic chemotherapy. On Follow-up after post-chemotherapy, the ^{18}F-FDG PET/CT showed a significant metabolic response with marked reduction in FDG uptake and lesion size, correlating clinically with improvement in proptosis and ocular symptoms. ***Conclusion:*** This case highlights the rare orbital manifestation of RDD and reinforces the role of ^{18}F-FDG PET/CT in both diagnosis and therapeutic monitoring. PET/CT enabled accurate disease assessment and demonstrated excellent treatment response, underscoring its value in guiding clinical management of extra-nodal RDD.

EP-1211

68Ga-DOTATATE PET/MRI for the Diagnosis of Optic Nerve Sheath Meningioma in an Adolescent with Progressive Unilateral Vision Loss

A. Giarratana, *M. Larson;*
University of Wisconsin - Madison, Madison, WI, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Optic nerve sheath meningioma (ONSM) is a rare, benign tumor originating from the arachnoid cap cells surrounding the optic nerve. [1] Differentiating ONSM from optic neuritis or inflammatory etiologies can be particularly challenging, especially in pediatric populations. [2, 3] We present a case of a 17-year-old male with progressive vision loss in the left eye where 68Ga- DOTATATE PET/MRI enabled a definitive diagnosis of ONSM, guiding successful radiation therapy. ***Materials and Methods:*** The patient presented with gradually worsening visual acuity and optic disc edema beginning in late 2022. Initial MRI findings were inconclusive, showing enhancement of the left optic nerve and sheath. Laboratory workup was notable for a transiently positive MOG antibody. Despite treatment with corticosteroids and plasmapheresis, vision worsened. 68Ga- DOTATATE PET/MRI was performed to clarify the diagnosis. ***Results:*** The 68Ga- DOTATATE PET/MRI revealed high uptake localized to the optic nerve sheath, consistent with somatostatin receptor-expressing meningioma. Radiation therapy was initiated (50.4 Gy in 28 fractions). Seven months after radiation, vision showed significant improvement. Quantitatively, his visual field scores improved from -31 dB to -13 dB, indicating better function though still below normal. Qualitatively, he estimated his left eye vision improved from 30% to 70%. Optic nerve swelling had completely resolved on exam. ***Conclusion:*** This case illustrates the diagnostic utility of 68Ga- DOTATATE PET/MRI in distinguishing ONSM from inflammatory optic neuropathies. In patients with atypical progression or treatment-refractory optic neuritis, 68Ga- DOTATATE PET/MRI can provide critical diagnostic clarity and inform effective management. ***References:*** 1.Parker, R.T., et al., Optic nerve sheath meningiomas: prevalence, impact, and management strategies. Int Med Case Rep J, 2015. 8: p. 159-63. 3.Joseph, A.K., et al., Imaging Findings of Pediatric Orbital Masses and Tumor Mimics. Radiographics, 2022. 42(3): p. 880-897.

EP-1212

A rare case of extramammary Paget's disease of the vulva: [^{18}F]FDG PET/CT in the evaluation of Radiotherapy efficacy and 30-months follow-up

M. Ricci[1], *A. Cimini*[2], *M. Ullo*[1], *M. Grivet Fojaja*[1], *F. Zarrelli*[1], *F. Perrotta*[3], *E. Lubrano di Scorpaniello*[3];
[1]*Cardarelli Hospital, Nuclear Medicine Unit, Campobasso, ITALY,*
[2]*Nuclear Medicine Unit, St. Salvatore Hospital, L'Aquila, ITALY,*
[3]*Department of Medicine and Health Sciences "Vincenzo Tiberio", University of Molise, Campobasso, ITALY.*

Aim/Introduction: Extramammary Paget disease is an intraepithelial neoplasm affecting cells rich in apocrine glands often located in the vulvar, scrotal, or perianal region. Surgical resection is still the main treatment for Vulvar Paget Disease (VPD) and Radiotherapy (RT) is suitable for VPD patients who refuse surgery or are not suitable for surgery. However, the efficacy of RT in VPD is controversial. ***Materials and Methods:*** A 73 years-old female patient presented a locally advanced intraepithelial lesion of the vulva. A subsequent biopsy revealed extrammamary Paget disease and, due to the perineal extension of the lesion, the patient was not suitable for surgery and RT was performed. The therapy monitoring protocol with [^{18}F]FDG PET/CT was planned. ***Results:*** [^{18}F]FDG PET/CT was performed 4 months after RT (Dual Time protocol; whole body at 45 min and pelvic acquisition at 90 min) and reported a minimal area of FDG uptake, that presented a reduction in late acquisition (SUVmax 3.23, SUVmax at 90 min 3.09). This area was interpreted as a post-actinic lesion. Further PET scans were performed - due both to the high risk of relapse of VPD and to the subsequent development of melanoma of the back area - 10 months, 17 months, 24 months and 30 months after RT and confirmed the efficacy of RT in this case of VPD. ***Conclusion:*** To our knowledge, this is the first case report that reported the role of [^{18}F]FDG PET/CT in the therapy monitoring of VPD. The [^{18}F]FDG PET/CT allowed a prompt evaluation of RT efficacy and can be considered in diagnostic algorithm of patients with VPD not suitable for surgery. Moreover, the Dual Time Protocol allowed the correct interpretation of the scan and it can be performed in order to support the differential diagnosis between residual and post-actinic lesions.

EP-1213

A rare case of metastatic Well differentiated Neuroendocrine Tumor of Prostate on hemodialysis treated with Concurrent Long Acting Octreotide and 177Lutetitium DOTATATE therapy achieving complete response- Case report and Literature Review

J. Bal, *S. Jha, P. Dougall;*
Max Super Specialty Hospital, Delhi, INDIA,

Aim/Introduction: Prostatic carcinoma is one of the leading causes of morbidity and mortality in men worldwide. However, the most common prostatic malignancy are conventional adenocarcinomas. A rare subgroup within adenocarcinomas comprises of stromal malignancies and other unusual epithelial malignancies. Well differentiated primary prostatic neuroendocrine tumors have been documented in the literature although as very rare cases. ***Materials and Methods:*** This is a case of a 74 year-old male patient with chronic kidney disease on regular hemodialysis, diagnosed with well to moderately differentiated neuroendocrine tumor of prostate who had metastases at initial presentation. His Somatostatin receptor (SSTR) imaging i.e. Ga68 DOTANOC scan showed high SSTR expression in primary and metastatic sites. He was initially treated with LAR Octreotide. This regimen initially kept the disease stable, but a year later there was progression in the primary mass and at the metastatic sites. He was then advised to start treatment with 177Lu-DOTATATE peptide receptor radionuclide therapy (PRRT) along with concurrent LAR Octreotide which was challenging for the dosimetry reasons as the patient was already renal compromised and sequencing the administration of PRRT with hemodialysis. He underwent 3 cycles of PRRT in a span of approximately 1 year. Subsequently, the primary tumor regressed with a remarkable response in the metastatic lymph nodes and skeletal lesions. 177Lu-DOTATATE peptide receptor radionuclide therapy may be an effective option for primary well differentiated metastatic or locally advanced neuroendocrine tumors of prostate, which has few effective treatment options and it can be effectively administered along with hemodialysis without compromising on dose administered. ***Conclusion:*** The diagnosis of low-grade neuroendocrine tumor (carcinoid tumor) should be reserved for those cases in which the histologic findings and the immunostains fit the case. It appears that a true prostatic carcinoid tumor may not show reactivity for prostate-specific antigen, a feature seen in our case, which may be useful in the separation of these neoplasms in more difficult biopsy specimens. 177Lu-DOTA-TATE demonstrates favorable efficacy in treating neuroendocrine tumors, but its current application primarily focuses on gastrointestinal neuroendocrine tumors. All physicians should familiarize themselves with the clinical and pathological features this histopathology, as well as the available treatment modalities, in order to prolong patient survival and enhance cure rates. Moreover, we recommend adopting a multidisciplinary

approach, involving urologists, oncologists, nuclear medicine physicians and pathologists, to collaboratively discuss treatment plans and improve the health and quality of life for patients.

EP-1214

The Role of FDG PET/CT in Treatment-Related Neuroendocrine Prostate Cancer: An Unusual Case of PSA and PSMA Double-Negative Disease with Squamous Differentiation

Y. Li, *Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: We report a rare case of treatment-related neuroendocrine prostate cancer (NEPC) with squamous differentiation, presenting as PSA and PSMA double-negative. FDG-PET/CT revealed extensive hypermetabolic bone lesions, along with retrocrural nodal diseases and pulmonary nodules, all of which showed no significant abnormalities on PSMA-PET. ***Materials and Methods:*** A 62-year-old man with a 5-year history of prostate cancer (status post-prostatectomy, radiation, hormone therapy, and enzalutamide) presented with a 9-month history of worsening lumbar and back pain, raising suspicion of bone metastasis progression. ^{68}Ga-PSMA PET/CT failed to show any focal intense recurrence, and the previously PSMA-avid lymph nodes near the right iliac vessels and pelvic wall were no longer visible compared to the prior PSMA scan. Biochemical tests revealed a very low prostate-specific antigen (PSA) level (<1.0 ng/ml) but an elevated neuron-specific enolase (NSE) level (23.35 ng/ml). ***Results:*** He subsequently underwent ^{18}F-FDG PET/CT due to the persistent pain and suspicion of progression. In contrast to the negative PSMA scan, the FDG scan revealed extensive bone lesions with hypermetabolism, morphologically osteolytic or insignificantly transformed. Additional findings included multiple hypermetabolic lymph nodes in the retrocrural space (SUVmax 12.2), and newly identified pulmonary nodules (SUVmax 4.9), indicative of rapid disease progression. The elevated NSE level and osteolytic bone lesions led to the suspicion of NEPC. A biopsy of the most hypermetabolic lesion in the left posterior rib was performed. Pathological examination revealed the histomorphologic appearance of small round cells, with immunohistochemical staining demonstrating positivity for Syn, partial positivity for CgA, CK5/6, and P63, and negativity for PSA and PSMA, consistent with NEPC with squamous differentiation. He was started on palliative chemoradiotherapy. ***Conclusion:*** The use of enzalutamide may be associated with treatment-related NEPC, while squamous differentiation is often reported in patients with a history of radiation therapy. NEPC and squamous differentiation are both typically associated with higher GLUT-1 expression and FDG metabolism. This combination is never reported, and more lethal, less responsive to conventional treatment. It may present unique features, including absence of PSA and PSMA, as well as osteolytic bone lesions—very uncommon in prostatic adenocarcinoma. This case underscores the critical role of FDG-PET/CT in detecting metastases, restaging, biopsy guidance and treatment planning for NEPC. FDG-PET/CT can identify hypermetabolic lesions that may appear normal on conventional imaging techniques. Therefore, FDG-PET may be considered as part of diagnostic workup for NEPC, especially in patients with low PSA levels or negative PSMA scans.

EP-1215

"Splenic Superscan" on [^{18}F]FDG PET/CT in a rare case of hepatosplenic T-cell lymphoma

N. Aydinbelge- Dizdar[1], *U. Han*[2], *D. Cayir*[3], *Y. Sari Cataldas*[2];
[1]*Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara Etlik City Hospital, Department of Pathology, Ankara, TÜRKIYE,* [3]*University of Health Sciences, Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Hepatosplenic T-cell lymphoma (HSTCL) is a rare, highly aggressive extranodal T-cell lymphoma that can be rapidly fatal. It is frequently diagnosed in younger men, accounting for 68% of cases, with a typical onset age of 34 years and manifests with B-symptoms (fever, night sweats, and weight loss) and cytopenia. The rare HSTCL disease poses a significant diagnostic challenge due to its numerous clinical and histologic manifestations and its symptoms mimicking various infectious and hematologic diseases. ***Materials and Methods:*** We present a rare case of HSTCL diagnosed and monitored using ^{18}F-FDG PET/CT scan. A 47-year-old man presented a history of intermittent fever, drenching night sweats, unintentional weight loss, diarrhea and abdominal distension for two months. On physical examination, hepatosplenomegaly was detected. Complete blood count parameters were consistent with pancytopenia (total white blood cell count of 3.02 10^3/µL, Hb 8.5 gr/dL, neutrophil count 1.64 10^3/µL and platelet count of 42 10^3/µL). The serology tests for Epstein-Barr virus, HIV and hepatitis B and C virus were all negative. Abdominopelvic CT revealed massive hepatomegaly (CC size 26 cm in the midclavicular line) and splenomegaly (CC size 35 cm in the midclavicular line) and showed no lymphadenopathy at any station. Based on CT, clinical and laboratory findings, ^{18}F-FDG PET/CT and bone marrow biopsy (BMB) were performed since lymphoma was considered as a differential diagnosis. FDG PET/CT scan showed an increased radiotracer uptake in massive splenomegaly and a mild uptake in massive hepatomegaly and bone marrow. ***Results:*** The biopsy findings of liver revealed infiltration of the sinusoids by medium-sized T cells. The flow cytometry showed abnormal CD3-positive T cells consistent with HSTCL. After multidisciplinary tumor board of all data, the patient was diagnosed with HSTCL, and chemotherapy (ifosfamide, carboplatin, and etoposide) was applied. After the fourth cycle, the clinical and laboratory parameters improved, and allogeneic bone marrow transplantation was performed.The follow-up FDG PET/CT demonstrated reduced liver and spleen size and the absence of pathologic metabolic activity uptake in the body, which was considered consistent with remission. ***Conclusion:*** In such rare cases, FDG PET/CT can help monitor chemotherapeutic responses and diagnose HSTCL by demonstrating the presence of massive hepatosplenomegaly and diffuse markedly increased radioactivity uptake in the bone marrow, especially in the spleen, and in the absence of hypermetabolic lymphadenopathies.

EP-1216

Metastatic Prostate Cancer with Pulmonary Involvement Mimicking Pneumonia: Findings on ^{18}F-FDG PET/CT s and ^{68}Ga-PSMA PET/CT

N. Aydinbelge- Dizdar[1], *E. Tatci*[2], *A. Cinar*[1], *B. Bozca*[1], *O. Ozmen*[2];
[1]*Department of Nuclear Medicine, Ankara Etlik City Hospital, Ankara, TÜRKIYE,* [2]*Department of Nuclear Medicine, University of Health Sciences, Ankara Etlik City Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: In prostate cancer (PCa), the most common metastatic sites are regional lymph nodes and bones, but lung metastases, which typically present with nodular involvement, may also occur. Ground-glass opacities, bilateral pleural effusions and thickenings, and pulmonary lymphangitic spread (PLC) are extremely rare in PCa. ***Materials and Methods:*** We report a case of 68-year-old man who presented with progressive exertional dyspnea lasting approximately one month, with no history of abdominal pain, dysuria, or pollakiuria. Contrast-enhanced thoracic CT was performed to rule out pulmonary thromboembolism, revealing moderate bilateral pleural effusion and thickenings, enlarged mediastinal lymph nodes, diffuse ground-glass opacities, peribronchial thickening, interlobular septal thickening, and consolidations with atelectasis in both lung bases. These radiological findings suggested pneumonia or alveolar edema. Despite treatment with antibiotics and

corticosteroids, follow-up CT performed due to worsening dyspnea showed disease progression. For further investigate, ^{18}F-FDG PET/CT was performed, revealing increased radiotracer uptake in the prostate, multiple mediastinal and intra-abdominal lymph nodes, and bilateral lung lesions. Given the low FDG uptake in the lymph nodes and an elevated plasma total PSA level of 523 µg/L (Normal value: <4.1µg/L), the biopsy confirmed PCa with Gleason score of 4+3=7 (Grade Group 3). ^{68}Ga-PSMA PET/CT showed mild to high radiotracer uptake in bilateral lung lesions and multiple lymph nodes. Intense radiotracer uptake was observed extending from the prostate gland to the urinary bladder and rectum. The immunohistochemical and histopathological assessments were consistent with pulmonary and pleural metastasis of PCa. ***Results:*** PSMA-ligand PET/CT plays a crucial role in the evaluation of PCa, particularly in cases of biochemical recurrence, and is increasingly valuable in the initial staging of intermediate-to high-risk disease. However, the role of ^{18}F-FDG PET/CT in the diagnosis and staging of primary PCa remains limited. Pulmonary lymphangitic spread (PLC) with ground-glass opacities, bilateral malignant pleural effusions and thickenings in PCa is exceedingly rare. PLC is usually observed in the terminal stages of carcinomas originating from the breast, stomach, lung, and pancreas, with PCa accounting for approximately 3% of all reported PLC cases. ***Conclusion:*** Although metastatic spread in the form of PLC is uncommon for the some carcinomas, clinicians should consider the possibility of metastatic PCa in cases of PLC with bilateral pleural effusions and thickening and ground-glass opacities, even in the absence of a previously known malignancy as demonstrated in this case.

EP-1217

Prostate cancer associated with polyostotic Paget disease : diagnostic challenges and the value of multimodal imaging

D. Tahmi, *F. Agboton, H. Labiod, A. Amimour;*
Service de Médecine Nucléaire CHU Bab El Oued, Algiers, ALGERIA.

Aim/Introduction: Prostate adenocarcinoma frequently metastasizes to the bone. 18F/68Ga-PSMA PET/CT has become an essential tool in the extension work-up, offering high sensitivity for detecting metastatic lesions. However, PSMA tracer uptake is not specific and may occur in benign hyper-vascular bone disorders such as Paget disease, causing diagnostic pitfalls. ***Materials and Methods:*** A 69-year-old man with prostatic adenocarcinoma diagnosed following an elevated prostate-specific antigen (PSA) level. The patient was initially underwent external-beam radiotherapy plus androgen-deprivation achieving a nadir PSA of 0.4 ng/mL. During follow-up, the patient presented clinically with bone pain and impotence of the right lower limb, associated biologically with an increase in PSA above 100 ng/mL. Systemic treatment with abiraterone followed by taxanes resulted in a significant response, with PSA dropping to 0.4 ng/mL. Successive bone scans showed focal hyperfixing osteocondensing lesions on the right tibia, then, at the end of 2024, this hyperfixation became spread out and heterogeneous over almost the entire bone specimen, with "mosaic" cortical enlargement and thickening suggestive of pagetoid remodeling, associated with moderate foot and pelvic foci of secondary appearance, making metastatic interpretation equivocal and prompting 68Ga-PSMA PET/CT followed by MRI, which confirmed the characteristic appearance of Paget's disease in the lower limb, with suspicion of incipient Paget's disease vs. metastatic localization at other sites. However, bone biopsy confirmed the final diagnosis of active polyostotic Paget's disease, mimicking early-stage metastatic disease on the various morphological and functional imaging examinations. ***Results:*** This case illustrates a major diagnostic challenge related to PSMA uptake in active Paget's disease. Although PSMA PET/CT performs well, it requires careful interpretation, particularly in patients with pre-existing bone pathologies. Rigorous integration of clinical, biological and imaging data (bone scan, PET/CT, CT, MRI) is crucial to distinguish metastatic lesions from benign processes such as Paget's disease, in order to avoid over- or under-classification and ensure appropriate therapeutic management. ***Conclusion:*** This case highlights that active bone Paget's disease can show significant PSMA uptake on PET/CT, constituting an important diagnostic pitfall. A multimodal approach and contextual interpretation are essential for accurate staging of prostate cancer in patients with bone comorbidities.

EP-1218

Unveiling Bile Leaks: The Power of Hepatobiliary Scintigraphy in Post-Traumatic Liver Injury

R. Solanki;
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Bile leaks are a significant complication following hepatic trauma, often requiring precise diagnostic tools for effective management. Hepatobiliary scintigraphy (HBS) using 99mTc-Mebrofenin is a sensitive modality for detecting bile leaks, offering functional insights that complement anatomical imaging. This study evaluates the utility of HBS in a 17-year-old male with a Strassberg Grade IV liver injury, presenting with a suspected bile leak post-subhepatic pigtail catheter insertion. ***Materials and Methods:*** A 17-year-old male with a history of Grade IV liver injury underwent follow-up evaluation for abdominal pain. Initial ultrasound revealed a subhepatic collection, and MRCP confirmed left hepatic duct disruption with bile extravasation. HBS was performed using 99mTc-Mebrofenin, with sequential dynamic imaging for 45 minutes, followed by static images pre- and post-fat-rich meal (1 hour 10 minutes post-injection) to assess gallbladder ejection fraction (GBEF). Hybrid SPECT/CT at 3 hours and delayed static images at 24 hours were acquired. Imaging assessed hepatocyte function, biliary drainage, and tracer accumulation indicative of bile leak. Bag statics evaluated drainage output. ***Results:*** HBS demonstrated preserved hepatocyte function with normal liver size and position. Tracer accumulation near the primary confluence indicated a bile leak from the left hepatic duct, forming a collection (6.5 x 4.3 x 4.8 cm) in the gastrohepatic space, extending to a subhepatic collection (13.2 x 8.5 x 6.1 cm). No tracer uptake was observed in the drainage bag at 45 minutes, 1, 2, or 4.5 hours, but uptake was noted at 24 hours. Patent bilio-enteric drainage via the right hepatic duct was confirmed. GBEF was impaired (28% at 30 minutes, 49% at 1 hour), indicating reduced gallbladder contractility. SPECT/CT provided precise anatomical localization of the leak. ***Conclusion:*** HBS with 99mTc-Mebrofenin effectively diagnosed a bile leak in a post-traumatic liver injury, guiding minimally invasive management. The addition of SPECT/CT enhanced anatomical localization, overcoming limitations of HBS alone. Impaired gallbladder contractility was an incidental finding, potentially influencing future management. HBS remains a critical tool for early bile leak detection and follow-up. ***References:*** 1. EP-1219

Utility of Radiolabeled Red Blood Cell SPECT/CT in Diagnosing Urinary Bladder Hemorrhage: A Case Report

K. Resuello, *P. Bautista-Peñalosa, A. Domingo;*
St. Luke's Medical Center - Global City, Taguig, PHILIPPINES.

Aim/Introduction: Radiolabeled red blood cell (RBC) scan is a non-invasive radionuclide imaging technique typically used to evaluate suspected gastrointestinal bleeding. Its application in

identifying genito-urinary bleeding is limited due to the excretion of free Technetium-99m (^{99m}Tc) pertechnetate into the genito-urinary tract, potentially obscuring pathological bleeding. A thorough search of the literature revealed only two documented cases globally and none within the Philippines or Southeast Asia. This case aims to demonstrate the rare but important utilization of radiolabeled RBC SPECT/CT in localizing urinary bladder hemorrhage and eventually directing management. ***Materials and Methods:*** A 63-year-old female with a history of triple primary cancer (Breast cancer Stage IA, Uterine adenocarcinoma Stage IB, Intrahepatic cholangiocarcinoma Stage IV) and pelvic radiation therapy presented with recurrent gross hematuria and weakness. Despite cystoscopy and CT urography, the source of bleeding remained unidentified. The procedure involved injection of autologous erythrocytes radiolabeled with 30 mCi of ^{99m}Tc using a modified in vitro method, followed by anterior dynamic imaging of the abdomen performed immediately and 40 minutes post intravenous injection. ***Results:*** Dynamic planar imaging revealed increasing tracer activity in the urinary bladder. SPECT/CT images localized tracer activity in the urinary bladder along the region of the previously identified soft tissue density which suggested active bleeding in the area. Following these findings, the patient underwent angiography with selective embolization. The post-embolization angiogram showed devascularization of the superior vesical artery and partial devascularization of the internal pudendal artery. This resulted to resolution of hematuria, and the patient was subsequently discharged. ***Conclusion:*** This first case report in the Philippines highlights the usefulness of radiolabeled RBC SPECT/CT in diagnosing bladder hemorrhage by allowing accurate localization of the bleeding source. Its diagnostic value is seen in complex cases where conventional imaging yields equivocal results. The successful application in this case underscores the potential of this modality to enhance diagnostic accuracy and guide clinical management in patients with bladder hemorrhage. Further research is warranted to establish its efficacy and standardize its use in routine practice. ***References:*** 1. Kalpna Prasad (2015). Multimodal Treatment in Advanced Hepatocellular Carcinoma: Yttrium-90 Radioembolization Following Stereotactic Body Radiation Therapy and TACE

M. Mutuleanu[1,2], *I. Ioana*[1], *I. Taciuc*[1], *C. Petroiu*[1], *M. Gherghe*[1,2]; [1]*Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, Romania, Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: The management of advanced unresectable hepatocellular carcinoma (HCC) remains a significant clinical challenge. Yttrium-90 (^{90}Y) radioembolization has emerged as an effective therapeutic option for both primary and secondary hepatic tumours. The application of personalized dosimetry in [^{90}Y] radioembolization has been shown to enhance treatment response, overall survival and patient quality of life. Stereotactic body radiation therapy (SBRT) is widely utilized in the treatment of liver malignancies, although its efficacy may vary among patients. The sequential use of [^{90}Y] radioembolization following SBRT is relatively uncommon, yet not contraindicated; however, it may increase the risk of radiation-induced complications. ***Materials and Methods:*** We present the case of an 80-year-old patient with advanced cardiovascular disease who was diagnosed on March 5, 2024 with HCC involving segments III and IV of a non-cirrhotic liver. The patient underwent transarterial chemoembolization (TACE) on March 7, 2024, followed by SBRT in June 2024 receiving a total dose of 45 Gy administered in six fractions. Post-SBRT imaging revealed residual tumour tissue. Four months later, on October 17, 2024, pre-treatment evaluation for radioembolization was conducted using 140 MBq of [^{99m}Tc]-human serum albumin (^{99m}Tc-HSA) followed by perfusion SPECT-CT. On October 31, 2024, radioembolization with [^{90}Y] resin microspheres was performed, the patient receiving a therapeutic dose of 1.1 GBq. ***Results:*** The [^{99m}Tc]-HSA SPECT-CT revealed a hepatopulmonary shunt fraction of 1.84%. Pre-treatment voxel-based dosimetry estimated an absorbed dose of 296 Gy in the target volume with a therapeutic intent of lobectomy. Post-treatment [^{90}Y] PET-CT imaging demonstrated relatively homogeneous distribution of radiolabelled microspheres within the tumour volume. Post-therapeutic dosimetry analysis yielded the following results: the absorbed dose to the tumour volume was 350.12 Gy; the mean dose to non-tumoral perfused liver was 159.11 Gy and to the non-perfused liver was 32.26 Gy. Although the patient received two radiation-based treatments in less than six months, the non-perfused liver dose was within the recommended limits. Follow-up imaging performed three months after radioembolization demonstrated a significant reduction in viable tumour volume and the patient evolution was favourable, with no radiation induced side effects. ***Conclusion:*** Given that radioembolization performed shortly after SBRT is an uncommon approach in current clinical practice and carries potential risks of hepatotoxicity, further studies are warranted to evaluate its safety and efficacy. However, in our case this combined treatment strategy proved successful. Careful patient selection, personalized dosimetry and multidisciplinary management form the cornerstone of a favourable therapeutic outcome.

EP-1221

"Blessing in disguise" Lu177-PSMA-617 for chemo naïve mCRPC patient with parkinsonism and embarrassing sialorrhea

M. Gupta[1], *P. Sarathi Choudhury*[1], *S. Goyal*[2], *A. Pathak*[1], *M. Seth*[1], *S. Rawal*[3]; [1]*Department of Nuclear Medicine, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [2]*Department of Medical Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA,* [3]*Department of GenitoUro-Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA.*

Aim/Introduction: Lu177-PSMA-617 has been approved for mCRPC post ARPi and at least one taxen chemotherapy. With a newer data from PSMAfore trial, it has showed benefit in progression free survival in chemo naïve mCRPC patient over change of ARPi. Sialorrhea is one of the commonest symptoms in parkinsonism. It is due to rigidity and dis-coordination of oral cavity muscle leads to pooling and drooling of saliva from the mouth. A continuous saliva discharge is embarrassing and have negative impact on patient social acceptance. We presented here a case of mCRPC patient with parkinsonism and embarrassing sialorrhea with remarkable response in both. ***Materials and Methods:*** Dry mouth is a drug specific side effect of Lu177-PSMA-617 therapy with no specific treatment available. Impact of Lu177 PSMA-617 induced dry mouth in parkinsonism associated sialorrhea is unknow. We searched on PubMed/Medline, and Google with the key words in Lu177 PSMA, dry mouth, sialorrhea, Parkinsonism. We have not come across any relevant literature. ***Results:*** Eighty-six-year-old male patient was diagnosed with synchronous disseminated bone metastatic prostate acinar adenocancer grade group 3. He was treated with goserelin for 4 years, enzalutamide for 2.1 years and abiraterone for 5 months. Following progression,

case was discussed in multispecialty clinics. In view old age, ECOG PS 3, and co-morbidities, chemotherapy was deferred and Lu177 PSMA-617 was planned. 68Ga-PSMA-11 PET-CT was suggestive of strongly PSMA avid disseminated bone lesions. His base line PSA was 143 ng/ml and brief pain inventory short form (BPI-SF) score was 6. Patient received two cycles of Lu177-PSMA-617 (200mCi / 7.4GBq per cycle) at 6 weeks interval. 12 weeks PSA was 2.45 ng/ml, and BPI-SF score improve to zero. 12 weeks 68Ga-PSMA-11 PET-CT revealed complete response. Further, from embarrassing sialorrhea to no sialorrhea also improved patient quality of life. ***Conclusion:*** Improvement of sialorrhea in this patient may open a new horizon for Lu177-PSMA-617 therapy in the future. Further studies are needed to evaluate long term outcome of this treatment for this entity.

EP-1222

Splenic hemangioma intensive uptake on 99mTc-PSMA scintigraphy - caution required in interpretation

I. Sisko Markos[1,2], *M. Romić*[1,2], *I. Blazekovic*[1,2], *T. Jukic*[1], *A. Frobe*[1];
[1]*UHC Sestre Milosrdnice, Zagreb, CROATIA,* [2]*Croatian Catholic University, School of Medicine, Zagreb, CROATIA.*

Aim/Introduction: We present a 68-year-old man with a history of high-risk prostate cancer (Gleason score 4+4), initially diagnosed 7 years ago. At the time of diagnosis, PSA was markedly elevated at 38.37 mcg/L. Initial staging performed with thoracic, abdominal, and pelvic CT as well as bone scintigraphy revealed skeletal metastases and involvement of paraaortic and pelvic lymph nodes. ***Materials and Methods:*** The patient was initially treated with an LHRH agonist and chemotherapy according to the CHAARTED protocol. In 2019, due to biochemical progression, treatment with abiraterone was initiated. In 2021, further PSA elevation prompted an 18F-FCH PET/CT scan, which demonstrated disease progression in iliac and retroperitoneal lymph nodes. Due to continued PSA rise, PSMA-targeted scintigraphy with 99mTc-HYNIC-PSMA was performed for restaging. The scan showed intense radiotracer uptake in bones and in paraaortic and pelvic lymph nodes, consistent with disease progression. As a result, the patient was subsequently treated with carboplatin. ***Results:*** A very intense focal uptake was observed in the spleen. This finding correlated with a splenic hemangioma confirmed with CT. The presence of such a lesion illustrates a significant pitfall in PSMA imaging—benign entities like hemangiomas can exhibit intense PSMA uptake and may lead to false-positive interpretations. ***Conclusion:*** This is the first reported case of a splenic hemangioma imaged with this radiopharmaceutical, whereas several similar cases using 68Ga-PSMA PET/CT have already been described, suggesting similar PSMA behavior in hemangiomas regardless of binding to either 68Ga or 99mTc.

EP-1223

^{99m}Tc-Ubiquicidin SPECT/CT in Diabetic Foot: Detection of Subclinical Infection in a Patient with Chronic Venous Ulcer

V. Heringer, *B. Alencar, T. Agnello, M. Osmak, E. Etchebehere, C. Ramos, M. Lima, B. Juarez, A. Santos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Diabetic foot complications are a significant cause of morbidity in patients with long-standing type 2 diabetes mellitus (DM2), particularly when associated with peripheral neuropathy and chronic venous disease. Differentiating between sterile inflammation and active infection remains challenging. Radiolabeled antimicrobial peptides, such as 99mTc-ubiquicidin (UBI), have emerged as promising molecular imaging tools for infection detection[1]. UBI 29-41 is a synthetic fragment of a naturally occurring antimicrobial peptide, with multiple cationic residues (arginine and lysine) that selectively bind to the negatively charged membranes of bacteria, enabling distinction between infection and sterile inflammation[2]. We report the case of a diabetic patient with a history of chronic ulceration and persistent symptoms, in whom UBI SPECT/CT contributed to identifying a subclinical soft tissue infection and guided conservative management. ***Materials and Methods:*** A 69-year-old male with poorly controlled DM2, peripheral neuropathy, chronic venous insufficiency (CEAP C6), and a previously healed ulcer on the right ankle, underwent ^{99m}Tc-UBI scintigraphy. Dynamic acquisition (2s/frame) was followed by equilibrium and delayed images at 1 and 2 hours post-injection, and SPECT/CT at 3 hours. A lesion-to-background (L/B) ratio was calculated to assess semi-quantitative tracer uptake[3]. ***Results:*** Early-phase images demonstrated increased perfusion in the right ankle and foot. Delayed planar and SPECT/CT images revealed discrete to moderate uptake in the lateral ankle and dorsal foot. The L/B ratio was 1.99, exceeding the accepted limite of 1.74 suggestive of active infection[3]. CT findings showed cutaneous thickening and degenerative joint changes but no bone involvement. Based on these findings, a diagnosis of localized soft tissue infection was made. The patient was managed conservatively with topical treatment, glycemic control, and physiotherapy. Follow-up demonstrated clinical improvement and complete wound healing without surgical intervention. ***Conclusion:*** This case highlights the role of ^{99m}Tc-ubiquicidin SPECT/CT in the detection of soft tissue infections in patients with diabetic foot. The technique is particularly useful in cases where clinical signs are ambiguous and vascular comorbidities coexist. The semi-quantitative L/B ratio is a valuable metric that supports diagnostic accuracy and therapeutic decisions[4]. UBI-based imaging offers an effective, noninvasive method for distinguishing infection from inflammation in complex diabetic foot presentations. ***References:*** 1) Welling MM, et al. J Nucl Med. 2000;41:275. 2) Ferro-Flores G, et al. Molecules. 2021;26:3159. 3) Palestro CJ. Q J Nucl Med Mol Imaging. 2020;64:138. 4) Signore A, et al. Nucl Med Commun. 2011;32:917.

EP-1224

Multisystemic malakoplakia revealed by ^{18}F-FDG PET/CT : A case of concomitant bilateral osteomyelitis and genitourinary involvement

F. Yasser, *P. Maliha, M. Morin;*
University of Montreal, Montreal, QC, CANADA.

Aim/Introduction: A 43-year-old male on immunosuppressive therapy was admitted to the emergency department with acute left knee and left groin pain. A combined bone/gallium study revealed multiple bilateral congruent intramedullary bone uptake in the lower limb, mainly localized at femoral and tibial diaphyseal-metaphyseal junctions. A diffuse left testicular uptake was also noted. ***Materials and Methods:*** ^{18}F-FDG PET demonstrated increased uptake in multiple intramedullary bone regions in the lower limbs, diffuse uptake in the left testicle, heterogenous prostate uptake and several retroperitoneal lymph nodes, all presenting with calcifications on CT. A transrectal prostate biopsy revealed chronic histiocytic inflammatory infiltrate with macrophages exhibiting Michaelis-Gutmann bodies, pathognomonic for malakoplakia. Based on the clinical suspicion of bilateral osteomyelitis, a debridement and lavage were performed revealing Escherichia coli. Based on clinical, imaging and pathological findings, a diagnosis of prostatic malakoplakia with involvement of the left testicle and retroperitoneal lymph nodes was made, complicated by bilateral lower limbs osteomyelitis. ***Results:*** Malakoplakia is a rare multisystemic granulomatous disease, first described in 1902 by Michaelis and Gutmann. Risk factors include immunosuppression and recurrent urinary tract infections, primarily with E. coli. While it predominantly affects the urinary tract, it can potentially involve any organ. Although not fully elucidated, a defect in phagocytic function seems to trigger a chronic inflammatory response. Histopathological examination remains the gold standard for diagnosis, as radiological features

may mimic malignant processes. To our knowledge, this is the first reported case of malakoplakia with concomitant bilateral lower limb osteomyelitis. Interestingly, the symmetric metaphyseal-diaphyseal subcortical uptake observed on both gallium and FDG imaging could also raise suspicion for alternative diagnoses such as Erdheim-Chester disease. ***Conclusion:*** This case highlights the potential value of ^{18}F-FDG PET/CT in characterizing the extent of involvement and guiding the diagnosis of this rare multisystemic entity. ***References:*** Nuciforo P and al. EP-1225

A Rare Case of Small Cell Lung Cancer Presenting with a Breast Mass

N. Aydinbelge Dizdar[1], *D. Cayir*[2], *H. Turksoy Karaca*[3], *A. T. Arikok*[3];
[1]*Ankara Etlik City Hospital, Ankara, TÜRKIYE,* [2]*University of Health Sciences, Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [3]*Ankara Etlik City Hospital, Department of Pathology, Ankara, TÜRKIYE.*

Aim/Introduction: The extramammary metastases to the breast are a rare manifestation and their prevalence has been reported to vary between 0.1% and 5.0%. The most frequent breast metastases or involvement of non-breast neoplasms are lymphoma, melanoma, lung, thyroid, gallbladder, and ovarian tumors. Lung carcinoma metastases to the breast are a rare presentation, and among published case reports, NSCLC (non-small cell lung cancer) metastases are more frequently documented than SCLC (small cell lung cancer) metastases, although SCLC breast metastases have occurred synchronously. ***Materials and Methods:*** Herein, we report a case of metastatic SCLC who presented with a breast mass and underwent FDG PET for staging. A 63-year-old woman who admitted to the emergency department with complaints of shortness of breath, chest pain and a lump in the right breast underwent non-contrast enhanced thorax CT. It synchronously showed a mass lesion with a diameter of 25 mm in the right breast, a mass lesion in the superior lobe of right lung and pleural effusion in the right hemithorax. Subsequently, ^{18}F-FDG was performed for lesions characterization and found that multiple increased radiotracer uptakes in lesions of right breast, right lung and liver, mediastinal and periportal lymph nodes, and bones. Afterwards, histopathological and immunohistochemical examinations of the breast mass sample confirmed that a small cell lung carcinoma (SCLC) metastasized to the breast. Round / oval blue cells with minimal cytoplasm; usually small to medium sized. The finely dispersed or salt and pepper chromatin with no distinct nucleoli is apparent in many of the cells. The high nuclear to cytoplasmic ratio is also demonstrated. Strong and diffuse positivity for TTF1 is seen in small cell lung carcinomas. Small cell lung carcinomas demonstrate positivity for Synaptophysin. High proliferation index (%80) with Ki67. ***Results:*** SCLC is a very aggressive entity that causes early and widespread haematological metastasis, often resulting in extensive brain, bone or liver involvement. The clinical presentation of breast metastases at the same time as primary lung carcinoma is extremely rare and has a significant impact on treatment strategies and mortality. Patients presenting with a breast mass without a known history of malignancy should be considered for the possibility of rare extramammary metastatic processes rather than primary breast cancer, such as in this case. ***Conclusion:*** The clinical presentation of breast metastases at the same time as primary lung carcinoma is extremely rare and has a significant impact on treatment strategies and mortality.

EP-1226

FDG-Negative but FES-Positive Vertebral Metastasis in ER-Positive Breast Cancer: A Case Highlighting the Complementary Role of Functional Receptor Imaging

A. Mahalik*, N. Kundu, K. Jain, M. Tripathi, R. Kumar;*
All India Institute of Medical sciences, New Delhi, INDIA.

Aim/Introduction: ^{18}F-FDG PET/CT is routinely used in staging and restaging of breast cancer. However, its sensitivity may be limited in detecting certain metastatic lesions, particularly in indolent or receptor-rich disease. 18F-FES PET/CT, a novel imaging modality targeting estrogen receptors (ER), offers a valuable complementary perspective by highlighting receptor expression independent of metabolic activity. ***Materials and Methods:*** A 39-year-old female with a history of ER-positive invasive ductal carcinoma of the breast, post-mastectomy and axillary lymph node dissection (ALND) in 2014, presented with complaints of backache in Dec, 2021. She underwent both ^{18}F-FDG PET/CT and 18F-FES PET/CT for evaluation. While the FDG PET/CT did not demonstrate any abnormal tracer uptake in the spine, FES PET/CT revealed a focal, intensely tracer-avid lesion in the D4 vertebral body, raising suspicion for a metabolically indolent but receptor-positive osseous metastasis. ***Results:*** This case underscores the potential for FDG PET/CT to miss clinically significant lesions in ER-positive breast cancer, particularly when lesions are slow-growing, well-differentiated, or exhibit low glycolytic activity. Possible reasons for FDG-negativity include low tumor cellularity, mucinous histology, treatment-induced metabolic suppression, or the lesion being masked by diffuse physiological FDG uptake in the vertebrae. In such scenarios, FES PET/CT provides critical diagnostic insight by detecting receptor-rich disease at sites that may otherwise be overlooked. This emphasizes the role of FES PET/CT in assessing symptomatic patients with negative FDG scans and known ER-positive status, supporting earlier detection and potentially altering treatment strategies. ***Conclusion:*** FES PET/CT can identify ER-positive, FDG-negative metastases that may not be evident on standard metabolic imaging. Its use in selected cases can enhance diagnostic accuracy and influence management decisions in hormone receptor-positive breast cancer. This case supports the inclusion of FES PET/CT in the imaging algorithm for symptomatic patients with negative or equivocal FDG findings.

EP-1227

Significance of ^{18}F-FDG PET/CT in Detecting Rare Breast Metastasis from Cervical Cancer: A Case Report

A. Leiva Montejo*, I. Sime Loayza, C. Balbin Garcia, B. Cueto Cañadas, A. Montellano Fenoy, J. Sanchez Catalicio, J. Delgado Moreno, M. Guerrero Ortiz;*
Hospital Universitario Torrecárdenas, Almeria, SPAIN.

Aim/Introduction: Cervical cancer is one of the most common malignancies in women, with squamous cell carcinoma being the most frequent histological subtype. While metastatic spread typically involves pelvic and para-aortic lymph nodes, lungs, liver, bones, and extrapelvic lymph nodes, breast metastasis is exceedingly rare. The incidence of non-mammary malignancies metastasizing to the breast is estimated to range between 0.4% and 3%. ***Materials and Methods:*** A 58-year-old woman presented with postmenopausal metrorrhagia. Gynecological examination revealed a 4 cm mass in the cervix infiltrating the vagina. A biopsy confirmed a high-grade undifferentiated carcinoma, most likely squamous cell carcinoma associated with HPV infection. MRI diagnosed stage IIB cervical carcinoma. A staging CT showed the cervical lesion without additional relevant findings. The gynecological- oncology committee recommended ^{18}F-FDG

PET/CT prior to treatment. ***Results:*** ^{18}F-FDG PET/CT revealed a hypermetabolic mass in the cervix measuring 3.7 x 4.7 cm (SULmax 35.1), indicative of a neoplastic process. Additionally, a right hilar lymph node with moderate FDG uptake of 0.8 cm (SULmax 8.8) was noted, along with two hypodense and hypermetabolic hepatic lesions, the largest in segment VII measuring 2.9 x 3.1 cm (SULmax 16.9). Three hypermetabolic bone lesions were observed in the right 9th costal arch (SULmax 8.3), left sacral wing (SULmax 4.4), and right femoral head (SULmax 8.2), all suggestive of metastasis. A diffuse, mildly intense FDG uptake in the gastric cardia (SULmax 4.9) raised suspicion for malignancy, but endoscopy was negative for neoplasia. A small hypermetabolic nodule in the left breast (LB) measuring 0.5 x 0.5 cm (SULmax 11.5), was also observed, suggesting malignancy. A targeted biopsy was recommended to confirm the presence of a synchronous tumor. In the committee, a tumorectomy of the LB nodule was proposed, as the biopsy was inconclusive, with the following outcome: metastasis of high-grade undifferentiated carcinoma, likely related to squamous cell carcinoma of the cervix associated with HPV infection. ***Conclusion:*** Breast metastasis from cervical cancer is an extremely rare entity and can mimic primary breast cancer, complicating diagnosis. This case highlights the critical role of ^{18}F-FDG PET/CT in identifying unusual metastatic sites that may be clinically silent or radiologically nonspecific. Histopathological confirmation is essential to rule out synchronous primary tumors. The presence of breast metastasis reflects systemic disease dissemination, which is associated with poor prognosis. Comprehensive imaging and multidisciplinary evaluation are crucial for the early and accurate detection of such metastases.

EP-1228

Quantitative [^{15}O]H_2O PET perfusion hybrid imaging reveals the correct diagnosis in a patient with cardiac amyloidosis and chest pain

V. Uusitalo*;*
Helsinki University Hospital, Helsinki, FINLAND.

Aim/Introduction: Microvascular disease is common in cardiac amyloidosis secondary to amyloid fibril infiltration of the myocardium and microvasculature. Unfortunately, microvascular disease is poorly detected by most of the common noninvasive imaging modalities used to diagnose coronary artery disease. Positron emission tomography (PET) perfusion using [^{15}O]H_2O is the gold standard for noninvasive quantitative myocardial perfusion imaging. Combining it with coronary computed tomography angiography (CCTA) at the same imaging session allows accurate evaluation of both epicardial and microvascular coronary artery disease. ***Materials and Methods:*** The patient was a 60-year-old male with a previously diagnosed light chain amyloidosis who developed chest pain, which was considered typical angina pectoris. In addition to chest pain, the patient had polyneuropathy. The light chain amyloidosis was confirmed from the muscle and gastrointestinal biopsy. Amyloid cardiomyopathy was diagnosed by cardiac magnetic resonance imaging. PET perfusion using [^{15}O]H_2O and during adenosine stress was obtained, and simultaneously CCTA was imaged for anatomical reference. There was a typical hemodynamic response to adenosine stress. ***Results:*** PET perfusion had a normal relative perfusion on visual evaluation, but quantitative perfusion analysis revealed diffuse myocardial ischemia during adenosine stress. Global left ventricular perfusion was 1.19 ml/min/g (normal >2.3). Highest perfusion was at the apical region (1.38 ml/min/g), which was similar to the typical apical sparing phenomenon seen on speckle tracking echocardiography in cardiac amyloidosis patients (spared longitudinal contraction at the apical region). CCTA revealed intermediate coronary stenosis on the mid left anterior descending artery (50-70 %). There was no regional reduction in PET perfusion at the LAD area. The calcium score was 218, and no other coronary stenoses of note were detected. The diagnosis of microvascular angina was made. ***Conclusion:*** Microvascular disease is a common cause of chest pain in cardiac amyloidosis. Hybrid imaging with quantitative PET perfusion and CCTA allows for its accurate evaluation in one imaging procedure.

EP-1229

Osteomesopyknosis, a Great Mimic of Osteoblastics Metastasis in Bone Scintigraphy.

M. Feriche Aragon*, C. Mas Pascasio, E. Espinosa Muñoz, A. Adarve Castro, T. Rudolphi Solero, S. Sanz Viedma;*
Hospital Virgen de la Victoria, Málaga, SPAIN.

Aim/Introduction: Osteomesopyknosis is a rare, benign, autosomal dominant (AD) genetic disorder causing irregular increased bone density, mainly in the spine, pelvis, and proximal femurs. Sclerotic lesions mimic blastic bone metastases on MRI, CT, and bone scintigraphy. Prevalence is <1 per million. Diagnosis is challenging due to the high incidence of tumors causing blastic metastases (prostate, breast cancer). ***Materials and Methods:*** A 46-year-old woman with HLA B27+ spondyloarthritis was evaluated at another center five years prior, with bone scintigraphy, thoracoabdominopelvic CT, and spine MRI suggesting blastic metastatic bone disease. ^{18}F-FDG-PET/CT showed hypometabolic blastic lesions without a primary tumor. A bone biopsy was negative for malignancy.Referred for bone scintigraphy due to suspected metabolic bone disease (persistent elevated alkaline phosphatase, increasing lower back pain), whole-body bone scintigraphy with 740 Mbq ^{99m}Tc-HDP showed pathological radiotracer distribution with increased uptake in the spine, iliac and pubic bones. Compared to a previous study, no significant changes were observed. The patient reported her father had a similar condition.Given no malignancy, negative biopsy, and family history, an exhaustive literature search identified Osteomesopyknosis. Baseline bone scintigraphy and MRI were recommended for first-degree relatives due to the potential future coexistence of tumors causing blastic lesions. ***Results:*** Osteomesopyknosis, an AD genetic disease, mimics blastic metastatic bone disease on imaging. Workup is complex as metastatic prostate or breast cancer is the initial consideration. After excluding a primary tumor and a negative biopsy, diagnosis is by exclusion based on the sclerosing pattern in the spine, pelvis, and femurs. Due to AD inheritance, baseline bone scintigraphy and MRI are recommended for relatives, as these patients may later develop tumors with blastic metastases, aiding management. ***Conclusion:*** Osteomesopyknosis is a very rare AD disease with challenging diagnosis. Its sclerotic bone lesions mimic blastic bone metastases on imaging, potentially leading to incorrect oncological diagnoses. Diagnosis relies on exclusion and the pattern of involvement. Baseline studies should be recommended for first-degree relatives. ***References:*** 1. Heursen EM, González Partida Mdel C, Paz Expósito J, Navarro Díaz F. EP-1230

Benign But Avid: Ga-68 DOTATATE Uptake In Lip Chondroid Syringoma Mimicking Neuroendocrine Tumor Metastasis

E. Pasini Nemir*, M. Pesorda, D. Huic;*
University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: Ga-68 DOTATATE PET/CT remains a cornerstone in the diagnosis, staging, and treatment response assessment of neuroendocrine tumors (NETs), due to its ability to detect somatostatin receptor (SSTR) expression. While SSTR overexpression is well-documented in NETs and other malignancies, it has not yet

been reported in chondroid syringoma; a rare, benign adnexal skin tumor that most commonly arise in the head and neck region, with malignant transformation being rare. ***Materials and Methods:*** We present a case of 69-year-old patient with a history of atypical lung carcinoid, diagnosed in 2020 after a right upper lobectomy (Ki-67 index 15-20%; CD56 and TTF-1 positive) and partial right lower lobe segmentectomy revealing an adenocarcinoma. Adjuvant chemotherapy was completed in 2020. There was no recurrence until 2024 when a lobulated subcutaneous mass in the right clavicular region was detected on follow-up chest CT. Surgical excision revealed metastasis of atypical carcinoid (Ki-67 25%) with lymphovascular and perineural invasion. A Ga-68 DOTATATE PET/CT was subsequently performed to evaluate disease activity and potential spread. ***Results:*** The PET/CT scan revealed increased tracer uptake in the right upper paratracheal (0.8 cm, SUVmax 4.5) and subcarinal (1.5 × 1.4 cm, SUVmax 8.0) mediastinal lymph nodes, consistent with metastatic involvement. No pathological uptake was observed in the lung parenchyma. Unexpectedly, the scan showed increased DOTATATE uptake in a subcutaneous lesion of the lower lip (1.1 × 0.8 cm, SUVmax 4.2), raising suspicion for a metastatic lesion given the patient's history of subcutaneous metastasis, so the lesion was surgically excised. Histopathological analysis revealed a 2.1 × 1.0 × 1.5 cm tumor composed of epithelial and mesenchymal elements without cytological atypia, consistent with chondroid syringoma (tumor mixtus). No other DOTATATE-avid lesions were detected in the scanned body volume. ***Conclusion:*** To our knowledge, this is the first report of Ga-68 DOTATATE uptake in a chondroid syringoma, highlighting a potential pitfall in nuclear imaging interpretation in patients with known NETs. While increased DOTATATE uptake typically indicates metastatic disease, this case underscores the importance of considering benign mimics such as chondroid syringoma, which can also express somatostatin receptors. Awareness of such rare false-positive findings is essential to avoid misdiagnosis and unnecessary aggressive treatment. ***References:*** Malan N, Vangu MD. Normal Variants, Pitfalls and Artifacts in Ga-68 DOTATATE PET/CT Imaging. Front Nucl Med. 2022 Feb 7.2 Di Guardo A et al. Clinical and Dermoscopic Characteristics of Cutaneous Chondroid Syringoma: A Systematic Review. Dermatol Pract Concept. 2024 Oct 30;14.

EP-1231

From back pain to bone lesion: A case of disseminated tuberculosis uncovered by PET/CT

G. Rakia*, A. Ezzine, S. Mensi, T. Dardouri, R. Mehri, K. Chatti;*
CHU Sahloul, Sousse, TUNISIA.

Aim/Introduction: Tubercuosis (TB) is the leading cause of infectious mortality worldwide.Its presentation varies widely,from asymptomatic cases to life-threatening conditions making clinical and radiological diagnosis challenging. 18FDG-PET/CT scan is particularly useful in detecting the disease in previously unknown sites, and allows the most approriate site of biopsy to be selected. ***Materials and Methods:*** A 33-year-old patient underwent ^{18}F-FDG PET/CT as part of the diagnostic workup for suspected tuberculosis. The distribution of hypermetabolic lesions was correlated with clinical, laboratory, and microbiological data to assess the diagnostic contribution of PET/CT in tuberculosis. ***Results:*** The case involves a 33-year-old patient experiencing isolated inflammatory spinal pain for two months,accompanied by an episode of rotational vertigo and recurrent tachycardia. A chest CT revealed homogeneous hepatosplenomegaly, right mediastino-hilar and latero-aortic retroperitoneal lymphadenopathy, and multiple osteolytic lesions. Notably, a right paravertebral mass at D4 infiltrated the spinal canal, and epiduritis was observed at D12.A cerebral MRI was requested finding 3 intra-axial supratentorial nodular lesions annularly enhanced after gadolinium injection with perilesional edema without mass effect.Biopsy was performed reporting chronic granulomatous inflammatory lesions with multinucleated giant cells with caseous necrosis without cellular atypia.Due to the atypical presentation, the doctors decided to perform another biopsy. The patient was referred for further investigation to identify potential biopsy sites and map the infection, if present. The patient underwent an 18FDG PET/CT scan revealing widespread metabolically active involvement consistent with tuberculosis. Findings included hypermetabolic nodular brain lesions, FDG-avid pulmonary, thoracic, and extrathoracic lymph nodes as well as FDG-avid nodular pleural thickening with multiple scattered hypermetabolic bilateral pulmonary nodules. There was also heterogeneously hypermetabolic splenomegaly with homogeneous hepatomegaly and nodular thickening of the peritoneal lining, showing focal FDG uptake with hypermetabolic tissue-dense nodules in the left flank. Differentiation between a tuberculous or malignant origin required histopathological correlation. Additionally, severe hypermetabolic multilevel spinal and sternal involvement was observed, consistent with spondylodiscitis. Treatment with Dotbal (rifampin, isoniazid, pyrazinamide, and ethambutol) was initiated, with two tablets administered every 12 hours. The patient is currently still undergoing treatment. An 18FDG PET/CT scan was recommended to assess the treatment response. ***Conclusion:*** 18FDG PET/CT plays a crucial role in staging TB, detecting extrapulmonary TB (EPTB), and identifying patients with subclinical TB. ***References:*** Batún-Garrido JADJ, Salas-Magaña M, García-Padrón OA, Valencia-Serrano N. Two cases of tuberculous spondylodiscitis: a rare manifestation of extrapulmonary tuberculosis. Quant Imaging Med Surg. févr 2017;7(1):1327.

EP-1232

Challenges in diagnosis of hepatocellular adenoma - a case study

Z. Zychowicz*, P. Cichocki, Z. Adamczewski;*
Medical University of Lodz, Nuclear Medicine Department, Lodz, POLAND.

Aim/Introduction: Hepatocellular adenoma (HCA) is a rare, benign liver tumor primarily associated with oral contraceptive use in women, although recent studies show an increased prevalence among men, with obesity and metabolic syndrome being the most prominent risk factors. HCAs can pose risks of hemorrhage and malignant transformation, which makes properly assessing and treating these lesions crucial. We present an interesting case of a male patient without notable risk factors of HCA, referred for evaluation of lesion in the right lobe of the liver after multiple non-conclusive imaging studies. ***Materials and Methods:*** 68-year-old male patient was referred for static liver scintigraphy due to a suspicion of focal nodular hyperplasia (FNH). Ultrasound showed a 80 x 70mm hypoechoic, cyst-like mass with dense, heterogenous contents and a hyperechoic rim. A contrast-enhanced CT scan showed a lesion with mildly increased density within a steatotic liver with enhancement in the arterial and portal venous phase followed by mild washout in delayed phases, occurring more rapidly centrally than peripherally. MRI showed a hypointense, well-separated mass in T1-weighted images with smaller peripheral hyperintense lesions measuring up to 7mm and features of a central scar. The whole mass showed arterial phase enhancement with gradual washout in later phases with persisting peripheral enhancement. Abovementioned findings were inconclusive. Epidemiology, along with clinical and radiological findings led to the suspicion of FNH, so the patient was referred for liver scintigraphy using Tc-99m sulfur colloid. ***Results:*** Liver scintigraphy revealed no radiopharmaceutical uptake in the location of the lesion, which is not typical for FNH. This result supported the exclusion of FNH, as well as some other benign lesions, such as regenerative nodules and focal steatosis. Exclusion of these benign lesions, despite the lack of clear features

of malignancy in morphological studies, prompted the referring physician to send the patient for urgent biopsy, which led to the diagnosis of HCA. ***Conclusion:*** Although the radiological imaging studies were inconclusive, they did not suggest malignant nature of the lesion. Liver scintigraphy allowed to narrow down the potential diagnoses and excluded FNH. This led to HCA, another benign tumor, to become one of the potential, and looking back to radiological results, most likely diagnosis. Although this benign lesion is more common in women, it should be considered in differential diagnosis in men as well.

EP-1233

Total-body [^{18}F]AlF-RESCA-T4 ImmunoPET/CT in Patients with Solid Tumors: Initial Experience and Potential Value in Navigating Clinical Decision-making

S. An, *G. Huang, J. Liu, W. Wei;*
Institute of Clinical Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: Precise selection of patients who could benefit from targeted or immunotherapy is essential in clinical practice. Trophoblast cell surface antigen 2 (Trop2) is an emerging biomarker of theranostic potential. We previously developed single domain antibody (sdAb)-derived tracers specific for Trop2. We translated two of the tracers (i.e., [^{68}Ga]Ga-NOTA-T4 and [^{18}F]AlF-RESCA-T4) for clinical use on a traditional short axial field-of-view PET/CT scanner. In this study, we report the diagnostic performance of [^{18}F]AlF-RESCA-T4 on a total-body PET/CT scanner and the value in navigating subsequent treatments in patients with solid tumors. ***Materials and Methods:*** [^{18}F]AlF-RESCA-T4 was freshly produced on-site and administered to patients recruited in an ongoing investigator-initiated clinical trial.Three patients with solid tumors underwent both low-dosewhole-body [^{18}F]AlF-RESCA-T4 and [^{18}F] FDG PET/CT scan imaging in two weeks. Immunohistochemistry staining was utilized to analyze Trop2 expressionin tumors. ***Results:*** All the lesionsclearly identifiedby low-dose [^{18}F]AlF-RESCA-T4immuno-positronemission tomography/computed tomography (immuno-PET/CT) imaging. Region of interest analysisshowed thatkidneys, pancreas, and glandsarethe organs/tissues withthe highest radiotracer uptake.[^{18}F]AlF-RESCA-T4 immuno-PET/CT allowed noninvasive visualization heterogeneous expression of Trop2 in patients with solid tumors, changing the re-staging and clinical decision-making of the patient ***Conclusion:*** Low-dose[^{18}F]AlF-RESCA-T4 immuno-PET/CT imaging on the total-body PET/CT scanner is feasible. [^{18}F]AlF-RESCA-T4 can be effectively used to detect primary and metastatic lesions in patients with solid tumors, suggesting potential of diagnostic and Trop-2-based therapeuticapplications.

EP-1234

Negative ^{99m}Tc-Ubiquicidin SPECT/CT in the Evaluation of Suspected Osteoradionecrosis of the Mandible in a Patient with Recurrent Tongue Carcinoma

V. Heringer, *B. Alencar, T. Agnello, M. Osmak, E. Etchebehere, C. Ramos, M. Lima, B. Amorim, A. Santos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Osteoradionecrosis (ORN) is a known late complication of radiotherapy in head and neck cancer patients. Differentiating ORN from neoplastic recurrence or secondary infection is clinically relevant, especially when surgical intervention is contraindicated. ^{99mTc}-ubiquicidin (UBI) SPECT/CT is a promising imaging modality in infection evaluation due to its specificity for bacterial cell membranes. UBI is a cationic synthetic peptide fragment that binds selectively to negatively charged bacterial surfaces via electrostatic interactions, enabling differentiation between infection and sterile inflammatory or necrotic tissue[1,2]. We report the case of a patient with prior oropharyngeal cancer undergoing evaluation of mandibular ORN using both UBI-SPECT/CT and MDP-SPECT/CT. ***Materials and Methods:*** A 49-year-old female with a history of squamous cell carcinoma (SCC) of tongue treated with radiotherapy and chemotherapy in 2022, currently under neoadjuvant treatment for SCC of the left tongue (T2N0M0), was referred for evaluation of suspected mandibular ORN. She underwent ^{99m}Tc-UBI SPECT/CT with dynamic acquisition (2s/frame), followed by whole-body planar imaging at 1 and 2 hours and focused SPECT/CT of the head at 2 hours. A lesion-to-background (L/B) ratio was calculated. Six days later, a ^{99m}Tc-MDP bone scintigraphy was performed. ***Results:*** ^{99m}Tc-UBI SPECT/CT showed physiological tracer distribution, with no focal uptake in the mandible. The L/B ratio was 1.0, below the 1.74 threshold for active infection. In contrast, bone scintigraphy with ^{99m}Tc-MDP revealed a lesion with markedly increased osteoblastic activity in the right hemimandible, particularly in the molar region, associated with cortical erosion, findings compatible with osteonecrosis, though neoplastic infiltration could not be excluded. ***Conclusion:*** In this case, ^{99m}Tc-ubiquicidin SPECT/CT was essential to exclude mandibular infection in a previously irradiated patient with suspected ORN. The physiologic uptake pattern and normal L/B ratio supported a noninfectious diagnosis, allowing the patient to avoid unnecessary antibiotics or surgical procedures[3,4]. UBI-SPECT/CT is a valuable noninvasive tool in the evaluation of complex oncologic cases with diagnostic uncertainty. ***References:*** 1) Welling MM, et al. J Nucl Med. 2000;41:275. 2) Ferro-Flores G, et al. Molecules. 2021;26:3159. 3) Palestro CJ. Q J Nucl Med Mol Imaging. 2020;64:138. 4) Signore A, et al. Nucl Med Commun. 2011;32:917.

EP-1235

Renal Ewing Sarcoma: "TripleMismatch" NuclearMedicine Signature

N. Kundu, *D. Khan, S. Sagar, A. Mahalik, A. Roy, K. Jain, V. Singh, J. Choudhary, J. Krishna, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: To illustrate how combined ^131ImIBG, ^68GaDOTANOC and ^18FFDG PET/CT can resolve the diagnostic dilemma of a paediatric suprarenal "smallroundbluecell" tumour by demonstrating a characteristic imaging mismatch that suggested renal Ewing sarcoma (rEWS). ***Materials and Methods:*** A 6yearold boy with a leftflank mass underwent ultrasound and contrastenhanced CT, both showing a 13 × 9 cm lobulated suprarenal lesion with calcification. The initial biopsy was inconclusive, favouring a malignant roundcell tumour negative for neuroblastoma, Wilms and rhabdomyosarcoma markers. Because neuroblastoma remained high on the differential, ^131ImIBG planar/SPECT imaging was performed, followed 48 h later by wholebody ^68GaDOTANOC PET/CT and, after 72 h, ^18FFDG PET/CT. All scans were evaluated qualitatively and semiquantitatively (SUVmax). A second core biopsy with immunohistochemistry (NKX2.2) and FISH for EWSR1 rearrangement served as the reference standard. ***Results:*** The mass was nonavid on mIBG, showed mild SSTR expression on DOTANOC (SUVmax ≈ 3.8) and was intensely FDGavid (SUVmax ≈ 12). No distant metastases were seen. This "triplemismatch" pattern prompted rebiopsy; tumour cells demonstrated strong NKX2.2 nuclear positivity and an EWSR1 translocation, confirming rEWS. The imaging constellation excluded neuroblastoma and guided timely referral for neoadjuvant chemotherapy followed by nephrectomy. ***Conclusion:*** A nonmIBGavid, mildly DOTANOCpositive yet highly FDGavid renal mass in a child should raise strong suspicion for rEWS. Recognising this nuclearmedicine signature can fasttrack definitive tissue diagnosis, avoid futile neuroblastomadirected therapy and underscores the value of multimodality functional imaging in rare paediatric renal tumours.

EP-1236

Multifocal avascular necrosis unmasked by Tc99m MDP Bone scan

N. Kundu, *D. Khan, S. Sagar, A. Mahalik, K. Jain, J. Krishna, V. Singh, J. Choudhary, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Avascular necrosis (AVN) refers to the cellular death of bone components due tointerruption of the blood supply, resulting in collapse, pain, loss of joint function and long-term joint damage. The disease can affect various joints such as the knee, shoulder, and ankle, although it most commonly involves the hip. Radiographs are often initially used to diagnose osteonecrosis. If disease is apparent radiographically, then often no other imaging or screening tests are necessary. However, disease often may not be detectable in early stages because radiographic abnormalities appear only after prolonged changes in ischemic tissue. Magnetic resonance imaging (MRI) is considered to be the gold standard for diagnosing AVN. Bone scintigraphy has been advocated as a useful diagnostic tool for patients with suspected osteonecrosis or in screening for multifocal disease. Here we report an interesting case where wholebody Tc99mMDP scintigraphy unexpectedly identified multifocal, clinically silent avascular necrosis (AVN) in a young adult scheduled for hip arthroplasty, thereby altering surgical planning. ***Materials and Methods:*** A 24 year old man with threeyear bilateralhip pain had MRIproven femoralhead AVN and previously underwent core decompression. Reemergent pain led to planned bilateral total hip replacement. Preoperative infection screening was requested with a threephase 740 MBq Tc99mMDP bone scan: dynamic flow, bloodpool statics and 3h wholebody delayed images, complemented by focused SPECT/CT of symptomatic and scanpositive joints (shoulders, elbows, knees, hips). ***Results:*** Delayed whole body images revealed avid peripheral tracer uptake with central photopenic zones in the left humeral head, right trochlea, both femoral heads and the right tibial plateau, classic for AVN. Corresponding SPECT/CT confirmed subchondral collapse only at the hips; extrahip lesions were structuralstage I. Findings prompted orthopaedic revision of the operative plan: staged hip arthroplasty plus prophylactic core decompression of the asymptomatic shoulder and knee lesions. The patient's management shifted from singlejoint replacement to a jointpreservation strategy for three additional sites. ***Conclusion:*** Wholebody Tc99mMDP scintigraphy with regional SPECT/CT can expose occult multifocal AVN that eludes conventional sitedirected MRI. Incorporating bone scan into the workup of young AVN patients scheduled for surgery enables early intervention at unsuspected sites and may forestall progressive joint collapse, affirming its complementary role alongside MRI in contemporary musculoskeletal practice.

EP-1237

Unexpected [^{18}F] Fluciclovine Uptake in Pilocytic Astrocytoma: A Paediatric Case Report

H. Koga[1,2], *S. Watanabe*[1,2], *K. Hirata*[1,2], *T. Harada*[1], *Y. Ishi*[3], *S. Yamaguchi*[3], *N. Wakabayashi*[1,2], *L. Hashimoto*[2], *K. Kudo*[1];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, Hokkaido, JAPAN,* [3]*Department of Neurosurgery, Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, JAPAN.*

Aim/Introduction: [^{18}F] Fluciclovine is a synthetic amino acid PET tracer primarily used in the evaluation of prostate cancer (1). Since June 2024, it has been covered by the Japanese National Health Insurance System for imaging of high-grade gliomas. In this case report, we present a paediatric patient with unexpectedly high fluciclovine uptake in a pilocytic astrocytoma, a benign tumor categorized as grade 1 glioma by World Health Organization (WHO) criteria. ***Materials and Methods:*** A 5-year-old boy undergoing neuroimaging after head trauma was incidentally found to have a well-circumscribed mass lesion in the region of the septum pellucidum. MR imaging demonstrated hyperintensity on both T2-weighted and FLAIR sequences. Gadolinium-enhanced T1-weighted imaging (Gd-T1WI) revealed heterogeneous peripheral enhancement. Given the imaging features, a glioma was suspected. To further characterize the lesion, [^{18}F] fluciclovine PET was performed. A dose of 96.6 MBq (4.31 MBq/kg) of [^{18}F] fluciclovine was administered intravenously, and PET-CT was acquired 40 minutes after injection. ***Results:*** [^{18}F] Fluciclovine PET demonstrated strong uptake in the tumour with a maximum standardised uptake value (SUVmax) of 2.37. The SUVmax in the surrounding normal cerebral cortex was 0.66, resulting in a tumour-to-normal ratio (TNR) of 3.56. FDG-PET showed no significant uptake compared to the cerebral cortex. The patient underwent partial resection of the lesion. Histopathological examination confirmed the diagnosis of pilocytic astrocytoma (WHO grade 1). Comprehensive genomic profiling revealed an in-frame KIAA1549 (exon 15)-BRAF (exon 9) fusion (chr7:138867975-chr7:140787584). The postoperative course was uneventful for 6 months, and the patient remains under routine surveillance without any symptoms. ***Conclusion:*** Although high uptake of [^{18}F] fluciclovine is typically associated with high-grade gliomas, this case demonstrates that pilocytic astrocytoma, a low-grade glioma, can also show significant tracer accumulation. The underlying mechanism of fluciclovine uptake in low-grade tumours remains unclear. Awareness of such atypical uptake patterns is essential to avoid overestimation of tumour grade. Further studies are warranted to elucidate the uptake mechanisms and diagnostic specificity of [^{18}F] fluciclovine PET in paediatric and low-grade gliomas. ***References:*** 1. Jain S, Dhingra VK. An overview of radiolabeled amino acid tracers in oncologic imaging. Front Oncol. 2023 Feb 17;13:983023. doi: 10.3389/fonc.2023.983023. PMID: 36874105; PMCID: PMC9981995.

EP-1238

Scintigraphic Patterns of Renal Osteodystrophy: Two Case Reports with Differential Diagnostic Challenges

G. Bianciardi[1], *G. A. Fuso*[1], *E. Greco*[1], *C. M. P. Sgro*[1], *P. E. Orlandi*[2], *A. Romeo*[3], *S. Fanti*[1,3];
[1]*Nuclear Medicine, Alma Mater Studiorum, University of Bologna, Bologna, ITALY,* [2]*Unit of Radiology, Maggiore Hospital, Bologna, ITALY,* [3]*Nuclear Medicine, IRCSS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Renal osteodystrophy is a skeletal complication of chronic kidney disease (CKD) resulting from impaired mineral metabolism, secondary hyperparathyroidism and bone remodelling dysfunction. It encompasses a variety of bone changes, including osteitis fibrosa, adynamic bone disease, osteomalacia and mixed uremic osteodystrophy. Extra-skeletal calcifications such as vascular or pulmonary deposits may also occur, particularly in advanced CKD or dialysis patients, due to altered calcium-phosphate homeostasis. Herein we describe two clinical cases of renal osteodystrophy with distinctive scintigraphic patterns, highlighting the role of bone scintigraphy in the differential diagnosis. ***Materials and Methods:*** The first case was a patient with end-stage renal disease (ESRD) on haemodialysis since 2009 and on the transplant waiting list. Chest CT showed diffuse ground-glass opacities (GGO) predominantly in the upper lobes with microcalcifications. The patient was asymptomatic at the time of imaging. Bronchoscopy with bronchoalveolar lavage (BAL) ruled out active infection, except for a previous H1N1 viral pneumonia during hospitalisation. Pulmonary function tests revealed a moderate to severe restrictive ventilatory defect with markedly reduced DLCO, suggesting interstitial involvement with calcific deposits. Bone scintigraphy showed intense radiotracer uptake in both lung fields, highly suggestive of metastatic

pulmonary calcifications secondary to CKD-related mineral bone disease. In the second case, a patient with a long history of CKD on haemodialysis underwent bone scintigraphy for diffuse skeletal pain and suspected bone metastases. The scintigraphy showed intense and diffuse radiotracer uptake throughout the axial and appendicular skeleton without visualisation of the kidneys, consistent with a "superscan" pattern. The clinical history included acute granulomatous tubulointerstitial nephritis in 2017, followed by papillary breast cancer in 2024. However, the stability of the bone lesions on imaging and laboratory data supported the diagnosis of renal osteodystrophy. ***Results:*** The two cases presented illustrate characteristic scintigraphic patterns of renal osteodystrophy: pulmonary calcifications with radiotracer uptake in the lungs in the first case; and a superscan-like skeletal involvement in the second. Accurate clinical and radiological correlation was essential for differential diagnosis. ***Conclusion:*** These cases highlight that the diagnosis of renal osteodystrophy was only possible by integrating several diagnostic modalities. The combined assessment of radiological imaging, bone scintigraphy and clinical data was crucial in distinguishing renal osteodystrophy from other differential diagnoses such as neoplastic or infectious processes. This multidisciplinary approach is essential in the evaluation of complex presentations of bone and extra-skeletal abnormalities in patients with chronic kidney disease.

EP-1239

Unexpected Diagnosis of Papillary Thyroid Carcinoma Following Degeneration of a Thyroglossal Duct Cyst in a Child

M. Ben Nasr, *D. Ben Sellem, L. Zaabar, A. Mhiri;*
Salah Azaiez Institute of Tunis, Tunis, TUNISIA.

Aim/Introduction: The thyroglossal duct cyst (TGDC) is the most common congenital malformation in the cervical region. It is often discovered incidentally, particularly in childhood. Its degeneration is rare, occurring in less than 1% of cases. We report the case of a child with a degenerated TGDC revealing multifocal papillary thyroid carcinoma with pulmonary metastasis. ***Materials and Methods:*** The patient was a 10-year-old child with no significant medical history, who presented with a left digastric lymphadenopathy persisting for several months. He underwent cervical surgery for excision of the lymph node measuring 25 mm. Intraoperative frozen section examination suggested a metastatic papillary carcinoma lymph node. He subsequently received a left recurrent and lateral neck dissection. ***Results:*** Intraoperative exploration revealed a 15 mm heterogeneous cystic mass located near the hyoid bone, suggestive of a TGDC. The thyroid gland appeared normal without nodules. The cystic mass was completely excised along with the hyoid bone. Histological analysis confirmed a degenerated TGDC. The patient underwent a second operation for total thyroidectomy and functional right neck dissection. The final pathological report confirmed bilateral papillary thyroid carcinoma with lymph node metastasis, classified as pT3b N1b (R+) M1 (pulmonary miliary). The child was treated with 9 cycles of radioiodine therapy (total cumulative activity of 24.3 GBq). The outcome was favorable, with remission of the pulmonary metastases. No recurrence was noted after 10 years of follow-up. ***Conclusion:*** Degeneration of the TGDC is rare and is usually discovered incidentally after excision. Papillary carcinoma is the most common histological type. A degenerated TGDC may be associated with primary thyroid carcinoma. The thyroglossal duct can serve as a natural pathway for the dissemination of thyroid cancer.

EP-1240

Two synchronous primary malignant neoplasms (lung cancer and thymoma) detected by FDG PET/CT in a patient undergoing initial workup for prostate cancer: A case report

J. Zivanovic[1], *M. Stojiljkovic*[1,2], *K. Petrovic*[1], *N. Pantic*[1], *D. Sobic Saranovic*[1,2], *V. Artiko*[1,2], *S. Odalovic*[1,2];
[1]*Center for Nuclear Medicine with PET, University Clinical Center of Serbia, Belgrade, SERBIA,* [2]*Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.*

Aim/Introduction: Synchronous multiple primary malignant neoplasms (SMPMNs) are defined as two or more unrelated primary malignant neoplasms that occur simultaneously or within six months of the diagnosis of the first tumor, involving one or more organs in the same individual. We present an interesting case of a patient with three simultaneous malignant tumors identified on FDG PET/CT. ***Materials and Methods:*** A 60-year-old male patient was diagnosed with prostate adenocarcinoma (Gleason score 7: 4+3) in May 2024. As part of his initial workup, chest and abdominal CT revealed two lesions in the right lower lung lobe, a soft tissue mass in the anterior mediastinum, and a hypervascular lesion in the pancreas, suspected to be a neuroendocrine tumor (NET). He was referred for an ^{18}F-FDG PET/CT in August 2024 for further evaluation. ***Results:*** The PET/CT showed increased FDG uptake in the two lung lesions (SUVmax 4.4 and 6.1), which were deemed malignant. The anterior mediastinal mass also demonstrated increased FDG uptake (SUVmax 3.6), reported as highly suspicious for malignant thymoma. No increased FDG uptake was observed in the pancreas, consistent with the working diagnosis of a NET. The prostate exhibited diffusely, but only slightly, increased FDG uptake. A lobectomy of the right lower lung lobe was performed in August 2024, confirming primary lung adenocarcinoma. Simultaneously, thymectomy revealed a malignant thymoma, type B1. The patient received two courses of chemotherapy in October 2024. Given the lack of FDG uptake in the pancreas, further evaluation for a NET included blood tests (normal NSE, Chromogranin A: 139.9 ng/ml) and a pancreatic biopsy, which showed no evidence of a neuroendocrine tumor. A decision was made to monitor the patient. He received radiotherapy for prostate carcinoma in January 2025 and is currently on LHRH analogues. A recent bone scintigraphy showed no osteoblastic metastatic deposits. However, a diagnostic chest CT performed in March 2025 revealed residual disease in the anterior mediastinum, suggestive of thymoma recurrence, with no new lung lesions reported. ***Conclusion:*** To the best of our knowledge, this is the first reported case of synchronous lung cancer and thymoma detected by FDG PET/CT in a patient with prostate cancer. Although SMPMNs are rare, they should be considered when interpreting FDG PET/CT findings due to FDG's lack of specificity.

EP-1241

[^{177}Lu]Lu-PSMA Radioligand Therapy to Prolong Androgen Deprivation Therapy Free Survival in Patient With Hormone-Sensitive Metastatic Prostate Cancer: a case report

I. Langrate[1], *H. Einspieler*[1], *E. Kretschmer-Chott*[1], *S. Schmitl*[1], *L. Nics*[1], *S. Shariat*[2,3], *M. Hacker*[1], *G. Kramer*[2], *S. Rasul*[1];
[1]*Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Urology, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Department of Urology, Comprehensive Cancer Center, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: [^{177}Lu]Lu radioligand therapy (RLT), which targets the prostate-specific membrane antigen (PSMA), is primarily used in patients with metastatic castration-resistant prostate cancer (mCRPC) after androgen deprivation therapy

(ADT) or at least one taxane-based chemotherapy has failed. In this case report, [^{177}Lu]Lu-PSMA RLT was recommended as primary treatment for a patient with metastatic hormone-sensitive prostate cancer (mHSPC) due to intolerance to ADT, personal preferences and existing comorbidities. ***Materials and Methods:*** A 65-year-old man diagnosed with mHSPC received 12 intermittent cycles of [^{177}Lu]Lu-PSMA RLT over a span of eight years as monotherapy, without prior systemic treatment. ***Results:*** After the first three consecutive cycles of [^{177}Lu]Lu-PSMA RLT every 4 weeks in 2016, the PSA level decreased significantly from 16 µg/L to 0.17 µg/L (P< 0.001). Molecular imaging showed a partial remission with a reduction in PSMA-expression in the local lymph nodes. The patient was treatment-free for the following five years and underwent regular laboratory and imaging monitoring. Five years later, PSA levels increased to 13.7 µg/L and new PSMA-avid lymph nodes were detected on PET scan, necessitating retreatment with RLT. Administration of six additional cycles of [^{177}Lu]Lu-PSMA RLT every 6 weeks resulted in a PSA reduction from 14.0 to 2.8 µg/L, with imaging confirming reduced PSMA uptake in the local recurrences, leading to a further pause in therapy. In 2024, the PSA level rose to 41.6 µg/L. A PET imaging revealed a constant size with advanced PSMA-expressing lymph nodes. A further three cycles of [^{177}Lu]Lu-PSMA RLT every 6 weeks were indicated to bring the PSA down to 24 µg/L. Response assessment by PET-CT revealed a new PSMA-positive lesion in the inferior pubic ramus, prompting the initiation of systemic hormone therapy. Over the eight-year treatment course, the patient maintained durable disease control with a progression-free survival of 38 months (169.9 weeks), an ADT-free survival of 104.9 months (456 weeks), and prolonged overall survival. No significant myelotoxicity or nephrotoxicity was observed, Patient reported no therapy-related side effects. The total cumulative dose administred was 86.4 GBq ***Conclusion:*** This case report suggests that [^{177}Lu]Lu-PSMA RLT therapy may be a viable and well-tolerated alternative to conventional hormonal and chemotherapeutic strategies in select patients with mHSPC, offering prolonged disease control with minimal toxicity.

EP-1242

Post-treatment Inflammation with Foamy Macrophages Mimicking Lymphoma Relapse on Sequential FDG PET

S. Howladar, *W. Zeng;*
University of Ottawa, Ottawa, ON, CANADA.

Aim/Introduction: Primary mediastinal B-cell lymphoma (PMBCL) is a rare and aggressive subtype of mature large B-cell lymphoma, typically involving the anterior mediastinum in young patients (median age: 37). FDG PET is essential for staging and response assessment. End-of-treatment (EOT) FDG PET is routinely performed; negative findings (Deauville score ([DS] 1-3) are associated with excellent negative predictive value. However, literature shows the positive predictive value of EOT DS 4-5 (representing ~30% of patients) is low. Recent guidelines recommend an observation approach with serial imaging for EOT PET with DS4, and re-biopsy for EOT DS5 with partial metabolic response. While false positive findings are well described, delayed inflammatory changes deserve emphasis, as they may represent interval worsening on FDG PET, mimicking relapsed lymphoma and leading to unnecessary treatment. We present such a case. ***Materials and Methods:*** A 28-year-old woman presented with a one-month history of cough, shortness of breath, and pleuritic chest pain with no past medical history. CT showed a large anterior mediastinal mass. Immunohistochemistry from a core biopsy confirmed aggressive lymphoma, and additional cytogenetic (FISH) testing established a final diagnosis of PMBCL. The baseline FDG PET scan showed a hypermetabolic mass with central necrosis (10.0 x 14.1 x 18.6 cm, SUVmax: 19.6). She received 6 cycles of DA-EPOCH-R. EOT FDG PET showed significant improvement with a residual mass (2.7 x 3.3 x 4.6 cm, SUVmax: 6.4). The case was discussed at tumor board; the consensus was to observe rather than proceed with biopsy. A follow-up FDG PET three months later demonstrated increased uptake in the mass with central necrosis (2.8 x 3.5 x 5.2 cm, SUVmax: 11.2). The case reviewed at tumor board; given the increased activity, relapsed disease was suspected. Treatment options—including radiation, salvage chemotherapy followed by stem cell transplant, and possible CAR-T cell therapy—were discussed. However, the patient remained asymptomatic and questioned the likelihood of active disease. Biopsy was performed, revealing numerous foamy, hemosiderin-laden macrophages, consistent with post-treatment inflammatory changes. The patient was followed clinically and has remained in complete remission over 3 years. ***Conclusion:*** For equivocal EOT findings in lymphoma,it is common to follow patients with serial FDG PET and retreat if there is evidence of disease progression. Caution is especially warranted in PMBCL, which is more prone to post-treatment inflammation than other types. Delayed inflammation should always be considered, and biopsy should be pursued when appropriate, as illustrated in this case.

EP-1243

Predictive Value of ^{18}F-FDG PET/CT in Early Detection of Pulmonary Squamous Cell Carcinoma: A Case Report

D. Silva, *D. Barbosa, N. Vasconcelos, R. Marão, I. Lopo, H. Duarte, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: [^{18}F]fluorodeoxyglucose positron emission tomography/computed tomography ([^{18}F]FDG PET/CT) plays an essential role in the assessment of indeterminate pulmonary nodules, aiding in the differentiation between benign and malignant lesions through metabolic characterisation. Our aim was to illustrate this important role in the early detection of pulmonary squamous cell carcinoma (SCC) in a patient under long-term surveillance, in whom malignancy was suspected years before histological confirmation. ***Materials and Methods:*** We present the case of a 70-year-old male with a prior history of epiglottic squamous cell carcinoma (treated in 2006 with surgery, chemotherapy, and radiotherapy), who was undergoing routine follow-up imaging. A thoracic computed tomography (CT) scan performed in 2016 revealed an 18 mm pulmonary nodule in the apex of the left upper lobe, for which imaging surveillance was recommended. In 2019, the lesion had enlarged to 23 mm, prompting a [^{18}F]FDG PET/CT scan. The study showed increased metabolic activity in the nodule (SUVmax 4.7), raising suspicion for malignancy. A CT-guided percutaneous biopsy was performed but returned negative. Surveillance continued with annual CT, and in 2024, a further increase in size (to 32 mm) led to a second biopsy, which confirmed the diagnosis of poorly differentiated squamous cell carcinoma. [^{18}F]FDG PET/CT demonstrated metabolic progression since 2019, with SUVmax rising to 14.9. The patient subsequently underwent surgical resection with curative intent. ***Results:*** This case highlights the utility of [^{18}F] FDG PET/CT in assessing indeterminate pulmonary nodules and illustrates the prognostic significance of metabolic findings, which preceded histopathological confirmation by several years. The FDG avidity, combined with progressive dimensional increase, guided continued monitoring and eventual diagnosis, despite an initially false-negative biopsy. ***Conclusion:*** [^{18}F]FDG PET/CT demonstrated high clinical utility in the early characterisation and risk stratification of a pulmonary nodule ultimately confirmed to be malignant. Although PET/CT sensitivity in detecting lung cancer is generally high, its accuracy is influenced by lesion size and metabolic activity. A recent meta-analysis reported a pooled sensitivity of 88% and specificity of 78% for PET/CT-based diagnostic models, with diagnostic performance improving in

nodules larger than 20 mm (Liu et al., 2024). This case reinforces the importance of integrating metabolic imaging findings into long-term follow-up strategies, particularly when biopsy results are initially discordant with morphological imaging. ***References:*** Li, Y., Shi, YB. & Hu, CF. ^{18}F-FDG PET/CT based model for predicting malignancy in pulmonary nodules: a meta-analysis. EP-1244

[^{18}F]FDG PET/CT imaging in two patients with diffuse skeletal muscle metastasis of thyroid carcinoma

Y. Wang, *J. Xiang, R. Li, X. Zhang, Y. Lin, Z. Zhu;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: Lymph nodes and lungs are the most common sites of metastasis in differentiated thyroid carcinoma. However, skeletal muscle metastasis is rare, with only isolated lesion reported previously. We herein present two cases of a 65-year-old man and a 70-year-old woman who underwent total thyroidectomy for papillary thyroid carcinoma (PTC) and radioiodine ablation therapies presented with painless nodules beneath the left thigh. ***Materials and Methods:*** To determine systemic lesions, the patients underwent [^{18}F] FDG PET/CT examination. In order to clarify the cell origin of the lesion, ultrasound-guided biopsy was performed on the male patient. H&E and immunohistochemical staining were performed on the biopsy tissues. ***Results:*** [^{18}F] FDG PET/CT revealed multiple soft tissue nodules with increased uptake in muscles of the two patients, with the largest nodule measuring 2.5×2.0 cm in size, SUVmax 13.0 in the male patient and 2.1×1.6 cm in size, SUVmax 6.9 in the female patient. In addition, [^{18}F]FDG PET/CT revealed other lesions in the lung, liver, lymph nodes and bones in the male patient, and in the lung, pleura, lymph nodes in the female patient. Histology of the soft tissue nodule near left knee joint showed atypical cells, which reacted positively to AE1/AE3, PAX - 8, TTF-1, and negatively to calretinin. Thyroglobulin in the puncture fluid was 20.72 ng/ml, which confirmed the thyroid origin of the nodule. ***Conclusion:*** [^{18}F]FDG PET/CT is crucial for detecting muscle lesions, and medical history, physical examination and relevant biological markers are valuable in differentiating cellular origins. The two cases provide a reference for the differential diagnosis in systemic muscle metastasis of thyroid carcinoma.

EP-1245

^{99m}Tc-Ubiquicidin SPECT/CT in Suspected Periprosthetic Infection: Case Series in Patients with Complex Orthopedic and Inflammatory Backgrounds

V. Heringer, *B. Alencar, T. Agnello, M. Osmak, E. Etchebehere, C. Ramos, M. Lima, B. Amorim, A. Santos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Patients with inflammatory arthritis history and extensive orthopedic interventions present significant diagnostic challenges, particularly in distinguishing active infection from sterile inflammation. SPECT/CT with 99mTc-ubiquicidin (UBI), a radiopharmaceutical that selectively binds to bacterial membranes, has proven useful in differentiating these conditions, even in clinically complex scenarios[1,2]. The UBI 29-41 fragment, composed of cationic residues such as arginine and lysine, binds electrostatically to negatively charged bacterial surfaces, enhancing the specificity of infection detection[3]. ***Materials and Methods:*** Case 1: 65-year-old man with multiple myeloma and chronic right lower limb pain following hip prosthesis removal due to infection underwent ^{99mTc}-UBI scintigraphy to evaluate for low-grade infection. Case 2: 62-year-old woman with rheumatoid arthritis and a history of hip prosthesis removal underwent 99mTc-UBI SPECT/CT to assess for infection before planned reimplantation. Case 3: 62-year-old woman with seronegative RA, chronic anemia, multiple comorbidities, and clinical suspicion of periprosthetic infection underwent the same SPECT/CT protocol to evaluate systemic inflammatory activity and rule out infection. A lesion-to-background (L/B) ratio was calculated by comparing tracer uptake in regions of interest to contralateral controls, based on established thresholds for infection. ***Results:*** Case 1: moderate focal uptake was observed around the proximal femoral stem in the right thigh (L/B ratio: 1.77), exceeding the 1.74 limit indicative of active infection[3]. Given the absence of systemic signs, a conservative pain management approach was adopted. Case 2: only mild uptake (L/B: 1.1) was seen surrounding the cemented stem, with no evidence of infection. Moderate radiotracer accumulation in the wrists and ankle was consistent with RA-related joint inflammation[1,2]. These findings may be partially explained by increased capillary permeability and vascular leakage in inflamed synovial tissues, a mechanism that can facilitate non-specific tracer diffusion in chronic inflammatory conditions. Case 3: similar moderate uptake was noted in peripheral joints and no scintigraphic signs of periprosthetic infection were present (L/B <1.74), supporting the diagnosis of non-infectious activity[4]. ***Conclusion:*** SPECT/CT with 99mTc-ubiquicidin can be explored as a valuable tool in distinguishing active infection from sterile inflammation in patients with overlapping rheumatologic and orthopedic conditions, especially on indeterminate cases by triphasic bone scintigraphy. The lesion-to-background (L/B) ratio served as an objective parameter for guiding therapeutic decisions and surgical planning[1-4]. ***References:*** 1) Welling MM, et al. EP-1246

Rare atypical case of Mayer Rokitansky Kuster Hauser (MRKH) type II syndrome with ectopic hydronephrotic renal disease on radionuclide scintigraphy

D. Singh, *P. Kumar, S. Jain;*
All India Institute of Medical Sciences, Bhopal, INDIA.

Aim/Introduction: Mayer Rokitansky Kuster Hauser (MRKH) is a rare congenital syndrome in female characterized by aplastic/ hypoplastic mullerian or paramesonephric ducts with normal karyotype (46, XX). Typical (type I) MRKH syndrome is characterized by absent/ hypoplastic uterus, cervix and upper 2/3rd of vagina. Atypical (type 2) MRKH syndrome may also be associated with abnormality of fallopian tubes, ovaries, kidneys, skeletal, cardiac and otological systems. We report a rare case of atypical MRKH syndrome with absent uterus, spondylolysis with Grade I spondylolisthesis, bilateral mild conductive hearing loss and grossly hydronephrotic obstructed single ectopic pelvic kidney on Tc-99m ethylene di-cysteine (EC) and Tc-99m dimercaptosuccinic acid (DMSA) scans. ***Materials and Methods:*** A 25-year-old woman with complaint of burning micturition, increased frequency, urgency, nocturia and history of recurrent urinary tract infection (UTI) since childhood was referred for radionuclide renal scintigraphy. She was a known case of primary amenorrhea with complaint of cyclical lower abdominal pain for 2-3 days every month since 12-13 years of age. We did Tc-99m EC dynamic renal scintigraphy with diuretic intervention using F+0 protocol. Following intravenous injection of tracer, sequential dynamic images of abdomen and pelvis were acquired in anterior and posterior views, followed by prevoid, postvoid, 2 and 4 hours delayed images. We also did Tc-99m DMSA scintigraphy on subsequent day in view of recurrent UTI, following injection of Tc-99m DMSA and acquisition of images at 3 hours. Following static images, SPECT/CT images were also acquired. ***Results:*** Tc-99m EC dynamic images showed moderate to grossly hydronephrotic ectopically located single kidney in pelvis above the urinary bladder with impaired parenchymal function and minimal drainage. The effective renal plasma flow was 159.4 ml/ min. Prevoid, postvoid and subsequent delayed images showed significant tracer retention in PCS and minimal slow drainage. Tc-99m DMSA scintigraphy revealed single ectopic pelvic kidney at

right superolateral aspect of urinary bladder with impaired cortical function and few areas of significant cortical thinning. The SPECT/CT images also showed ectopic pelvic kidney with DJ stent in situ and thinned cortical parenchyma. The uterus was not visualized in the images. ***Conclusion:*** We are highlighting the importance of radionuclide renal scintigraphy to thoroughly investigate patients of primary amenorrhea with associated renal anomalies in MRKH type 2 syndrome to avoid further complication by loss of renal parenchyma due to obstructed drainage and/ or pyelonephritic changes and prone to end stage renal disease if left untreated especially in patients with single kidney.

EP-1247

Metabolic Imaging of Pembrolizumab-Associated Biliary Inflammation: A Case of Spontaneous Resolution on [^{18}F] FDG PET/CT

I. Ferreira[1], *O. L. Silva*[1], *M. Simões*[2], *J. A. Sequeira*[1], *A. I. Santos*[1];
[1]*Unidade Local de Saúde de Almada-Seixal, E.P.E, Almada, PORTUGAL,* [2]*Unidade Local de Saúde do Arco Ribeirinho, E.P.E, Montijo, PORTUGAL.*

Aim/Introduction: Immune-checkpoint inhibitor (ICI) mediated hepatobiliary injury is an emerging concern in cancer treatment, with most adverse reactions being attributed to Nivolumab and characterised by panlobular hepatitis. Large duct cholangiopathy in this context is extremely rare. Pembrolizumab-related cholangiopathy has only been described in isolated case reports. In such cases, metabolic imaging with [^{18}F]FDG PET/CT is scarcely reported. To the best of our knowledge, this is the first case reported of diagnosis, follow-up and resolution of Pembrolizumab-related cholangiopathy demonstrated with [^{18}F]FDG PET/CT. ***Materials and Methods:*** We report the case of a 64-year-old patient with squamous cell carcinoma of the right lung who received chemotherapy followed by Pembrolizumab, with an apparent complete response. After 4 years of continual treatment, [^{18}F]FDG PET/CT for disease monitoring revealed intense FDG uptake in the intra- and extrahepatic biliary tree, suggesting an extensive inflammatory process. The patient complained of slight abdominal discomfort only when questioned. Aspartate transaminase and gamma-glutamyl transferase were mildly elevated with no other analytical changes. Pembrolizumab was therefore continued. A follow-up PET/CT performed 9 months later showed increased intensity of FDG uptake in the biliary tree. Despite this metabolic progression, the patient remained clinically stable with good therapeutic response of the primary tumour, leading to uninterrupted Pembrolizumab administration. ***Results:*** A subsequent [^{18}F]FDG PET/CT performed 21 months later demonstrated complete resolution of biliary hypermetabolism, concurrent with normalisation of liver enzymes, indicative of spontaneous resolution of the inflammatory process while still on Pembrolizumab. A systematic review of 53 cases of immune-mediated cholangitis by Pi et al. (2021) identified only 2 cases assessed with FDG PET/CT, with just 1 displaying increased biliary metabolism in the context of Pembrolizumab-induced sclerosing cholangitis. Additionally, previous reports have relied primarily on biochemical and conventional imaging findings (e.g., bile duct dilation and wall enhancement on CT and ultrasound) to diagnose immune-related cholangiopathy. ***Conclusion:*** This case illustrates the rare occurrence of Pembrolizumab-induced biliary inflammation and its spontaneous metabolic resolution on continued immunotherapy, as demonstrated by serial [^{18}F] FDG PET/CT imaging. These findings emphasise the utility of [^{18}F] FDG PET/CT in evaluating immune-related hepatobiliary toxicities and highlight the potentially self-limiting nature of some ICI-mediated responses. Further research is warranted to elucidate the underlying mechanisms, optimal management, and long-term implications of such adverse events.

EP-1248

A Case Of Skeletal Tuberculosis

M. Mehesen*, R. Shera;*
National Cancer Institute, Cairo university, Cairo, EGYPT.

Aim/Introduction: Tuberculosis affecting the skeletal system constitutes merely 2% of all tuberculosis cases, while the involvement of the foot and ankle joints represents approximately 10% of skeletal cases. The low specificity of the clinical condition and the limited suspicion of tuberculosis likely contributed to the diagnostic delay. In most instances, skeletal tuberculosis is not conclusively diagnosed until considerable bone destruction has transpired due to its diverse manifestations; approximately 20% of all mycobacterial infections in pediatrics manifest as extra-pulmonary tuberculosis (EPTB). ***Materials and Methods:*** A 12-year-old female patient presented with fever, pain, and swelling in her right foot. The patient had neutropenia. A superficial ultrasound of the right ankle revealed a 4x2 cm lobulated turbid cystic lesion, accompanied by overlying subcutaneous edema. This suggests an inflammatory process with the formation of an abscess. Plain x-ray showed an ill-defined, irregular-shaped area of an erosive, heterogeneous bony lesion with ST opacity at the posteromedial aspect of the right calcaneal bone. A poorly defined erosive lesion was identified by local MRI, which produced a low T, heterogeneous high T2/STAIR signal with a ST component of 2.4x2x3.5 cm at maximum axial and CC diameters. ***Results:*** The patient was referred to our nuclear medicine department to examine the rest of the body and find additional lesions. FDG PET/CT revealed the right calcaneal lesion and several other lytic bone lesions along the axial skeleton and long bones, some of which were linked to the ST component. The largest lesion, measuring 6.6x6.3 cm SUVmax of 5.8 with intraspinal extension through the corresponding right neural exit foramen, was located at D12, while the most active lesion, measuring 3.7x3.6 cm SUVmax of 10.2, was located at the left side of the sacrum. Additionally, small, low-grade, FDG-avid pulmonary nodules are visible, the largest of which measures 8 mm with an SUVmax of 1. Cytology and fluid aspiration from the cystic lesion revealed acute inflammatory cells and hypocellular necro-inflammatory material. Necrotizing/caseating granulomatous inflammation was discovered during an open biopsy of the calcaneal bone. ***Conclusion:*** Extra-pulmonary skeletal tuberculosis presents non-specifically, necessitating numerous investigations to achieve a diagnosis.

EP-1249

A Rare Case of Osteopoikilosis Differentiated from Sclerotic Metastatic Lesions by Bone Scintigraphy

G. Inal[1], *N. Aydinbelge Dizdar*[1], *A. Cinar*[1], *C. O. Engur Uyanik*[1], *O. Ozmen*[2];
[1]*Ankara Etlik City Hospital Nuclear Medicine Clinic, Ankara, TÜRKIYE,* [2]*University of Health Science, Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Osteopoikilosis (OPK) is a rare benign bone disorder characterized by the presence of multiple and often symmetrical hyperostotic foci localized predominantly in the periarticular regions of the bones, which may be mistaken for osteoblastic metastases. As it is usually asymptomatic, it is detected incidentally during radiological imaging. We report a 23-year-old male patient with OPK whose difficulties in definitive diagnosis were resolved with the contribution of whole-body bone scan (WBS) with SPECT/CT images and clinical follow-up. ***Materials and Methods:*** A 23-year-old male patient with low back pain who underwent the lumbosacral spine and pelvic bone X-ray and multiple sclerotic lesions were detected. For investigating the etiology of sclerotic bone lesions, Tc-99m MDP WBS performed. ***Results:*** On the planar images, it showed heterogeneous increased radioactivity accumulations in bilateral hip joint and proximal femur. Pelvic SPECT/CT images showed that most of the sclerotic

lesions in the pelvic bones and bilateral proximal femurs did not correspond to radioactivity uptake on planar images. The findings obtained from pelvic SPECT/CT and the planar images excluded bone metastasis. Afterwards, magnetic resonance imaging (MRI) of the pelvis demonstrated multifocal areas consistent with sclerotic foci in both the iliac bones and the proximal femurs. These regions existed hypointense on T1 and T2 sequences and exhibited no significant enhancement with contrast. Considering the patient's age, lack of known malignancy, and normal physical examination and the imaging findings, OPK was deemed the most likely cause of the sclerotic foci. Accordingly, the patient was followed up. ***Conclusion:*** Osteopoikilosis is a rare type of bone dysplasia that may occur at any age and affect genders at similar rates. It is assumed that mutations in the LEMD3 gene are associated with the condition and are inherited in an autosomal dominant manner. It usually presents incidentally as sclerotic, oval, multiple, well circumscribed and symmetrical lesions on the phalanges, carpal and metacarpal bones, pelvis and femur. Therefore, osteoblastic metastases should be considered mainly in the differential diagnosis of these lesions. Hybrid SPECT/CT imaging provides both functional and anatomical information and may be more useful than planar WBS, especially in patients with multiple sclerotic lesions and unexplained bone pain as in this rare case. Thus, it is important for physicians to recognize the imaging findings to avoid unnecessary interventions and treatments.

EP-1250

Utility of complimentary functioning and cortical imaging scintigraphy in assessing delayed graft function in a paediatric patient with suspected vascular thrombosis: A Case Report

K. Hlongwa, *A. Al-Marrani, M. P. Rivombo, A. Coetzee, S. More; University of Cape Town, Cape Town, SOUTH AFRICA.*

Aim/Introduction: Renal transplantation is a common treatment for end-stage kidney disease (ESKD) in paediatric patients. Complications such as vascular thrombosis can lead to graft failure. Nuclear medicine imaging, including [^{99m}Tc]Tc-MAG3 renogram and less routinely, [^{99m}Tc]Tc-DMSA scintigraphy, have demonstrated a role in assessing graft function. This case reports on a 7-year-old male with ESKD secondary to posterior urethral valves (PUV) whose post-transplant course revealed conflicting imaging findings, which underscore the complexity of diagnosing renal graft dysfunction. This case demonstrates the beneficial role of nuclear medicine imaging in assessing graft function and guiding management decisions. ***Materials and Methods:*** Case Presentation: A 7-year-old male with ESKD secondary to posterior urethral valves (PUV) underwent deceased donor renal transplant. Post-operative ultrasound demonstrated good flow, however, on day 2 the patient had decreased urine output and decreased flow suggestive of vascular thrombosis. A [^{99m}Tc]Tc-MAG3 renogram on day 2 post-transplant showed no perfusion or uptake, suggesting vascular thrombosis. Despite thrombectomy, a repeat [^{99m}Tc]Tc-MAG3 renogram on day 6 still showed no graft function. On discussion by the multidisciplinary team, a [^{99m}Tc]Tc-DMSA scan with SPECT/CT was performed to assess cortical function, revealing uptake in the graft kidney similar to the native kidneys which confirmed some cortical function of the graft kidney. However, renal biopsy showed extensive necrosis extensive necrosis with one fragment of viable renal tissue showing 3 normal glomeruli and prominent interstitial chronic inflammation composed of lymphocytes with prominent ATN. The graft was eventually removed and the child resumed haemodialysis. ***Results:*** Discussion: The complementary roles of the [^{99m}Tc]Tc-MAG3 renograms and [^{99m}Tc]Tc-DMSA scintigraphy in evaluating renal transplant complications is demonstrated in this case. While MAG3 suggested complete graft non-function, DMSA confirmed an element of viable cortical tissue which suggested severely delayed graft function in this kidney. Such discrepancies may arise due to differences in uptake mechanism of the different tracers with MAG3 being tubular and DMSA demonstrating mainly cortical uptake. This case demonstrates the need for multimodal assessment in complex cases in conjunction with multidisciplinary discussion. ***Conclusion:*** This case highlights the potential complementary roles of MAG3 renogram in assessing graft function in certain situations and the utility of DMSA SPECT/CT in providing valuable information on cortical function. The case demonstrates the importance of multimodality imaging and multidisciplinary discussion in managing complex cases of renal transplantation and guiding management decisions.

EP-1251

Unmasking Synchronous Primaries: The Crucial Role of ^{18}F-FDG PET/CT in Diagnosing Concurrent Breast and Small Cell Lung Cancer with Atypical Metastases

A. Leiva Montejo, *B. Cueto Cañadas, C. Balbin Garcia, I. Sime Loayza, J. Delgado Moreno, J. Sánchez Catalicio, A. Montellano Fenoy, M. Guerrero Ortiz;*
Hospital Universitario Torrecárdenas, Almeria, SPAIN.

Aim/Introduction: Multiple primary malignant tumors (MPMTs) are defined as two or more distinct malignant tumors in the same individual, classified as synchronous (<6 months) or metachronous (≥6 months). Three conditions are required to qualify as MPMTs: the diagnosed tumors must be confirmed as malignant, they must have different histological characteristics and one must not be a metastasis of the other. ***Materials and Methods:*** A 59-year-old female smoker detected a lump in her left breast (LB) during self-examination four months ago. A mammogram was performed, revealing multiple BI-RADS 4 lobulated nodular lesions. Pathological analysis confirmed an infiltrating ductal carcinoma (IDC) in the upper outer quadrant (UOQ) of the LB. The patient also reported the progressive appearance of hard subcutaneous nodules in the upper limbs, abdomen and left scapular region. A ^{18}F-FDG PET/CT was performed for staging. ***Results:*** ^{18}F-FDG PET/CT showed multiple hypermetabolic nodules in both breasts, with a prominent lesion in the UOQ of the LB (3.3 × 4.0 cm, SULmax 9.0). Additional hypermetabolic nodules were identified in the mesenteric and retroperitoneal regions, the most significant in the mesogastrium adjacent to the abdominal wall (1.3 × 1.6 cm, SULmax 7.2). Both adrenal glands showed increased uptake (SULmax 5.5, higher than hepatic uptake SULmax 2.9). Hypermetabolic subcutaneous and paramuscular nodules were noted in the arms, anterior and posterior thorax, and abdominopelvic region (SULmax up to 9.3) suggestive of tumor implants. A right frontal lobe hyperdense hypometabolic lesion raised suspicion of metastasis. Finally, a moderately hypermetabolic left parahilar mass (6.3 × 6.3 cm SULmax 9.5) was identified as a potential primary lung tumor. The case was presented to the tumor committee, which recommended a biopsy of a left arm nodule that confirmed a small cell lung carcinoma (SCLC) metastasis. ***Conclusion:*** The incidence of synchronous breast and lung cancer is rare, affecting less than 0.5% of patients diagnosed with breast cancer. Distinguishing primary tumors from metastases is crucial, as the lung is a frequent metastatic site for breast cancer. The malignant nature of each tumor must be confirmed through histopathological and immunohistochemical analysis. Brain metastases could originate from either tumor; however, given the patient's smoking history, and the cutaneous and adrenal gland involvement observed on ^{18}F-FDG PET/CT, the possibility of a synchronous lung primary tumor was supported. SCLC cutaneous metastases indicate a poor prognosis. Due to the rarity of this oncologic scenario, no standard treatment exists, requiring further research..

EP-1252

Local perinerural invasion in sacral plexus in recurrent metastatic adenocarcinoma prostate as seen on ^{68}Ga PSMA PET-CT; a rare finding.Local perinerural invasion in sacral plexus in recurrent metastatic adenocarcinoma prostate as seen on ^{68}Ga PSMA PET-CT; a rare finding.

J. Bal, *S. Jha, K. Shanker, P. Dougall;*
Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: Adenocarcinoma of prostate accounts for second most common malignancy in males and accounts for approximately 15% of newly diagnosed cases every year. We present a case of 65 year old male who was diagnosed as adenocarcinoma prostate (Gleason's score-4+5) 3 years back. He was upfront metastatic with multiple skeletal sites. He received Doectaxel, Degarelix and Denosumab and was reported to be in complete remission biochemically and radiologically for 2 years. ***Materials and Methods:*** Lately he presented with rising S. PSA values of 2.02ng/ml and complaints of vague lower back pain and mild weakness in left leg. His ^{68}Ga PSMA PET-CT scan revealed PSMA expressing soft tissue mass in the prostate with local perineural extension into left hypogastric, sacral plexus at L5-S1 vertebral levels, exiting nerve roots on left side and left sciatic foramen. The other metastatic sites including bones were still in remission. He was treated with local treatment in the form of EBRT to the sacral neural plexus. ***Results:*** Prostate cancer is known to spread to lymph nodes and hematogenously to distant organs, bones being the most common site. Perineural invasion as local spread is reported on biopsy specimens in intermediate to high risk categories and rarely seen on any imaging. Local spread to lumbosacral neural plexus is very rare and has been reported in very few cases in imaging. Patient with perineural spread of carcinoma prostate can present with sensory, motor or autonomic symptoms of the specific nerve roots involved. Patients presenting with such complaints can be confused for intervertebral disc prolapse, radiation neuritis, or cord compression due to vertebral metastases. MRI and ^{68}Ga PSMA PET-CT can differentiate intervertebral disc prolapse and cord compression from the rest. ***Conclusion:*** Direct perineural spread of lumbosacral plexus should be suspected in addition to other common causes, when patient with carcinoma prostate are being evaluated for back. ^{68}Ga PSMA PET CT is a useful imaging tool in identifying such atypical presentation of carcinoma prostate.

EP-1253

Prostatic adenocarcinoma masquerading as rectal primary- diagnostic dilemma aided by ^{68}Ga PSMA scan to reach conclusion.

J. Bal, *K. Shanker, P. Dougall;*
[1]Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: Prostatic acinar adenocarcinoma is only the second most common malignancy in male population and the incidence is rising worldwide. Usually the patients present with lower urinary tract symptoms; however rarely these patients can also present with unrelated symptoms which can mislead the clinical diagnosis. ***Materials and Methods:*** We present a case of 71 year old male presenting with symptoms of altered bowel habits and occasional episodes of rectal bleed. He underwent colonoscopy which revealed a circumferential growth involving mid and lower rectum with narrowing of lumen. Biopsy taken from rectal growth was suggestive of moderately differentiated carcinoma. He also underwent MRI of the pelvis which showed circumferential growth involving rectum with close abutment of the prostate; however prostate and seminal vesicles were commented to be normal. However note was made of some pelvic lymph nodes and an indeterminate lesion in sacrum. ***Results:*** His battery of blood investigations revealed S. CEA, CA 19.9 within normal limits but raised S.PSA of 50.7 ng/ml. His 18F FDG PET-CT showed circumferential growth in mid and lower rectum with no significant metabolid activity in the primary lesion, lymph nodes or skeletal lesion. This prompted us to do ^{68}Ga PSMA scan to clarify the diagnostic dilemma. ^{68}Ga PSMA scan showed intensly increased PSMA expression in the rectal growth and in the prostate gland; however there was no contiguous extension between the two lesions. Pelvic lymph nodes and sacral lesion also showed increased PSMA expression prompting to review the rectal biopsy. IHC revealed the initial rectal biopsy specimen to be PSA positive. A separate 12 core TRUS guided biopsy was also done from prostate which showed Acinar Adenocarcinoma prostate with LVI and Gleason's score of 4+5. ***Conclusion:*** Patients with no specific urinary tract symptoms and presenting with non specific symptoms can remain eluded from reaching correct diagnosis. A multidisciplinary approach, thorough work up and specific molecular imaging targets can aid in reaching the correct diagnosis.

EP-1254

A case of diffuse bone tracer myocardium uptake after thoracic trauma in a patient with suspected Transthyretin-related cardiomyopathy.

I. Badrane[1], *C. Cittanti*[1], *L. Urso*[1], *L. Uccelli*[1], *M. Bartolomei*[2];
[1]Department of Translational Medicine, University of Ferrara, Ferrara, ITALY, [2]Nuclear Medicine Unit, Department of Onco-Hematology, Ferrara, ITALY.

Aim/Introduction: Transthyretin-related cardiomyopathy (ATTR-CM) is un underdiagnosed condition determined by amyloid fibrils deposits within the myocardium. Early diagnosis is crucial for improving outcomes, and Nuclear Medicine has a pivotal role to confirm diagnosis of ATTR-CM employing scintigraphy with bone-seeking agents such as 99m-technetium 3,3-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD). ***Materials and Methods:*** We present the case of a 84-year-old woman with multiple clinical red flags for cardiac amyloidosis (CA) images with ^{99}mTc-DPD scintigraphy. ***Results:*** The patient complained of asthenia and dyspnea with a class II according to the New York Heart Association classification system. However, at echocardiography, she showed a preserved ejection fraction (65%), asymmetrical left ventricular hypertrophy, with a non-dilated cavity. Some typical electrocardiographic features were identified as well, in particular atrial fibrillation and a first-degree atrioventricular block. Moreover, the patient also had a recent history of transcatheter aortic valve implantation (TAVI) due to severe aortic stenosis. All this led to investigate the presence of CA. Laboratory investigations were assessed, which ruled out immunoglobulin light chains-CA form. Concomitantly a bone scintigraphy (BS) was performed showing a modest, diffuse radiotracer uptake within the left ventricular myocardium, corresponding to a Perugini grade 1 pattern. As incidental findings, areas of increased osteotropic tracer accumulation were observed in correspondence with the left shoulder and the anterior part of the 6th, 7th and 8th ipsilateral ribs, consistent with post-traumatic changes. Approximately one year later, during a follow-up cardiologic evaluation, the patient was referred for repeat BS to further investigate and clarify the suspicion of CA. This second BS study revealed complete resolution of the previously observed myocardial radiotracer uptake. This normalization is most likely attributable to non-specific tracer accumulation secondary to a significant thoracic trauma, which was reported anamnesticly by the patient, and that occurred few days before the first BS. The shoulder and costal findings have also disappeared supporting the traumatic genesis. ***Conclusion:*** The ability of bone radiopharmaceuticals to deposit in the context of soft tissues that are sites of previous surgical trauma, recent ischemic lesions or chemotherapy treatments is well documented in the literature. So we report a rare a case of non-specific

deposition of a bone-seeking agent in the myocardium tissue due to a recent thoracic trauma, initially mistaken for a Perugini grade I pattern, in a patient with multiple red flags for ATTR-CM.

EP-1255

Postoperative Complications in Scimitar Syndrome: The Role of Lung Scintigraphy

J. Duarte[1], *J. P. Carvalho*[1], *A. Marques*[1,2], *F. Abreu*[1,2], *S. Pintão*[1];
[1]*Unidade Local de Saúde de Lisboa Ocidental, Lisbon, PORTUGAL,* [2]*Instituto de Medicina Nuclear da Faculdade de Medicina de Lisboa, Lisboa, PORTUGAL.*

Aim/Introduction: Scimitar syndrome is a rare congenital condition involving partial anomalous pulmonary venous return, in which part or all of the right lung is drained by pulmonary veins that anomalously connect to the inferior vena cava. Surgical correction is indicated in symptomatic patients, yet postoperative complications such as baffle obstruction may occur and require nuanced management. ***Materials and Methods:*** We report the case of a 58-year-old woman with history of a corrected Scimitar syndrome approximately 18 months earlier. The patient presented with subacute persistent dyspnea, fatigue, and wheezing. Cardiac catheterization and echocardiography revealed complete thrombosis of the pericardial baffle redirecting pulmonary venous return to the left atrium. To assess right lung viability and inform treatment planning, a lung ventilation/perfusion (V/Q) scintigraphy was performed. The study consisted of tomographic (SPECT/CT) acquisition of the thorax immediately after inhalation of [^{99m}Tc] Technegas for ventilation imaging, followed by intravenous administration of [^{99m}Tc]Tc-albumin macroaggregates and subsequent thoracic SPECT/CT for perfusion assessment. ***Results:*** The V/Q scan revealed severely diminished perfusion to the entire right lung (7%) with relatively preserved ventilation, consistent with profound functional compromise and likely underlying hypoplasia. Left lung perfusion was preserved (93%) without segmental or subsegmental defects. Based on these findings, the multidisciplinary team concluded that the right lung was already virtually excluded. Therefore, surgical pneumonectomy or transplant were not indicated, so the patient was discharged with a plan for close clinical monitoring and symptom-guided management. ***Conclusion:*** This case illustrates the key role of lung scintigraphy in evaluating postoperative Scimitar syndrome. Functional imaging, particularly SPECT/CT-based V/Q scanning, was crucial in demonstrating the physiological impact of the baffle obstruction and supported the decision to avoid further high-risk surgical intervention. In complex congenital heart disease, especially when anatomical repair fails, nuclear imaging can provide decisive functional insight to guide clinical management.

EP-1256

Diagnostic complexity of Hepatopulmonary Syndrome: a case report

I. Casimiro*, D. Carvalho, S. Barata, S. Paiva, J. Silva, M. Monteiro, A. Moreira, T. Saraiva, G. Costa;*
Unidade Local de Saúde de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Hepatopulmonary syndrome (HPS) is a rare and potentially fatal pulmonary vascular complication of liver disease. Characterized by intrapulmonary vascular dilatations and hypoxemia, this condition requires a multidisciplinary approach for timely diagnosis and treatment. ***Materials and Methods:*** A 57-year-old woman with a history of active smoking, hepatitis C, and secondary thrombocytopenia had been followed by Pulmonology after presenting to the emergency department with hypoxemic respiratory failure (pO_2 54.8 mmHg in room air). Laboratory findings included thrombocytopenia, polycythemia, and elevated D-dimers. Initial work-up ruled out pulmonary embolism and revealed upper lobe centrilobular emphysema. No signs of pulmonary hypertension were identified on echocardiography. After being discharged, despite oxygen therapy, the patient experienced progressive fatigue and worsening symptoms. Further investigations, including a ventilation/perfusion (V/Q) scintigraphy, failed to reveal the cause of her persistent hypoxemia. At follow-up, the patient presented with worsening dyspnea, central and peripheral cyanosis, and very severe hypoxemia (pO_2 38.7 mmHg), requiring hospitalization. Pulmonary angiography showed no vascular abnormalities. Transthoracic echocardiography raised suspicion of a right-to-left extracardiac shunt. A transesophageal echocardiogram with agitated saline contrast demonstrated complete opacification of the left heart chambers, with microbubbles arising from the pulmonary veins, confirming an extracardiac shunt and ruling out a patent foramen ovale. ***Results:*** A lung perfusion scan with Technetium-99m-labeled macroaggregated albumin (MAA) later performed showed an intrapulmonary right-to-left shunt of 50%, with radiotracer uptake in the brain, kidneys, and spleen, confirming the diagnosis of hepatopulmonary syndrome. The high degree of shunting and clinical history prompted a retrospective review of the V/Q scan performed a year earlier. It was noted that there had been increased radiotracer uptake in the kidneys, although those organs had not been specifically targeted during imaging. This subtle finding, if recognized earlier, could have been described as suspected and led to an earlier diagnosis of HPS. The patient remains on long term oxygen therapy while awaiting liver transplant evaluation, as only potential curative treatment. ***Conclusion:*** This case highlights the diagnostic complexity of HPS, especially in patients with coexisting pulmonary conditions, highlighting the importance of re-evaluating prior diagnostic tests when clinical findings remain unexplained. Severe hypoxemia in the context of liver disease should also prompt consideration of HPS, even in V/Q scans. Early recognition and a multidisciplinary approach are crucial for improving outcomes in these patients.

EP-1257

Posterior Reversible Encephalopathy Syndrome In a Child with Langerhans cell histiocytosis

M. Mehesen*, R. Shera;*
National Cancer Institute, Cairo University, Cairo, EGYPT.

Aim/Introduction: Posterior reversible encephalopathy syndrome (PRES) is related to a specific disorder of cerebrovascular auto-regulation of multiple etiologies. The presence of a typical neuro-image demonstrating vasogenic edema primarily affecting the posterior brain region is typically used to diagnose PRES. The clinical and neuro-radiological spectrum of childhood PRES appears to be wider than that of adult cases. In children with a range of neurological manifestations, PRES can be linked to different underlying comorbidities, medication use, and therapeutic approaches. Furthermore, atypical MRI findings outside of the normally posterior cerebral regions are more likely to occur in pediatric patients with PRES. ***Materials and Methods:*** A 3-year-old child with LCH on stratum III therapy developed seizures and underwent local MRI brain & 18 F-FDG PET/CT to assess the therapy response. ***Results:*** A local brain MRI study revealed bilateral posterior occipital cortical areas of bright FLAIR signal. An FDG PET/CT study showed detected FDG uptake at the temporal and parietal lobes as well as the right basal ganglia with NO definite corresponding CT changes with SUV max 6.3. Both studies suggested the possibility of Posterior Reversible Encephalopathy Syndrome (PRES). The therapy was discontinued, and supportive treatment was given; then follow-up by local brain MRI was done, and improvement had occurred. ***Conclusion:*** Posterior reversible encephalopathy syndrome (PRES) is a rare but serious complication in pediatric oncology patients. There is an obvious need to develop clinical criteria for PRES to enhance the diagnosis and care of PRES patients, especially in the pediatric oncology population.

EP-1258

18F-Choline PET-CT as a Decisive Tool for Detecting HCC Recurrence After locoregional therapy: When Morphological Imaging Falls Short

A. Genova, *F. Porcaro, L. Turchetta, M. Prisco, V. Piscopo, I. Annarumma, M. Catalano;*
Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Naples, ITALY.

Aim/Introduction: In hepatocellular carcinoma (HCC), post-treatment imaging is often challenging due to therapy-induced changes. 18F-Choline PET/CT can be a useful tool when conventional imaging is inconclusive, especially in well-differentiated tumors with limited FDG avidity. ***Materials and Methods:*** A 80-year-old man with a history of HCC multifocal treated with radiofrequency ablation and two TACE procedures presented a rising AFP level. Abdom TC showed near the site of retroaction and likely post-tratment change, an oval-shaped lesion with uncertain significance. Subsequentely 18F-Choline PET/CT revealed a focal area of increased uptake in the previously treated IV hepatic segment, near the hypodense area identified on CT scan consistent with tumor recurrence. Based on these findings of disease progression, the patient was selected for TARE treatment. ***Results:*** The case demonstrates how choline PET/CT can clarify uncertain imaging findings and detect viable tumor in treated HCC. Compared to FDG, choline shows higher uptake in well-differentiated HCC, making it a suitable tracer in selected cases. ***Conclusion:*** 18F-Choline PET/CT may significantly contribute to the post-treatment evaluation of HCC, particularly when AFP levels rise and morphological imaging is non-diagnostic. It may guide therapeutic decisions and improve patient selection for loco-regional therapies.

EP-1259

^{18}F-FDG PET/CT in Renal Cell Carcinoma Presenting as Urinary Retention with Extensive Local Invasion and IVC Tumor Thrombus: A Rare and Illustrative Case

A. Mahalik, *N. Kundu, A. Roy, G. Lalitha, J. Krishna P., S. Singh, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Renal cell carcinoma (RCC) with inferior vena cava (IVC) tumor thrombus is a recognized but relatively rare presentation, seen in 4-10% of cases. The role of ^{18}F-FDG PET/CT in differentiating bland from tumor thrombus and in staging advanced RCC is increasingly appreciated. However, FDG PET/CT findings in RCC with simultaneous IVC tumor thrombus, contiguous organ infiltration, and distant metastases—presenting with an atypical symptom like urinary retention—are uncommon and not widely illustrated. ***Materials and Methods:*** A 54-year-old male presented with urinary retention for 1 month. CECT suggested a left renal mass with IVC thrombus. FDG PET/CT was performed for further evaluation. Imaging revealed a large FDG-avid heterogeneous mass replacing the left kidney (19 x 15 x 13 cm), with extensive infiltration into the spleen hilum, diaphragm, abdominal aorta, pancreas, mesentery, and intercostal muscles. The mass involved the left proximal ureter and closely abutted multiple adjacent organs. A metabolically active soft tissue lesion was seen in the IVC (7.1 cm long), consistent with malignant thrombus. Additional FDG-avid metastases were noted in both lungs, liver (largest 3.0 x 2.1 cm), and renal capsular deposits. ***Results:*** This case highlights the role of FDG PET/CT in: Identifying and characterizing an FDG-avid IVC tumor thrombus. Delineating the full extent of contiguous local invasion, which may be underappreciated on conventional imaging. Uncovering multifocal distant metastases for accurate staging. The unusual clinical presentation (isolated urinary retention) in the context of widely metastatic disease underscores the diagnostic value of whole-body metabolic imaging. ***Conclusion:*** FDG PET/CT served as a comprehensive problem-solving modality in this rare presentation of RCC, enabling precise assessment of IVC tumor thrombus, extensive local infiltration, and distant metastases. This case reinforces its utility in staging and surgical planning, especially when clinical presentation is a typical and anatomical imaging may be inconclusive.

EP-1260

Primary breast malignancy presenting as paraneoplastic dermatomyositis role of 18fdg pet-ct in primary staging and response evaluation- a case report

J. Bal, *S. Jha, P. Dougall;*
[1]Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: Abstract Dermatomyositis is a rare complement mediated immune-modulatory disorder often presenting as skin rashes, papules and proximal muscles weakness. Its presentation as a paraneoplastic syndrome is not uncommon however its association with primary breast malignancy is an unusual presentation. As of 2019 only 22 cases of breast malignancy with dermatomyositis have been reported and 75% of the cases are in stage in III-IV. 18F FDG can play a crucial role in evaluating the quantum of disease at baseline, to assess response to treatment by visual assessment and semiquantative parameters and in cases of suspected relapse ***Materials and Methods:*** We present a case of 42 year old female, presenting with features of skin rashes, palpable nodules all over the body, fatigue and muscle weakness. On examination she was found to have palpable left breast mass and underwent lumpectomy. She was found to have Invasive ductal carcinoma of breast. 18 F FDG PET-CT was done which showed left breast mass with left axillary lymph nodes and diffuse FDG uptake in the entire visualized muscles. ***Results:*** She underwent 6 cycles of chemotherapy. Subsequently follow up FDG PET CT was done for response evaluation which showed complete metabolic resolution of left breast mass, axillary lymph nodes and FDG uptake in the muscles demonstrating complete metabolic response to therapy. ***Conclusion:*** Dermatomyositis as paraneoplastic syndrome appears to be associated usually with more-advanced breast cancer stage; however the presentation of such symptoms warrants to rule out malignancy. In such cases treatment of cancer alone is insufficient to adequately control the cutaneous and myopathic manifestations of dermatomyositis, which can significantly affect quality of life. A multidisciplinary approach, including close collaboration with rheumatologists and dermatologists, is therefore important in the diagnosis and management of oncology patients with dermatomyositis. 18F FDG can play an important role in baseline evaluation of quantum of disease, response evaluation and in case of suspected clinical relapse.

EP-1261

Incidentally diagnosed synchronous vaginal adenocarcinoma on SSTR imaging (68Ga DOTANOC) done for primary Gastric NET

J. Bal, *S. Jha;*
Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: SSTR imaging are done with various SSTR agents for SPECT and PET-CT imaging for staging and restaging of well differentiated (Grade 1 to Grade 3) neuroendocrine tumors, medullary carcinoma thyroid, pheochromocytoma and paraganglioma. It characterizes the tumor, stage the disease, evaluate response assessment and assist in selecting patients for PRRT. ***Materials and Methods:*** We present a case of 54 year old female who was recently diagnosed grade 1 NET of stomach on endoscopic biopsy and excision. She underwent whole body 68Ga DOTANOC scan for staging the disease. The scan revealed no abnormal SSTR expression in the stomach or any perigastric lymph nodes. However a note was made of post hysterectomy

status a large bulky vagina showing heterogenous enhancement on contrast enhanced CT scan acquired as part of the 68Ga DOTANOC scan. An MRI pelvis was suggested which showed a large mass measuring ~4.6x4.2cm in the vagina. Biopsy from the vagina was suggestive of adenocarcinoma. ***Results:*** As we advance in hybrid imaging techniques it is important to not just report on the molecular imaging but also corresponding CT images to look for any abnormality not expressing the injected radiopharmaceutical. ***Conclusion:*** This approach reflects on the importance of knowing the various aspects of oncoimaging and avoiding missing out any synchronous malignancies with different molecular expression.

EP-1262

Sacral Neurolymphomatosis In Refractory Diffuse Large B-Cell Lymphoma: Multimodal Imaging Including PET/CT and MRI For Diagnosis And CAR-T Response Monitoring

L. Henrich Malizia[1], *A. Roteta Unceta Barrenechea*[1], *F. Arraut Serrano*[1], *A. Garin Rodriguez*[1], *N. Etxabeguren Gallo*[1], *I. Cillero Etxebeste*[1], *B. Mendibil Esquisabel*[2], *I. Olazabal Eizaguirre*[2], *I. Zeberio Etxetxipia*[2], *V. Rodriguez Ortega*[1], *I. Sanchez Oscoz*[1], *S. Sanchez Eguiguren*[1], *I. Jauregui Larrea*[1], *G. Rodriguez Rodriguez*[1], *I. Leon Zubizarreta*[1], *A. Iztueta Iturbe*[1], *I. Lopez Sanchez*[1], *A. Gomez Lopez*[1];
[1]*Hospital Universitario Donostia - Onkologikoa, San Sebastian, SPAIN,* [2]*Hospital Universitario Donostia, San Sebastian, SPAIN.*

Aim/Introduction: Neurolymphomatosis (NL), a rare Diffuse Large B-Cell Lymphoma (DLBCL) complication, poses diagnostic challenges. Standard ^{18}F-FDG PET/CT plays a role in identifying suspicious metabolic activity, but MRI is often crucial for detailed anatomical assessment, underscoring the importance of multimodal imaging and clinical correlation. ***Materials and Methods:*** A 41-year-old male diagnosed (01/2024) with Stage IVB non-germinal centre DLBCL received 6 cycles of R-CHOP chemotherapy. At the end of treatment (05/2024), he developed severe sacral neuropathic symptoms. PET/CT scan (01/07/2024) revealed a focal area of intense hypermetabolism (SUVmax 8.58 g/ml) involving the left sacral nerve roots/foramina, highly suspicious for active NL, which was concordant with the patient's symptoms. An urgent lumbosacral MRI (10/07/2024) depicted extensive nerve root thickening/enhancement and an associated presacral mass, confirming diagnosis of sacral NL. Subsequent CT-guided biopsy of the mass confirmed persistent non-Germinal Center B-cell like (non-GCB) DLBCL, indicating primarily refractory disease. ***Results:*** Following bridging radiotherapy and standard lymphodepletion, the patient received Axicabtagene Ciloleucel (Axi-cel) infusion (09/2024). The only significant reported toxicity was Grade 1 Cytokine Release Syndrome, managed successfully with Tocilizumab and corticotherapy. Serial PET/CT scans (month 1, 3 and 6) demonstrated sustained Complete Metabolic Response at all previously involved sites (including metabolic normalisation of the NL focus). A control MRI at 2 months confirmed excellent morphological response with minimal residual left S3 root changes. Clinically, neuropathic symptoms resolved almost entirely, with only mild residual S1 hypoesthesia persisting at 6 months follow-up. ***Conclusion:*** This case illustrates the role of PET/CT scan in detecting metabolically active foci concerning for NL in patients with refractory DLBCL and concordant neurological symptoms, prompting confirmatory anatomical evaluation with MRI. It demonstrates the synergistic value of multimodal imaging (PET/CT and MRI) for accurate diagnosis and comprehensive monitoring of treatment response. The case also supports Axi-cel's efficacy in achieving durable metabolic remission, even in refractory DLBCL with complex extranodal presentations like NL.

EP-1263

Complete Resolution Of Severe Refractory Hypoglycaemia Following Lutetium-177 DOTATATE Peptide Receptor Radionuclide Therapy In A Metastatic Dual Insulinoma-Gastrinoma Pancreatic Neuroendocrine Tumour: A Case Report

L. Henrich Malizia[1], *A. Gomez Lopez*[1], *A. Roteta Unceta Barrenechea*[1], *F. Arraut Serrano*[1], *A. Garin Rodriguez*[1], *N. Etxabeguren Gallo*[1], *B. Sanchez Casi*[2], *M. Perez de Ciriza Cordeu*[2], *V. Rodriguez Ortega*[1], *I. Sanchez Oscoz*[1], *S. Sanchez Eguiguren*[1], *I. Jauregui Larrea*[1], *G. Rodriguez Rodriguez*[1], *I. Leon Zubizarreta*[1], *A. Iztueta Iturbe*[1], *I. Lopez Sanchez*[1], *I. Cillero Etxebeste*[1];
[1]*Hospital Universitario Donostia - Onkologikoa, San Sebastian, SPAIN,* [2]*Hospital Universitario Donostia, San Sebastian, SPAIN.*

Aim/Introduction: Malignant insulinoma is a rare Pancreatic Neuroendocrine Tumour (PNET) characterised by excessive insulin secretion, leading to severe hypoglycaemia. Managing hypoglycaemia is challenging due to its refractory nature and limited efficacy of conventional treatments such as diazoxide, somatostatin analogues, and chemotherapy. We report a case of a dual PNET (Gastrinoma-Insulinoma) presenting with life-threatening refractory hypoglycaemia that was successfully controlled with radionuclide therapy after failure of conventional treatment. ***Materials and Methods:*** A 51-year-old male's diagnostic evaluation included endoscopy, Computed Tomography (CT), tumour biopsy (well-differentiated Grade 1 [G1] PNET, Ki67 <3%), serum gastrin/Chromogranin A (CgA), and Somatostatin Receptor (SSR) scintigraphy (baseline/follow-up). Initial therapies were somatostatin analogues (Lanreotide 120 mg/28d), Everolimus, then diazoxide. Following Multidisciplinary Tumour Board consensus due to treatment failure, Peptide Receptor Radionuclide Therapy (PRRT) was given: four cycles of Lutetium-177 DOTATATE (177Lu-DOTATATE), 7.4 GBq/cycle (Mar-Sep 2024), with amino acid nephroprotection. Monitoring included clinical assessment, serial glucose/insulin/CgA levels, and follow-up SSR scintigraphy and CT. ***Results:*** The patient initially presented with persistent abdominal pain, significant weight loss, and symptoms suggestive of Zollinger-Ellison syndrome (heartburn, peptic ulcers, altered bowel habits). Subsequent workup confirmed a metastatic G1 PNET with elevated gastrin and CgA levels, consistent with the initial gastrinoma component. Baseline SSR scintigraphy showed high tumour uptake (Krenning score 3-4). Subsequently, the patient developed severe progressive hypoglycaemia refractory to diazoxide (nadir glucose 34 mg/dL), requiring hospitalisation and intensive support (Intravenous glucose, Nasogastric Tube feeding). Pre-PRRT scintigraphy confirmed persistently high Krenning 3-4 uptake with increased pancreatic receptor density. PRRT initiation led to an excellent and rapid clinical response: complete and sustained resolution of refractory hypoglycaemia was observed from the first cycle, enabling progressive and complete withdrawal of intensive support and diazoxide. Glucose levels normalised, and serum insulin dropped (from crisis peaks >30 µU/mL to sustained normalised levels <12 µU/mL). Euglycaemia has been maintained post-initial PRRT. Treatment was well-tolerated (mild, transient Grade 1-2 haematological toxicity). Twelve-month follow-up SSR scintigraphy showed stable disease. Additionaly, subsequent CT scan (15 months), revealed a decrease in size of liver metastases and a discrete decrease in pancreatic involvement and associated tumoral thrombosis, suggesting delayed morphological response. ***Conclusion:*** PRRT with 177Lu-DOTATATE provided safe, well-tolerated, and effective treatment, resulting in rapid and persistent remission of life-threatening refractory hypoglycaemia in this metastatic dual PNET case. PRRT represents a promising treatment option, controlling severe hypoglycaemic episodes refractory to conventional therapies, achieving disease control (stabilisation/slight regression), and offering a valuable alternative to conventional treatments.

EP-1264

Renal involvement in diffuse large B-cell lymphoma detected by ^{18}F-FDG PET/CT: analysis of three clinical cases

J. Charfi, *H. Boudriga, R. Sfar, K. Ayed, M. Nouira, K. Chatti; Sahloul Hospital, Sousse, TUNISIA.*

Aim/Introduction: Diffuse large B-cell lymphoma (DLBCL), the most common non-Hodgkin lymphoma subtype, is aggressive and often involves extranodal sites, typically the skin, small intestine, and stomach. Primary renal involvement is rare. ^{18}F-FDG PET/CT is essential for detecting and evaluating extranodal disease. ***Materials and Methods:*** This retrospective descriptive study includes three cases of DLBCL with renal involvement, followed over five years at the Nuclear Medicine Department of Sahloul University Hospital. All underwent at least one ^{18}F-FDG PET/CT using a standardized protocol. Disease evaluation followed the Deauville scale and Ann Arbor/Lugano staging systems. ***Results:*** A 33-year-old male was diagnosed with stage IV diffuse large B-cell lymphoma (DLBCL) after detection of a mediastinal mass and pulmonary nodules. Initial ^{18}F-FDG PET/CT showed lymph node, lung, and persistent renal involvement despite diuretic administration. He received four R-CHOP cycles, achieving interim complete metabolic response (CMR). After four additional cycles, end-of-treatment PET/CT confirmed complete remission (CR).A 42-year-old female presented with widespread nodal and tumor involvement, including bilateral renal masses and progressive renal failure. Initial ^{18}F-FDG PET/CT confirmed pleuropulmonary, peritoneal, and renal involvement. Classified as unfavorable stage IV, she received 8 R-CHOP cycles and 4 intrathecal treatments, with clinical improvement. However, end-of-treatment PET/CT revealed metastatic progression (Lugano). A fatal outcome was observed despite salvage therapy. FDG PET/CT showed frontal tumor involvement and multivisceral lymphomatous disease, including bilateral renal cortical hypertrophy (SUVmax 14.5). Classified as high-risk stage IV, R-CHOP therapy was initiated. ***Conclusion:*** Physiological ^{18}F-FDG renal uptake complicates detection of pathological involvement. Techniques such as delayed imaging or contrast-enhanced studies help differentiate tumors from normal structures. Renal involvement is an independent risk factor for CNS relapse, requiring close monitoring. ***References:*** Inayat F, Bokhari MR, Mansoor A. Primary renal lymphoma: a comprehensive review of the pathophysiology, clinical presentation, imaging features, management and prognosis. EP-1265

The Diagnostic Value of Bone Scan in Tertiary Syphilis With Skeletal Involvement

J. Duarte[1], *A. Marques*[1,2], *J. P. Carvalho*[1], *F. Abreu*[1,2], *S. Pintão*[1]; [1]*Unidade Local de Saúde de Lisboa Ocidental, Lisbon, PORTUGAL,* [2]*Instituto de Medicina Nuclear da Faculdade de Medicina de Lisboa, Lisboa, PORTUGAL.*

Aim/Introduction: Syphilis, caused by Treponema pallidum, remains a significant global health concern with rising incidence. Musculoskeletal involvement is relatively rare and more commonly associated with congenital and tertiary stages. Osseous lesions in tertiary syphilis can mimic inflammatory or systemic diseases with bone involvment, often leading to diagnostic delays. ***Materials and Methods:*** We present the case of a 46-year-old woman with a history of HIV-1 infection, past HCV infection, and active intravenous drug use, who presented with a one-month history of headache, visual and auditory disturbances, and diffuse limb tenderness. The patient was admitted to the infectious diseases department. Serologic testing revealed positive Treponema pallidum antibodies and a high VDRL titer. Cerebrospinal fluid analysis confirmed CNS involvement, supporting the diagnosis of secondary/tertiary syphilis. Limb X-rays and head CT revealed lytic bone lesions with periosteal reaction, raising suspicion for periostitis or osteomyelitis. To further assess the extent of skeletal involvement, a whole-body bone scintigraphy was performed. ***Results:*** A whole-body bone scan was acquired two hours after intravenous injection of [^{99m}Tc]Tc-HDP, along with a SPECT/CT of the lower limbs. The scan revealed increased tracer uptake in the frontal bone, clavicles, left humerus, both radii and ulnae, left hand, both tibiae, and the left fibula. The latter corresponded to subcortical lytic lesions with periosteal reaction on CT. These findings confirmed extensive osseous involvement due to syphilis. The patient completed a 14-day course of intravenous benzylpenicillin. A follow-up bone scan showed a marked decrease in tracer uptake in the previously involved sites, consistent with clinical improvement and positive treatment response. ***Conclusion:*** This case highlights the importance of recognizing bone involvement as a manifestation of tertiary syphilis, particularly in high-risk patients. Bone scintigraphy was crucial for delineating the full extent of skeletal disease and for monitoring therapeutic response. A comprehensive, multimodal diagnostic approach—integrating clinical findings, serology, and advanced imaging—is essential for timely and accurate diagnosis and effective management of syphilitic bone disease.

EP-1266

Uncommon penile metastasis emerges in patient with mCRPC during Radium223 radioligand therapy : A Rare Case Highlighted by PSMA PET/CT

D. Nakro[1], *L. Augusto*[2], *F. Nouhaud*[3], *S. Makhloufi-martinage*[4], *D. Tonnelet*[1]; [1]*Service de médecine nucléaire, Centre Henri Becquerel, Rouen, FRANCE,* [2]*Département d'oncologie urologique et digestive, CHU Rouen, Rouen, FRANCE,* [3]*Service d'Urologie, Clinique du Cèdre, Bois Guillaume, FRANCE,* [4]*Service d'oncologie médicale, Clinique Saint Hilaire, Rouen, FRANCE.*

Aim/Introduction: Penile metastases from prostate cancer represent a highly uncommon and often under-recognized site of disease dissemination, typically associated with advanced or castration-resistant stages.We present an uncommon penile metastasis in patient with metastatic Castration Resistant Prostate Cancer (mCRPC) while undergoing Radium 223 radioligand therapy (RLT). ***Materials and Methods:*** A 72-year-old man was diagnosed in 2012 with Gleason [4+3], ISUP 3, extracapsular extension, BRCA2 somatic mutation prostate cancer and underwent radical prostatectomy with pelvic lymph node dissection, followed by androgen deprivation therapy after biochemical recurrence. In 2021 he developed mCRPC and received several lines oftreatment, including hormone therapy (enzalutamide), chemotherapy (docetaxel), targeted therapy (olaparib), 177Lu PSMA 617 RLT and was referred in January 2025 for Radium 223 RLT. After two Radium administrations of 4 MBq every 4 weeks and despite clinicalresponse on bone metastasis patient developed a painful lump in the groin with episodes of macroscopic hematuria. Of note, patient had no priapism. ***Results:*** [68Ga]Ga-PSMA 11 PET/CT (PSMA PET) was performed and revealed compared to preRadium 223 PSMA PET a dissociated response, including new metastatic lesions in the right hemipelvis, penis, and supradiaphragmatic/ subdiaphragmatic lymph nodes while stabledisease was noted in the lombo-aortic area and skull base and a partial metabolic response was observed in the sacrum and left hemipelvis.The penile metastases involved both corpora-cavernosa SUVmax 12.1, TMTV 16.8 cm3,TLG 87.3 cm3.Pelvic ultrasound and pelvic MRI were concordant with the PSMA PET findings. Radium 223 was interrupted patient was re-challenged with Androgenreceptor pathway inhibitors(ARPI). Patient is still alive to this day.Penile metastasis, although extremely rare in prostate cancer and have

been described on PSMA and FDG PET. The physio pathological mechanisms of metastatic spread remains debated, with retrograde venous and lymphatic dissemination being the most widely acceptedhypotheses. The differential diagnosis is Peyronie's syndrome. However our case , is, to the best of our knowledge the first case of penile progression during Radium 223 RLT. ***Conclusion:*** This case highlights a rare occurrence of penile metastasis in patient with highly pretreated mCRPC while undergoing Ra223 RLT. Despite its rarity, penile metastasis can emerge in advanced stages, and advanced imaging plays a critical role in detecting such atypical sites. ***References:*** -Mansbridge MM, Strahan A, Parker J, Rhee H. PSMA-PET/CT-avid metastatic prostate cancer to the penis.BMJ Case Rep. 2020 Mar 24;13(3):e233522. doi: 10.1136/bcr-2019-233522. PMID: 32209576; PMCID: PMC7103797.

Functional Evaluation of Musculoskeletal Infections with ^{99m}Tc-Ciprofloxacin SPECT/CT in Complex Patients Undergoing Limb Amputation: Case Series

V. Heringer, *B. Alencar, T. Agnello, M. Osmak, R. Tineo, E. Etchebehere, C. Ramos, M. Lima, B. Amorim, A. Santos;*
UNICAMP, Campinas, BRAZIL.

Aim/Introduction: Chronic musculoskeletal infections such as diabetic foot and post-traumatic osteomyelitis pose significant diagnostic challenges, particularly in distinguishing between sterile inflammation and active bacterial infection. ^{99m}Tc-ciprofloxacin SPECT/CT targets bacterial DNA gyrase and has been studied as a functional imaging tool in such cases[1,2]. Despite limitations in specificity, it remains a potentially valuable modality in selected clinical scenarios[3,4]. ***Materials and Methods:*** Case 1: A 57-year-old male with a 25-year history of chronic femoral osteomyelitis underwent multiple debridements and intramedullary procedures, culminating in a transfemoral amputation. Case 2: A 51-year-old insulin-dependent diabetic patient underwent transtibial amputation after partial foot amputations due to infection. Both patients underwent dynamic perfusion imaging, followed by planar scans at 90 and 270 minutes and SPECT/CT, also, MDP-SPECT/CT were performed for additional parameters. ***Results:*** In Case 1, preoperative SPECT/CT showed intense uptake in the distal two-thirds of the femur and adjacent soft tissues, consistent with active infection[1,2], also matching with bone scintigraphy findings. Intraoperative cultures confirmed Staphylococcus aureus and Pseudomonas stutzeri, and the patient had a favorable clinical recovery. In Case 2, SPECT/CT revealed moderate uptake in soft tissues near the 2nd and 3rd metatarsals without bone involvement, ruling out osteomyelitis[2,4] as bone scintigraphy also confirmed. The lesion-to-background ratio remained below the limit of 11:2 for active infection[3], supporting a diagnosis of soft tissue inflammation. ***Conclusion:*** ^{99m}Tc-ciprofloxacin SPECT/CT was clinically useful in distinguishing active infection from sterile inflammation in two complex patients with musculoskeletal infections. This modality provided decisive information for surgical and therapeutic management, despite its debated specificity in some contexts[1-4]. ***References:*** 1) Britton KE, et al. Dynamic [68Ga]Ga-DOTANOC LAFOV PET/CT in a Synchronous Ileum Metastatic NET

E. Fortunati[1], *I. Brusa*[1], *G. Bianciardi*[2], *M. Di Franco*[2], *D. Dall'Olio*[3], *M. Assenza*[4], *D. Campana*[5], *E. Andrini*[5], *C. Ricci*[6], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [3]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY,* [4]*Professional Development and Implementation of Research in Health Professional Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Department of Medical and Surgical Sciences (DIMEC), Medical Oncology Unit, Alma Mater Studiorum-University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [6]*Department of Internal Medicine and Surgery (DIMEC), Alma Mater Studiorum, University of Bologna, Bologna, ITALY.*

Aim/Introduction: A 68y.o. female patient with a history of surgically-treated sigmoid adenocarcinoma (left hemicolectomy and terminal ileostomy) was referred to the local Oncology Unit to investigate a CT-detected mass of the pancreatic head. Abdominal-MRI also showed a 5mm liver lesion (IV segment), suspicious for secondary lesion. Endoscopic-ultrasound with fine needle biopsy documented a NET G2 lesion of the pancreatic head, likely of intestinal origin (Ki67:4%). ***Materials and Methods:*** [68Ga]Ga-DOTANOC PET/CT was performed for staging and after surgery. PET/CT scans were acquired as a 60' dynamic acquisition on LAFOV scanner (uExplorer, United Imaging). The static images were reconstructed with last 5'list mode acquisition. VOIs were manually drawn on suspect lesions and reference tissues. Time-to-activity curves (TACs) were fitted using two different graphical models, i.e. Patlak (for irreversible model) and relative equilibrium (RE) (for reversible model). Mean absoluted-scaled error (MASE) and Akaike Information Criterion (AIC) were utilized to perform model selection for each VOI. ***Results:*** PET/CT confirmed intense and focal uptake at the known pancreatic head mass (SUVmax=23.2) and liver lesion (SUVmax=12.7; IV segment). PET/CT also revealed a mass showing intense uptake near the ileocecal valve (SUVmax=32.9) and a smaller cutaneous/subcutaneous nodule with intense uptake (SUVmax=30.7) within the ileostomy loop in the anterior right pelvic wall. Milder and diffuse uptake was also evident at the ileostomy cutaneous site (SUVmax=3.3), compatible with reactive/inflammatory nature. Dynamic assessment demonstrated a better-fit using the Patlak model and higher Ki at NET lesions level (ileum=0.1, pancreas=0.1, liver=0.05) as compared to the background (healthy liver=0.04, healthy pancreas=0.03). The reactive/inflammatory finding on the ileostomy showed a Ki value lower (Ki=0.02) than both the tumour lesions and the background. The patient underwent ileocecal resection and construction of ileocolic anastomosis: both ileum lesions resulted positive for ileum NET G2, Ki-67:4%. Cold somatostatin analogue treatment was initiated. Post-surgical [68Ga]Ga-DOTANOC PET/CT showed disease stability of the known lesions in the head of the pancreas and in the IV liver segment, while the liver background biodistribution was significantly reduced. In the post-surgical dynamic assessment, RE reported the best fit, likely due to cold somatostatin analogue treatment. Accordingly, NET lesions showcased higher DV values (ileum=5.8, pancreas=3.5) compared to background (healthy liver=2.5, healthy pancreas=2.1). ***Conclusion:*** [68Ga]Ga-DOTANOC-LAFOV PET/CT can be useful for the characterisation of small-sized NET liver lesions. Dynamic data may highlight the different behaviour of NET lesions as compared to background and inflammation.

EP-1269

Complementary Imaging and Targeted Therapy in Progressive Metastatic MTC: A Clinical Case

R. Marão, *D. Barbosa, D. Silva, N. Vasconcelos, S. Gil Santos, R. Calheiros, J. Ferro, S. Fontão de Castro, I. Inácio, R. Ferreira, A. Santos, I. Lucena Sampaio;*
Instituto Português Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor arising from parafollicular C cells, frequently presenting with metastatic disease at the time of diagnosis. Positron Emission Tomography/Computed Tomography (PET/CT) using different radiopharmaceuticals —particularly [^{18}F]FDG, [^{18}F]FDOPA, and [^{68}Ga]Ga-DOTA-SST— has demonstrated an increasingly important role in the assessment of this pathology.

These imaging modalities have proved to be sensitive and accurate in detecting MTC recurrences/metastases, evaluating clinical and biological tumor aggressiveness and guiding treatment strategies. The treatment of metastatic MTC involves a multimodal approach, including surgery, local ablative therapies, tyrosine kinase inhibitors (TKIs), and, in selected cases, peptide receptor radionuclide therapy (PRRT). ***Materials and Methods:*** We present the case of a 64-year-old woman with stage IV medullary thyroid carcinoma, diagnosed in 2011, presenting with cervical and mediastinal lymph node metastases. She underwent total thyroidectomy with cervical lymph node dissection, but mediastinal lymph node metastases persisted postoperatively. In 2017, the patient showed disease progression with multifocal hepatic metastases documented on CT. The patient underwent two sessions of hepatic embolization in November 2017 and November 2021, resulting in radiological stabilization of the lesions up to the present. In 2023, a rise in tumour markers (CEA and calcitonin) was observed, which, despite stable findings on CT and MRI, also appeared on [^{68}Ga]-DOTA-TOC PET/CT, which demonstrated new evidence of disease progression, including local tumor recurrence and newly identified supradiaphragmatic lymph node and bone metastases. These lesions showed no significant uptake on [^{18}F] FDG-PET/CT. As a result of this progression, in December 2023, the patient was referred for treatment with ^{177}Lu-DOTATATE, receiving four cycles of therapy at a median activity of 7400 MBq per cycle. The treatment was well tolerated, with no significant toxicity. ***Results:*** Post-treatment evaluation demonstrated preserved overall clinical condition, a reduction in serum calcitonin levels (from 3451 to 2706 pg/mL), dimensional reduction of the thyroid nodule and imaging stability on follow-up [^{68}Ga]-DOTA-TOC PET/CT. ***Conclusion:*** This case highlights the complementary roles of [^{68}Ga]-DOTA-TOC PET/CT and [^{18}F]FDG PET/CT in tumor phenotyping and guiding personalized, multimodal treatment strategies in patients with metastatic MTC. Moreover, this case illustrates the potential of PRRT as an effective therapeutic option for both locoregional and systemic disease control, either as an isolated treatment or in combination with other modalities, in selected patients.

EP-1270

A Rare Case of Abernethy Type I Malformation: Is FDG PET/CT a Valuable Tool in Pre-Transplant Evaluation of Hepatic Lesions?

I. Ozturk, *B. Esen Akkas, M. Kaya;*
S.B.U Basaksehir Cam ve Sakura Sehir Hastanesi, Istanbul, TÜRKIYE.

Aim/Introduction: Abernethy Malformation Type 1(AMT1) is a rare and severe congenital extrahepatic portosystemic shunt,characterized by the complete absence of intrahepatic portal venous flow due to the diversion of portal blood directly into the systemic circulation.Nodular liver lesions are observed in nearly half of the reported AMT1 cases,due to the absence of portal flow and compensatory increased hepatic arterial perfusion.The most common lesion is focal nodular hyperplasia(FNH),though others,including nodular regenerative hyperplasia,hepatoblastoma,hepatic adenoma and hepatocellular carcinoma(HCC) have also been documented.Liver transplantation is the treatment of choice since surgical correction is not feasible in the absence of portal venous flow.Routine imaging surveillance is essential for monitoring hepatic lesions,with magnetic resonance imaging(MRI) being the preferred modality.However, f18-fluorodeoxyglucose positron emission tomography-computed tomography(FDG PET-CT) may be useful due to the potential risk of malignant transformation. ***Materials and Methods:*** We present the case of an 18-year-old female diagnosed with AMT1,who had been under regular MRI follow-up for multiple FNH.Prior to liver transplantation,the patient underwent FDG PET-CT to assess the metabolic activity of the lesions. ***Results:*** The scan revealed four hepatic parenchymal mass lesions,one of which showed intense FDG uptake,while the others demonstrated low metabolic activity similar to surrounding parenchyma.Given the potential for malignant transformation,histopathological evaluation of the hypermetabolic lesion was recommended.Fine-needle aspiration biopsy indicated benign features and the patient subsequently underwent liver transplantation.Postoperative histopathological evaluation revealed no definitive evidence of malignancy.The lesions were described as well-differentiated hepatocellular neoplasia with steatohepatitic,pelioid and focal nodular hyperplasia-like areas.The liver parenchyma showed degeneration,mild portal fibrosis and inflammation,sinusoidal dilatation and congestion.No lymphovascular invasion was found. The nodules exhibited heterogeneous morphology with minimal atypia.While immunohistochemistry did not support HCC,due to the absence of portal areas,differential diagnoses such as hepatic adenoma,dysplastic nodules,macroregenerative nodules and well-differentiated HCC could not be definitively excluded.The patient is currently in the 4th month of clinical follow-up with no lesions detected on postoperative imaging. ***Conclusion:*** The hypermetabolic parenchymal lesion suggested its histopathological behavior might differ from the others,implying the possibility of aggressive malignancy.However, histopathological analysis revealed no significant differences between lesion characteristics or definitive evidence of malignancy.This underscores that high FDG uptake does not always indicate malignancy;FNH or other well-differentiated neoplastic lesions can also show high glucose metabolism.Still, lesions with high FDG uptake should always be recommended for histopathological evaluation to assess the malignant transformation.This case is a unique clinical observation examining the role of FDG PET/CT in determining the metabolic characteristics of hepatic lesions in AMT1.

EP-1271

Sacral Malignant Proliferating Trichilemmal Tumor: A Rare Case Evaluated by F-18 FDG PET/CT

H. Eroglu Elden, *A. Akbulut, K. Demirel, G. Koca, M. Korkmaz;*
University of Health Sciences, Ankara Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Proliferating trichilemmal tumors (PTTs) are rare neoplasms that originate from the outer root sheath of hair follicles. In literature, they are more frequently observed in women and generally located on the scalp. Most PTTs show benign behavior, with local recurrence and distant metastasis are not common. In this report, we present a rare case of metastatic malignant PTT (MPTT) located in sacral region, evaluated by F-18 fluorodeoxyglucose positron emission tomography/computed tomography (F-18 FDG PET/CT). ***Materials and Methods:*** A 47-year-old male patient presented to the dermatology clinic with complaints of pain and ulceration in the sacral area. Pelvic magnetic resonance imaging (MRI) revealed a large soft tissue mass invading sacral bone and gluteal muscles within the intergluteal region. An incisional biopsy of sacral lesion demonstrated neoplastic cells beneath the stratified squamous epithelium, which show squamous differentiation with keratinization, pleomorphic nuclei, eosinophilic clear cytoplasm, and atypical mitotic figures, consistent with diagnosis of malignant PTT. The patient underwent F-18 FDG PET/CT for further evaluation. ***Results:*** F-18 FDG PET/CT imaging demonstrated pathological FDG uptake in the soft tissue mass extending from skin to anal canal, with invasion of bilateral gluteal muscles and destructive changes in sacrum and coccyx (SUVmax: 11.49). Additionally, focal metastatic FDG uptakes were noted within bilateral gluteal muscles. Although metastases are rarely reported in MPTT, pathological FDG uptakes were also observed in left obturator, bilateral external iliac and inguinal multiple lymph nodes (SUVmax: 6.78), which were indicative of nodal

metastases. During follow-up, the patient had died approximately eight months after diagnosis. ***Conclusion:*** Metastatic malignant PTT detected in the sacral region is an extremely rare tumor. F-18 FDG PET/CT is a valuable imaging technique in these rare cases by identifying nodal or distant metastases, which may not be apparent through conventional imaging modalities.

EP-1272

Pitfall in 18F-FES PET/CT: A Case of ^{18}F-FDG Avid Hepatic Metastasis Masked by Physiological Tracer Uptake in ER-Positive Breast Cancer

A. Mahalik*, N. Kundu, K. Jain, M. Tripathi, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: [18F] FES PET/CT is increasingly used for imaging estrogen receptor (ER) expression in breast cancer, particularly for lesion characterization and therapy guidance. However, physiological uptake in certain organs can pose interpretational challenges, leading to false-negative results. ***Materials and Methods:*** A 47-year-old female with known ER-positive invasive ductal carcinoma, post chemotherapy and post trastuzumab therapy, was referred for response assessment. On [^{18}F]FDG PET/CT, a solitary hepatic lesion in segment VI was identified with an SUVmax of 3.17 and SUVmean of 1.53, without any significant anatomical correlate on CT. However, the corresponding [18F]FES PET/CT showed intense physiological tracer uptake in the liver, obscuring the lesion completely and rendering it undetectable on visual assessment. ***Results:*** This case highlights a crucial diagnostic limitation of [18F]FES PET/CT in detecting hepatic metastases due to high physiological hepatic uptake. Despite being ER-positive, the lesion would have been missed if solely assessed on FES PET/CT. Furthermore, the absence of CT changes could potentially delay detection in centers relying only on CT. ***Conclusion:*** [18F]FES PET/CT has inherent limitations in liver lesion detection due to physiological hepatic uptake. FDG PET/CT remains a complementary modality, especially for detecting small, early metastatic lesions with minimal anatomical distortion. This case underscores the importance of multimodality imaging in comprehensive metastatic assessment and treatment planning in ER-positive breast cancer.

EP-1273

Chilaiditi Syndrome Mimicking Hepatic Metastases on FDG PET/CT in a Patient with Metastatic Lung Adenocarcinoma

A. Giarratana[1]*, M. Larson*[1]*, K. Capaccione*[2]*;*
[1]*University of Wisconsin - Madison, Madison, WI, WI, UNITED STATES OF AMERICA,* [2]*Columbia University, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: Chilaiditi syndrome is a benign anatomical variant in which a loop of colon becomes interposed between the liver and diaphragm. [1] Though asymptomatic, it may lead to imaging findings that resemble hepatic pathology, particularly in fused PET imaging. [2] In oncology patients undergoing FDG PET/CT, such findings can raise concern for metastatic disease and influence treatment decisions. [3] This case highlights a potential interpretive pitfall in a patient with advanced lung adenocarcinoma. ***Materials and Methods:*** A 74-year-old male with metastatic lung adenocarcinoma to bone and pleura, previously treated with systemic therapy and enrolled in a clinical trial, underwent FDG PET/CT for restaging during an inpatient admission for pain and swelling related to treatment side effects. Maximum intensity projection (MIP) images showed a focus of intense radiotracer uptake in the right upper quadrant, initially raising concern for hepatic metastasis in the setting of known widespread disease. ***Results:*** Review of the cross-sectional fused PET/CT images revealed interposition of the colon anterior to the liver, with radiotracer uptake localized to the colon rather than the liver. These findings were consistent with benign Chilaiditi syndrome. Correlation with CT helped avoid misinterpretation, and the scan was ultimately interpreted as showing stable metastatic disease without new hepatic involvement. ***Conclusion:*** Chilaiditi syndrome can produce false-positive findings on FDG PET/CT due to physiologic bowel uptake overlying the liver. In patients with metastatic cancer, this may mimic hepatic metastases and lead to misclassification of disease status. Other anatomical variants, such as ectopic or horseshoe kidneys or urinary diversion anatomy, can also result in false-positive findings if not properly identified on cross-sectional imaging. [4] This case highlights the importance of careful CT correlation to avoid diagnostic errors and unnecessary changes in clinical management. It also underscores the risk of interpreting PET or SPECT studies without corresponding anatomic imaging, particularly in patients with variant anatomy, due to lack anatomic correlation. This case reinforces the value of hybrid imaging and the need to recognize benign anatomical variants in nuclear medicine. ***References:*** 1.Mendes, E., et al., Chilaiditi Sign and Syndrome as a Finding in the Emergency Room: A Case Report. EP-1274

Osteonecrosis of the Jaw Detected on Bone Scan in a Patient with Metastatic Breast Cancer Receiving Denosumab

A. Giarratana[1]*, M. Larson*[1]*, K. Capaccione*[2]*;*
[1]*University of Wisconsin - Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*Columbia University, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: Osteonecrosis of the jaw (ONJ) is a known potential complication of antiresorptive therapies such as denosumab, which is used to treat osteoporosis and has played an important role in cancer patients with osseous metastases. [1-3] ONJ may present with exposed bone or more obvious symptoms in later stages, but early on, patients may be asymptomatic or have only nonspecific signs such as jaw pain or swelling. As a result, ONJ may go unrecognized without imaging or dental evaluation. [4] In such cases, it may be incidentally detected on nuclear medicine bone scintigraphy, where it can appear as mandibular uptake, potentially mimicking osseous metastasis or infection. [5] Awareness of this imaging pattern is essential to avoid confusion with malignancy and ensure appropriate clinical follow-up. ***Materials and Methods:*** A 76-year-old woman with metastatic triple-negative breast cancer involving the liver and bone, on treatment with denosumab and capecitabine, underwent a routine bone scan as part of disease surveillance. At the time of imaging, she reported no jaw pain, dental complaints, or recent dental procedures. There was no clinical suspicion for osteonecrosis, and her scan was performed in the context of routine oncologic follow-up. ***Results:*** The nuclear medicine bone scintigraphy demonstrated diffusely increased uptake of the right side of the jaw, a pattern suggestive of osteonecrosis of the jaw. No corresponding clinical concern was documented at the time of imaging. The findings were interpreted in the context of denosumab use and communicated to the care team. ***Conclusion:*** This case illustrates how nuclear medicine bone scintigraphy can detect ONJ as an incidental finding in asymptomatic patients on denosumab. Recognizing this imaging pattern can help avoid confusion with osseous metastasis and supports timely referral for dental evaluation and appropriate clinical management. ***References:*** 1.Bełch, M., et al., Analysis of potential risk factors for the development of medication-related osteonecrosis of the jaw. EP-1275

A case of invasive fibromatosis misdiagnosed as a metastatic tumor

X. Li[1,2];
[1]Department of Nuclear Medicine, the First Hospital of Shanxi Medical University, Taiyuan, CHINA, [2]Collaborative Innovation Center for Molecular Imaging of Precision Medicine Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: The patient is a 55-year-old female. She was admitted to the hospital with a left lung nodule that was identified during a physical examination. A meticulous CT scan of the chest revealed the following findings:The presence of a soft tissue nodule exhibiting moderate enhancement in the lingual segment of the upper left lobe, which prompts consideration of the possibility of lung cancer. The second finding is an irregular soft tissue density shadow in the left adrenal region. To improve the examination, it is recommended that further evaluation be conducted. Consequently, the patient underwent adrenal enhancement CT and enhancement MRI, which revealed progressive enhancement in the left adrenal gland and did not exclude the presence of a metastatic tumor.^{18}F-FDG PET/CT showed: The initial findings indicate an elevated level of FDG metabolism in the soft tissue nodule located in the lingual segment of the left upper lobe of the lung. This observation prompts the consideration of lung cancer as a potential underlying diagnosis. The second finding is the presence of an irregular soft tissue shadow in the left adrenal region, accompanied by mildly increased FDG metabolism. The presence of a metastatic tumor is not excluded. To elucidate the nature of the lesion, the patient underwent a series of surgical procedures, including resection of the lingual segment of the upper lobe of the left lung and resection of the retroperitoneal mass. The pathological diagnosis revealed two distinct entities: low differentiated adenocarcinoma in the lingual segment of the upper lobe of the left lung and a morphology combined with immunohistochemistry phenotype consistent with invasive fibromatosis in the retroperitoneal mass. Immunohistochemical findings (retroperitoneal mass): The following markers were observed: β catenin (nuclear +), SMA (foci +), Desmin (+), Ki67 (3% +), SOX10 (-), S100 (-), STAT6 (-), CD34 (-), CKpan (-), Calretinin (+), WT1 (-), D2-40 (-). A review of the patient's medical history reveals that they underwent a total adrenalectomy three years prior for left adrenocortical hyperplasia. ***Conclusion:*** This observation underscores the imperative for comprehensive patient histories to be obtained.

EP-1276

Intense FDG Uptake Mimicking Hepatic Metastasis on PET/CT: Focal Hepatic Steatosis

F. Yildiz Kabaca[1], *M. Acar Tayyar*[1], *M. Biçen Altın*[1], *T. Özülker*[1], *T. Oğuzsoy*[2];
[1]Department of Nuclear Medicine, University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, TÜRKIYE,
[2]Department of Pathology, University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: PET/CT imaging is commonly used for staging in patients with primary malignancies and detecting metastases. The liver is a common site for metastases, especially in cancers like colorectal, breast, and prostate, which are among the most commonly diagnosed malignancies in the general population. Increased FDG uptake can also be seen in various benign lesions and should be reported with caution as it affects patient survival. The most common condition affecting the physiological FDG distribution in the liver is hepatosteatosis, because it causes a difference in attenuation. In hepatosteatosis, FDG uptake is expected to decrease in fat-rich areas and cause a heterogeneous distribution of activity in the parenchyma.In this case, we aimed to highlight the fact that, unlike usual practice, very intense FDG uptake can be seen in hepatosteatosis. ***Materials and Methods:*** The patient was administered 0.15 mCi/kg FDG intravenously. PET/CT imaging was obtained from wholebody at 60th minute after the injection. ***Results:*** A 41-year-old woman with operated breast cancer underwent PET/CT imaging for re-staging with suspicion of metastasis,after a newly developed surrenal lesion was detected on abdominal CT imaging.PET/CT imaging demonstrated a hypodense lesion measuring approximately 2 cm with moderate FDG uptake in the left adrenal gland.In addition, a well-defined,intensely hypermetabolic, hypodense mass lesion was observed,occupying almost the entire left hepatic lobe.The lesion was considered suspicious for either a primary hepatic malignancy or metastatic carcinoma, and further evaluation with MR imaging and histopathological confirmation was recommended.On contrast-enhanced abdominal MR imaging,the surrenal gland was interpreted in favor of metastasis,while the lesion site in the liver was consistent with atypical steatosis.US-guided biopsy was performed due to the very intense FDG uptake observed in the lesion on PET/CT imaging.Histopathological examination revealed marked macrovesicular and microvesicular steatosis along with prominent balloon degeneration in the parenchyma,findings that were primarily consistent with steatohepatitis.Surgical treatment was decided as the patient only had a surrenal metastasis. ***Conclusion:*** Liver metastases are critical for guiding treatment decisions and predicting survival. In the literature, steatosis is typically associated with decreased FDG uptake.Previous studies have reported that focal FDG uptake in small areas of fatty liver in patients with known extrahepatic malignancies can be misdiagnosed as hepatic metastases, a finding that is exceptionally rare, as observed in our case.This may be attributed to increased Kupffer cell activity in these regions, which is consistent with the proposed pathophysiological mechanism in the literature, involving inflammation induced by hepatic steatosis and subsequent Kupffer cell activation.

EP-1277

Rapidly Progressive Cutaneous Metastases in Recurrent Breast Cancer Detected on F-18 FDG PET/CT

H. Eroglu Elden, *K. Demirel, A. Akbulut, G. Koca, M. Korkmaz;*
University of Health Sciences, Ankara Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Cutaneous metastasis is a rare situation and indicative of poor prognosis in oncologic patients. Among malignancies, cutaneous metastasis is mostly observed in breast cancer. F-18 FDG PET/CT is a critical imaging method for detecting and monitoring cutaneous and subcutaneous metastases. We present a rare case of rapidly progressive cutaneous metastases in recurrent breast cancer, demonstrated by F-18 FDG PET/CT. ***Materials and Methods:*** A 61-year-old female patient with a history of invasive ductal breast carcinoma (ER+, PR+ and HER2neu+), treated with left modified radical mastectomy and chemoradiotherapy in 2019, referred to re-staging with F-18 FDG PET/CT due to the detection of a mass in her right breast. ***Results:*** Her F-18 FDG PET/CT scan showed pathological uptake of F-18 FDG in subcutaneous nodular lesions located in the left mastectomy region, the right breast mass, and the right axillary lymph nodes. Furthermore, abnormal FDG uptake was noted in the linear skin thickening in the left upper quadrant of the abdomen. Histopathological examination of a punch biopsy from the skin lesion on the left upper abdomen revealed metastasis

from invasive ductal carcinoma. A follow-up F-18 FDG PET/CT scan was performed three months later to assess treatment response following the initiation of chemotherapy for recurrent metastatic breast cancer. This scan revealed disease progression, with increased size and metabolic activity in the right breast mass, subcutaneous lesions in the left mastectomy area, and skin thickening in the left upper abdomen. Additionally, new pathological FDG uptake was identified in the muscles and subcutaneous tissues surrounding the left axilla. A third F-18 FDG PET/CT scan, conducted six months later for restaging, revealed widespread pathological FDG activity in the extensive areas of skin thickening, multiple subcutaneous nodular lesions throughout the thoracoabdominal region, as well as involvement of the muscles and subcutaneous tissues of the left arm. ***Conclusion:*** Cutaneous metastases are uncommon and typically present as a solitary, asymptomatic lesion, as observed in our case, which remained unnoticed by the patient. We emphasized a case of rapidly progressive cutaneous metastases of recurrent breast cancer detected on F-18 FDG PET/CT. F-18 FDG PET/CT is a valuable imaging technique for the advanced evaluation of patients, as it helps detect cutaneous and subcutaneous metastases that the patient may not even notice, so improving diagnostic accuracy.

EP-1278

Resolving Curve-Image Discordance: A Case of Rising Renogram Pattern with Preserved Delayed Clearance in Post-Neobladder Pediatric Patient

J. Choudhary, *A. Mahalik, N. Kundu, K. Jain, S. Singh, J. Krishna P., V. Singh, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To highlight a clinically significant discrepancy between the renogram curve pattern and static image-based clearance in a child post-neobladder formation, and to emphasize the role of delayed imaging in accurate interpretation of drainage. ***Materials and Methods:*** A 12-year-old male patient with a history of bladder exstrophy and gastric neobladder underwent 99mTc-LLEC diuretic renography using the F0 protocol. Imaging protocol included dynamic acquisition for 17 minutes, pre-void static image, post-void image, and delayed static image at 4 hours. Hydration and voiding protocols were adequately followed. Renogram curves and static image kidney counts were evaluated, and percent clearance between static phases was calculated. ***Results:*** The dynamic renogram demonstrated a rising pattern in both the kidneys with no definite T½, suggestive of obstruction. However, the delayed 4-hour static image showed significant clearance of tracer. Quantitative analysis revealed >90% clearance between the pre-void and delayed images. This discrepancy was interpreted as non-obstructive drainage, possibly due to a compliant renal pelvis or gravity-aided clearance over time. No technical errors were identified. ***Conclusion:*** Relying solely on the renogram curve may result in misclassification of renal drainage patterns. In this case, static imaging and quantitative analysis provided critical insights that refuted an obstructive diagnosis. Delayed imaging should be considered essential in complex cases, especially in post-surgical anatomy like neobladders, to guide appropriate clinical management.

EP-1279

Evaluating ^{68}Ga-Trivehexin PET/CT Avidity in Hyperparathyroidism with Inconclusive Standard Imaging

A. Sadeq, *S. Dashti, F. Marafi;*
Jaber AlAhmad center for Molecular Imaging, Shuwaikh medical area, KUWAIT.

Aim/Introduction: A 54-year-old female was referred with high parathyroid hormone (PTH) levels and negative ^{99m}Tc -MIBI SPECT/CT parathyroid scintigraphy as well as 4D CT. She had a ^{68}Ga-Trivhexine PET/CT as part of local institution trail. ***Materials and Methods:*** Patients had ^{68}Ga-Trivehexin PET/CT scan after signing an informed consent. A 7.31 mCi of ^{68}Ga-Trivehexin was injected and after 60 minutes images were acquired with 2 min/bed on digital PET/CT camera. The images were then analyzed visually and semi-quantitively in terms of SUVmax. ***Results:*** Images demonstrate focal intense radiotracer localization posterior to the lower pole of the right thyroid lobe upon which she underwent the surgery. ***Conclusion:*** This case provided evidence of potential role of ^{68}Ga-Trivehexin PET/CT in identify hyperfunctioning parathyroid tissuewith high detection rate and supporting further investigation into its potential role in the management of primary hyperparathyroidism (PHPT)

EP-1280

The Role of FDG PET/CT in the Staging of a Poorly Differentiated Malignant Epithelioid and Spindle Cell Neoplasm of the Pleura

A. Giarratana[1], *M. Larson*[1], *K. Capaccione*[2];
[1]*University of Wisconsin - Madison, Madison, WI, UNITED STATES OF AMERICA,* [2]*Columbia University, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: Malignancy of the pleura are most often caused by mesothelioma or metastatic lung cancer, but rare tumor types can present with similar imaging and clinical features. [1] Spindle cell neoplasms of the pleura are uncommon and may exhibit mixed epithelial and mesenchymal features, complicating definitive classification. [2] This case highlights the role of FDG PET/CT in the evaluation of an aggressive, poorly differentiated epithelioid and spindle cell neoplasm of the pleura, with an atypical clinical and histopathologic profile. ***Materials and Methods:*** A 41-year-old male with no smoking or known asbestos exposure presented with progressive respiratory symptoms. He was initially seen as an outpatient after developing persistent cough and decreased exercise tolerance and was diagnosed with COVID-19. Despite antibiotics, symptoms persisted. On follow-up, a chest X-ray revealed a large left pleural effusion. Thoracentesis drained reddish fluid, consistent with an exudative lymphocytic effusion; cytology was negative for malignancy. As his condition worsened, he required hospitalization, chest tubes, and ultimately surgical decortication and pleurectomy. Pathology from the surgical specimen revealed a high-grade malignant epithelioid and spindle cell neoplasm with extensive necrosis and complex cytogenetic abnormalities. The case was reviewed extensively with pathology, and based on histologic appearance and immunohistochemistry markers, the tumor did not fit a specific diagnosis of mesothelioma, sarcoma, or lung primary. FDG PET/CT was performed to assess extent of disease. ***Results:*** FDG PET/CT demonstrated nodular circumferential hypermetabolic thickening of the left pleura with likely extension into the right atrium, as well as FDG-avid ipsilateral mediastinal and axillary lymphadenopathy. Additional findings included multiple contralateral pulmonary nodules and widespread hypermetabolic lytic bone lesions. The intensity and distribution of tracer uptake were consistent with aggressive disease. These imaging features helped differentiate the neoplasm from more localized or indolent pleural processes. The FDG PET/CT scan confirmed disseminated metastatic involvement at presentation and provided essential information for staging, prognostication, and treatment planning. ***Conclusion:*** In patients with undifferentiated or histologically ambiguous malignancy of the pleura, such as spindle cell neoplasms, FDG PET/CT plays a vital role in accurate staging and guiding treatment decisions. This case underscores the importance of whole-body metabolic imaging in detecting metastatic spread and characterizing disease behavior. ***References:*** 1.Boyraz, B. and Y.P. EP-1281

A case of bone inflammation in a Patient with prostate cancer on PSMA-PET imaging: a possible pitfall in ^{18}F-PSMA-1007 PET/CT interpretation

F. Russo[1], *A. Cimini*[1], *G. Grimaldi*[2], *M. De Feo*[3], *A. Marzullo*[1], *H. Dadgar*[4], *H. Arabi*[5], *A. Di Sibio*[6], *M. Menichini*[1];
[1]*Nuclear Medicine Unit, St. Salvatore Hospital, L'Aquila, ITALY,* [2]*Radiation Oncology, San Pietro Fatebenefratelli Hospital, Rome, ITALY,* [3]*Nuclear Medicine Unit, Department of Radiological Sciences, Oncology and Anatomo-Pathology, Sapienza University of Rome, Rome, ITALY,* [4]*RAZAVI Hospital, Imam Reza International University, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [5]*Department of Medical Imaging, Geneva University Hospital, Geneva, SWITZERLAND,* [6]*Department of Radiology, St. Salvatore Hospital, L'Aquila, ITALY.*

Aim/Introduction: ^{18}F-PSMA-1007 and ^{18}F-Piflufolastat are two PET radiopharmaceuticals used for the detection of Prostate Specific Membrane Antigen (PSMA), a transmembrane glycoprotein overexpressed in prostate cancer but also present in benign conditions such as inflammations, that may present high uptake. In this case report we describe the findings of a prostate cancer patient with bone inflammation, evaluated with ^{18}F-PSMA-1007 PET/CT and subsequently with ^{18}F-Piflufolastat PET/CT (4 months later). ***Materials and Methods:*** An 82-year-old patient with history of prostate cancer (previously treated with radical prostatectomy and radiation therapy) underwent ^{18}F-PSMA-1007 PET/CT scan due to biochemical recurrence (serum prostate specific antigen value (PSA) was 0.74 ng/ml thirteen years after surgery). 318 MBq of ^{18}F-PSMA-1007 were administered intravenously, and images acquired 90 minutes later after the injection of radiopharmaceutical. PET images highlighted high uptake of the radiopharmaceutical in the upper plate of L5 vertebra, doubt for metastasis: lumbo-sacral MRI was performed to better define this finding. Moreover, PET images were not suggestive for disease recurrence in lymph-nodes and prostatic bed. Clinical symptoms were investigated: the patient was suffering from lumbar pain and MRI revealed an inflammatory condition in the site of ^{18}F-1007 -PSMA uptake. Four months later the patient underwent a ^{18}F-Piflufolastat PET/CT as a result of further increased levels of serum PSA (0.9 ng/ml); moreover, the patient was still symptomatic with the same lower back pain. About 270 MBq of ^{18}F-Piflufolastat were administered intravenously and images after 90 minutes were acquired. ^{18}F-Piflufolastat PET/CT scan was negative for metastases, and no radiopharmaceutical uptake was detected in L5 vertebra. ***Results:*** The first PET/CT scan with ^{18}F-1007 PSMA revealed high uptake on the upper plate of L5 vertebra with SUV max 5.2, with CT signs of sclerosis; the subsequent MRI demonstrated linear T1 hypointensity, T2 hyperintensity and edema in that site. The second PET/CT scan with ^{18}F-Piflufolastat showed no significant uptake in the upper plate of L5, but bone sclerosis was still present. ***Conclusion:*** in a patient with prostate cancer in biochemical recurrence and persistent lower back pain, inflammatory bone condition was detected only on ^{18}F-1007-PSMA CT scan, suggesting a possible higher sensitivity of this radiopharmaceutical for this condition (compared to ^{18}F-Piflufolastat): nuclear medicine physicians should be aware of this potential pitfall of ^{18}F-1007-PSMA due to inflammation.

EP-1282

Bone Scintigraphy Characteristics in Patients with Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO) Syndrome

X. Wang, *Q. Li, M. Chen;*
The First Hospital of Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: This retrospective study aimed to analyze the significance of whole-body ^{99m}Tc-MDP SPECT imaging and to assess the scintigraphic pattern in patients with Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO) syndrome. ***Materials and Methods:*** The study population had an average age of 43.8 ± 15.8 years, consisting of five males and four females. Disease duration ranged from 1 to 60 months. The most common presenting symptom was chest pain (n=8), and seven patients also had skin lesions. ***Results:*** SPECT/CT imaging revealed the "bullhead" sign in six of nine patients (66.7%), indicating cortical hyperostosis and sclerosis of the sternal manubrium and bilateral clavicles with intense ^{99m}Tc-MDP uptake. At the same time, the remaining cases showed incomplete "bullhead" signs. Among all patients, five out of nine (5/9, 55.6%) had abnormal metabolism in the sacroiliac joints. ***Conclusion:*** Bone scintigraphy is the preferred imaging modality for diagnosing skeletal involvement in SAPHO. It shows the typical uptake in the sternal manubrium and bilateral clavicles and could reveal unexpected locations of the skeletal system in most cases in combination with a bullhead-like tracer uptake. The " bullhead " is the typical and particular SPECT manifestation of SAPHO and aids in medical treatment. ***References:*** ADDIN EN.REFLIST 1. EP-1283

FDG-PET imaging results of a large BMI (~77) patient with colon adenocarcinoma

S. Lokitz, *T. Bartel, K. Harris, L. White;*
Center for Molecular Imaging and Therapy, Shreveport, LA, UNITED STATES OF AMERICA.

Aim/Introduction: We have recently imaged a 33-year old male patient with colon adenocarcinoma. This patient had an unusually high BMI of 77. Patients of this size are typically not eligible for FDG-PET/CT due to scanner weight limitations. We report our clinical experience here. ***Materials and Methods:*** This patient was referred for two scanning procedures about four months apart. The patient had biopsy-proven colon adenocarcinoma. The patient was imaged on a United Imaging Healthcare uMI Panorama. The patient's height is 185.5 cm and weight was 264 kg at the time of the first scan and 268.5 kg at the time of the second. The patient was injected with 433 MBq of ^{18}F-FDG for the first scan and 456 MBq for the second. Uptake time for both acquisitions was 73 min. PET images were reconstructed using an OSEM algorithm with 2 iterations and 10 subsets utilizing all available corrections with resulting images reconstructed to 3 mm thick slices with a transaxial FOV of 760 mm. Final image matrix size was 256 x 256 which corresponded to a pixel size of 2.97 x 2.97 mm. CT images were reconstructed using an artificial intelligence iterative reconstruction. ***Results:*** Images of diagnostic quality were produced and interpreted by board certified nuclear medicine physicians utilizing dedicated PET/CT software (Mirada Medical). While there were some banding artifacts due to truncation in the CT images, images were interpreted both qualitatively and quantitatively. In the first scan, a 7 mm nodule in the left lower lung lobe (max SUV 1.9) was identified along with a

1.7 cm left common iliac chain lymph node (max SUV 7.2) and a 2.7 cm left external iliac chain lymph node (max SUV 8.7). At the second scan, the previously seen lung nodule was still identifiable along with several other small lung nodules without significant uptake. These were suggestive of an infectious or inflammatory process due to the waxing and waning pattern. The left common iliac node was larger (2.1 x 1.5 cm) and with a significantly higher max SUV (30.5) and was suspicious for worsening of the metastatic nodes. ***Conclusion:*** A patient with very high BMI (~77) successfully underwent FDG-PET twice at our center. Images were interpreted and diagnostic data was qualitatively and quantitatively extracted and reported. FDG-PET is indicated in cases such as these and will be offered in the future to patients typically excluded due to high BMI and weight.

EP-1284

Role of [^{18}F]FDG PET/CT in Pulmonary Epithelioid Hemangioendothelioma

K. L. Chiu, *T. K. Chow, K. M. Ma, W. H. Ma;*
Tuen Mun Hospital, Hong Kong, HONG KONG.

Aim/Introduction: Pulmonary epithelioid haemangioendothelioma (EHE) is a rare pulmonary malignant neoplasm of vascular origin. Majority of patients are asymptomatic at presentation with lung lesions detected as incidental findings. Symptomatic patients are associated with a poor prognosis. Despite various imaging features on CT thorax have been described, there are limited reports on [^{18}F]FDG PET/CT findings in pulmonary EHE. This case report illustrates a patient with uncommon imaging findings of pulmonary EHE and highlights the role of [^{18}F]FDG PET/CT in detecting multiorgan disease as well as differentiating pulmonary EHE from metastatic lung disease. ***Materials and Methods:*** A 54-year-old woman presented with chest pain to emergency department. Physical examination and investigations were unremarkable except an opacity in the left upper lung zone on chest radiography. She had no hisotry of malignancy. A CT thorax was arranged and a lobulated mass was found in the superior lingular segment with additional small bilateral lung nodules. In view of suspected lung malignancy, she was referred for [^{18}F]FDG PET/CT. ***Results:*** [^{18}F]FDG PET/CT revealed moderate hypermetabolism in the lingular lung mass (SUVmax 7.2) without pleural invasion. There was no hypermetabolism in other small lung nodules; no hypermetabolic lesion elsewhere to suggest other primary malignancy with metastatic lung disease. The patient therefore underwent a wedge resection for both diagnostic and therapeutic purposes, with histopathological confirmation of EHE. The patient subsequently underwent a complete lobectomy and recovered well postoperatively. ***Conclusion:*** Pulmonary EHE is a rare malignancy with variable imaging manifestations. Although histopathological evaluation is essential, [^{18}F]FDG PET/CT plays a crucial role not only in assessing tumour characteristic and detecting multiorgan involvement, but also in differentiating metastatic lung disease of other origin. This enables better evaluation of disease distribution and directly influences treatment decisions. [^{18}F]FDG PET/CT can also be valuable in post-treatment patient to monitor recurrence or disease progression, but further follow-up and studies would be required. ***References:*** 1. EP-1285

Vanishing lung syndrome pattern on lung perfusion scintigraphy - significance of the hybrid imaging.

O. Lang[1], *M. Salomanina*[2];
[1]*Dept Nucl Med, Praha 1 – Nové Mesto, CZECH REPUBLIC,*
[2]*Cardiology and angiology Ltd., Praha 10, CZECH REPUBLIC.*

Aim/Introduction: Chronic obstructive pulmonary disease (COPD) with emphysema is a serious disease which can cause pulmonary hypertension. Clinical symptoms can mimic pulmonary embolism (dyspnea, hemoptysis). The optimal procedure to exclude pulmonary embolism is lung perfusion scintigraphy. Its interpretation, however, could be difficult if the bullous emphysema is present. ***Materials and Methods:*** 50y old patient was sent to our department to assess possible pulmonary hypertension due to difficult echocardiographic examination. He was admitted for pulmonary embolism as an accidental finding on CT examination several months ago. His pneumological history was abundant. He suffered from repetitive bronchopneumonia including non-tuberculous mycobacteriosis with a mycetoma in the left upper lobe. He was followed for COPD, grade 4, stage D with vanishing lung syndrome. His blood oxygen saturation was 99 %, blood and biochemical examination was without significant pathology. Patient was treated with anticoagulants and was clinically stable. We performed lung perfusion scintigraphy with 99mTc MAA, images were done on hybrid SPECT gamma camera with non-diagnostic CT. ***Results:*** We detected the absence of perfusion of almost the whole right lung on the perfusion scan, distribution of perfusion of the left lung was non-homogenous, but without segmental defects and with the absence of perfusion in the ventral part without any relation to lung anatomy. Non-diagnostic CT shows almost no lung parenchyma of the right lung and ventral part of the left lung, giant cavities filled with air, right mediastinal shift. Cavities on CT correlated with the absence of perfusion on scintigraphy, we, therefore, can exclude pulmonary embolism as well as chronic thromboembolic pulmonary hypertension (CTEPH). ***Conclusion:*** Hybrid lung scintigraphy in patients with vanishing lung syndrome can detect the relation of lung perfusion to the present lung parenchyma and thus exclude possible pulmonary embolism including CTEPH.

EP-1286

Myasthenia gravis-like syndrome: 18FFDG-PET/CT findings in a patient with breast cancer treated with Pembrolizumab.

M. Tagliatori Nogueira, *M. de la Rubia Marcos, A. Herrero Muñoz, C. Paniagua Correa, L. Castillejos Rodriguez, S. Perez Quiros, A. Ortega Valle, D. Rodriguez Oviedo, C. Galindo Fernandez, K. Guichay, J. Sanchez Calderon, P. Garcia Alonso;*
Hospital Universitario de Getafe, Madrid, SPAIN.

Aim/Introduction: We present the findings observed in ^{18F}FDG PET/CT scans performed on a patient with breast cancer treated with an immune checkpoint inhibitor (ICI) in the context of myasthenia gravis-like syndrome (MS). ***Materials and Methods:*** A 43-year-old woman was diagnosed with infiltrating ductal carcinoma of the left breast (G3) with negative hormone receptors, HER2 negative, and a Ki67 of 70%. She received neoadjuvant therapy, tumor resection + sentinel lymph node biopsy (SLNB), and adjuvant therapy with Pembrolizumab + PTX-CBDCA. An ^{18F}FDG PET/CT scan was performed at diagnosis, during adjuvant therapy, and one year later for follow-up. The protocol was performed from the skull to the proximal third of the thighs, 60 minutes after the intravenous administration of 300 MBq of ^{18F}FDG. After two cycles of adjuvant therapy, the patient developed significant proximal weakness in the lower limbs and difficulty standing up from a chair without support and climbing stairs. Due to suspicion of myasthenic syndrome, Pembrolizumab was discontinued, and the clinical presentation was correlated with the PET/CT images

and other complementary studies. ***Results:*** Electromyography (EMG), cervical/extremity MRI, blood tests for autoimmunity and anti-neuronal antibodies were performed, with negative results for all of them. Due to the diagnostic uncertainty, the PET/CT images taken during adjuvant therapy were reviewed, revealing a soft tissue lesion in the anterior mediastinum with increased metabolism, suggestive of thymic hyperplasia, not present in the disease staging study. Therefore, a seronegative myasthenic syndrome caused by Pembrolizumab and/or thymic hyperplasia was considered. Pembrolizumab was discontinued, and corticosteroids and pyridostigmine were started, with progressive clinical improvement. The follow-up PET/CT was evaluated, showing a reduction in both the size and metabolism of the previously described thymic hyperplasia. ***Conclusion:*** According to the literature, the development of myasthenic syndrome may be due to the presence of thymic hyperplasia (TH) or the use of ICI. The incidence of ICI-related MG is very low but potentially severe (30% mortality), typically presenting early (2nd-3rd cycle). In our case, both factors co-existed, supporting the clinical diagnosis in light of negative complementary studies. The literature indicates that both TH and ICI, individually, can lead to the development of MG, but no clear associations between ICI (Pembrolizumab) and thymic hyperplasia have been established. Further studies are needed to confirm whether this association could trigger the presentation of MG, and ^{18}FFDG PET/CT may play a key role due to its use in the routine follow-up of many tumors.

EP-1287

A rare case of metastatic prostate cancer to the external auditory canal evaluated with ^{18}F-Piflufolastat PET/CT

A. Cimini[1], *F. Russo*[1], *A. Marzullo*[1], *M. Menichini*[1], *L. Travascio*[2], *G. Amiconi*[3], *E. Lupi*[4], *M. Ricci*[5];
[1]*Nuclear Medicine Unit, St. Salvatore Hospital, L'Aquila, ITALY,* [2]*Nuclear Medicine Unit, P.O. Spirito Santo, Pescara, ITALY,* [3]*Oncology Unit, Civil Hospital of Avezzano, Avezzano, ITALY,* [4]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, ITALY,* [5]*Nuclear Medicine Unit, Cardarelli Hospital, Campobasso, ITALY.*

Aim/Introduction: ^{18}F-Piflufolastat (known also as ^{18}F-DCFPYL) is a PET radiopharmaceutical that targets Prostate Specific Membrane Antigen (PSMA), used for the evaluation of prostate cancer. In this case report we describe the findings of ^{18}F-Piflufolastat PET/CT in a patient with metastatic prostate cancer to the external auditory canal, an extremely rare condition that can be misdiagnosed. ***Materials and Methods:*** A 65-year-old man with recent hearing loss and history of prostate cancer (previously treated with radiotherapy, Gleason Score 9) underwent ^{18}F-Piflufolastat PET/CT scan due to biochemical recurrence (serum prostate specific antigen (PSA) value was 0.76 ng/ml). About 270 MBq of ^{18}F-Piflufolastat were administrated intravenously. PET/CT acquisition was performed 90 minutes after radiopharmaceutical injection. ***Results:*** PET/CT scan documented high and pathologic uptake of ^{18}F-Piflufolastat in the right scapula (SUVmax 6.1), in a lung nodule of the left lung (SUVmax 6.1, diameter 1 cm), and in a pelvic lymph-node (SUVmax 14.3, diameter 0.9 cm): these findings were referred to prostate cancer metastases. No evidence of disease recurrence was observed in prostate gland. Furthermore, PET/CT images revealed increased uptake of the radiotracer in a tissue localized in the left external auditory canal (SUVmax 22.4, diameter 1.6 cm): due to the non-univocal nature of this tissue (initially this finding was referred to possible inflammatory disease), a biopsy was performed. The result of the biopsy was consistent with prostate cancer metastasis (Ki67 proliferation index was 30%). ***Conclusion:*** To the best of our knowledge, this is the first report describing a prostate cancer metastasis in the external auditory canal evaluated with PSMA-PET/CT. In a patient with metastatic prostate cancer and PSA value < 1 ng/ml, ^{18}F-Piflufolastat PET/CT demonstrated high uptake of the radiopharmaceutical in the tissue localized in the external auditory canal, resulting useful as guidance for biopsy: nuclear medicine physicians should be aware of this possible atypical metastatic localization (that can be misdiagnosed), especially in patients with history of prostate cancer and recent hearing loss.

EP-1288

Acute Pulmonary Embolism and Brachiocephalic Vein Thrombus Detected on 99mTc-MDP Bone Scan-A Case Series

J. Lanctôt-Bédard*, A. Ciarallo, K. Provost;*
Centre Hospitalier de l'Université de Montréal, Montréal, QC, CANADA.

Aim/Introduction: We present a case series of two patients in whom acute and chronic thromboembolic disease was detected on ^{99m}Tc-MDP bone scan. The first case involves a 70-year-old patient who presented to the emergency room with dyspnea and chest pain. Additionally, there was a suspicious right breast mass. A CT pulmonary angiography was performed to rule out pulmonary embolism. It revealed no evidence of pulmonary embolism, but a sclerotic lesion at L1 vertebral body which needed further investigation with bone scan. The second case involves a 62-year-old patient referred for re-staging of prostate cancer in the context of biochemical recurrence post-prostatectomy. ***Materials and Methods:*** Both patients underwent ^{99m}Tc-MDP bone scan with wholebody planar images and SPECT-CT of the chest. ***Results:*** Bone scan of the first patient revealed no evidence of bone metastasis. An intense focus of uptake projecting to the left chest on planar images was noted. On SPECT-CT, there was linear uptake in the left lung corresponding to a vascular structure. No underlying abnormalities on non injected CT. Acute pulmonary embolism demonstrating focal MDP uptake was felt to be the most likely diagnosis despite the negative CT angiogram two days previously. CT-angiogram of the chest repeated on the same-day as bone scan showed a new segmental pulmonary embolism involving the upper division of the lingula, exactly matching the MDP uptake. It confirmed the detection of acute pulmonary embolism on bone scan. The patient was anticoagulated. Bone scan of the second patient revealed no evidence of bone metastasis. A focus of moderate-intensity uptake was noted in the mediastinal vasculature on SPECT-CT, corresponding to faint calcifications within the brachiocephalic trunk. C+ CT scan of the chest confirmed the presence of an intra-luminal thrombus of the brachiocephalic vein. Images of 1-year prior bone scan were reviewed, and in retrospect showed faint activity at the same level, with documentation of the thrombus on C+ CT scan from the same period. ***Conclusion:*** To our knowledge, these are the first reported cases of acute pulmonary embolism and central venous thrombosis identified using 99mTc-MDP SPECT/CT. Only a few previous case reports had described focal uptake in the lung due to radiotracer microemboli mostly with FDG PET, unrelated to thrombo-embolic disease. MDP activity may occur in acute (case 1) or chronic (case 2) cases. There should be a high degree of suspicion for acute thrombo-embolic phenomenon in any unexplained focal vascular uptake of MDP.

EP-1289

Plasmablastic transformation of multiple myeloma- An unusual entity detected with ^{18}F-FDG PET/CT

T. Moreno-Monsalve*, M. I. Castellon-sanchez, L. Frutos-Esteban, J. L. Navarro-Fernandez, L. Mohamed-Salem, T. E. Rodriguez-Locarno, M. J. Ibañez-Ibañez, A. C. Hernandez-Martinez, N. Sanchez-Izquierdo, J. F. Contreras-Gutierrez;*
Hospital Universitario Virgen De La Arrixaca, Murcia, SPAIN.

Aim/Introduction: A 66-year-old man with a history of IgA kappa multiple myeloma with Bence-Jones proteinuria, high-risk

cytogenetics, ISS stage III and Durie-Salmon stage III-B, received multiple lines of therapy. After a partial response to fourth-line treatment, he underwent autologous stem cell transplant (ASCT), followed by progression. A sixth-line treatment with daratumumab was ineffective, and seventh-line therapy with anti-BCMA CAR-T cells achieved a very good partial response. ***Materials and Methods:*** At three months post-infusion, an [^{18}F]FDG PET/CT showed multiple bone lesions without abnormal uptake, suggesting complete metabolic response. However, at six months, a follow-up PET/CT revealed a new large retroperitoneal hypermetabolic mass infiltrating both kidneys, compressing the ureters, and extending to the pelvis, along with a hypermetabolic left adrenal nodule. Bone marrow biopsy confirmed diffuse infiltration by plasmacytoid cells with high Ki67, consistent with plasmablastic myeloma (PBM). Urgent treatment with bendamustine and dexamethasone was initiated. PBM is a rare, aggressive variant of multiple myeloma, characterized by ≥2% plasmablasts among clonal plasma cells. It is associated with extramedullary disease (EMD), rapid progression, and poor outcomes. In this case, the patient presented with plasmablastic transformation, developing retroperitoneal and adrenal extramedullary plasmacytomas, a pattern linked to adverse prognosis. ***Results:*** This case emphasizes the importance of considering plasmablastic transformation when evaluating disease progression in MM. Early and sensitive detection through [^{18}F]FDG PET/CT plays a crucial role. PET imaging not only aids in identifying aggressive phenotypes like PBM but also provides prognostic information: the presence of >3 focal lesions or EMD correlates with poor survival. Additionally, higher FDG uptake has been associated with increased plasma cell burden and reduced overall survival. FDG PET/CT is also valuable in monitoring treatment response, as changes in metabolic activity often precede anatomical alterations. In aggressive cases like PBM, early PET/CT can support timely clinical decision-making and prompt the initiation of salvage therapies or inclusion in experimental protocols. ***Conclusion:*** In conclusion, this case illustrates a rare and aggressive transformation of MM, marked by several poor prognostic indicators: plasmablastic histology, high-risk cytogenetics, and extramedullary spread. Early detection using sensitive imaging modalities such as [^{18}F]FDG PET/CT is essential for guiding appropriate management strategies and improving clinical outcomes in this challenging setting. ***References:*** Greipp PR et al. Aggressive PBM with cord compression. Anticancer Res, 2021.

EP-1290

Müller-Weiss Syndrome on ^{99m}Tc-MDP Bone Scintigraphy

D. Alami, *M. Zekri, A. Taalabi, N. Mahrsi, L. Taoussi, I. Zehfir, M. Aboussabr, Z. Laadissi, O. Ait Sahel, A. Doudouh;*
Mohamed V Military Instruction Hospital, Rabat, MOROCCO.

Aim/Introduction: With fewer than 300 reported cases in the literature, Müller-Weiss syndrome remains a rare condition that predominantly affects women between 40 and 60 years of age. Its pathogenesis is poorly understood, involving a combination of vascular insufficiency and mechanical stress. Diagnosis typically relies on weight-bearing radiographs, supplemented by CT, bone scan or MRI. Initial management is conservative, incorporating anti-inflammatory medications, analgesics, and non-weight-bearing immobilization. In refractory cases, surgical intervention—such as central decompression or arthrodesis—may be considered. Due to its rarity and often subtle clinical presentation, diagnosis is frequently delayed. We present a clinical case highlighting the pivotal role of bone scintigraphy in refining diagnosis and guiding appropriate management. ***Materials and Methods:*** We describe the case of a 59-year-old female patient with a three-month history of chronic pain in the right midfoot. Clinical examination revealed a flatfoot deformity with localized tenderness, in the absence of inflammatory signs, and normal laboratory findings. Initial plain radiographs of the right foot were unremarkable. However, MRI of the right ankle revealed osteonecrosis of the navicular bone. A 99mTc-MDP bone scintigraphy was subsequently performed for further assessment. ***Results:*** Triphasic bone scintigraphy demonstrated hyperemia during the vascular phase and increased radiotracer uptake in both the soft tissue and delayed bone phases at the level of the right tarsus, with marked intensity over the navicular bone, suggestive of early-stage osteonecrosis. The patient was referred to orthopedic surgery for specialized care. A conservative treatment regimen was initiated, including immobilization with a walking boot, NSAIDs for pain control, reduced weight-bearing activity, and the administration of bisphosphonates. As such, scintigraphy not only confirmed MRI findings but also provided additional insights into disease activity, supporting the decision for conservative treatment and deferring surgical intervention at this stage. ***Conclusion:*** Although uncommon, Müller-Weiss syndrome warrants heightened clinical awareness to avoid misdiagnosis and inappropriate management. Bone scintigraphy, by corroborating MRI findings and providing functional information on disease activity, plays a crucial role in guiding conservative treatment strategies and minimizing the need for invasive procedures.

EP-1291

Pulmonary Metastasis of Grade 1 Meningioma Mimicking a Carcinoid Tumor: A Case Report with FDG PET/CT, DOTATATE PET/CT and Pathological Confirmation

X. Rabbath, *C.-H. Shih, M.-A. Morin;*
Centre Hospitalier de l'Université de Montréal, Montréal, QC, CANADA.

Aim/Introduction: We report what appears to be the first documented case of a pulmonary metastasis from a WHO Grade 1 meningioma, detected by both FDG and DOTATATE PET/CT and confirmed by histopathology. ***Materials and Methods:*** A 68-year-old woman with no significant medical history underwent subtotal resection of a falcine meningioma. Pathological analysis confirmed a WHO Grade 1 (benign) meningioma with no histologic or immunohistochemical markers of aggressiveness. However, FISH analysis revealed a 1p deletion, a finding associated with increased clinical aggressiveness. A post-operative CT incidentally identified a lobulated lesion measuring 17 x 13 mm in the lung's left upper lobe. ***Results:*** ^{18}F-FDG PET/CT revealed mild hypermetabolism of the pulmonary nodule (SUVmax 2.2), without associated lymphadenopathy or additional hypermetabolic foci. A neoplastic process was suspected, and differential diagnoses included a well-differentiated carcinoid tumor. Additional evaluation with histopathological correlation or DOTATATE PET/CT scan was advised. Bronchoalveolar lavage, endobronchial brushing, and EBUS-guided lymph node biopsy were all negative for malignancy. ^{68}Ga-DOTATATE PET/CT demonstrated focal high uptake in the posterior sagittal sinus, corresponding to known residual meningioma. The pulmonary lesion demonstrated intense somatostatin receptor expression (SUVmax 10.7, Krenning score 3), consistent with a well-differentiated carcinoid tumor. No lymph node or distant metastasis were identified.The patient underwent left upper lobectomy within 2 weeks. Histopathological examination revealed a meningioma morphologically consistent with the intracranial lesion, with a Ki-67 index of 5-10%, confirming the diagnosis of a pulmonary metastasis from a WHO Grade 1 meningioma. This ruled out the working diagnosis of carcinoid tumor. The pulmonary lesion thus demonstrated mild FDG uptake and high DOTATATE avidity, paralleling the molecular profile of the primary intracranial tumor. ***Conclusion:*** Extracranial metastases from meningiomas are exceedingly rare, with less than 1% of cases

reported to metastasize (1). To our knowledge, this represents the first reported case of a Grade 1 meningioma metastasizing to the lung, detected by both FDG PET/CT and DOTATATE PET/CT and confirmed histologically. This case highlights the value of molecular imaging and the potential for even histologically benign meningiomas to exhibit unexpected aggressive behaviour.

EP-1292

Increased PSMA expression in synchronous high-grade pleomorphic sarcoma of the thigh and a rare giant liver hemangioma detected on ^{68}Ga-PSMA PET/CT staging of prostate cancer (PC)

M. Dyankova[1,2], *T. Stoeva*[1], *S. Chausheva*[1], *Z. Dancheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*St. Marina University Hospital, Varna, Bulgaria,* [2]*Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy, Varna, BULGARIA.*

Aim/Introduction: Synchronous ^{68}Ga-PSMA-positive malignancies are rare, occurring in approximately 0.7% of patients with prostate cancer (PC). Beyond PC, PSMA expression has also been observed in the tumor-associated neovascular endothelial cells of various non-prostatic malignancies, including sarcomas. Sarcomas represent a heterogeneous group of malignant tumors arising from connective tissues and are broadly classified into soft tissue sarcomas and bone sarcomas. Collectively, they constitute less than 1% of all newly diagnosed malignancies. Owing to their low incidence, coupled with considerable histopathological and anatomical heterogeneity, the diagnosis of sarcomas remains particularly challenging. ***Materials and Methods:*** We report the case of a 66-year-old male in whom a second primary malignancy—identified as a soft tissue sarcoma of the thigh demonstrating increased PSMA expression—was incidentally detected on ^{68}Ga-PSMA PET/CT. Additionally, a rare giant hepatic hemangioma, showing no increased PSMA uptake, was observed. The patient had recently been diagnosed with prostate adenocarcinoma, Gleason score 7 (3 + 4), ISUP Grade Group 2, with an initial serum prostate-specific antigen (PSA) level of 12.0 ng/mL. He was referred for staging with PSMA-PET/CT prior to initiation of treatment. ***Results:*** ^{68}Ga-PSMA PET/CT was performed for staging, revealing not only findings consistent with primary PC but also a synchronous tumor demonstrating increased PSMA uptake. Fused PET/CT images showed a heterodense mass located in the proximal third of the right thigh, exhibiting intense pathological PSMA activity. Histopathological analysis subsequently confirmed the lesion as a high-grade pleomorphic sarcoma. Additionally, a large heterodense parenchymal lesion was identified, involving almost the entire right hepatic lobe. This lesion demonstrated no increased PSMA uptake and contained a central hypodense region with amorphous, calcified inclusions. The imaging findings were consistent with a giant hepatic hemangioma, later confirmed by conventional imaging modalities including contrast-enhanced CT and MRI. Furthermore, PET/CT images demonstrated diffusely heterogeneous increased PSMA expression throughout both lobes of the prostate gland, which appeared enlarged, particularly at the mid-apical level—findings indicative of the known primary PC. ***Conclusion:*** In the present case report, we highlight the importance of histopathological confirmation of lesions with increased PSMA expression, but atypical for PC involvement and provide a rationale for further investigation into the potential role of PSMA-targeted radiopharmaceutical therapy in non-prostatic malignancies, offering a novel therapeutic perspective for patients with sarcoma. A comprehensive evaluation—including the patient's clinical history, morphological characteristics of the lesions, and findings from complementary imaging modalities—is essential to accurately assess the relevance and clinical significance of the observed findings.

EP-1293

PSMA-Avid Osteitis Deformans in Pelvic Bones Mimicking Prostate Cancer Metastasis on ^{68}Ga-PSMA PET/CT Imaging: A Case Report

M. Dyankova[1,2], *T. Stoeva*[1], *S. Chausheva*[1], *Z. Dancheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*St. Marina University Hospital, Varna, BULGARIA,* [2]*Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy, Varna, BULGARIA.*

Aim/Introduction: The introduction of prostate-specific membrane antigen (PSMA)-targeted positron emission tomography/computed tomography (PET/CT) using ^{68}Ga-labeled tracers has significantly improved the detection of recurrent and metastatic disease, even at low PSA levels. However, PSMA expression is not exclusive to prostate carcinoma (PC) and may also be present in benign or non-prostatic malignant lesions, potentially complicating image interpretation. ***Materials and Methods:*** A 66-year-old male with a history of prostate adenocarcinoma (Gleason score 7 [3 + 4], ISUP Grade Group 2) underwent radical prostatectomy. The patient was referred for ^{68}Ga-PSMA PET/CT due to biochemical recurrence, with actual serum prostate-specific antigen (PSA) level of 6.65 ng/mL. The patient underwent whole-body ^{68}Ga-PSMA-11 PET/CT imaging using a standard protocol. SUVmax and visual scoring were used to evaluate the PSMA expression pattern of all lesions. Follow-up MRI and CT imaging were used to correlate and confirm the bone lesion etiology. ***Results:*** A lobulated soft tissue mass was visualized in the prostatic bed, extending into the right seminal vesicle. The lesion demonstrated pathological PSMA expression, consistent with a local recurrence of the PC. In addition, pelvic bones, including the right hemipelvis (ischium, pubic ramus, acetabulum, and iliac body/wing), showed altered bone architecture, with osteoporotic and osteolytic remodeling, prominent trabeculation, and osteoblastic areas with mild to moderate tracer uptake (visual score 1). These findings, characterized by a combination of osteolytic (lucent) regions, areas of coarsened trabeculation, and sclerotic changes, were interpreted as likely benign and suggestive of deforming osteitis (Paget's disease), which was subsequently confirmed by MRI and CT imaging. Furthermore, a wedge compression fracture of the Th12 vertebral body was noted, without increased PSMA uptake, supporting the diagnosis of a benign compression fracture. ***Conclusion:*** Incidental findings such as deforming osteitis may present with PSMA uptake, potentially mimicking metastatic disease. This case highlights the importance of careful interpretation of PSMA-avid lesions and emphasizes the need for a comprehensive diagnostic approach, integrating clinical history, morphological features, and additional imaging modalities, all of which are essential for accurate diagnosis and to guide appropriate treatment strategies.

EP-1294

PSMA-positive incidental parathyroid adenoma in a prostate cancer (PC) patient detected during a routine staging PET/CT scan using the newly synthesized radiopharmaceutical 18F-siPSMA-14

M. Dyankova[1,2], *T. Stoeva*[1], *S. Chausheva*[1], *Z. Dancheva*[1], *T. Yordanova*[1], *B. Chaushev*[1], *A. Klisarova*[1];
[1]*St. Marina University Hospital, Varna, BULGARIA,* [2]*St. Marina University Hospital. Department of Nuclear Medicine., Varna, BULGARIA.*

Aim/Introduction: Primary hyperparathyroidism is a common endocrine disorder characterized by excessive secretion of parathyroid hormone (PTH), resulting in hypercalcemia and associated renal and skeletal complications primarily caused by parathyroid adenoma. Accurate localization of hyperfunctioning

parathyroid tissue is crucial for definitive surgical treatment but often poses a significant challenge for conventional imaging modalities. Due to the increased expression of carboxypeptidase type II in the endothelial lining of neovasculature of various solid tumors, increased uptake of ^{68}Ga-labeled prostate-specific membrane antigen (PSMA) on PET/CT imaging has been observed in numerous benign and malignant non-prostatic conditions, including parathyroid adenomas. ***Materials and Methods:*** A 69-year-old man was diagnosed with prostatic acinar adenocarcinoma, Gleason score 8 (4 + 4), ISUP Grade Group 4, with an initial serum prostate-specific antigen (PSA) level of 7.51 ng/ml. He was referred for staging with 18F-siPSMA prostate-specific membrane antigen (PSMA) PET/CT prior to treatment. A whole-body PET/CT scan was performed at the 90th minute following the administration of 350.0 MBq of [18F]siPSMA-14, without the application of furosemide. ***Results:*** PSMA PET/CT study with newly synthesized radiopharmaceutical ^{18}F-siPSMA-14, revealed an enlarged prostate gland with diffusely heterogeneous, increased PSMA expression in both lobes, predominantly in the left lobe at the mid/apex level, with higher uptake in the peripheral zones—findings consistent with a primary prostate cancer, histologically confirmed. The seminal vesicles appeared intact on imaging. No lesions with pathologically increased PSMA expression suggestive of regional malignant lymphadenopathy or distant metastatic disease were detected. Coincidentally, a nodular lesion with increased PSMA expression was observed in the lower pole and dorsal to the left thyroid lobe. This incidental finding was further clarified with complementary four-dimensional CT. Blood tests revealed elevated serum calcium and parathyroid hormone levels, as well as hypophosphatemia, consistent with primary hyperparathyroidism. Subsequently, parathyroidectomy was performed, and histopathological examination of the nodule confirmed a parathyroid adenoma. ***Conclusion:*** In the present case, the novel [^{18}F]siPSMA-14 PET radiotracer aided in the diagnosis of a parathyroid adenoma. Future prospective studies are needed to investigate the potential diagnostic value of the hybrid PSMA PET/CT method in evaluating patients who present with not uncommon false-negative results from conventional imaging modalities.

EP-1295

FDG PET/MRI Demonstration of Extensive Spinal Cord Metastases in a Patient with Ovarian Carcinoma

C. Güneren*, S. Asa, H. B. Sayman;*
Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Central nervous system (CNS) involvement is an uncommon manifestation of metastatic ovarian carcinoma. Though the liver is the most frequent site of distant spread, spinal cord metastases remain rare. The anatomical distribution of metastases is an independent prognostic factor (1). ***Materials and Methods:*** We present a case of spinal cord metastasis from high-grade serous ovarian carcinoma, emphasizing the diagnostic value of ^{18}F-FDG PET/MRI compared to conventional MRI. ***Results:*** In 2020, the patient was diagnosed with high-grade serous ovarian carcinoma following total abdominal hysterectomy, bilateral salpingo-oophorectomy, omentectomy, and excision of peritoneal implants. Multiple lines of chemotherapy were administered. During follow-up, brain metastases were detected, and the patient received whole-brain radiotherapy with palliative intent.On subsequent ^{18}F-FDG PET/MRI imaging, newly emerged, millimetric to sub-centimetric, hypermetabolic foci were observed along the spinal canal, predominantly in the cervical region, adjacent to the spinal cord. These findings were interpreted as spinal cord metastases. Complementary contrast-enhanced spinal MRI demonstrated nodular enhancement in the corresponding areas on post-contrast T1-weighted images, consistent with metastatic involvement. However, lesion detectability and delineation were notably superior on PET/MRI compared to MRI alone. Targeted radiotherapy was administered based on PET/MRI findings. ***Conclusion:*** Intramedullary spinal cord metastases are extremely rare, comprising 0.9-2.1% of cancer autopsies and 8.5% of all CNS metastases. Ovarian cancer cases with spinal involvement are scarcely reported, mostly via MRI (2-5). While MRI remains the gold standard for anatomical evaluation and surgical planning (6), ^{18}F-FDG PET/MRI adds diagnostic value, especially for detecting subtle or widespread lesions. As demonstrated in this patient, PET/MRI may represent a diagnostically superior modality in selected clinical contexts. ***References:*** 1)Deng K. et al. EP-1296

Incidental Detection of Pulmonary Carcinoid Tumor During Cardiac SPECT Perfusion Imaging: A Case Report

E. Gharepapagh*[1], S. Rezaei[1], S. Dabiri[1], M. Karbasi[2];*
[1]Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF, [2]Department of radiology, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Pulmonary carcinoid tumors are rare neuroendocrine neoplasms. While most commonly arising in the gastrointestinal tract, they represent the second most frequent neuroendocrine tumors found in the lungs. These tumors typically grow slowly and may remain asymptomatic for years, often being discovered incidentally during imaging studies conducted for unrelated clinical indications. ***Materials and Methods:*** We present the case of a 66-year-old female undergoing preoperative assessment for uterine surgery due to medication-resistant fibroma. As part of the cardiac clearance process, she was referred for myocardial perfusion SPECT imaging. A two-phase (stress and rest) myocardial perfusion SPECT was performed using 99mTc-MIBI, acquired on a dual-head gamma camera. ***Results:*** The myocardial walls demonstrated normal perfusion, with no evidence of ischemia (LVEF = 66%). However, an incidental finding on the raw and MIP images prior to processing revealed a relatively large abnormal soft tissue mass in the lower lobe of the right lung. The mass exhibited notable 99mTc-MIBI uptake, prompting further investigation. A non-contrast CT scan confirmed the presence of a 64×54 mm soft tissue mass with internal calcifications in the medial basal segment of the right lung, causing compression of the adjacent bronchus. Based on imaging features, the differential diagnosis included bronchial carcinoid tumor and primary lung carcinoma. Bronchoscopy and biopsy confirmed the diagnosis of a pulmonary carcinoid tumor. ***Conclusion:*** This case underscores the importance of thoroughly reviewing extracardiac regions during myocardial SPECT imaging. Incidental findings, such as pulmonary masses, can lead to the early diagnosis of potentially serious conditions. Vigilance in assessing adjacent thoracic structures during routine nuclear medicine procedures enhances diagnostic value and improves patient care.

EP-1297

Left Frontal Lobe Hypoperfusion and Progressive Speech Impairment: A Case Study Using SPECT Imaging

E. Gharepapagh[1], *S. Rezaei*[1], *M. Karbasi*[2];
[1]*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of radiology, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Speech production is primarily controlled by Broca's area, typically located in the left frontal lobe. Other regions, including Wernicke's area, the arcuate fasciculus, the cerebellum, and the motor cortex, also contribute to language processing. In adults, speech disorders may result from neurological diseases, stroke, trauma, psychological factors, medication side effects, hearing loss, and aging. Neuroimaging plays a crucial role in the early identification and evaluation of these disorders. ***Materials and Methods:*** We report the case of a 77-year-old woman with progressive speech impairment beginning in early 2022, now accompanied by difficulty eating. She underwent several sessions of speech therapy with limited benefit. Brain MRI revealed generalized atrophy, ischemic changes, and ventricular enlargement. To further evaluate cerebral perfusion, a brain SPECT scan using 99mTc-ECD was performed. ***Results:*** SPECT imaging demonstrated lateral ventricular dilation, cortical thinning, and diffuse loss of cerebral gyri and sulci. Quantitative analysis showed a significant decrease in radiotracer uptake in the left frontal and temporal lobes (Lt/Rt counts ratio = 0.77), suggesting functional impairment of Broca's area and its associated speech network. These findings are consistent with the patient's severe expressive aphasia. ***Conclusion:*** This case highlights the utility of functional imaging in detecting hypoperfusion in language-related brain regions, particularly in elderly patients with progressive speech impairment. Early implementation of SPECT or other neuroimaging techniques may assist in diagnosis and guide management strategies, especially when structural MRI findings are inconclusive**.**

EP-1298

Vertebral Hemangioma in Disguise: A Ga-68 DOTATATE False Positive

M. Pešorda*, E. Pasini Nemir, D. Huic;*
University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: Ga-68 DOTATATE PET/CT is a highly sensitive and specific imaging modality used in the evaluation of neuroendocrine tumors (NETs). Ga-68 DOTATATE is a radiolabeled somatostatin analog that binds with high affinity to somatostatin receptors, which are overexpressed in many NETs.In addition to NETs, Ga-68 DOTATATE uptake can be observed in other tumors (e.g., meningioma, small cell lung carcinoma), inflammatory conditions, and osteoblastic osseous processes. Tracer uptake in vertebral hemangiomas can lead to false-positive findings, making correlation with CT or MRI extremely important. ***Materials and Methods:*** We present a case of 69-year old female patient that has been under follow-up since 2006 for small lung nodules initially identified on a chest X-ray performed as part of preoperative evaluation for thyroid surgery.In 2021, the nodule in the anterior segment of the right upper lobe began increasing in size, and a new nodule appeared in the anterior segment of the left upper lobe.Both lesions showed increased uptake on an F-18 FDG PET/CT scan performed in 2022.The patient declined invasive diagnostics until early 2024, when bronchoscopy with biopsy was finally conducted. The small biopsy sample favored the diagnosis of a neuroendocrine tumor over neuroendocrine carcinoma (Ki-67 <10%). At that time, the patient chose not to proceed with further invasive procedures required for more detailed analysis. The patient was referred to our department for a Ga-68 DOTATATE PET/CT scan in April 2024. ***Results:*** Ga-68 DOTATATE PET/CT revealed increased uptake in the right lung hilum (SUVmax 7.2), the right upper lobe nodule (SUVmax 8.6), and the left upper lobe nodule (SUVmax 18.1). An unexpected finding was increased uptake in the body of the T3 vertebra (SUVmax 8.9), which appeared only mildly altered on low-dose CT. A metastatic lesion could not be ruled out based on this. However, contrast-enhanced CT findings of T3 were consistent with a vertebral hemangioma. The patient also had a known vertebral hemangioma at L3, with only mild tracer uptake (SUVmax 3.5).In March 2025, the patient began treatment with octreotide LAR. ***Conclusion:*** While Ga-68 DOTATATE PET/CT is an excellent imaging tool for NET diagnosis, potential pitfalls such as false-positive uptake must be recognized. Vertebral hemangiomas are benign lesions typically non-avid on Ga-68 DOTATATE PET/CT but may occasionally show radiotracer uptake, mimicking metastasis. Misinterpretation of such uptake can lead to incorrect staging and management, emphasizing the importance of correlating PET/CT findings with CT or MRI to avoid misdiagnosis of skeletal metastases.

EP-1299

Splenic Hemangioma: A Noteworthy Incidental Finding on ^{18}F-PSMA PET/CT

O. Bourogianni[1], *G. Lamprakopoulos*[1], *N. Kapsoritakis*[1], *M. Stathaki*[1], *S. Koukouraki*[2];
[1]*Nuclear Medicine Department, University Hospital of Crete, Heraklion, GREECE,* [2]*Nuclear Medicine Department, School of Medicine, University of Crete, Heraklion, GREECE.*

Aim/Introduction: Prostate cancer is the most prevalent malignancy among men, with the highest incidence observed in elderly individuals (> 65 years of age). It is typically identified by elevated prostate-specific antigen (PSA) levels and confirmed through imaging and biopsy. Recent advancements in imaging, particularly prostate-specific membrane antigen (PSMA) positron emission tomography (PET)/computed tomography (CT), have significantly enhanced the staging and management of this disease. PSMA PET/CT offers high sensitivity and specificity for detecting both primary tumors and metastatic lesions. However, atypical findings may occasionally complicate staging. ***Materials and Methods:*** A 75-year-old male patient presented with progressively increasing PSA levels over the past six months and underwent a comprehensive diagnostic evaluation. Pelvic MRI revealed a PI-RADS 4 lesion located in the left posterolateral peripheral zone at the mid-gland level. Prostate biopsies were performed, and the pathology report indicated the following: Lesion: adenocarcinoma, Gleason score 7 (3+4), 90% involvement, Left lobe: adenocarcinoma, Gleason score 7 (3+4), 40% involvement. To assess the extent of the disease, an 18F-PSMA PET/CT scan was conducted. ***Results:*** The 18F-PSMA PET/CT scan revealed abnormal tracer uptake in the posterior peripheral zone of the prostate mid-gland and base, with the most intense signal located in the left posterolateral region of the mid-gland. No abnormal uptake was observed elsewhere in the pelvis or abdominal lymph nodes. Notably, intense PSMA tracer activity was identified in multiple splenic lesions, the largest of which measured 50 mm in diameter, along with the presence of an accessory spleen. To exclude the rare possibility of metastatic prostate cancer, an abdominal MRI was performed. The MRI findings were more consistent with splenic hemangiomas than metastatic lesions. ***Conclusion:*** PSMA PET/CT is a powerful imaging modality for staging prostate cancer, offering high sensitivity and specificity for both primary and metastatic disease. However, it is important to recognize that benign conditions can also show PSMA avidity. Splenic hemangiomas, the most common benign tumors of the spleen, can mimic metastatic lesions on PSMA PET/CT. As PSMA-targeted imaging becomes more widely adopted, familiarity with these potential pitfalls will be crucial for accurate interpretation.

EP-1300

Perineural dissemination in head and neck epidermoid carcinoma on ^{18}F-FDG PET/CT

P. Guardia Jimena, *A. Santos Bueno, M. Sanchez Torrente, S. Martin Aguilar, M. Ureña Lara;*
Hospital Universitario de Jaén, Jaén, SPAIN.

Aim/Introduction: Perineural dissemination in head and neck tumours is associated with decreased survival, a higher risk of recurrence and worse prognosis, and its diagnosis may change the therapeutic management of patients. Its detection by ^{18}F-FDG PET/CT is influenced by physiological uptake in the head and neck area and the lower anatomical resolution, so MRI findings must be taken into account for its localization. The most frequently affected nerves are the trigeminal and facial nerves. ***Materials and Methods:*** We present the case of a 60-year-old patient with a history of right maxillary epidermoid carcinoma T4N0Mx treated by radiotherapy and chemotherapy; he presented local recurrence two years later, treated by total maxillectomy and right cervical dissection, revealing affected margins. Adjuvant treatment was ruled out due to previous radiotherapy, and close follow-up was maintained.Subsequently, discordant results were obtained in the morphological follow-up tests, describing local recurrence by MRI with suspected perineural dissemination of the infraorbital nerve, with no evidence of disease in the CT study. Based on these results, the multidisciplinary committee decided to complete the study with ^{18}F-FDG PET/CT for better assessment. ***Results:*** A PET/CT study was performed 50 minutes after intravenous administration of 181 MBq of ^{18}F-FDG, acquiring a full body and head and neck study confirming local recurrence in the inferior orbital fissure and pterygopalatine fossa, as well as linear hypermetabolism extending from the orbital fissure, caudally and anteriorly through the theoretical maxillary sinus to the theoretical right maxillary region, tracing the route of the infraorbital nerve, supporting the suspicion of perineural dissemination. Following these results and taking into account the treatments performed, he was transferred to another centre to receive proton therapy (not available in our hospital) and chemotherapy. After treatment, a follow-up ^{18}F-FDG PET/CT scan revealed discrete hypermetabolism in the treated area of probable post-treatment inflammatory origin without being able to exclude persistent disease and without findings of perineural linear metabolism, showing a good response to treatment. In the MRI, changes persist in the treated area, and so close follow-up is maintained. ***Conclusion:*** Despite the limitations of ^{18}F-FDG PET/CT for the diagnosis of perineural dissemination, it can support the information provided by other imaging techniques to justify changes in the treatment and management of patients.

EP-1301

Silent Intramedullary Metastasis From Lung Carcinoma : Early Detection by ^{18}F-FDG PET/CT

M. Aboussabr, *I. Zahfir, M. Zekri, N. Mahrsi, Z. Laadissi, A. Taalabi, D. Alami, L. Taoussi, Y. Benameur, A. Doudouh;*
Department of Nuclear Medicine, Mohammed V Military Teaching Hospital, Rabat, MOROCCO.

Aim/Introduction: Intramedullary spinal cord metastases (ISCMs) are exceptionally rare, accounting for approximately 0.9% to 2.1% of all spinal metastases. They most frequently originate from primary lung carcinomas. While MRI remains the gold standard for detailed anatomical evaluation, ^{18}F-FDG PET/CT has emerged as a powerful tool for comprehensive systemic assessment. Due to its high sensitivity in detecting metabolically active lesions, PET/CT allows early identification of metastatic foci, including clinically silent or MRI-occult ISCMs. ***Materials and Methods:*** We present the case of a 72-year-old male patient diagnosed with lung adenocarcinoma. He was initially treated with concomitant radio chemotherapy, achieving partial remission. Five months later, he developed severe back pain associated with progressive lower limb weakness. Given the suspicion of disease progression, a restaging with ^{18}F-FDG PET/CT was performed. ***Results:*** A PET/CT scan was performed 60 minutes after the injection of 270 MBq of 18F-FDG. The sagittal fused PET/CT images revealed a highly FDG-avid lesion within the cervical spinal cord at the C5-C6 level, with a SUVmax:13.1, strongly suggesting the presence of ISCMs. A gadolinium-enhanced spinal MRI was then conducted. Sagittal, coronal, and axial images showed multiple nodular leptomeningeal enhancements at both the cervical (C5-C6) and thoracic (D5-D6) levels. Additionally, a central intramedullary lesion, extending from the medulla oblongata to C7, exhibited contrast enhancement on T2-weighted images. ***Conclusion:*** ISCMs represent a rare clinical entity, most commonly arising from primary lung carcinoma, particularly small cell lung cancer, which accounts for approximately 50% of cases. Other primary tumors include breast cancer, melanoma, lymphoma, renal cell carcinoma, and, more rarely, colorectal cancer. The onset of ISCMs is frequently associated with severe neurological deficits and a poor overall prognosi, highlighting the importance of early detection to delay neurological deterioration and optimize therapeutic management. Although MRI remains the reference modality for morphological assessment, ^{18}F-FDG PET/CT emerges as a crucial diagnostic tool. With a high sensitivity of up to 96%, it enables comprehensive metabolic evaluation and facilitates the detection of metastatic lesions including intraspinal involvement. Its role is pivotal in guiding early diagnosis, directing targeted MRI, and expediting appropriate therapeutic intervention. Therefore, ^{18}F-FDG PET/CT stands out as an indispensable imaging modality for the detection of rare but clinically significant metastases such as ISCMs.

EP-1302

Unmasking Tuberculosis in a Patient with Sarcoidosis : The Pivotal Role of ^{18}F-FDG PET/CT

M. Aboussabr, *I. Zahfir, M. Zekri, Z. Laadissi, N. Mahrsi, D. Alami, L. Taoussi, A. Taalabi, S. Oueriagli, A. Doudouh;*
Department of Nuclear Medicine, Mohammed V Military Teaching Hospital, Rabat, MOROCCO.

Aim/Introduction: Tuberculosis and sarcoidosis are the two main granulomatous diseases, posing a diagnostic challenge due to their overlapping clinical, radiological, and histopathological features. Their coexistence in the same patient is rare, and the disease course is a key element in refining the diagnosis. ^{18}F-FDG PET/CT proves valuable in identifying active disease, assessing its extent, and guiding biopsy procedures, thereby enhancing diagnostic accuracy. ***Materials and Methods:*** We report the case of a 45-year-old patient with a known history of systemic sarcoidosis with mediastinal-pulmonary and hepatic involvement, previously managed with corticosteroid therapy, which yielded a favorable clinical and radiological response. Six months after, the patient developed a persistent inflammatory syndrome associated with hypercalcemia, occurring in the context of weight loss estimated at 10 kg. As part of the etiological assessment, a ^{18}F-FDG PET-CT was performed. ***Results:*** The ^{18}F-FDG PET-CT demonstrated a bilateral interstitial lung pattern associated with intensely hypermetabolic alveolar micronodules (SUVmax = 16.6). In addition, multiple calcified mediastinal and hilar lymphadenopathies were noted, without significant FDG uptake, consistent with metabolically inactive lesions. Biological work-up revealed hypercalcemia, and an elevated erythrocyte sedimentation rate at 70 mm/h, indicative of a systemic inflammatory response. Microbiological analysis of sputum samples tested positive for acid-fast bacilli, and histopathological examination of a pleuropulmonary biopsy confirmed the diagnosis of caseo-follicular tuberculosis. ***Conclusion:*** The coexistence of pulmonary tuberculosis and sarcoidosis is a rare clinical entity. However, several reported cases suggest a potential association between these two conditions.

Corticosteroid therapy, the standard treatment for sarcoidosis, induces a state of immunosuppression that may facilitate the development of secondary tuberculosis. Additionally, some authors have reported concomitant cases of tuberculosis and sarcoidosis, suggesting the possibility of an underlying pathophysiological interaction. In this context, ^{18}F- FDG PET/CT stands out as a leading metabolic imaging modality for the detection and characterization of tuberculous lesions. Its primary value lies in its ability to detect active infectious foci at an early stage particularly in extrapulmonary forms with atypical presentations. It also plays a significant role in sarcoidosis by enabling whole-body assessment of metabolically active granulomatous involvement, including sites inaccessible to biopsy. In this case, PET/CT revealed active lesions that guided further investigations, ultimately leading to the diagnosis of coexistent caseo-follicular tuberculosis. Due to overlapping metabolic patterns, PET findings must be interpreted alongside histopathological and microbiological results to ensure diagnostic accuracy.

EP-1303

Giant Parathyroid Adenoma: a Multidisciplinary Clinical Case

I. Grierosu[1,2], *A. Florescu*[1,3], *R. Danila*[1,4], *C. Stefanescu*[1,2];
[1]*University of Medicine and Pharmacy „Grigore T. Popa", Iasi, ROMANIA,* [2]*Nuclear Medicine Laboratory, County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA,* [3]*Endocrinology Department, County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA,* [4]*Surgery Department, County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA.*

Aim/Introduction: The prevalence of parathyroid adenomas in the general population is about 22 cases per 100,000. Out of these, parathyroid adenomas comprise the highest percentage, 80-90%, while hyperplasia situates itself between 10 and 20%, and only under 1% are diagnosed with parathyroid carcinomas [1]. Atypical parathyroid adenomas are even more infrequent, being considered as benign disorders but associated with the potential of malignant transformation over time (parathyroid carcinoma). When a parathyroid adenoma grows more than 2 cm and weighs more than 3.5 grams, the condition is referred to as giant parathyroid adenoma. ***Materials and Methods:*** A male patient from the Endocrinology Department was referred to our laboratory to perform a ^{99m}Tc-MIBI scintigraphy. Static images after 20 minutes and 2 h, respectively, followed by SPECT-ldCT images, were acquired using a General Electric Optima NM/CT 870DR SPECT-CT gamma camera. ***Results:*** We report the clinical case of a 73-year-old man. He previously presented to the hospital with fatigue and bone aches. Being diagnosed with prostate adenocarcinoma with a Gleason score of 7 and a PSA of 5 ng/mL, MRI and CT images raised the suspicion of bone metastases. The whole-body scintigraphy mentioned many bone fixations in the skull, clavicle, ribs, and pelvis. In the meantime, the bloodwork showed increased levels of serum calcium (13.3 mg/dL) and a PTH value of 1741.7 pg/mL. ^{99m}Tc-MIBI scintigraphy identified a large uptake site on delayed images in the left thyroid lobe. A similar localization and uptake pattern as the bone scan were observed, indicating that SPECT-ldCT might diagnose multiple brown tumors. After referral to the surgical department, the large parathyroid adenoma of 5 cm was operated on. The pathology and the immunohistochemistry reports describe the anomaly as an atypical parathyroid adenoma with a Ki67 under 1%. The patient came for follow-up after 3 months. The phosphatase alkaline, calcium and PTH values were within normal limits. ***Conclusion:*** This clinical case shows the importance of the multidisciplinary approach in the management, diagnosis and subsequent treatment. This patient was a medical emergency, and the expeditious intervention with optimal communication between medical departments limited the damage that could have occurred to the other organs and systems. ***References:*** [1] Rahim Mahmodlou, Amin Sedokani, Apameh Pezeshk, Bita Najafinejad. Giant parathyroid adenoma: a case report. J Med Case Rep. 2022; 16(1):150.

EP-1304

Complete response of HCV-associated primary extranodal Diffuse Large B-cell Lymphoma to direct-acting antiviral therapy alone assessed by [^{18}F]FDG PET/CT

L. Atakishieva[1], *A. Khalimon*[2], *N. Kadymova*[1], *V. Bobrov*[2], *A. Leontev*[2];
[1]*N. Lopatkin Scientific Research Institute of Urology and Interventional Radiology - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION,* [2]*P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Chronic hepatitis C virus (HCV) infection may present a wide spectrum of extrahepatic manifestations, including lymphoproliferative disorders. Marginal zone lymphoma and diffuse large B-Cell lymphoma (DLBCL) are the subtypes of B-cell non-Hodgkin lymphoma (B-NHL) most commonly associated with HCV infection. The molecular mechanisms of relationship between HCV infection and B-NHL lymphomagenesis are still poorly understood. The evidence supporting this relationship is the regression of B-NHL observed after successful HCV eradication through antiviral therapy (AVT). The effectiveness of direct-acting antivirals (DAA) against HCV-associated indolent lymphomas in first-line therapy, especially those of marginal zone type, has been proven. Concurrent or subsequent application of DAA-based AVT and standard immunochemotherapy can be used to improve treatment outcome of DLBCL. ***Materials and Methods:*** Baseline and follow-up whole-body [^{18}F]FDG PET/CT were performed before and after DAA-based AVT alone in a patient diagnosed with primary extranodal DLBCL and a long history of HCV infection. ***Results:*** A 64-year-old female patient with a long history of untreated chronic HCV infection (genotype 1b; viral load was not measured, and AVT was not been performed since 2002) noted a mass in the left scapular region. Surgical excision with subsequent morphological study was performed. The immunohistochemical staining was negative for CD10, TdT, CD23, and EBV, and positive for CD20/PAX5, CD3/CD5, BCL2, BCL6, and MUM1, confirming the diagnosis of non-GCB DLBCL. 95% of tumor cells were Ki67-positive. To evaluate the extent of the disease, a whole-body [^{18}F]FDG PET/CT was performed. Multiple metabolically active nodules up to 21mm and SUVmax 20.6 were identified in soft tissues. HCV RNA in the blood was also quantified: 5.79 log IU/ml. The patient received a 12-week course of DAA-based AVT with sofosbuvir and daclatasvir. Following AVT, HCV RNA in the blood was undetectable. The patient underwent follow-up PET/CT, which demonstrated the elimination of all previously identified nodules in soft tissues with no pathological tracer uptake, and it was decided not to initiate standard of care immunochemotherapy. A follow-up PET/CT performed three months later showed a sustained complete metabolic and anatomical response. A sustained virological response has also been maintained. The patient has been under follow-up for six months with no signs of recurrence to date. ***Conclusion:*** The presented clinical case demonstrates that DAA-based AVT alone, as a first-line therapy, can facilitate a complete response in patients with HCV-associated DLBCL. Prospective studies are necessary to evaluate the outcomes of HCV-associated DLBCL treated with DAA-based AVT alone.

EP-1305

Peritoneal Gliomatosis vs. Carcinomatosis in Immature Ovarian Teratoma: Diagnostic Challenges of ^{18}F-FDG PET/CT

T. Moreno-Monsalve, *M. I. Castellon-Sanchez, L. Frutos-Esteban, j. L. Navarro-Fernandez, L. Mohamed-Salem, N. Sanchez-Izquierdo, T. E. Rodriguez-Locarno, A. C. Hernandez-Martinez, M. J. Ibanez-Ibanez, J. Contreras-Gutierrez;*
Hospital Universitario Virgen De La Arrixaca, Murcia, SPAIN.

Aim/Introduction: Peritoneal gliomatosis (GP), a rare benign condition characterized by mature glial tissue implants typically associated with ovarian immature teratomas, can mimic malignant peritoneal carcinomatosis on imaging. ***Materials and Methods:*** We present the case of a 27-year-old woman with a history of stage IIIC ovarian immature teratoma (treated with hysterectomy, bilateral salpingo-oophorectomy, and chemotherapy) who developed progressive left hypochondrium/flank pain, postprandial vomiting, and weight loss over two months. CT imaging demonstrated multiple peritoneal implants, including a prominent lesion in the epiploic foramen. The ^{18}F-FDG PET/CT revealed heterogeneous FDG uptake in these lesions (SUVmax 2-16), making it impossible to reliably differentiate between malignant implants and GP. Histopathological confirmation through laparoscopic biopsy ultimately demonstrated mature glial tissue without atypia or increased mitotic activity, confirming GP. ***Results:*** This case underscores several important considerations. First, GP can exhibit variable FDG avidity that overlaps significantly with malignant patterns due to the inherent metabolic activity of glial tissue. Second, while PET/CT cannot definitively distinguish GP from carcinomatosis, it remains clinically valuable both for detecting metabolically active lesions and for guiding biopsies to the most active sites. Third, histopathological confirmation is absolutely essential given the radically different treatment approaches required. The case highlights that elevated FDG uptake does not necessarily indicate malignancy in patients with ovarian teratomas and demonstrates PET/CT's dual role as both a sensitive detection tool and a guide for targeted biopsy ***Conclusion:*** Ultimately, this reinforces the need for a multidisciplinary approach when evaluating peritoneal lesions in ovarian teratoma patients, particularly when confronting diagnostically challenging, morphologically overlapping entities like GP and carcinomatosis. In such scenarios, ^{18}F-FDG PET/CT proves invaluable as both a metabolic imaging modality and a strategic guide for diagnostic intervention.

EP-1306

PSMA PET/CT uptake in metastatic melanoma: a case report

G. Barbosa, *T. Alves, C. Torricelli, L. Macedo, D. Mendanha, H. Sousa, E. Nogueira-Lima, V. Heringer, N. Tobar, J. Sousa, C. Lima, E. Etchebehere;*
Unicamp, Campinas, BRAZIL.

Aim/Introduction: Melanoma is the most aggressive skin cancer, and it has become a significant public health concern. ^{18}F-FDG PET/CT has been widely used for clinical management in patients with melanoma. Recent studies highlight the potential of PSMA PET/CT as an additional diagnostic modality in cases of metastatic melanoma. ***Materials and Methods:*** A 20-year-old male patient was diagnosed with a malignant melanoma (Breslow <4mm / Clark IV) in the left region of the neck. After 1 year he progressed and was submitted to surgical excision of metastatic cervical lymph nodes. The patient was submitted to a restaging FDG PET/CT and within 24 hours a ^{18}F-PSMA-1007 PET/CT. The SUV max was calculated semi automatically for each lesion in both exams and compared. ***Results:*** FDG PET/CT showed increased radiotracer uptake consistent with multiple metastases in cervical, mediastinal, thoracic, and axillary lymph nodes, pulmonary nodules, a left lung mass, both adrenals, liver nodules, peritoneal implants, bones, multiple skin lesions (especially in the chest and right abdomen) and muscle implants. The highest FDG uptake was noted in the left iliac bone (SUV = 34). PSMA PET/CT demonstrated uptake in the same sites of metastases identified on FDG PET/CT, with the exception of liver metastases, only identified in the latter exam. In PSMA PET/CT the highest uptake was in a subcarinal lymph node (SUV =18). Differently, PSMA PET/CT demonstrated a brain metastasis, not identified on FDG PET/CT. ***Conclusion:*** Beyond its established role in the staging of prostate cancer, PSMA PET/CT may be a potential tool to evaluate metastatic melanoma, offering promising avenues for theranostic applications. ***References:*** 1) Gosman L. et al. EP-1307

Bilateral Cerebellar Atrophy and Hypometabolism on Brain FDG PET/CT in a Case Using Antiepileptic Drugs for 38 Years Due to Drug-Resistant Epilepsy

B. Bozca[1], *N. Aydinbelge Dizdar*[1], *E. Tatci*[1], *A. Cilliler*[2], *D. Cayir*[1], *A. Cinar*[1], *O. Ozmen*[1];
[1]*Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Etlik City Hospital, Department of Neurology, Ankara, TÜRKIYE.*

Aim/Introduction: Epilepsy is a chronic neurological condition characterised by recurrent seizures and is one of the most common neurological disorders. Antiepileptic drug (AED) therapy is the first-line treatment option used to control seizures. In patients with epilepsy, cerebellar atrophy may be observed as a finding caused both by anoxic-cellular damage due to seizure activity and as a result of AED use. This report presents the findings of a 40-year-old male patient with drug-resistant epilepsy who has been using AEDs for 38 years. Brain FDG PET/CT was performed to identify the epileptogenic focus, revealing bilateral symmetrical cerebellar hypometabolism and cerebellar atrophy, accompanying a hypometabolism consistent with an epileptogenic focus in the left temporal lobe. ***Materials and Methods:*** Following a febrile convulsion at the age of two, the patient developed generalised tonic-clonic epilepsy and has been on AEDs for 38 years. He presented to the neurology clinic due to experiencing seizures 3-4 times per month. During seizures, the patient described tonic contractions in the right arm and abdominal pain prior to the episodes. MRI showed reduced hippocampal volume on the left and increased signal intensity on T2-weighted images. These findings were considered potentially consistent with mesial temporal sclerosis. Video EEG monitoring revealed focal epileptiform activity originating from the left temporal region. Brain FDG PET/CT was performed to identify the epileptogenic focus in this patient with AED-resistant seizures. PET/CT showed marked hypometabolism in the mesial and lateral aspects of the left temporal lobe, supporting the presence of an epileptogenic focus. Additionally, symmetrical and severe hypometabolism was observed in the bilateral thalami and cerebellum, accompanied by bilateral cerebellar atrophy on CT imaging. ***Conclusion:*** Mesial temporal lobe epilepsy (MTLE) is the most common type of epilepsy and is associated with cerebellar degeneration. FDG PET/CT plays a significant role in the diagnosis of MTLE. Under normal conditions, FDG uptake in the cerebellum is high, and the cerebellum is one of the regions used as a reference in the interpretation of brain FDG PET/CT scans. However, as seen in this case, cerebellar hypometabolism may accompany long-standing epilepsy and should be taken into consideration.

EP-1308

Differential diagnosis of a pancreatic lesion in a pediatric patient: contribution of Nuclear Medicine - A case report

A. Sagastegui Alca, *G. Martinez Gomez, C. Ruiz Corbalán, T. Rodríguez Locarno, M. Castellón Sánchez, A. Hernández Martínez, N. Sánchez Izquierdo, L. Frutos Esteban, L. Mohamed Salem, M. Ibáñez Ibáñez, J. Navarro Fernandez, T. Moreno Monsalve, J. Contreras Gutiérrez;*
Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Pancreatic lesions in pediatric patients are uncommon and present a diagnostic challenge in individuals with complex genetic backgrounds such as neurofibromatosis type 1 (NF1). Patients with NF1 have a 2-4 fold increased risk of tumor development, with malignancy rates estimated between 5-15 %. The differential diagnosis includes both benign and malignant entities, such as intrapancreatic accessory spleen (IPAS) and neuroendocrine tumors (NETs). Nuclear medicine techniques offer a non-invasive and specific approach to clarify the etiology of the mass, potentially avoiding invasive procedures such as laparoscopic surgery or laparotomy. ***Materials and Methods:*** A 12-year-old female pediatric patient with a history of NF1 and deletion of the 3q28-29 gene was admitted to the Emergency Department due to abdominal pain. Abdominal ultrasound revealed a hypoechoic lesion adjacent to the spleen. Subsequent MRI evaluation identified a pancreatic tail lesion (3.5 × 2,9 × 2.7 cm) that appeared to receive at least one branch from the splenic artery. The differential diagnosis included malignant conditions such as NET and IPAS. ***Results:*** A PET-CT scan with intravenous injection of 118 Megabecquerels (MBq) of [^{68}Ga]Ga-DOTA-TOC was performed under sedation to evaluate somatostatin receptor expression. To further assess the possibility of ectopic splenic tissue, a scintigraphy with [^{99m}Tc]Tc-heat-denatured red blood cells (HDRBC) with intravenous injection of 22,2 MBq and abdominal SPECT-CT was also conducted. The PET-CT revealed physiological uptake in the spleen and pancreas, with no abnormal tracer uptake in the pancreatic lesion, ruling out a somatostatin receptor-positive NET. On the [^{99m}Tc]Tc-HDRBC scintigraphy with additional SPECT-CT, the pancreatic lesion appeared as a hypodense, cystic-appearing structure without focal tracer uptake, making the diagnosis of IPAS unlikely. Considering the imaging findings alongside the clinical context and underlying conditions of the patient, a conservative approach with follow-up imaging was decided. ***Conclusion:*** This case highlights the complementary role of nuclear medicine techniques in the study of pancreatic lesions in pediatric patients with complex syndromic backgrounds. [^{68}Ga]Ga-DOTA-TOC PET-CT provides valuable information in ruling out neuroendocrine tumors by assessing receptor expression, while [^{99m}Tc]Tc-HDRBC scintigraphy combined with SPECT-CT serves as a reliable method for identifying splenic tissue due to its high sensitivity and specificity. The combined use of both techniques provided valuable diagnostic clarity, helping to avoid invasive procedures in a vulnerable patient population. ***References:*** Hernández Muela S, Navío Anaya M, De la Osa Langreo A, Gargallo P, Menor F, Zúñiga A, et al. Neurofibromatosis tipo 1. Protoc diagn ter pediatr. 2022;1:341-352.

EP-1309

Silent Until Late: the Diagnostic Power of 24-hour ^{99m}Tc-PYP RBC Scintigraphy in Gastrointestinal Angiodysplasia

M. Epure[1], *I. Grierosu*[1,2], *C.-M. Antohie*[1], *A.-M. Statescu*[1], *W. Jalloul*[1,2], *C.-R. Stolniceanu*[1,2], *R.-R. Ion*[1], *S. Dejmasu*[1], *A.-M. Nistor*[1], *C. Stefanescu*[1,2];
[1]*Nuclear Medicine Laboratory, „Sf. Spiridon" County Emergency Hospital, Iasi, ROMANIA,* [2]*Grigore T. Popa University of Medicine and Pharmacy, Iasi, ROMANIA.*

Aim/Introduction: Angiodysplasia is an abnormal dilation of small blood vessels located within the mucosal and submucosal layers of the gastrointestinal (GI) tract. This is one of the most common causes of occult bleeding, particularly in elderly patients. The most frequent location of angiodysplasia is the colon [1]. Diagnosis is often difficult due to the episodic pattern of the bleeds. This case series aimed to evaluate the utility of ^{99m}Tc-pyrophosphate-labeled red blood cell (RBC) scintigraphy in identifying angiodysplasia, with particular attention to findings at delayed images (24-hour). ***Materials and Methods:*** A retrospective analysis was conducted on 24 patients with severe anemic syndrome, referred for identifying GI bleedings in our laboratory. For five of them we noticed the absence of a visibile spot during the first 4 hours. The technique used is the in vivo labeling method of RBC with 740 MBq ^{99m}Tc-PYP. Dynamic during 1 hour and static images at 1h, 2h, 3h, 4h were acquired. If no radiopharmaceutical accumulation is observed on the initial images in the first day of acquisition, additional images were performed at 24 hours on GE Medical Systems, OPTIMA NM/CT 870DR. ***Results:*** In the series of five patients, the prior investigations didn't identify a source of bleeding. Scintigraphic images interpretation focused on identifying sites of active or intermittent bleeding. Earlier acquisitions, up to 4 hours, didn't reveal any bleeding spots. Extended acquisition times at 24 hours improved lesion detection and localization. The static images highlighted angiodysplasic lesions which have been confirmed with SPECT-CT low-dose in the wall of the proximal portion of the ascending colon, ileo-cecal junction, distal jejunum and ileum. Even if the prevalence of angiodysplasia increases with age, mainly occurring in patients over 60 years old [2], one of them is a 29-year-old young adult. ***Conclusion:*** Scintigraphy with labeled RBC proved to be a sensitive and non-invasive method for accurately locating the source of GI hemorrhage. The delayed 24h images have a crucial role in the detection of angiodysplasic lesions, when standard 4 hours protocol is unable to identify the bleeding source. Therefore, in relation with our experience, we suggest extending acquisition time to improve a correct diagnostic. ***References:*** [1]. Ueno S, et al. Clinical features of Japanese patients with colonic angiodysplasia. J Gastroenterol Hepatol. 2008 ;23(8 Pt 2):e363-6; [2].Dodda G, Trotman BW. Gastrointestinal angiodysplasia. J Assoc Acad Minor Phys. 1997;8(1):16-9.

EP-1310

Ectopic Thyroid Tissue in the Hepatic Hilum: A Rare Case of a 40-Year-Old Woman Presenting with Epigastric Pain

B. Yilmaz, *E. Gokdemir, M. Kaya, B. E. Akkas;*
University of Health Sciences Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicin, Istanbul, TÜRKIYE.

Aim/Introduction: Ectopic thyroid tissue is rare embryological anomaly caused by abnormal migration of the thyroid gland. Localization in the hepatic hilum is extremely uncommon. This report presents a case of a 40-year-old woman who presented with epigastric pain and was found to have ectopic thyroid tissue in the hepatic hilum. ***Materials and Methods:*** The patient initially underwent endoscopy and abdominal MRI at an external center. MRI incidentally revealed a suspicious lesion adjacent to the hepatic hilum. She was referred to our institution, where contrast-enhanced abdominal CT, FDG PET/CT, and endoscopic ultrasound (EUS) were performed. Tumor markers were within normal limits such as carcinoembryonic antigen and carbohydrate antigen 19-9 . Due to suspicion of gastrointestinal stromal tumor (GIST), fine-needle aspiration biopsy (FNAB) was followed by robotic excisional biopsy. Postoperatively, the patient underwent whole-body thyroid scintigraphy and thyroid ultrasound. FNAB of iso-echoic thyroid nodules confirmed benign pathology. Thyroid function tests were within normal range. ***Results:*** MRI revealed a 4×3 cm lesion at the hepatic hilum with showing mild contrast enhancement and signal intensity similar to the liver on T1- and T2-weighted sequences, raising suspicion for gastrointestinal stromal tumor (GIST). Although differential diagnoses included

pathological lymph node or cyst . Contrast-enhanced CT showed a 41×35 mm well-circumscribed iso-hyperdense lesion with millimetric hypoattenuated cystic-like components (HU: 62.61), suspected to be pedunculated hepatic mass.PET/CT was concluded as follows: well-defined nodular lesion at the level of the hepatic hilum with no significant hypermetabolic activity (SUVmax: 3.4) ; a hypodense nodular lesion without pathological metabolic activity in the mid-portion of the right thyroid lobe; and no findings suggestive of malignancy elsewhere in the body. FNAB suggested metastasis from well-differentiated thyroid carcinoma characterized by predominant follicular pattern . Robotic surgical resection was performed. Histopathology revealed nodular colloidal thyroid tissue with follicular pattern, confirming ectopic thyroid. Postoperative Tc-99m sodium pertechnetate scintigraphy showed no additional ectopic foci. The patient remained euthyroid. ***Conclusion:*** Ectopic thyroid tissue in the hepatic hilum is extremely rare. It should be considered in the differential diagnosis of well-circumscribed, non-FDG-avid porta hepatis masses that demonstrate hyperattenuation on non-contrast CT and have negative tumor markers. The differential diagnosis includes hilar cholangiocarcinoma, lymphoma, and other perihilar hepatic lesions. Histopathological confirmation remains crucial. Treatment decisions should be guided by patient age, lesion location, symptoms, malignancy potential, and surgical risk. This case aims to raise awareness of this rare entity, which may mimic malignant tumors of the porta hepatis.

EP-1311

Use of [^{99m}Tc]Tc-heat-denatured red blood cells scintigraphy in the evaluation of renal metastases versus splenic implants in a patient with renal carcinoma

A. Sagastegui Alca, *G. Martínez Gomez, C. Ruiz Corbalán, M. Castellón Sánchez, T. Rodríguez Locarno, N. Sánchez Izquierdo, T. Moreno Monsalve, J. Navarro Fernandez, A. Hernández Martínez, M. Ibáñez Ibáñez, L. Frutos Esteban, L. Mohamed Salem, J. Contreras Gutiérrez;*
Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Abdominal splenosis is an uncommon, benign condition resulting from the autotransplantation of splenic tissue after splenic trauma or splenectomy. While typically asymptomatic, it may mimic malignant lesions on imaging, posing a diagnostic challenge, particularly in patients with an oncologic background. [^{99m}Tc]Tc-heat-denatured red blood cells (HDRBC) scintigraphy combined with SPECT-CT offers a non-invasive, sensitive, and specific method to differentiate splenosis from tumoral tissue, potentially avoiding unnecessary invasive procedures and supporting clinicians in the diagnostic and therapeutic decision-making process. ***Materials and Methods:*** A 58-year-old male with a history of papillary renal cell carcinoma underwent left radical nephrectomy, followed by robotic splenectomy due to hypodense splenic lesions of uncertain etiology. On follow-up abdominal CT, new nodular changes were observed in the former splenic bed, raising suspicion of either local tumor recurrence or splenosis. Given the patient's oncologic history and persistent fatigue, further diagnostic evaluation was required. A [^{99m}Tc]Tc-HDRBC scintigraphy with abdominal SPECT-CT was performed to help determine the etiology of the lesions. ***Results:*** A scintigraphy with intravenous injection of 445 Megabecquerels (MBq) of [^{99m}Tc]Tc-HDRBC and abdominal SPECT-CT was conducted. Planar imaging demonstrated focal tracer uptake in the left upper abdominal quadrant. Hybrid SPECT-CT further localized this activity to nodular lesions anterior to the left quadratus lumborum muscle, with anatomical correlation to previously documented findings on CT. These images were consistent with intraperitoneal splenic tissue implants (splenosis), thereby excluding the possibility of malignant recurrence. Given the absence of clinical progression and the benign imaging profile, a conservative management strategy with follow-up imaging was adopted. ***Conclusion:*** This case highlights the diagnostic value of [^{99m}Tc]Tc-HDRBC scintigraphy in differentiating splenosis from malignant recurrence in a patient with complex surgical and oncologic history. SPECT-CT imaging allows for precise localization and characterization of ectopic splenic tissue due to its high sensitivity and specificity. This enables accurate diagnosis and prevents unnecessary invasive procedures or oncologic treatments. In asymptomatic patients, conservative management with follow-up imaging can be safely considered. By resolving diagnostic ambiguity, nuclear medicine imaging plays a pivotal role in optimizing patient management and reducing the risk of overtreatment in challenging clinical cases.

EP-1312

Chylothorax After Pericardiectomy: A Case Study Utilizing Lymphoscintigraphy for Diagnosis and Follow-up

G. Martínez Gómez, *C. Ruiz Corbalán, A. Sagastegui Alca, T. Rodríguez Locarno, N. Sánchez Izquierdo, T. Moreno Monsalve, M. Castellon Sánchez, A. Hernández Martínez, L. Mohamed Salem, L. Frutos Esteban, J. Navarro Fernández, M. Ibáñez Ibáñez, J. Contreras Gutiérrez;*
Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Chylothorax is an abnormal accumulation of chyle in the pleural space, resulting from injury or disruption of the thoracic duct. In adults, the most common cause of chylothorax is thoracic duct trauma secondary to surgical procedures. Lymphoscintigraphy with ^{99m}Tc-labelled human serum albumin nanocolloid evaluates the lymphatic system, enabling the detection of obstructions, leaks, or drainage abnormalities. ***Materials and Methods:*** A 44-year-old male was admitted with constrictive pericarditis, mediastinal adenopathy, and interstitial lung involvement. Treatment with corticosteroids, colchicine, and diuretics was initiated. A month later, the patient developed a right posterior tibial deep vein thrombosis in the context of immobilization, treated with fondaparinux. He was admitted for thoracentesis, which yielded pleural fluid compatible with chylothorax. He underwent pericardiectomy via median sternotomy, during which a large amount of chylous effusion was aspirated from the right pleural space. Intranodal lymphangiography was performed via inguinal lymph node puncture with Lipiodol injection, showing no detectable leaks. He was readmitted due to right-sided pleural effusion, again consistent with chylothorax and left arm swelling. ***Results:*** Physical examination revealed diffuse edema, induration, collateral circulation, violaceous discoloration, and absent radial pulse. He had no fever, dyspnea, cough, or constitutional symptoms. Doppler ultrasound of the upper limbs and pulmonary artery computed tomography angiography demonstrated thrombosis of the left jugulosubclavian vein and increased pleural effusion. A lower limb lymphoscintigraphy was requested to investigate a possible lymphatic leak. Early and delayed dynamic image acquisition, along with delayed Single Photon Emission Computed Tomography/Computed Tomography (SPECT/CT) imaging, revealed findings suggestive of lymphatic leakage, with tracer accumulation in the left pleural effusion and around the heart. Partial obstruction of the right lower limb lymphatic drainage was also observed.Fibrinolysis with continuous urokinase perfusion was administered for 48 hours, followed by discontinuation and re-initiation of fondaparinux. Control venography showed recanalization of the subclavian vein.A follow-up lymphoscintigraphy showed no evidence of lymphatic leakage into the pleural space or pericardium. Based on the imaging findings, the patient was discharged with nutritional recommendations and scheduled follow-up. ***Conclusion:*** Chylothorax may arise as a complication following pericardiectomy and can be exacerbated by left jugulosubclavian vein thrombosis. Lower limb lymphoscintigraphy, complemented by SPECT/CT, played a crucial role in diagnosing lymphatic leakage and during follow-up, confirming its resolution after treatment. This imaging

modality is essential as it provides functional information that complements conventional structural techniques and informs therapeutic decision-making.

EP-1313

The importance of radiosynoviorthesis in the treatment of pigmented villonodular synovitis in pediatric patients

J. Weissensteiner[1], *D. Genšor*[2];
[1]*Department of Nuclear Medicine, Hospital Poprad, Poprad, SLOVAKIA,* [2]*Clinic of Children and Adolescents, Jessenius Faculty of Medicine in Martin, University Hospital Martin, Martin, SLOVAKIA.*

Aim/Introduction: Pigmented villonodular synovitis (PVNS) is a locally aggressive disease of the synovium characterized by joint effusion, synovial hypertrophy, hemosiderin deposition, and bone erosion. It most commonly affects the knee, but may also involve the hip, ankle, shoulder, or elbow joints. ***Materials and Methods:*** A 5-year-old boy diagnosed with juvenile idiopathic arthritis was initially treated with antimetabolites and systemic corticosteroids. Due to polyarthritis and persistent arthritis of the left knee joint, biological therapy was initiated. Sonographic examination of the knee joint revealed synovial hypertrophy and hemarthrosis. Magnetic resonance imaging demonstrated synovial proliferation along with small hypointense hemosiderin deposits. The presence of synovitis in the left knee joint was confirmed by three-phase skeletal scintigraphy. ***Results:*** Radiosynoviorthesis of the left knee joint was performed three months after the skeletal scintigraphy examination. During knee joint aspiration, 35 milliliters of sanguineous synovial fluid were obtained. Subsequently, 50 megabecquerels of colloidal Rhenium-186 sulfide (Re-186) were administered intra-articularly. The injection was followed by needle flushing using a combination of a local anesthetic and corticosteroid. Post-procedurally, the joint was immobilized with an elastic bandage, and the patient was advised to avoid weight-bearing on the affected limb for three days. ***Conclusion:*** Radiosynoviorthesis represents a potentially effective localized treatment for pigmented villonodular synovitis (PVNS) of the knee joint in pediatric patients. When combinated with other therapeutic approaches, it may offer a viable alternative to surgical intervention.

EP-1314

Incidental Occipital Spur Uptake on Tc-99m PYP Scintigraphy: An Uncommon Finding in Cardiac Amyloidosis

B. Arca, *E. G. Isik, E. Inal, Y. Sanli;*
Istanbul University, Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE.

Aim/Introduction: An occipital spur is an abnormal bony protrusion that generally develops at the external occipital protuberance (EOP). The EOP has three distinct morphological variants: type I (smooth surface), type II (crest-like shape), and type III (spine-like appearance). Occipital spurs are generally associated with spondylosis or osteoarthritis and may also develop because of repeated trauma. Although incidental and benign, it is important to recognize the entity to differentiate it from metastatic lesions. ***Materials and Methods:*** A 31-year-old male, diagnosed with common variable immune deficiency (CVID) and Thrombospondin Type 1 Domain Containing 1 (THSD1) gene mutation which leads to primary lymphedema, was referred to Tc-99m pyrophosphate (PYP) scintigraphy upon suspicious amyloidosis findings in cardiac-MRI. ***Results:*** Tc-99m PYP scintigraphy revealed no significant myocardial uptake on either the early or late images and corresponding to a grade 0. However, an incidental finding revealed focal increased uptake in the occipital bone on the whole-body posterior images and SPECT-CT images was showed a focal spine-like hyperostosis which was seen in the occipital protuberance extending in a craniocaudal direction which was confirmed to be an occipital spur (Type III spine form). ***Conclusion:*** Tc-99m PYP scintigraphy is a reliable imaging tool primarily used for the noninvasive diagnosis of ATTR cardiac amyloidosis; however incidental uptake in other regions of the body has occasionally been reported. Although only a limited number of cases have been reported in the literature with Tc99m MDP, to our knowledge this is the first reported case demonstrating the visualization of an occipital spur using Tc-99m PYP scintigraphy. ***References:*** 1) Marshall RC, Abela C, Eccles S. Painful exostosis of the external occipital protuberance. J Plast Reconstr Aesthet Surg. 2015;68: e174-e176 2) Muzaffar R, Alassi A, Mashal M, Osman MM. EP-1315

When Conventional Imaging Does not Reveal the Etiology: ^{18}F-FDG PET-CT Diagnosis of Spondylodiscitis in Recurrent Fever

G. Martínez Gómez, *C. Ruiz Corbalán, A. Sagastegui Alca, T. Moreno Monsalve, T. Rodríguez Locarno, N. Sánchez Izquierdo, M. Castellon Sánchez, A. Hernández Martínez, M. Ibáñez Ibáñez, L. Mohamed Salem, J. Navarro Fernández, L. Frutos Esteban, J. Contreras Gutiérrez;*
Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Spondylodiscitis is the inflammation and/or infection of the vertebral bodies and adjacent intervertebral discs. Due to its nonspecific symptoms and need for prolonged treatment, a multidisciplinary approach is crucial for accurate diagnosis. ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET-CT) has demonstrated superior sensitivity and specificity compared to conventional imaging in diagnosing this condition. ***Materials and Methods:*** A 94-year-old patient was hospitalized multiple times for recurrent fever of unknown origin. No identifiable infectious focus was found despite extensive testing, including blood and urine cultures, chest radiography, echocardiography and abdominal ultrasound. Laboratory analyses consistently showed elevated inflammatory markers. He received empirical intravenous antibiotic treatment, with transient clinical improvement. ***Results:*** During the fourth hospitalization, an ^{18}F-FDG PET-CT was performed to localize a potential occult source of infection. The ^{18}F-FDG PET-CT revealed marked erosive changes and irregularity of the endplates of vertebrae D12 and L1, with mild but significant metabolic hyperactivity (increased ^{18}F-FDG uptake) at the same level, strongly suggestive of spondylodiscitis. These findings were not previously detected with conventional imaging. A follow-up lumbar spine MRI confirmed the diagnosis, showing characteristic features of vertebral osteomyelitis and adjacent disc involvement. A vertebral biopsy was performed, yielding reactive trabecular bone with areas of necrosis and reduced hematopoietic tissue. Microbiological cultures for bacteria and fungi were negative, likely due to prior antibiotic exposure. Despite the absence of a microbiological isolate, the clinical, metabolic, and radiological findings were consistent with spondylodiscitis. Antimicrobial therapy was adjusted, and the patient showed clinical stability without new febrile episodes.The ^{18}F-FDG PET-CT in this case, allowed not only localization of the infectious focus

but also differentiation from other possible etiologies such as degenerative changes or malignancy. The ability of ^{18}F-FDG PET-CT to depict metabolic activity enables the detection of early-stage infectious processes and facilitates diagnosis in cases with inconclusive or non-specific findings on conventional imaging modalities. Furthermore, ^{18}F-FDG PET-CT has demonstrated utility in delineating disease extent, monitoring therapeutic response and providing prognostic information through quantification of metabolic activity, particularly via standardized uptake values (SUVmax). ***Conclusion:*** Spondylodiscitis is a rare, but serious cause of fever of unknown origin, particularly in elderly patients. Early diagnosis requires a multidisciplinary approach, with ^{18}F-FDG PET-CT emerging as a key imaging modality. Its ability to detect metabolically active lesions makes it superior to conventional imaging in complex cases. Alongside MRI, ^{18}F-FDG PET-CT should be considered in persistent or unexplained fevers, especially when standard tests are inconclusive.

EP-1316

Beyond Lytic Lesions: A Rare Case of Sclerotic Multiple Myeloma Without POEMS Syndrome

P. Spiridon[1,2], *T. Cristica*[2], *C. Mazilu*[3,2];
[1]*Carol Davila University of Medicine and Pharmacy, Bucharest, ROMANIA,* [2]*Affidea, Bucharest, ROMANIA,* [3]*Carol Davila Central Emergency Military University Hospital, Bucharest, ROMANIA.*

Aim/Introduction: Multiple myeloma is a hematologic malignancy characterized by the uncontrolled proliferation of plasma cells and is often associated with lytic bone. Osteosclerotic lesions are an uncommon manifestation of multiple myeloma (presented in less than 3% of all cases), typically associated with POEMS syndrome [1]. The aim of this paper is to present a rare case of multiple myeloma with sclerotic lesions, in the absence of POEMS syndrome. ***Materials and Methods:*** We report the case of a 70-year-old male with a medical history of hypertension, type 2 diabetes and benign prostatic hyperplasia, who presented with thoraco-lumbar pain, spinal cord compression and grade D spinal cord injury according to the Frankel scale. ***Results:*** Preoperative imaging (CT and IRM) revealed a lesion involving the T3 vertebral body, extending into the spinal canal and infiltrating adjacent soft tissues. Surgical intervention included posterior decompression and vertebral stabilization. Histopathological and immunohistochemical analysis confirmed a malignant plasma cell proliferation, with predominant lambda light chain expression**.**A whole-body F18-FDG PET-CT was performed for staging. It revealed increased FDG uptake at the T3 left posterior lamina, with additional metabolically active osteosclerotic lesions at T6 and L3. Several metabolically inactive sclerotic lesions were observed diffusely throughout the skeleton.No clinical or paraclinical signs of POEMS syndrome (polyneuropathy, endocrinopathy, organomegaly, skin changes, etc.) were present. ***Conclusion:*** This case illustrates a rare presentation of multiple myeloma with osteosclerotic lesions and no clinical signs of POEMS syndrome. This case underscores the need for awareness of atypical imaging patterns in multiple myeloma and highlights the diagnostic value of PET-CT in staging and therapeutic planning. ***References:*** 1. Lost in Migration: A Rare Case of Ectopic Parathyroid Adenoma

R.- . Ion[1], *I. Grierosu*[1,2], *A. Ungureanu*[3], *E. Palade*[4,5], *I. Titu*[4,5], *M. Mlesnite*[5], *M. Epure*[1], *S. Dejmasu*[1], *A. Nistor*[1], *C. Stefanescu*[1,2];
[1]*Nuclear Medicine Laboratory, „Sf. Spiridon" County Emergency Hospital, Iasi, ROMANIA,* [2]*"Grigore T. Popa" University of Medicine and Pharmacy, Iasi, ROMANIA,* [3]*Emergency Clinical Hospital, Piatra Neamt, ROMANIA,* [4]*Department of Surgery, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [5]*Thoracic Surgery Clinic, "Leon Daniello" Clinical Hospital of Pneumology, Cluj-Napoca, ROMANIA.*

Aim/Introduction: Parathyroid adenoma (PA) accounts for approximately 80-85% of primary hyperparathyroidism cases. Among these, 6-16% are located ectopically, and their identification is crucial for addressing the underlying cause of hyperparathyroidism (1). Due to their anatomical position, ultrasound visualization can be challenging or even impossible, and in some cases, even CT imaging fails to provide a clear diagnosis. Consequently, nuclear imaging has become an essential tool in the diagnostic workup of parathyroid pathology. ***Materials and Methods:*** From 1,061 parathyroid scintigraphies performed in our laboratory, over the past 15 years, 67 cases are a PA with ectopic localisation. We selected a case with a rare ectopic localisation of the PA in the paracardiac region. The other ectopic localisation founded are in: superior cervical region (5), inferior thyroidal region (34), anterior-superior mediastinum (17) and thymus region (10). The imaging protocol involved intravenous administration of 740 MBq of ^{99m}Tc-sestamibi, followed by static image acquisition at 20 and 120 minutes post-injection. Additionally, a hybrid low-dose SPECT/CT scan was performed at 120 minutes. Image acquisition was conducted using a General Electric Medical System gamma camera, model OPTIMA NM/CT 870DR. ***Results:*** The patient, 68-year-old male, presented to the emergency department with lumbar pain and was diagnosed with reno-ureteral lithiasis and underwent surgical intervention. A subsequent recurrence required reoperation. In the middle time, biochemical analyses revealed markedly elevated PTH levels (624.10 pg/mL), prompting further investigation of the parathyroid glands. Ultrasound and CT examination did not reveal any pathological parathyroid tissue, therefore the patient was referred to our laboratory for scintigraphic exploration. The scintigraphic findings were positive for an ectopic PA located in the anterior-inferior mediastinum, paracardiac region. The patient subsequently underwent videothoracoscopic parathyroidectomy, and histopathological examination confirmed the diagnosis of PA. ***Conclusion:*** PA is a benign tumour responsible for hyperparathyroidism, which disrupts calcium and phosphorus homeostasis. Surgical excision remains the only definitive treatment. Due to their small size and anatomical location, the parathyroid glands pose significant challenges for imaging. Moreover, ectopic migration during early embryological development further complicates their detection, as was the situation in our case. The identification of the ectopic PA represented a turning point in the patient's management, leading to an improved quality of life, cessation of renal stone formation, and prevention of further deterioration in renal function. ***References:*** 1. Roy M, Mazeh H, Chen H, Sippel RS. Incidence and localization of ectopic parathyroid adenomas in previously unexplored patients. World J Surg. 2013; 37(1):102-6.

EP-1318

Necrotizing external otitis - Can ^{68}Ga-citrate PET/CT have a role?

J. Rebelo[1], *A. Moreira*[1], *R. Silva*[1], *G. Costa*[1,2], *S. Barata*[1], *S. Paiva*[1], *L. Diogo*[1], *C. Isabel*[1];
[1]*Unidade Local de Saúde de Coimbra - CHUC, Coimbra, PORTUGAL,* [2]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Necrotizing external otitis (NEO) is a potentially life-threatening infection that often leads to skull base osteomyelitis. Early diagnosis and evaluation of disease extent are critical, as delayed treatment can result in significant morbidity. While anatomical imaging modalities such as CT and MRI are valuable, they may fall short in differentiating active infection from post-

treatment changes. On the other hand, traditional scintigraphic techniques, such as 67Ga-citrate scintigraphy, present a challenge in this pathology, primarily due to their low spatial resolution. ^{68}Ga-citrate PET/CT, by leveraging the infection-targeting properties of gallium alongside all the advantages of PET/CT, may serve as a valuable tool in the diagnosis and management of these patients. Here we present the case of a patient with NEO, highlighting the potential role of ^{68}Ga-citrate PET/CT in the workup of these patients. ***Materials and Methods:*** A 72-year-old male was admitted to the hospital in November 2023 with clinical suspicion of NEO. ***Results:*** During hospitalization, a CT scan was performed, revealing findings suggestive of NEO involving the left temporomandibular region and the parapharyngeal spaces. Subsequently, a bone scan was done, with increased radiotracer uptake in the left temporomandibular joint and asymmetric uptake in the clivus, increased on the left side. Following clinical improvement, the patient was discharged and scheduled for follow-up. In February 2024, the patient was re-admitted due to symptom recurrence. A new CT scan showed apparent progression of the infeccious process, and MRI findings were concordant. A repeat bone scan showed maintained uptake in the left temporomandibular joint. A ^{68}Ga-citrate PET/CT scan was then performed, revealing increased radiotracer uptake predominantly in the right prevertebral and carotid spaces. The patient continued treatment and showed gradual clinical improvement. Approximately two months later, after the symptoms had nearly resolved, a follow-up ^{68}Ga-citrate PET/CT was performed, demonstrating a marked reduction in radiotracer uptake. No signs of recurrence have been observed to date. ***Conclusion:*** The observed correlation between PET/CT findings and clinical evolution in this patient supports the potential utility of ^{68}Ga-citrate PET/CT, especially in monitoring treatment response. As experience grows, it may emerge as an adjunct in the management of NEO, potentially reducing unnecessary prolonged antimicrobial therapy. Further studies are warranted to validate its use in clinical settings. Nonetheless, this case underscores the promising role of ^{68}Ga-citrate PET/CT in addressing a longstanding imaging gap in complex infectious diseases of the skull base.

EP-1320

The role of ^{18}F-FDG PET in Familial Fatal Insomnia

J. Rebelo[1], *M. Cunha*[1], *R. Silva*[1], *G. Costa*[1,2], *S. Barata*[1], *S. Paiva*[1], *D. Lameirão*[1], *I. Casimiro*[1];
[1]*Unidade Local de Saúde de Coimbra - CHUC, Coimbra, PORTUGAL,* [2]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Fatal Familial Insomnia (FFI) is na inherited prion disease characterized by progressive and intractable insomnia, followed by autonomic dysfunction, motor abnormalities, and ultimately death. Clinically, FFI presents with a constellation of neuropsychiatric symptoms that initially resemble primary sleep disorders or psychiatric conditions, often leading to misdiagnosis. Neuroimaging frequently reveal characteristic abnormalities, particularly in the thalamus, which plays a central role in the regulation of sleep-wake cycles. ***Materials and Methods:*** This case report presents a patient with a clinical suspition of FFI, highlighting the crucial role that functional brain imaging on the early diagnosis of this condition. ***Results:*** A 51-year-old male with a known family history of FFI on his paternal side presented in August 2022 with initial complaints of insomnia, which began in the context of psychosocial stress related to a recent divorce. The insomnia initially showed some improvement. A brain MRI performed in July 2023 was unremarkable, showing no significant structural abnormalities. The patient remained under outpatient follow-up with persistent, fluctuating insomnia. Laboratory investigations, including HIV and syphilis serologies, thyroid function tests, serum vitamin B12, and folate levels, were within normal limits. Due to previous surgical interventions complicating the procedure, a lumbar puncture was deferred. Given the strong family history and ongoing sleep disturbances, an ^{18}F-FDG PET scan was performed in March 2024. The imaging revealed subtle hypometabolism in the precuneus, parietal, and frontal lobes, with more pronounced hypometabolism in the thalamus, particularly on the right side. At the subsequent follow-up in July 2024, the patient exhibited marked clinical deterioration, characterized by worsening insomnia with complex sleep disturbances, including REM behavior disorder-like symptoms (dream enactment), dysautonomia, especially temperature regulation dysfunction, neuropsychiatric symptoms, including delirium, and progressive bulbar signs, most notably dysarthria and dysphagia. Following this visit, the patient was lost to regular follow-up due to relocation abroad and is currently reported to be enrolled in a clinical trial for FFI. ***Conclusion:*** This case highlights the diagnostic challenge of FFI in its early stages, particularly when initial symptoms are mild and neuroimaging is unremarkable, and emphasizes the importance of maintaining a high index of suspicion in individuals with a positive family history and subtle sleep disturbances, and it supports the utility of ^{18}F-FDG-PET as an early diagnostic tool in these patients.

EP-1321

FDG PET/CT in the Localization of Cardiac Device Infections: Discriminating Between LVAD and ICD Infection

E. Isleyen Çolak*, S. Bilgic, E. Alper;*
Bursa Uludag University, Bursa, TÜRKIYE.

Aim/Introduction: The increasing use of cardiac devices has been accompanied by a rise in associated infections. Implantable devices such as pacemakers, defibrillators, and left ventricular assist devices (LVADs) are increasingly common. This growth has led to more frequent evaluations for device-related infections and endocarditis [1]. LVADs, often used as a bridge to transplant, are particularly vulnerable, with infection rates up to 13.6% within the first three months [2]. ***Materials and Methods:*** A 45-year-old male with ischemic cardiomyopathy had an ejection fraction of 17%, moderate-to-severe mitral regurgitation, severe tricuspid regurgitation, and elevated pulmonary pressure. He underwent HeartMate 3 LVAD (Abbott ©) implantation. ***Results:*** Postoperatively, purulent discharge at the driveline site led to pus culture collection and empirical antibiotics. FDG PET/CT was performed to evaluate for infection involving either the LVAD or ICD. FDG PET/CT showed no pathological uptake around the ICD device or leads. In contrast, the extracardiac portion of the LVAD along the lateral chest wall showed a ~35 mm area of homogeneous FDG uptake, likely related to local inflammation to surgical adhesives. More importantly, heterogeneous uptake was noted at the distal vascular graft anastomosis site (SUVmax: 5.2), and a linear tract of intense uptake extended from this area along the driveline to the abdominal skin, consistent with active infection (SUVmax: 7.3). Although pus cultures returned negative, a positive purified protein derivative (PPD) test measuring 16 mm prompted the initiation of empiric antitubercular therapy. ***Conclusion:*** Device removal is a key component of infection management but is complex in patients with life-sustaining hardware. In this case, both the LVAD and ICD were essential. PET/CT revealed infection limited to the driveline, sparing the pump and ICD. This allowed a focused surgical approach, avoiding unnecessary extraction and reducing risk [3]. ***References:*** 1.Aguilera J, Hutt E, Jaber WA. Imaging of Cardiac Device-Related Infection. EP-1322

Detection Using ^{18}F-FDG PET-CT of Rare Metastases in a Patient with Endometrioid Endometrial Carcinoma

S. Perez Quiros, *C. Paniagua Correa, L. Castillejos Rodriguez, M. Tagliatori Nogueira, A. Ortega Valle, K. Guichay Duran, M. García Alonso, C. Galindo Fernández;*
Hospital Universitario de Getafe, Getafe-Madrid, SPAIN.

Aim/Introduction: We present the finding by ^{18}F-FDG PET-CT of multiple hypermetabolic osteolytic lesions with signs of extraosseus extension, in a patient with poorly differentiated endometrioid adenocarcinoma ***Materials and Methods:*** 77-year-old woman with poorly differentiated endometrioid adenocarcinoma, stage IIIC, with the following immunohistochemical profile: preserved expression of DNA repair proteins, positive estrogen and progesterone receptors, and altered p53. She underwent initial surgical treatment, followed by adjuvant chemotherapy and radiotherapy. Three months after diagnosis, the patient began to experience pain in the right lower limb, which progressively became disabling for walking, and without apparent traumatic cause. This was initially suggestive of postoperative polyneuropathy, with no evidence of malignancy in other diagnostic techniques and no increase in serum tumor markers. ***Results:*** A whole-body PET-CT, performed for disease surveillance a year and a half later, demonstrated multiples hipermetabolic osteolytic lesions with signs of extraosseus extension, in the right lower limb and ipsilateral ischiopubic ramus. This finding was particularly striking in the middle and lower thirds of the fibula and in the tarsal, metatarsal bones, and proximal phalanges, raising suspicion of malignancy. Based on these findings, a biopsy was performed on the right ankle, which confirmed metastasis from an endometrial adenocarcinoma. ***Conclusion:*** Endometrioid adenocarcinoma is one of the most common types of endometrial cancer and is the fourth leading cause of cancer in women in developed countries, with most cases diagnosed at early stages of the disease. Metastasis usually occurs via direct spread, lymphatic dissemination, or hematogenous routes, with the most common distant metastatic sites being the lungs and liver. Bone involvement is generally considered rare, with clinical incidence rates of <1%. Recently, endometrial carcinoma has been divided into four subtypes based on its immunohistochemical profile: (i) ultramutated DNA polymerase epsilon (POLE), (ii) abnormal tumor protein 53 (TP53), (iii) microsatellite instability, and (iv) no specific molecular profile (NSMP).The vast majority of the few cases reported in the literature of aggressive metastatic bone involvement have been found in patients with microsatellite instability. In our case, the patient only had an alteration of the tumor protein p53 which, although associated with more aggressive tumors and with a greater probability of distant metastatic spread, has only been described in a few cases in the literature. This highlights the rarity of this disease and its clinical presentation, with a significant delay in the diagnosis of metastasis in these patients.

EP-1323

When Endocarditis Isn't What It Seems: Cardiac Hemangiosarcoma with Multiple Metastases- A case report

A. Militaru[1], *C. M. Popescu*[1], *A. Marin*[1], *R. M. Mititelu*[1,2];
[1]*Clinic of Nuclear Medicine- Central Universitary Emergency Military Hospital, Bucharest, Bucuresti, ROMANIA,* [2]*Nuclear Medicine Department- University of Medicine and Pharmacy "Carol Davila" Bucharest, Bucuresti, ROMANIA.*

Aim/Introduction: Cardiac angiosarcoma is a rare malignant tumor with a predilection for the right atrium that usually occurs in men in the third-fifth decade of life. It is characterized by early metastasis most commonly to the lungs. Clinical presentation is non-specific with symptoms mimicking infectious or inflammatory disease.[1] Angiosarcomas are hemorrhagic tumors with poorly defined margins that aggressively invade adjacent structures. Histologically, they show anastomosing vascular channels, pleiomorphic endothelial cells, high mitotic activity and necrosis. Immunohistochemistry is usually positive for CD31, factor VIII and von Willebrand factor.[1],[2] ***Materials and Methods:*** A 26-year-old man was admitted with a clinical infection and positive blood cultures for Staphylococcus lugdunensis, suggestive of infective endocarditis. One month later, he developed cardiac tamponade requiring pericardial drainage; Imaging showed a cardiac mass; parasternal biopsy revealed a diagnosis of angiosarcoma NOS. The patient underwent four cycles of neoadjuvant chemotherapy and a follow-up CT revealed a large, invasive cardiac tumor in various areas, with bilateral pulmonary nodules as metastases. A thoracotomy with partial tumor excision revealed extensive invasion into the right atrium, superior vena cava, coronary sinus, tricuspid valve, and great vessels, making complete resection impossible. [18F]FDG-PET-CT scan revealed a large tumor involving right atrium, atrial septum and roots of great vessels, with intense FDG avidity (SULmax = 21.35). It also showed FDG avid mediastinal lymph nodes, pulmonary and hepatic lesions, and a hypermetabolic lesion adherent to a loop of small bowel, consistent with secondary disease. ***Results:*** Primary cardiac sarcomas are rare, highly aggressive malignancies with a poor prognosis. Treatment usually consists of complete surgical resection if possible; however, resection is often compromised by tumor invasion. Adjuvant radiotherapy and chemotherapy can potentially improve outcomes, although limited evidence supports this. Radiotherapy is associated with risks due to the sensitivity of the heart. For inoperable tumors, palliative treatment may be considered. Despite multidisciplinary strategies, median survival is poor, so further research and individualized therapeutic approaches are warranted. ***Conclusion:*** This case demonstrates that age is not a contraindication to early and aggressive disease. In light of recent literature and therapeutic challenges, such as limited evidence for adjuvant therapies, this case highlights the urgent need for earlier diagnosis methods, molecular characterization and multidisciplinary strategies to optimize outcomes in young patients with these aggressive malignancies. ***References:*** [1] A. Orlandi,et al, "Cardiac sarcomas: An update," 2010, Lippincott Williams and Wilkins. doi: 10.1097/JTO.0b013e3181e59a91. [2] J. Butany,et al, "Cardiac tumours: Diagnosis and management," Apr. 2005. doi: 10.1016/S1470-2045(05)70093-0

EP-1324

^{18}F-PSMA PET/CT and ^{18}F-FDG PET/CT in the evaluation of desmoid tumors: A case report

E. Nogueira Lima, *M. B. Silva, T. Freire, C. Torricelli, G. Barbosa, T. Alves, V. Heringer, N. Tobar, A. Santos, M. Lima, J. Barreto, M. Etchebehere, E. Etchebehere;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Desmoid tumor is a rare soft tissue neoplasm that promotes chronic pain, reducing the quality of life (1,2). ^{18}F-FDG PET/CT has been used to grade sarcomas, predict their prognosis, and assess therapy response (3). Since PSMA has been shown to be avid in non-prostatic tissues, including desmoid tumors (4,5), we aim to evaluate the potential of 18F-PSMA-1007 PET/CT (PSMA PET/CT) in diagnosing desmoid tumors compared to FDG PET/CT, to expand the clinical management of these patients and possible therapeutic applications. ***Materials and Methods:*** Four patients (mean age = 56 years; two females) underwent PSMA PET/CT and FDG PET/CT on subsequent days. In both studies, the SUV max was calculated semi-automatically for each lesion. ***Results:*** All patients

presented uptake of both radiotracers at the primary tumor site. In patient 1, the primary tumor was located in the left hip (SUV_{FDG} = 12 vs SUV_{PSMA} = 4); in patient 2, located in the right axilla (SUV_{FDG}= 4 vs SUV_{PSMA}=6). In both cases, no metastases were detected. In patient 3, the primary tumor was located in the left arm (SUV_{FDG}=3 vs SUV_{PSMA}=4), and PSMA PET/CT also identified bone metastases in the upper limbs (SUV_{PSMA}=5). In patient 4, the primary tumor originated in the right thigh (SUV_{FDG}=5 vs SUV_{PSMA}=7), and again, only PSMA PET/CT detected bone metastasis in the second left costal arch and locoregional lymph node metastases. ***Conclusion:*** Our preliminary findings indicate the potential for PSMA PET/CT to diagnose and stage desmoid tumors since PSMA uptake was generally similar to FDG uptake in the primary tumor. However, more metastases, especially bone lesions, were detected on PSMA PET/CT. Therefore, PSMA PET/CT may be promising for staging patients with desmoid tumors. Future studies can expand upon these results to investigate PSMA as a promising Theranostics radiotracer for desmoid tumors.This study was supported by São Paulo State Foundation for Teaching and Research Support (Cancer Theranostics Innovation Center, CancerThera, CEPID FAPESP #2021/10265-8). ***References:*** 1. EP-1325

Rare and Challenging:^{18}F-FDG Uptake in Femoral Vein Leiomyosarcoma

I. Zahfir, *M. Aboussabr, M. Zekri, Z. Laadissi, N. Mahersi, L. Taoussi, A. Taalabi, D. Alami, S. Nabih Oueriagli, A. Doudouh;*
Mohammed V Military teaching Hospital, Rabat, MOROCCO.

Aim/Introduction: Primary vascular leiomyosarcoma (LMS) is a rare malignant tumor arising from smooth muscle cells within the vessel wall and carries a poor prognosis. While most cases involve the inferior vena cava (IVC), LMS can also occur in other veins, including the femoral, iliac, popliteal, saphenous, and renal veins. ***Materials and Methods:*** We present a case of a 51-year-old woman with left thigh swelling and a painless mass. Ultrasonography revealed a heterogeneous mass with non-visualization of the femoral vein. Subsequent contrast-enhanced MRI demonstrated a heterogeneously enhancing soft tissue mass encasing and infiltrating the superficial femoral vein lumen. Surgical exploration confirmed the mass's continuity with the venous wall and intraluminal extension. ***Results:*** Histopathology confirmed a grade III leiomyosarcoma. Staging ^{18}F-FDG PET/CT revealed intense hypermetabolism in the proximal left femoral vein, correlating with the primary tumor, along with non-FDG-avid pulmonary nodules in both lungs. ***Conclusion:*** Intravascular neoplasms remain diagnostically challenging, necessitating a multimodal imaging approach. Contrast-enhanced CT or MRI is essential for detecting venous LMS, distinguishing it from thrombus, assessing intra- versus extraluminal involvement, and defining disease extent for surgical planning. FDG-PET/CT further aids in differentiating malignant from benign thrombus and detecting metastases, playing a critical role in staging and therapeutic decision-making.

EP-1326

The Added Value of [^{18}F] FDG PET/CT in Assessing Malignant Degeneration in Patients with Hereditary Multiple Exostoses : A Case Report

I.-A. Ioana[1], *A. Barabas*[1], *R. Lita*[1], *M. Mutuleanu*[1,2], *M. Gherghe*[1,2];
[1]*Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy „Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Hereditary multiple exostoses (HME) is a rare autosomal-dominant skeletal dysplasia characterized by the formation of multiple osteochondromas arising from the metaphyseal regions of long bones, with a prevalence of 1:50,000 in Western countries. The disorder is primarily caused by biallelic inactivation of the tumour suppressor genes EXT1 or EXT2, leading to disrupted heparan sulphate biosynthesis and aberrant endochondral ossification. Malignant progression, occurring in approximately 2-5% of affected individuals, often presents insidiously and poses a diagnostic and therapeutic challenge. Early identification of malignant degeneration is critical, particularly in symptomatic patients. ***Materials and Methods:*** We present the case of a 53-year-old male patient, known with HME since childhood, presenting with painful large right inguinal mass, who underwent a pelvic CT scan on December 24, 2024. The contrast enhanced study revealed a space-occupying lesion originating from the right superior pubic ramus invading the abdominal wall and pectineus muscle and in contact with the inguinal vessels, measuring 127/98/170 mm, indicating a possible malignant degeneration. Additionally, the CT evaluation identified one lytic lesion located in the T5 vertebra and osteochondromatous lesions located near the right costovertebral joint C VI and right scapulae. Because of the increased risk of presenting other malignant degenerated lesions a 18F-Fluorodeoxyglucose [^{18}F] FDG PET/CT scan was recommended for disease staging. ***Results:*** The PET/CT scan identified multiple lesions with low metabolic activity located bilaterally in the scapulae and in the spinous process of the T5 vertebra. Additionally, a large tumoral mass was observed in the right inguino-femoral region, with axial dimensions of 13/9.4 cm, possibly originating from the right pubic ramus, suggestive of malignant degeneration, confirmed through biopsy as grade 1 chondrosarcoma. The lesion with the highest uptake was located on the right scapulae with an SUVlbm value of up to 2.16 g/ml. Other osteochondromas presenting no metabolic activity were localized in the humerus bilateral, ribs, pelvic bones and femur bilateral and were characterized as benign lesions. A minimal active metabolic inguino-femoral adenopathy was also observed, with an SUVlbm value of up to 1.77 g/ml. ***Conclusion:*** This case emphasizes the role of [^{18}F] FDG PET/CT in evaluating the extent and distribution, as well as the metabolic activity of the extraosseous lesions, providing crucial information in determining the appropriate therapeutic approach and assessing potential metastatic spread.

EP-1327

Molecular Imaging with 99mTc-EDDA-HYNIC-TOC in Tumour-Induced Osteomalacia: Diagnostic Impact in a Challenging Case

M. Nistor[1], *D.-M. Ionescu*[1], *M. Abas*[1], *A. Badea-Selea*[1], *M. Gherghe*[1,2];
[1]*Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Tumour-induced osteomalacia (TIO) is a rare paraneoplastic syndrome resulting from phosphaturic mesenchymal tumours (PMTs) that secrete fibroblast growth factor 23 (FGF-23), leading to hypophosphataemia and bone mineralization defects. PMTs can occur in bones or soft tissues, making whole-body molecular imaging essential for detecting lesions with increased uptake of radiolabelled somatostatin analogues. ***Materials and Methods:*** We present the case of a 49-year-old male diagnosed with phosphataemic osteomalacia in 2018, exhibiting elevated FGF-23 levels (167 kRU/l) and hypophosphataemia (1.73 mg/dl). His symptoms included anterior chest pain and low back pain radiating to the lower limbs. Despite scintigraphy with radiolabelled somatostatin analogues undertaken in 2020 showing no pathological uptake, an MRI performed in October 2023 identified a 1.5 cm lesion in the left femoral trochanter. On 1st October 2024, he underwent scintigraphy with ^{99}Tc-EDDA-HYNIC-TOC. A planar whole-body scan at 2 hours and a whole body single photon emission

computer tomography-computed tomography (SPECT-CT) 4 hours post-injection, were performed. We implemented the following SPECT-CT protocol: a 128 by 128 matrix size, step and shoot mode, 60 steps, with 30 seconds per step, and a dual-energy window for scatter correction. For improved diagnostic accuracy and attenuation correction, the SPECT scan was completed by a low-dose CT scan. ***Results:*** The somatostatin receptor scintigraphy revealed focal uptake (SUVlbm = 8.27 g/ml) localized in the left femoral trochanter, corresponding to an osteolytic lesion with osteosclerotic borders, a nodular structure, and expansive characteristics, without cortical disruption visible on the CT images. This finding corresponds to the result of the MRI examination performed in October 2023 and suggests the presence of a mesenchymal tumour associated with osteomalacia. A biopsy of the lesion was performed and the histology revealed monomorphic spindle cell proliferations with minimal nuclear atypia, proliferation infiltrating the medullary spaces and involving the bone trabeculae. The immunohistochemistry results showed reduced Ki-67, SATB2 and diffuse ERG positive expression on most tumour cells, with weak focal nonspecific positivity of CD99, while SMA and CD34 were negative. These findings confirmed the diagnosis of a phosphaturic mesenchymal tumour. ***Conclusion:*** This case highlights the diagnostic value of ^{99}Tc-EDDA-HYNIC-TOC scintigraphy in identifying PMTs, which are rare tumours with approximately 450 cases documented in the literature. Molecular imaging provides crucial information for accurate diagnosis and therapeutic approaches.

EP-1328

Synchronous Malignancies in Bloom Syndrome: The Value of Molecular Imaging

M. Abas[1], *M. Paunescu*[1], *M. Mutuleanu*[1,2], *M. Gherghe*[1,2];
[1]*Bucharest Oncology Institute "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Bloom Syndrome (BS) is an exceptionally rare autosomal recessive genetic disorder with fewer than 300 cases reported worldwide, caused by mutations in both copies of the BLM gene and is typically diagnosed in childhood through cytogenetic analysis. This deficiency in DNA repair mechanisms leads to an increased susceptibility to various types of cancers. Other clinical features include: short stature, phototoxicity, café-au-lait spots and immune-related recurrent infections. Given the high predisposition to multiple, early-onset, different types of cancer, molecular imaging could play a crucial role in management of these patients. ***Materials and Methods:*** We are presenting the case of a 43-years old patient diagnosed with Bloom Syndrome in October 2024 via genetic testing. After an insidious onset of nausea, vomiting and watery diarrhoea, the patient underwent a colonoscopy which revealed familial adenomatous polyposis. A year later, a repeat colonoscopy due to similar symptoms confirmed a colonic adenocarcinoma (G3, Ki67 90%) on biopsy. One month later, an echoendoscopy revealed a pancreatic body adenocarcinoma (G3, Ki67 40%), which tested positive for synaptophysin and SSTR2 receptors. Additionally, conventional imaging were indicative of a potential breast tumour and multiple secondary pulmonary nodular lesions. Subsequently, she received chemotherapeutic treatment. ***Results:*** The patient was referred to nuclear medicine following the positive neuroendocrine markers expressed in the pancreatic tissue sample, which raised the suspicion for a neuroendocrine component within the pancreatic lesion. However, a [^{99m}Tc]-EDDA-HYNIC-TOC (Tektrotyd) SPECT/CT scan demonstrated no significant radiotracer uptake in the pancreatic lesion. A week later, a [^{18}F]FDG PET/CT with intravenous contrast-enhanced CT showed an area of increased metabolic activity in the pancreatic body (SUVlbm 2.06) and the recto-sigmoidian colon (SUVlbm 3.04), locations consistent with the lesions vizualised on prior investigations, suggesting the diagnosis of poorly differentiated tumours. Also the bilateral pulmonary nodules presented no radiotracer uptake, but with morphological appearance consistent with secondary lesions ***Conclusion:*** Although Bloom syndrome is usually identified in early childhood due to its specific clinical features, our patient was diagnosed at adult age following the detection of synchronous malignancies of the breast and the gastrointestinal tract (spaced one month apart). Molecular imaging proved to be valuable in the diagnosis, evaluation and management of the patients presenting this rare disease.

EP-1329

An [^{18}F]FDG PET-CT Conundrum. Adrenal Oncocytoma: A Case Report

M. Matei[1], *S. Solomon*[1], *C. Mazilu*[1], *R. Mititelu*[1,2];
[1]*Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*Department of Nuclear Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.*

Aim/Introduction: Adrenal oncocytomas are a rare entity, more commonly diagnosed in female patients. Other sites where oncocytoma may arise include the kidney, thyroid and salivary glands. The aim of this report is to underline the importance of [^{18}F]FDG PET-CT in evaluating the metabolic activity of an adrenal incidentaloma and, as well, its utility as a follow-up method. ***Materials and Methods:*** We present a case of a 65-year-old male patient, a former smoker, known with a history of a pulmonary neuroendocrine carcinoma with large cells (LCNEC). The pulmonary tumor had a diameter of 26/20/20 mm and was located in the superior segment of the right inferior lobe. An inferior right lobectomy associated with a mediastinal lymphadenectomy were performed in 2022, which were followed by histopathological studies and immunohistochemical staining showing a poorly differentiated (G3), CD56+, C-Kit+, Syn-, CGA- with a variable expression of PD-L1 in 69% of the cells, with lymph node extension (interlobar). A Contrast Enhanced Computed Tomography (CECT) scan was performed in order to assess the disease extension, on which an enhanced, well-defined solid nodule measuring 18/20 mm was discovered in the medial limb of the left adrenal gland, thus raising the suspicion of an adrenal metastasis. ***Results:*** The patient underwent a PET/CT scan with [^{18}F]FDG two months after surgery, which revealed moderate uptake of the radiotracer in the right inferior paratracheal and subcarinal nodes and high metabolic activity of the left adrenal nodule with a SULmax of 7.53. Due to the aggressive nature of the pulmonary tumor, which presented high anaplastic features and the radiological and molecular imaging studies were highly suggestive of a distant metastasis, the patient underwent a left adrenalectomy. The histopathological report and immunohistochemical staining results were compatible with the diagnosis of adrenal oncocytoma (CROMO-, S100-, Ki67 2%). Two additional [^{18}F]FDG PET-CT scans were performed as follow-up, both examinations showed no metabolic activity suggestive of regional or distant recurrence of the disease. ***Conclusion:*** While benign adrenal lesions usually don't display high avidity for [^{18}F]FDG, oncocytomas may demonstrate a variable uptake of the radiotracer. Thus, adrenal oncocytomas, while rare, should be considered in the differential diagnosis of adrenal tumors. In such cases, the PET-CT scan is a valuable tool in the follow-up protocol.

EP-1330

Reactive Imaging Changes Following CAR-T Cell Therapy in Multiple Myeloma: A Diagnostic Challenge

T. Stoeva, *M. Dyankova, Z. Dancheva, S. Chausheva, T. Yordanova, B. Chaushev, A. Klisarova;*
UMHAT "Sveta Marina", Varna, BULGARIA.

Aim/Introduction: Multiple myeloma (MM) is a clonal plasma cell malignancy with a highly variable clinical and imaging presentation. Despite significant treatment advances, MM remains

incurable, with most patients eventually experiencing relapse. In recent years, chimeric antigen receptor T-cell (CAR-T) therapy has emerged as a promising option for relapsed/refractory MM. However, the increasing use of immune-based therapies has introduced new diagnostic challenges, particularly in interpreting post-treatment imaging. While FDG PET/CT remains a cornerstone for disease assessment, immune-mediated reactive changes can mimic active disease and complicate response evaluation. ***Materials and Methods:*** We present the case of a 54-year-old male diagnosed with MM in 2017, with evidence of lambda light chain paraproteinemia and 70% plasma cell infiltration on bone marrow biopsy. Baseline [F-18] FDG PET/CT revealed diffuse bone marrow involvement. The patient initially achieved complete remission following chemotherapy and autologous stem cell transplantation. However, disease relapse occurred two years later, and five subsequent treatment lines failed to achieve sustained response. Given the aggressive disease course, CAR-T cell therapy was administered. The patient developed cytokine release syndrome (CRS) post-treatment, which was effectively managed with supportive care. Two months after CAR-T infusion, an [F-18] FDG PET/CT was performed to evaluate therapeutic response. ***Results:*** Post-treatment PET/CT revealed diffusely increased, symmetric FDG uptake in the long bones, indicative of activated hematopoietic marrow rather than malignant infiltration. Multiple osteoblastic and mixed lesions (osteolytic with sclerotic borders) were observed in both the axial and appendicular skeleton. These lesions exhibited metabolic activity not exceeding liver background levels. Although these findings raised concerns for residual disease, normal laboratory results and the patient's clinical stability supported a reactive post-treatment process. A multidisciplinary review confirmed the interpretation of reactive marrow regeneration, with no evidence of active myeloma. ***Conclusion:*** This case underlines a potential imaging pitfall in MM patients undergoing CAR-T therapy. Reactive bone marrow activation and osteoblastic remodeling may mimic active disease on FDG PET/CT, posing a risk of misdiagnosis. Recognizing these patterns is essential to avoid unnecessary interventions. Accurate assessment of treatment response post-CAR-T therapy requires integrating imaging findings with clinical and laboratory data.

EP-1331

Can You Guess The Source? Metastatic Bone Lesion as a Rare First Presentation of Hepatocellular Carcinoma- a Case Report

S. Chausheva[1,2], *M. Dyankova*[3], *T. Stoeva*[3], *Z. Dancheva*[3], *A. Klisarova*[3], *B. Chaushev*[3], *T. Yordanova*[3];
[1]*University Hospital St Marina Varna, Varna, BULGARIA,* [2]*Medical University Varna, Varna, BULGARIA,* [3]*UMBAL St. Marina Hospital-Varna, University Hospital St Marina Varna, Varna, BULGARIA.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy that usually presents in patients with already established liver disease, most common etiological factors are Hepatitis B virus (HBV), Hepatitis C virus (HCV), alcoholic liver disease, and non-alcoholic liver steatohepatitis. Most commonly extrahepatic metastatic involvement includes the lungs, regional lymph nodes and adrenal glands, while osseous spread remains uncommon. Even more uncommon is the initial presentation of HCC as a solitary bone lesion, which can easily mimic primary bone tumors or metastases from other primary malignancies with common bone involvement as types of the prostatic, breast, or lung cancer. ***Materials and Methods:*** We present a case of a 72-year-old male presented at the hospital with chest pain localized in the area of the sternum with no history of trauma. Radiograph of the thorax showed an expansile osteolytic bone lesion in the sternum. In view of the radiographic appearance of the bone lesion, investigations for a provisional diagnosis of bone metastasis and in a search for primary site a CT of the neck and thorax was performed. The images reveal a large, expansile osteolytic lesion involving the sternum, with cortical destruction and infiltration into the retrosternal soft tissues. No definitive primary neoplasm was identified on initial imaging. Whole-body 18F-fluorodeoxyglucose PET/CT was conducted to evaluate for additional metastatic sites and to localize a primary tumor. Biopsy of the bone lesion was performed for histological examination. The biopsy cores comprised a tumor with morphology consistent with that of a metastatic hepatocellular carcinoma. ***Results:*** Whole-body 18F-fluorodeoxyglucose PET/CT study was performed to localize a primary tumor and additional metastatic sites. An expansive osteolytic lesion in the manubrium sternum was revealed with extensive soft tissue component infiltrating the retrosternal space/anterior mediastinum. A second metabolically active osteolytic lesion in the transversal process of Th7 on the left- with metastatic appearance. ^{18}F-FDG PET/CT revealed the primary tumor as a hypodense lesion of irregular shape with metabolic activity slightly exceeding that of the remaining liver parenchyma in the region of Sg VII/VIII. ***Conclusion:*** This case underlines the diagnostic complexity of isolated bone metastases as the first manifestation of HCC. The FDG PET/CT demonstrated a high sensitivity in detection of both primary tumor location and other metastatic bone lesions regarding HCC.

EP-1332

Time Is Tissue: Early Nuclear Imaging and Prognostic Markers in Cardiac Amyloidosis. A Case Report

B. Constantinescu[1], *C. Mazilu*[1], *S. Stanciu*[2,3];
[1]*Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*Clinic of Cardiology, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [3]*University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.*

Aim/Introduction: Due to spectacular advances in diagnostic methods and new therapies over the last decade, cardiac amyloidosis (CA) is no longer considered a rare and incurable disease. Nevertheless, CA remains an underdiagnosed cause of death in patients with heart failure. The aim of this paper is to raise awareness of prevalent prognostic factors associated with CA, which, if diagnosed early, may provide further insight into the overall prognosis of disease. ***Materials and Methods:*** We report the case of an 88-year-old male patient with a history of atrial fibrillation (AF), aortic disease and chronic coronary syndrome. The patient had hypertrophic cardiomyopathy with left ventricular hypertrophy, mild ventricular dysfunction, right ventricular and biatrial dilatation. A 'whole-body' scan followed by SPECT/CT was conducted after intravenous injection of 99m-Tc-hydroxydiphosphonate (99m-Tc-HDP). ***Results:*** 'Whole-body' scan revealed extra-osseous uptake in the cardiac region with Perugini score 3, consistent with transtiretin amyloidosis (ATTR). SPECT/CT showed diffuse biventricular uptake and mild uptake in the right atrium. Atrial amyloid deposits often lead to cardiovascular complications — valvular heart disease and cardiac rhythm abnormalities. In our patient, there was a strong suspicion of CA due to history of aortic stenosis and paroxysmal AF. Emerging research[1] shows that AF is predictor of progressive CA leading to worsening prognosis; it is often associated with ATTR and advanced age. AF leads to progressive loss of function and carries an increased risk of endocardial and systemic thrombosis. It is of great importance to facilitate early diagnosis, to improve disease prognosis and overall life expectancy. A recent national study[2] identified further opportunities for improvement in nuclear medicine physicians' awareness of CA imaging and space for interdisciplinary collaboration, highlighting the urgent need for standardized protocols and cardiology-focused guidelines to improve early diagnosis and patient outcomes. ***Conclusion:*** CA remains a challenging disease to diagnose and treat. Better recognition of clinical manifestations is essential for proper disease management and treatment. Scintigraphy with radiolabeled bisphosphonates is a valuable non-invasive imaging technique

for diagnosis of CA, but also for identification of atrial or right ventricular wall uptake, markers of poor prognosis. ***References:*** 1. Donnellan, E., Wazni, O. M., Hanna, M., & Desai, M. Y. EP-1333

The clinical role of 68GaPSMA/68GaDOTA PET/CT imaging in patient with prostate adenocarcinoma with neuroendocrine differentiation

K. Verbanova*, S. Sergieva, V. Marinov;*
Acibadem City Clinic Tokuda, Sofia, BULGARIA.

Aim/Introduction: Neuroendocrine differentiation (NED) in prostate carcinoma is a significant field of ongoing research as prostate adenocarcinoma with neuroendocrine differentiation (PC-NED) represents as more aggressive and resistant to conventional androgen-deprivation therapy (ADT) subtype of prostate carcinoma (PC). The involvement of neuroendocrine compounds in prostatic neoplasia can play a crucial role in the diagnostic process and consideration of further treatment strategies to improve the monitoring and life expectancy of patients diagnosed with this heterogenous pathology. ***Materials and Methods:*** PET/CT scans with 68GaPSMA and 68GaDOTA were performed. Therapy response was assessed by two experienced nuclear medicine physicians independently from each other. ***Results:*** We report the rare case of a 72 year old man, initially diagnosed in 11/2023 with PC-NED. The patient presented with PSA of 169 ng/ml, Gleason score 10 (5+5), Grade group 5. The first PET/CT-PSMA evaluation showed metastatic involvement of lymph nodes and bones. The patient was treated with palliative radiotherapy, LH-RH agonist drugs, Denosumab and underwent 6 chemotherapy courses with Etoposide/Carboplatin. A second Ga68-PSMA PET/CT scan was performed in 12/2024 to evaluate the treatment response as the PSA significantly dropped to 1,37 ng/ml. The imaging study revealed a partial response to treatment with persistent high activity in primary tumor, bone lesions and lymph nodes. In addition, high chromogranin levels were detected. Considering the neuroendocrine differentiation of the tumor the patient underwent scanning with PET/CT-68Ga-DOTA in order to evaluate the possible neuroendocrine metastatic involvement. Results of the later performed 68Ga-DOTA PET/CT showed newly detected active lesion located in the left femur head that was not previously detected via 68Ga-PSMA. ***Conclusion:*** Combining different nuclear imaging methods based on the histhological type of the carcinoma can show complementary results that could be interpreted together in order to properly determine the therapeutic approach in patients with mixed adeno/neuroendocrine tumors.

EP-1334

Unmasking the Silent Progression: The Role of Serial [^{18}F] FDG PET/CT in the Surveillance of Recurrent Klatskin Tumor

A. Marin*, A. M. Budau, A. S. Militaru, C. V. Mazilu;*
Clinic of Nuclear Medicine, Central University Emergency Military Hospital, Bucharest, ROMANIA.

Aim/Introduction: Klatskin tumors are aggressive malignant tumors that occur at the bifurcation of the hepatic duct and represent the majority of bile duct carcinomas. Due to their insidious onset and deep anatomic location, patients often present at advanced stages.[18F]FDG-PET/CT has been shown to be effective in detecting metastases and nodal involvement not always visible on conventional imaging (1,2). ***Materials and Methods:*** A 51-year-old female patient presented with intermittent abdominal pain, jaundice, diarrhea, and weight loss. Imaging revealed biliary lithiasis, ductal dilatation and lymphadenopathy. Intraoperatively, a Bismuth-Corlette IIIB Klatskin tumor was found. Patient underwent en bloc resection of the extrahepatic bile duct, regulated left hepatectomy with caudate lobe resection, and Roux-en-Y hepaticojejunal anastomosis. Histology confirmed well-differentiated biliary adenocarcinoma with lymphovascular invasion and one positive lymph node(pT2 pN1). She received adjuvant chemotherapy. ***Results:*** [18F]FDG PET-CT revealed FDG avid pseudonodular lesion near biliary stent, along with nodal and pulmonary metastases. One year later, follow-up PET-CT revealed increased activity in previous lesion, along with new FDG avid perihepatic mass (differential: abscess vs. necrotic tumor), secondary lymph node and pulmonary lesions. Overall imaging appearance was consistent with progressive disease.[18F]FDG PET-CT provides added value in identifying occult nodal and distant metastases in cholangiocarcinoma, influencing therapy in 20% of cases(3). Although false-positive results can occur, particularly in inflammatory lesions, elevated SUVmax remains a prognostic marker for poor outcome(2). Similar to hepatocellular carcinoma, metabolic changes often precede anatomical ones, reinforcing PET/CT's role in early recurrence detection and treatment planning (4). In our case, PET/CT accurately captured progression when conventional imaging remained inconclusive.. ***Conclusion:*** This case supports the use of serial [18F]FDG-PET-CT for postoperative surveillance of hilum cholangiocarcinoma. It provided critical information beyond conventional imaging and aided management decisions, emphasising its value for routine follow-up protocols. ***References:*** 1.Reinhardt MJ, Strunk H, Gerhardt T, et al. EP-1335

Benign Cause or Malignancy Progression? Rethinking PET/CT Findings in a Burkitt Lymphoma Case

A. Constantin*[1], A. I. Taciuc[1], M. Gherghe[1,2];*
[1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.

Aim/Introduction: ^{18}F-FDG PET/CT is the cornerstone of staging procedures in management of aggressive non-Hodgkin's lymphoma. It plays an important role in staging, restaging, prognostication, planning appropriate treatment strategies, monitoring therapy, and detecting recurrence. However, FDG is a non-specific tracer, and its uptake may also reflect infectious, inflammatory, or post-therapeutic changes - frequently complicating interpretation in immunocompromised patients. ***Materials and Methods:*** A 54-year-old male diagnosed with stage IVA Burkitt-type non-Hodgkin lymphoma underwent three cycles of CVAD chemotherapy (cyclophosphamide, doxorubicin, vincristine, dexamethasone). After two treatment cycles, PET-CT showed bilateral hypermetabolic pulmonary lesions, associated with low-grade fever and fatigue, suggestive of possible extranodal involvement. ***Results:*** After the third chemotherapy cycle, a follow-up PET-CT showed decreased radiotracer uptake in the pulmonary nodules, with only two inactive lesions located in the left lung. However, new FDG-avid

lesions were noted: multiple hypodense hepatic nodules (up to 1.1 cm, SUVlbm up to 6.69) affecting all liver segments, mixed predominantly osteolytic lesions in the T8-T11 vertebral bodies (SUVlbm up to 11.59), and sclerotic lesions in the sacrum and bilateral iliac wings (SUVlbm up to 3.73), these findings raising suspicion for lymphoma progression. To identify the nature of the lesions, both bone marrow and laparoscopic liver biopsies were performed. Histopathological and immunohistochemical analyses revealed reactive inflammatory infiltrates, with no evidence of lymphomatous involvement. Although no specific infectious agent was identified, the imaging pattern, clinical symptoms, and biopsies results, the patient was started on empirical broad-spectrum antibiotic therapy, with a favorable evolution. A follow-up PET-CT demonstrated significant decreased metabolic activity of the bone and hepatic lesions under antibiotic therapy. There was complete resolution of FDG uptake in the thoracic spine (T8-T11) and substantial regression of the hepatic lesions, with only a single residual subcapsular FDG-avid lesion remaining in segment VIII (SUVlbm 4.37 g/ml). The overall imaging evolution, together with the histopathological findings, and the favorable evolution under antibiotics strongly supported the diagnosis of a infectious process, most likely initiated by a pneumonic episode, as suggested by the early pulmonary FDG-avid lesions. ***Conclusion:*** This case illustrates the challenge of distinguishing between residual malignant disease and benign causes in FDG PET-CT imaging, particularly in immunocompromised patients. High glycolytic activity in inflammatory or infectious foci can produce SUV values overlapping with aggressive lymphoma. Multisite involvement further complicates interpretation. This case reinforces the importance of histopathologic correlation and multidisciplinary assessment to prevent characterization of infection related lesions as disease progression.

EP-1336

Subcutaneous Splenosis Mimicking Malignancy: A Very Rare Complication of Laparoscopic Splenectomy for Hereditary Spherocytosis Identified on ^{99m}Tc-Colloid SPECT/CT

P. Gadzicki, *A. Aulich, M. Kwapisz, Z. Adamczewski;*
Medical University of Lodz, Nuclear Medicine Departament, Lodz, POLAND.

Aim/Introduction: Hereditary spherocytosis is an inherited haemolytic anaemia characterized by the presence of abnormal red blood cells - spherocytes - which are damaged in the spleen, leading to haemolysis. Laparoscopic splenectomy is one of the surgical procedures used to treat this condition; although rare, complications may occur. One such complication is splenosis - the autotransplantation of splenic tissue deposits in various compartments of the body. We present a case of subcutaneous splenosis, a very rare location, which mimicked malignancy on MRI eight years after surgery. SPECT/CT with ^{99m}Tc-colloid was crucial in confirming the benign nature of the lesion - splenic tissue implantation at the surgical incision site scar. ***Materials and Methods:*** A 20-years old women was referred for spleen and liver scintigraphy with ^{99m}Tc- colloid because of focal lesions located subcutaneous. In the past, patient as 12-years-old girl diagnosed with hereditary spherocytosis with typical complications such as cholelithiasis, haemolytic episodes, was treated successfully by laparoscopic splenectomy. After that hematologic parameters and bilirubin concentration improved. CT scan performed seven years after surgery reveled splenosis in various locations at abdomen and pelvis. Eight years post-splenectomy in a pelvic MRI scan subcutaneous focal lesions, soft tissue abdominal wall masses and soft tissue masses in left iliac fossa were detected (T1: hypointense,T2: hyperintense, T1 C+ (Gd): enhancement, and significant restriction in diffusion-weighted images). Clinical interpretation was inconclusive, and subcutaneous lesions were considered as malignancy. Latter performed ultrasound exam reveals that subcutaneous focal lesions and soft tissue abdominal wall masses were located in the site of incision due to laparoscopic splenectomy. ***Results:*** SPECT/CT scan after administration of ^{99m}Tc-colloid showed increased uptake in all focal lesions previously identified as splenosis on CT. All lesions detected on MRI (T1: hypointense, T2: hyperintense, T1 C+ (Gd): enhancing, with significant diffusion restriction) were consistent with these findings. ***Conclusion:*** ^{99m}Tc-colloid uptake was crucial in the non-invasive diagnosis of subcutaneous splenosis - a benign entity and helped distinguish it from more sinister mimicking pathology. ***References:*** 1)Perrotta S, Gallagher PG, Mohandas N. Hereditary spherocytosis. Lancet. 2008 Oct 18;372(9647):1411-26. doi: 10.1016/S0140-6736(08)61588-3. PMID: 18940465. 2)Vecchio R, Cacciola E, Cacciola RR, Intagliata E. EP-1337

Role of ^{18}F-FDG PET/CT in the Evaluation of a Patient with Pulmonary Artery Sarcoma: Case Report

K. Guichay Duran, *M. De la Rubia Marcos, C. Galindo Fernández, D. Rodriguez Oviedo, J. Sanchez Calderón, A. Herrero Muñoz, M. Castillejos Rodriguez, A. Ortega Valle, C. Paniagua Correa, S. Peréz Quirós, M. Álvarez Moreno, M. García Alonso, M. Tagliatori Nogueira;*
Department of Nuclear Medicine, Getafe University Hospital, Madrid, SPAIN.

Aim/Introduction: Primary pulmonary artery sarcoma (PAS) is a rare and aggressive tumor arising from mesenchymal tissue of the cardiovascular system; the clinical and radiological presentation often mimic pulmonary thromboembolism (PTE), so early and accurate diagnosis is essential for subsequent treatment. We present the findings from an 18FFDG PET/CT performed on a patient in whom PAS vs PTE was suspected. ***Materials and Methods:*** A 52-year-old woman, non-smoker, with a past medical history of hypertension, dyslipidemia, hypothyroidism, and chronic gastritis, who presented with dyspnea, right-sided chest pain, and unintentional weight loss (8 kg) in the last month. Chest CT had revealed a peripheral filling defect in the right main pulmonary artery containing intralesional/mural calcified material, suggestive of pulmonary artery sarcoma or chronic PTE. A whole-body PET/CT was performed 60 minutes after intravenous administration of 218 MBq of 18F-FDG. PET, CT, and fusion images were analyzed in axial, sagittal, and coronal planes and correlated with symptoms, laboratory tests, and prior CT findings. ***Results:*** PET/CT demonstrated an intraluminal occupation of the right main pulmonary artery with linear intralesional/mural calcifications with focal increased FDG uptake (SUVmax 3.85), suggestive of intimal sarcoma as the first possibility. Multiple nodular lesions in the right lung were also described, likely related to pulmonary metastases. An endovascular biopsy of the intraluminal pulmonary artery lesion confirmed the clinicradiologic suspicion of primary intimal sarcoma of the pulmonary artery. After diagnostic confirmation and evidence of pulmonary dissemination, chemotherapy was initiated, but local and pulmonary progression occurred after six cycles. A secondline chemotherapy regimen and palliative radiotherapy were started because of hemoptysis following documented tumor progression. ***Conclusion:*** PAS is a rare tumor and is often misdiagnosed as a PTE. The survival is closely related to early diagnosis and since most patients with PAS have elevated glucose metabolism, ^{18}F-FDG PET/CT imaging has been established as an effective modality in the differential diagnosis between these two entities and the study of their possible metastases.

EP-1338

Paraganglioma - a New Approach of Metastatic vs. Multifocal Disease. A Case Report.

Z. Patko[1,2], *E. Kocsak*[3], *B. Bako*[3], *S. Barna*[4], *J. Gombos*[3];
[1]*Helse Møre og Romsdal, Ålesund, Norway,* [2]*University of Miskolc, Miskolc, HUNGARY,* [3]*Borsod County Central Hospital and University Teaching Hospital, Miskolc, HUNGARY,* [4]*ScanoMed Debrecen, Debrecen, HUNGARY.*

Aim/Introduction: Paragangliomas are rare neuroendocrine tumors arising from extra-adrenal paraganglia. These tumors often secrete catecholamines, leading to severe symptoms even when small. Identifying the exact location of smaller lesions can be challenging, and receptor scintigraphy remains a key diagnostic tool. Although paragangliomas rarely metastasize, it has traditionally been considered a marker of malignancy. In recent years, new classification systems have emerged to better assess their malignant potential. The latest WHO classification distinguishes between true metastatic disease and multifocal presentations, reflecting a shift in understanding their biological behavior. [1,2]This case highlights the relevance of the updated WHO classification and illustrates the evolving diagnostic and therapeutic approach to multifocal paragangliomas. ***Materials and Methods:*** A 46-year-old man presented to our department with fatigue and microcytic anemia. Abdominal CT revealed a tumor in the lower duodenum, for which duodenal resection was performed. Histopathological analysis confirmed the diagnosis of paraganglioma.Two and a half years later, during routine follow-up, a 25 mm hepatic lesion was detected by ultrasound and CT which was removed surgically. Histology identified it as a metastasis of the previously excised duodenal paraganglioma. Postoperatively, I-123 MIBG scintigraphy showed focal uptake in the left hepatic lobe, though low-dose CT did not reveal a clear morphological lesion. A contrast-enhanced MRI detected a suspicious lesion on the diaphragmatic surface of the left lobe, which showed interval growth on follow-up imaging. Biochemical tests, including catecholamine metabolites and chromogranin A, were within normal limits.In multidisciplinary review, the imaging characteristics of the new left-lobe lesion mirrored those of the prior right-lobe metastasis, strongly suggesting a new hepatic metastasis. Octreoscan confirmed a 3 cm somatostatin receptor-expressing tumor in the left lobe. ***Results:*** Considering the lesions' location, progression, and molecular features of both the duodenal and hepatic tumors, multifocal disease was suspected. Treatment with lutetium-177-labeled somatostatin analog was initiated. ***Conclusion:*** With this case, we aim to draw attention to specific features of metastatic paraganglioma, such as unusual localization and molecular patterns, that may suggest multifocal disease rather than true metastasis. We briefly highlight the criteria of the new WHO classification, which may influence both diagnostic categorization and therapeutic strategy. [1,2] ***References:*** [1] Mete O et al. Overview of the 2022 WHO Classification of Paragangliomas and Pheochromocytomas. Endocr Pathol. 2022 Mar;33(1):90-114. doi:10.1007/s12022-022-09704-6. [2] Mete O det al. EP-1339

FAPI-Based Theranostics in Medullary Thyroid Cancer: A Viable Alternative When Somatostatin Receptor Based Theranostics Show Limited Efficacy—A Clinical Experience

A. Saber Tanha, *F. Jafari Zarrin Ghabaei, N. Raeisi, K. Aryana, s. shafiei;*
Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: A 36-year-old man with medullary thyroid carcinoma (MTC) underwent total thyroidectomy and left neck lymph node dissection 12 years ago. His medical history included polycythemia and a previous episode of upper limb deep venous thrombosis. Ten years post-diagnosis, he developed multiple metastatic pulmonary nodules, with a serum calcitonin level rising to 2000 pg/ml, although he remained asymptomatic. ***Materials and Methods:*** The patient developed a cough, leading to a ^{99m}Tc-octreotide scan as a prerequisite for peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTATATE. The scan revealed multiple metastatic lymph nodes, lung metastases, and a solitary hepatic metastasis, all showing mild octreotide avidity. He received two cycles of PRRT at dosages of 7.4 GBq of ^{177}Lu-DOTATATE. ***Results:*** A positive biochemical response was noted after the first cycle, with a 28% reduction in serum calcitonin levels and partial remission of cough. However, a post-treatment scan after the second cycle indicated faint uptake in tumoral lesions. A subsequent ^{99m}Tc-FAPI-46 scan revealed tracer uptake in liver lesions, mediastinal lymph nodes, and pulmonary nodules, suggesting ^{177}Lu-FAPI as a viable treatment alternative. ***Conclusion:*** Despite the promising potential of FAPI in managing MTC, the patient opted to continue treatment with tyrosine kinase inhibitors. This case highlights the role of FAPI as an innovative theranostic strategy being a potential last resort in the evolving landscape of MTC management.

EP-1340

Langerhans Cell Histiocytosis with cutaneous presentation: a case report

K. Kapansahin, *B. Okudan Tekïn;*
Ankara Bilkent Şehïr Hastanesi, Ankara, TÜRKYE.

Aim/Introduction: Langerhans cell histiocytosis (LCH) is a complex disease characterized by clonal proliferation of Langerhans cells, primarily affecting children and adolescents, and can involve multisystem organs. The condition exhibits a wide spectrum of clinical presentations that require a multidisciplinary approach for diagnosis, treatment, and follow-up. The cutaneous manifestations of LCH are significant, mimicking common dermatoses and creating diagnostic challenges. ***Materials and Methods:*** Our case is a 26-year-old male patient who is being followed up by dermatologists and venereal diseases with a preliminary diagnosis of hidradenitis suppurativa. In his physical examination, there were erosions, erythema, and discharge lesions in the bilateral axillary region, and discharges in the bilateral inguinal region that were erythematous and unresponsive to antibiotics. At the same time, the patient's lungs had a bullous appearance and pneumothorax occurred from time to time. In the diagnosis, the histopathology of the bullostemia wedge resection material revealed widespread fibrosis findings, cystic changes, and histiocyte-like cells that stained positively with langerin and CD1a. The axillary biopsy revealed findings consistent with LCH. In the patient's PET/CT imaging, increased F-18 FDG uptake was observed in the cutaneous area of the bilateral axillary region and the left groin region. ***Results:*** Langerhans cells are dendritic mononuclear cells normally found in the epidermis, mucosa, lymph nodes, and bone marrow. Their normal function is to process antigens and present them to T lymphocytes; however, in LCH, literature review suggests that monoclonal proliferation of Langerhans cells leads to destruction of hard and soft tissues. LCH usually occurs in children aged 1-15 years, with a peak incidence between 2-4 years, occurring twice as often in boys as in girls. The most common clinical findings seen in the majority of cases are single or multiple bone lesions. ***Conclusion:*** In the presented case, the patient was diagnosed with cutaneous lesions without any skeletal involvement. FDG-PET/CT has proven to be highly sensitive, providing comprehensive staging and effective follow-up during treatment. We have shown that FDG-PET/CT is effective in detecting all types of LCH lesions, including cutaneous lesions,

and in assessing the extent of disease involvement. ***References:*** Rao DG, Trivedi MV, Havale R, Shrutha SP. A rare and unusual case report of Langerhans cell histiocytosis. J Oral Maxillofac Pathol. 2017 Jan-Apr;21(1):140-144. doi: 10.4103/jomfp.JOMFP_10_17. PMID: 28479703; PMCID: PMC5406796.

EP-1341

Primary neurolymphomatosis: Value of 18F-FDG-PET/CT in the diagnosis and assessment of response to treatment

S. Georga[1], *D. Katsampoukas*[1], *V. Mpalaris*[1], *A. Morfesi*[1], *M. Spilioti*[2], *G. Zafeiridou*[2], *N. Vavlas*[1], *G. Kaiafa*[3], *E. Moralidis*[1], *G. Arsos*[1];
[1]*3rd Department of Nuclear Medicine, Aristotle University Medical School, Papageorgiou General Hospital, Thessaloniki, GREECE,* [2]*1st Neurology Department, Aristotle University Medical School, AHEPA General Hospital, Thessaloniki, GREECE,* [3]*1st Propaedeutic Department of Internal Medicine, Aristotle University Medical School, AHEPA General Hospital, Thessaloniki, GREECE.*

Aim/Introduction: Primary neurolymphomatosis (PNL) is a very rare subtype of primary central nervous system lymphoma, defined as infiltration of cranial, spinal or peripheral nerve roots or nerve plexuses by lymphomatous neoplastic cells in the absence of systemic lymphoma. Nerve biopsy is the gold standard for the diagnosis, but is often difficult to perform or may be inconclusive. 18F-FDG-PET/CT, by detecting the very characteristic pattern of isolated hypermetabolic neuropathy, is a well-established imaging modality for the diagnosis and evaluation of PNL. ***Materials and Methods:*** We report on the case of a 74-year-old woman referred to our department for an 18F-FDG-PET/CT scan for investigation of multiple cranial mononeuritis. The patient had signs of multiple cranial nerve dysfunction, dysphagia and respiratory infection, and had a positive monoclonal IgM fraction in CSF. Initial gadolinium-enhanced brain MRI demonstrated asymmetric thickening and enhancement of multiple cranial nerves (bilateral III and V and right VII, VIII, IX and X), proposing a wide differential diagnosis including infectious and granulomatous diseases, demyelinating polyneuropathy, secondary carcinomatosis, lymphoma and multiple myeloma. After being unsuccesfully treated for a month with corticosteroids, IgG immunoglobulins and antibiotics, she was scheduled for plasmapheresis. Before starting this, an 18F-FDG-PET/CT scan led to the diagnosis of PNL, prompting specific treatment, followed by an interim one 2 months later. ***Results:*** Initial 18F-FDG-PET/CT scan revealed bilateral increased metabolic activity along the intracranial and extracranial course of multiple cranial nerves and along multiple nerve roots in the cervical spine up to the brachial plexuses, bilaterally. There was relative concordance between PET/CT and MRI in relation to the involved cranial nerves. The absence of abnormal metabolic activity in the rest of the body, excluded other sites of active inflammatory, granulomatous or malignant process. Overall, in this clinical setting, the 18F-FDG-PET/CT findings were very suggestive of the rare entity of PNL, and CSF lymphocyte immunocytochemistry confirmed the diagnosis of a Non Hodgkin lymphoma. Accordingly, the patient underwent systemic treatment with Mabthera and intrathecal infusion of Methotrexate and Ara-C. Interim 18F-FDG-PET/CT scan performed two months later showed complete metabolic remission in line with substantial clinical improvement. ***Conclusion:*** Our case shows that 18F-FDG-PET/CT is a valuable noninvasive imaging modality for the correct diagnosis of the rare entity of primary neurolymphomatosis, as it can reveal the affected neural structures and determine the extent of nerve involvement in the absence of other sites of disease. Furthermore, 18F-FDG-PET/CT is useful for assessing response to treatment.

EP-1342

Exploring the potential role of ^{18}F-FDG and ^{18}F-PSMA PET/CT in detecting neurofibromas: a case report

C. Torricelli, *T. Alves, G. Barbosa, M. Silva, E. Nogueira-Lima, V. Heringer, N. Tobar, M. Etchebehere, E. Etchebehere;
University of Campinas (UNICAMP), Campinas, BRAZIL.*

Aim/Introduction: Neurofibromatosis (NF) is a genetic disorder that predisposes individuals to nervous system tumors, including plexiform neurofibromas, malignant peripheral nerve sheath tumors and optic pathway gliomas[1]. While traditional imaging techniques, such as MRI and CT, are commonly used for diagnosis[2], ^{18}F-FDG-PET/CT is performed for differentiating benign and malignant lesions[3]. As an additional tool, radiolabeled PSMA-PET/CT offers potential for detecting and monitoring neurofibromas, expanding its use beyond prostate cancer[4], as well as a therapeutic resource. This case report describes the potential role of PSMA in NF. ***Materials and Methods:*** A 42-year-old male patient with a history of NF complained of cervical pain irradiating to the upper limbs for the past 7 months. The patient presented multiple cutaneous, subcutaneous and intramuscular neurofibroma nodules distributed throughout the body especially in the right thigh, gluteus and thoracic spine (T10/T11) as demonstrated by MRI. He was submitted to an ^{18}F-FDG-PET/CT imaging for primary staging and to evaluate the potential malignant transformation of the neurofibromas. After a 72-hour interval, an ^{18}F-PSMA-1007-PET/CT was performed. SUV_{max} was calculated semi automatically for each lesion in both exams. ***Results:*** ^{18}F-FDG-PET/CT revealed multiple mildly hypermetabolic cutaneous, subcutaneous and intramuscular neurofibroma nodules in the left periorbital/nasal region, right arm, left chest, gluteus, right thigh and knees (highest SUV = 2.3 in the right thigh). A subpleural pulmonary mass in the left lower lobe originating from the left T10/T11 neural foramen (SUV = 4.5) was also detected. ^{18}F-FDG-PET/CT findings were consistent with multiple benign nodules and possible malignant transformation of the lung mass infiltration from the T10/T11 neural foramen. The ^{18}F-PSMA-1007-PET/CT images showed higher uptake in all NF nodules compared to ^{18}F-FDG uptake (highest SUV = 6.5 in the left periorbital/nasal region). There was no PSMA uptake in the pulmonary lesion. The patient was referred to neurosurgery of the lung mass. ***Conclusion:*** This case highlights the potential role of ^{18}F-PSMA-1007-PET/CT in detecting and staging neurofibromas because of its higher radiotracer uptake in various nodules, compared to ^{18}F-FDG-PET/CT, suggesting complementary roles for both tracers in the functional evaluation of lesions at different sites. ^{18}F-PSMA-1007-PET/CT may contribute to improved diagnostic accuracy, clinical management and possible Theranostics applications. Its role in prognosis is unclear. ***References:*** 1.Yu X, et al. Neurooncol Adv, 2025; 2.Liu J, et al. Front Oncol, 2022; 3.Chirindel A, et al. J Nucl Med, 2015; 4.Gulhane B, et al. Clin Nucl Med, 2017. Research Funding: FAPESP - Cancer Theranostics Innovation Center, CEPID (Process#2021/10265-8).

EP-1343

Osteoid Osteoma - Presenting Two Cases of Rare Localizations and Diagnostic Challenges

Z. Patko[1,2], *E. Kocsak*[3], *L. Kostyal*[3], *J. Gombos*[3];
[1]*Helse Møre og Romsdal, Ålesund, Norway,* [2]*University of Miskolc, Faculty of Health Sciences, Miskolc, HUNGARY,* [3]*Borsod County Central Hospital and University Teaching Hospital, Miskolc, HUNGARY.*

Aim/Introduction: Osteoid osteoma is a common, benign bone lesion that typically occurs in children and adolescents, most frequently affecting the long tubular bones. However, even a relatively common condition with characteristic symptoms may present a diagnostic challenge in an atypical localization or if accompanied by a misleading patient history. ***Materials***

and Methods: In our first case an 11-year-old girl was admitted to our department with recurrent gluteal pain that had been present for approximately one year. A few months prior to the onset of symptoms, she had begun horseback riding. Shortly after she developed pain in the lower back and ischial region. Her medical history was negative for trauma. Physical examination revealed right-sided gluteal tenderness. Her symptoms showed temporary improvement with NSAID treatment but subsequently recurred. Laboratory and immunological investigations revealed no abnormalities or signs of inflammation. Physiotherapy and rehabilitative exercises proved ineffective. MRI scans showed oedema in the iliac bone, which was considered stress related. Due to persistent complaints we performed bone scintigraphy which revealed increased activity in the region of the sacroiliac joint, localized ventrally in the joint on SPECT reconstructions. CT imaging confirmed the presence of a nidus with surrounding sclerosis. In our second case a 10-year-old girl presented at our department with uncertain onset of foot pain that had persisted for several weeks. Her medical history was unremarkable, with no prior significant illness or trauma. She had taken up dancing a year earlier. Initial X-ray imaging did not reveal any trauma or structural abnormalities. Due to persistent symptoms, an MRI scan was performed, which revealed oedema in the calcaneus beneath the subtalar joint. Based on suspicion of a stress fracture, immobilization, gradual weight-bearing, and physiotherapy were recommended. Despite these interventions, her symptoms did not improve. Bone scintigraphy with SPECT/CT was performed which showed intense focal uptake in the subtalar region of the calcaneus, and the CT scan identified a nidus near the subtalar joint accompanied by surrounding sclerotic bone. ***Results:*** In both cases the diagnosis of osteoid osteoma has been stated. Following adequate treatment, the patients became symptom-free. ***Conclusion:*** In some cases, the clinical history and presentation may be misleading, making the selection and combination of appropriate imaging modalities essential for accurate diagnosis and effective treatment planning.

EP-1344

^{18}F-FDG PET/CT in sporadic Creutzfeldt-Jacob disease: A case report

C. Caldas[1], *D. Isasi*[1], *N. Laines*[2], *L. Apaza*[3], *L. Apaza*[3];
[1]EsSalud, Lima, PERU, [2]Universidad Nacional Mayor de San Marcos, Lima, PERU [3]Intituto Nacional de Ciencias Neurologicas, Lima, PERU.

Aim/Introduction: Creutzfeldt-Jakob disease (CJD) is a rare, rapidly progressive, and fatal neurodegenerative disorder caused by prion proteins. Due to its variable presentation, diagnosis often relies on a combination of clinical features, neuroimaging, electroencephalography (EEG), and cerebrospinal fluid biomarkers. We present a case report that illustrates a confirmed diagnosis of sporadic CJD in a patient with subacute neurological deterioration and FDG PET/CT findings. ***Materials and Methods:*** A 68-year-old female presented to the Hospital with two weeks of progressive lower limb weakness, followed by upper limb involvement, memory impairment, and coordination difficulties. Neurocognitive tests revealed significant deficits: Pfeiffer score of 3, Mini-Mental State Examination score of 11, and a TAM of 22. EEG showed mild generalized dysfunction without epileptiform discharges or triphasic waves. Patient had significant mental deterioration without a clear etiology through different test including MRI. Eight-week later, she underwent a FDG PET/CT scan. It was found a global bilateral cortical-subcortical hypometabolism, predominantly in fronto-temporal and striata. The diagnosis of CJD was confirmed by RT-QuIC analysis of cerebrospinal fluid. The patient later developed right frontotemporal epilepsy, attributed to prion-related cortical involvement. ***Results:*** Imaging findings on PET/CT were characteristic of prion-related encephalopathy, showing marked bilateral hypometabolism in grey matter structures. Despite the absence of EEG triphasic waves, clinical progression, cognitive testing, and PET/CT findings were consistent with sporadic CJD. Two-week after PET/CT, the real-time quaking-induced conversion (RT-QuIC) assays had confirmed the diagnosis. The patient remained hemodynamically stable but in an akinetic mutism state, without myoclonus, and on valproic acid for seizure control. Prognosis remained poor due to the underlying pathology. ***Conclusion:*** This case highlights the diagnostic value of FDG PET/CT in rapidly progressive dementias, particularly when EEG findings are non-specific. Correlation with clinical evolution and advanced biomarker testing such as RT-QuIC is essential for accurate and timely diagnosis of CJD. Early metabolic imaging may guide suspicion and prompt further investigation even in atypical EEG presentations.

EP-1345

Uncommon Presentation of Primary Adrenal Lymphoma with Bilateral Adrenal Hypermetabolic Activity on ^{18}F-FDG PET/CT: A Case Report

P. Sahafi[1], *F. Karamian*[1], *F. Emami*[2], *M. Samadi*[1], *R. Sadeghi*[1];
[1]Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [2]Nuclear Medicine and Molecular Imaging Department, Imam Reza International University, Razavi Hospital, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this case report is to highlight the importance of ^{18}F-FDG PET/CT imaging in the evaluation of bilateral adrenal masses and to emphasize the need to consider primary adrenal lymphoma (PAL) in the differential diagnosis of hypermetabolic adrenal lesions. ***Materials and Methods:*** An 80-year-old male patient presented with abdominal pain and fatigue. Initial abdominal CT imaging revealed bilateral adrenal masses of unknown origin. To further assess the nature of these masses, ^{18}F-FDG PET/CT imaging was performed following intravenous administration of 6.19 mCi of 18F-fluorodeoxyglucose. Scanning commenced 62 minutes post-injection. PET/CT findings, including size measurements, standardized uptake values (SUV_{max}), and evidence of additional hypermetabolic lesions, were documented. A histopathological evaluation was subsequently performed through adrenal gland biopsy to confirm the diagnosis. ***Results:*** ^{18}F-FDG PET/CT imaging demonstrated significantly enlarged bilateral adrenal glands with intense FDG uptake. The right adrenal gland measured 74 × 43 × 82 mm (SUV_{max} = 30.09), and the left adrenal gland measured 76 × 46 × 70 mm (SUV_{max} = 29.91). Mild FDG uptake was observed in small lymph nodes within the superior mesenteric and para-aortic regions, but no other abnormal or hypermetabolic lesions were identified elsewhere in the body. Based on these imaging findings, differential diagnoses included malignancies such as primary adrenal lymphoma. A subsequent adrenal gland biopsy confirmed the diagnosis of B-cell lymphoma. This case demonstrates the utility of ^{18}F-FDG PET/CT in identifying malignant adrenal lesions and underscores the importance of considering PAL in patients with bilateral adrenal hypermetabolic masses. ***Conclusion:*** In cases of bilateral hypermetabolic adrenal masses detected on FDG PET/CT imaging, the differential diagnosis should include both common and rare conditions, including primary adrenal lymphoma.

EP-1346

FAPI Uptake in Malignant Ascites: A Case Report

P. Sahafi, *M. Samadi, A. Aghaee;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this case report is to demonstrate the potential utility of ^{99m}Tc-FAPI imaging in detecting malignant ascites and recurrent renal cell carcinoma in a patient with a rising PSA level and a retroperitoneal mass of unknown origin. ***Materials and Methods:*** A 69-year-old man with a history of right-sided papillary renal cell carcinoma (nuclear grade I) and prior nephrectomy was evaluated for a retroperitoneal mass identified on recent CT and sonographic imaging. He also exhibited elevated PSA levels (84.1 ng/mL) and malignant ascites confirmed via abdominal paracentesis. Due to contraindications for biopsy, the

patient underwent ^{99m}Tc-FAPI and ^{99m}Tc-PSMA SPECT/CT imaging as part of an investigational clinical protocol. Tracer uptake patterns were analyzed to assess the origin and nature of the mass and ascitic fluid. ***Results:*** ^{99m}Tc-FAPI imaging revealed increased radiotracer uptake within the abdominal cavity, consistent with malignant ascites. The retroperitoneal mass also demonstrated significant FAPI uptake but was non-avid on the ^{99m}Tc-PSMA scan, suggesting recurrence of renal cell carcinoma rather than prostate cancer metastasis. These imaging findings provided critical diagnostic insights in the absence of tissue biopsy. ***Conclusion:*** This case illustrates the potential of ^{99m}Tc-FAPI imaging to detect malignant ascites and differentiate tumor recurrence in complex clinical settings. The observed FAPI uptake in malignant ascitic fluid suggests a novel application of FAPI imaging, although the exact mechanism remains to be elucidated.

EP-1347

Simultaneous visualization of a Meckel's diverticulum and its active bleeding on Tc-99m Pertechnetate scintigraphy: an unusual presentation

P. Sahafi, *M. Samadi, R. Sadeghi;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this case report is to illustrate the diagnostic challenges posed by active gastrointestinal bleeding during ^{99m}Tc-Pertechnetate scintigraphy in detecting Meckel's diverticulum, and to highlight the rare simultaneous presentation of Meckel's diverticulum with active bleeding. ***Materials and Methods:*** A 2-year-old girl with a recent history of rectorrhagia was referred for ^{99m}Tc-Pertechnetate scintigraphy to evaluate for the presence of ectopic gastric mucosa. Dynamic imaging, static anterior and posterior views, and delayed imaging were performed following standard protocols. Careful attention was given to the differentiation of physiological uptake from pathological activity. H2 blocker administration was confirmed prior to imaging to minimize physiological gastric secretion and improve diagnostic accuracy. ***Results:*** Initial imaging demonstrated focal radiotracer uptake in the mid-lower abdomen consistent with Meckel's diverticulum, appearing concurrently with normal gastric activity. Additionally, a diffuse area of abnormal radiotracer accumulation was observed in the left abdomen, showing movement during dynamic imaging, suggesting active bowel bleeding. Delayed imaging revealed widespread intraperitoneal radiotracer distribution, confirming significant hemorrhage. Surgical exploration validated the presence of a Meckel's diverticulum, and histopathology confirmed ectopic gastric mucosa. The dynamic nature of the bleeding and the movement of radiotracer uptake were critical in distinguishing active bleeding from potential imaging artifacts. ***Conclusion:*** This case represents a unique instance of simultaneous detection of Meckel's diverticulum and active gastrointestinal bleeding using ^{99m}Tc-Pertechnetate scintigraphy. Active bleeding can mimic or obscure findings, complicating accurate interpretation. Awareness of this potential pitfall, along with careful dynamic assessment and appropriate preparation with H2 blockers, is crucial for accurate diagnosis. This report underscores the importance of recognizing the rare but significant presentation of concurrent Meckel's diverticulum and active bleeding in patients undergoing nuclear imaging.

EP-1348

Complete Pathological Response After Neoadjuvant Radioligand Therapy in a Case of Pancreatic Neuroendocrine Tumor: A Case Report

P. Sahafi, *M. Samadi, M. Ghahraman, E. Soltani, A. Aghaee;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this report is to demonstrate the potential role of peptide receptor radionuclide therapy (PRRT) with ^{177}Lu-DOTATATE as a neoadjuvant approach in enabling surgical resection of initially unresectable pancreatic neuroendocrine tumors (pNETs), and to highlight the possibility of achieving complete pathological response following such treatment. ***Materials and Methods:*** A 30-year-old woman diagnosed with a low-grade (Ki67 = 3%) pancreatic neuroendocrine tumor involving major vascular structures was deemed ineligible for surgery. The patient underwent four cycles of ^{177}Lu-DOTATATE therapy, receiving 200-240 mCi per cycle with concurrent amino acid infusion for renal protection, administered every 8-12 weeks. Imaging assessment included serial whole-body scintigraphy and SPECT/CT after each treatment cycle, and a preoperative three-phase CT scan following completion of therapy. ***Results:*** Post-PRRT imaging revealed a marked reduction in tumor size and disappearance of contrast enhancement, suggestive of a complete radiological response. Subsequently, the patient underwent Whipple surgery. Histopathological evaluation of the resected specimen demonstrated only dense fibrosis without any viable tumor cells, confirming a complete pathological response. The case highlights a rare but significant outcome where PRRT facilitated surgical resection and achieved complete tumor eradication. ***Conclusion:*** This case underscores the potential effectiveness of neoadjuvant 177Lu-DOTATATE therapy in downstaging locally advanced pancreatic neuroendocrine tumors, enabling curative surgery and achieving complete pathological remission. Further research is necessary to validate these findings and identify predictors of response, potentially broadening the therapeutic indications for PRRT in the management of complex pNET cases.

EP-1349

Enhancing Restaging of a Colorectal Cancer Patient: The Advantage of ^{99m}Tc-FAPI-46 over Conventional CT in Detecting Metastases

M. Ahmadi, *A. Aghaee, M. Samadi, P. Sahafi, E. Soltani;*
Nuclear medicine research center, Mashhad university of medical sciences, Mashhad, Khorasan Razavi, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Colorectal cancer is the third most common cancer and the leading cause of cancer-related deaths worldwide, with a five-year survival rate of about 60% across all stages. However, metastatic colorectal cancer has a grim prognosis, with only 14% of patients surviving five years post-diagnosis despite treatment advancements. Accurate detection of metastatic lesions is vital for effective management, traditionally done through contrast-enhanced computed tomography (CECT). Recent developments in molecular imaging, particularly with 99mTc-FAPI, show promise in improving sensitivity for metastasis detection. This article discusses a case study of a 73-year-old man with colon adenocarcinoma, diagnosed 18 months ago, who underwent total colectomy and chemoradiotherapy. Due to recurrent abdominal pain, he was evaluated using both CECT and 99mTc-FAPI-46 SPECT/CT for metastatic workup. ***Materials and Methods:*** The planar whole-body images in anterior and posterior views and SPECT/CT acquisition were performed 1 hour after injection of 20 mci of ^{99m}Tc-FAPI-46. ***Results:*** CECT images showed a hypodense lesion with heterogeneous enhancement in the left abdomen, near the psoas muscle. In contrast, 99mTc-FAPI-46 SPECT/CT identified three distinct peritoneal metastatic lesions, confirmed by re-surgery and histology. While CECT detected only one of these lesions, the other two were small and obscured by bowel loops, making them undetectable on conventional CT. ***Conclusion:*** In this case, 99mTc-FAPI SPECT/CT demonstrated greater sensitivity than CECT in detecting metastatic lesions in a postoperative colorectal cancer patient. Incorporating 99mTc-FAPI

as an additional imaging tool alongside conventional methods like CECT could improve staging accuracy and impact clinical decision-making for colorectal cancer patients.

EP-1350

PSMA Scintigraphy in Metastases of Prostate Cancer Within the Genital Tract

F. Rabani, *M. Samadi, A. Saber Tanha, N. Afshari, A. Aghaee; Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted imaging has advanced the detection of prostate cancer metastases, particularly in atypical sites. We present a rare case of vas deferens involvement (VDI) in high-grade prostate adenocarcinoma, identified through both ^{68}Ga-PSMA PET/CT and ^{99m}Tc-PSMA SPECT/CT imaging, emphasizing the utility of PSMA imaging. ***Materials and Methods:*** A 68-year-old man presented with lower urinary tract symptoms (LUTS) and was diagnosed with prostate adenocarcinoma (Gleason score 4+5) with a PSA level of 97.5 ng/mL. He underwent staging with ^{68}Ga-PSMA PET/CT performed 60 minutes after intravenous administration of 3.24 mCi (119.88 MBq) of ^{68}Ga-PSMA, with acquisition from the skull to mid-thigh. After initial androgen deprivation therapy, the patient discontinued treatment and was lost to follow-up. Due to persistent symptoms and a PSA of 88 ng/mL after one year, he underwent restaging with ^{99m}Tc-PSMA scintigraphy, including whole-body planar imaging and SPECT/CT three hours after intravenous injection of 20 mCi (740 MBq) of ^{99m}Tc-HYNIC-PSMA. Additionally, we reviewed 59 reported cases of rare PSMA-avid metastases involving male genital structures. ***Results:*** The initial ^{68}Ga-PSMA PET/CT scan demonstrated moderate PSMA uptake within the primary prostate tumor, the left seminal vesicle base, and a rounded nodule medial to the seminal vesicle, corresponding to the ampulla of the vas deferens, consistent with locoregional invasion. Restaging with ^{99m}Tc-PSMA SPECT/CT closely mirrored these findings, confirming persistent disease confined to the prostate, left seminal vesicle, and vas deferens, without evidence of nodal, skeletal, or visceral metastases. Vas deferens involvement (VDI) in prostate cancer is rare and typically identified during restaging for biochemical recurrence, though occasionally seen at initial staging. Limited literature suggests VDI may have independent prognostic significance similar to seminal vesicle invasion, indicating a more aggressive disease phenotype. Despite the patient's high-risk features, including a Gleason score of 4+5 and elevated PSA levels, disease remained locoregional across staging and restaging. Additionally, we reviewed 59 reported cases of PSMA-avid prostate cancer metastases to male genital structures, including the vas deferens, scrotal sac, testes, epididymis, penis, vesicourethral junction, and perineum. These cases involved patients aged 45-88 years, most often during recurrence, with high Gleason scores and predominantly moderate to intense PSMA expression (scores 2 or 3). ***Conclusion:*** This case highlights the clinical utility of PSMA-targeted imaging in detecting rare metastatic patterns such as vas deferens involvement. It also demonstrates that ^{99m}Tc-PSMA SPECT/CT is an effective and accessible alternative to PET/CT, aiding accurate staging and management in prostate cancer.

EP-1351

^{68}Ga-FAPI and ^{18}F-FDG PET/CT: Complementary Imaging Modalities for Detecting Unusual Metastasis in a Patient with Osteosarcoma

P. Sahafi[1], *G. Divband*[2], *H. Amini*[3], *E. Askari*[1], *A. Noferesti*[1]; [1]*Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF of,* [2]*Jam Nuclear Medicine Center, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Khatam PET/CT Center, Tehran, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: To evaluate the complementary role of ^{18}F-FDG PET/CT and ^{68}Ga-FAPI PET/CT imaging in the characterization of equivocal soft tissue lesions in a patient with a history of osteosarcoma, emphasizing the tumor heterogeneity and the importance of multimodality imaging. ***Materials and Methods:*** A 32-year-old male with a history of left humerus osteosarcoma, previously treated with surgery, orthopedic device placement, and lung metastasectomy, underwent ^{18}F-FDG PET/CT imaging due to two suspicious lesions near the left kidney observed on prior anatomical evaluations. One lesion demonstrated FDG uptake (SUV_{max} = 4.52), while the second lesion was non-FDG-avid. To further characterize these equivocal findings and as part of a clinical trial, a ^{68}Ga-FAPI- PET/CT scan was performed. Imaging findings were compared and correlated with surgical pathology after resection. ***Results:*** The ^{18}F-FDG PET/CT scan showed significant uptake in one lesion, while the adjacent lesion lacked FDG avidity. The ^{68}Ga-FAPI PET/CT scan revealed uptake in the previously non-FDG-avid lesion (SUV_{max} = 3.77), demonstrating a heterogeneous uptake pattern between the two imaging modalities. Surgical resection and histopathological examination confirmed both lesions as metastatic osteosarcoma. This case demonstrated that tumor heterogeneity could lead to variable tracer uptake, highlighting the complementary nature of ^{18}F-FDG and ^{68}Ga-FAPI imaging. ***Conclusion:*** In osteosarcoma patients, particularly when evaluating equivocal or oligometastatic lesions, the use of both ^{18}F-FDG and ^{68}Ga-FAPI PET/CT imaging can provide a more comprehensive assessment. This case underlines the importance of multimodality imaging to account for tumor heterogeneity, which can significantly impact diagnosis and clinical decision-making.

EP-1352

Significant ^{99m}Tc-MDP uptake in metastatic lymph nodes of a patient with synovial sarcoma, a case report

P. Sahafi, *F. Karamian, A. Aghaee; Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: To describe a rare case of synovial sarcoma with metastatic lymph node involvement detected by ^{99m}Tc-MDP bone scintigraphy, and to emphasize the potential role of bone imaging agents in identifying lymphatic metastases in soft tissue sarcomas. ***Materials and Methods:*** A 15-year-old girl with a history of synovial sarcoma posterior to the left knee underwent a ^{99m}Tc-MDP whole-body bone scan after experiencing tumor recurrence in the left inguinal region, confirmed by biopsy. The patient had previously received surgical resection, chemotherapy, and radiotherapy. Bone scintigraphy findings were further evaluated using SPECT/CT imaging to assess tracer uptake patterns. ***Results:*** The ^{99m}Tc-MDP bone scan demonstrated increased tracer uptake in the left inguinal region during both the blood pool and delayed phases. SPECT/CT images confirmed the presence of increased uptake in multiple enlarged lymph nodes in the left inguinal region, consistent with metastatic involvement. ***Conclusion:*** This case highlights the rare occurrence of lymph node metastasis in synovial sarcoma and its detection via bone scintigraphy using ^{99m}Tc-MDP. The findings suggest that bone-seeking agents can accumulate in metastatic lymph nodes of soft tissue sarcomas, possibly due to mechanisms such as increased vascularity, altered calcium metabolism, and changes in tissue pH. To our knowledge, this is the first reported case demonstrating bone agent activity in lymph node metastases of synovial sarcoma.

EP-1353

Comparison of ^{99m}Tc-FAPI, ^{99m}Tc-octerotide, and ^{68}Ga-DOTATATE PET/CT in the Evaluation of a Patient with Neuroendocrine Tumor

P. Sahafi, *A. Aghaee;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: To present a case of a patient with metastatic neuroendocrine tumor (NET) in which ^{99m}Tc-FAPI imaging demonstrated superior detection of skeletal metastases compared to ^{99m}Tc-Octreotide and ^{68}Ga-DOTATATE scans, highlighting the potential role of FAPI-bounded radionuclides in the diagnosis and treatment planning of NETs. ***Materials and Methods:*** A 30-year-old woman with a history of a moderate differentiation neuroendocrine tumor and multiple skeletal metastases was evaluated. Initial imaging with ^{99m}Tc-MDP bone scan, ^{99m}Tc-Octreotide, and ^{68}Ga-DOTATATE PET/CT was performed. After limited response to two cycles of ^{177}Lu-DOTATATE therapy, the patient underwent ^{99m}Tc-FAPI SPECT/CT imaging to reassess the extent of disease. ***Results:*** The ^{99m}Tc-MDP scan revealed multiple skeletal metastases. The ^{99m}Tc-Octreotide and ^{68}Ga-DOTATATE scans showed only mild increased uptake throughout the skeleton. In contrast, the ^{99m}Tc-FAPI scan clearly demonstrated multiple lytic and sclerotic bone metastases and a soft tissue mass adjacent to the left parietal bone, indicating superior lesion visualization compared to previous imaging modalities. ***Conclusion:*** This case illustrates that FAPI-based imaging may provide enhanced detection of metastatic lesions in neuroendocrine tumors compared to somatostatin receptor-based imaging. FAPI-radiolabeled agents could offer improved diagnostic accuracy and aid in identifying candidates for targeted therapy, especially in patients with suboptimal response to conventional PRRT.

EP-1354

Tumor Lysis Syndrome After Radioligand Therapy in a Case of Metastatic Prostate Cancer

P. Sahafi, *M. Samadi, K. Aryana, E. Askari;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The aim of this study is to present a rare case of tumor lysis syndrome (TLS) following ^{177}Lu-PSMA radioligand therapy in a patient with metastatic castration-resistant prostate cancer (mCRPC), and to emphasize the importance of recognizing patients at risk for TLS prior to treatment. ***Materials and Methods:*** A 65-year-old man with a history of mCRPC, who had previously developed resistance to taxane-based chemotherapy and abiraterone, underwent treatment with ^{177}Lu-PSMA therapy. The patient had extensive bone metastases identified on initial imaging. Following the second session of radioligand therapy, he developed new clinical symptoms including difficulty walking. Laboratory studies were performed, alongside post-treatment imaging, to assess the cause of his clinical deterioration. ***Results:*** Post-therapy laboratory findings demonstrated a significant elevation in serum lactate dehydrogenase (LDH) levels, rising from 314 IU/L to 543,000 IU/L. Imaging revealed massive bilateral axillary and cervical lymphadenopathy, an atypical metastatic pattern for prostate cancer. Based on laboratory abnormalities, clinical presentation, and imaging findings, tumor lysis syndrome was diagnosed. Additionally, due to the atypical pattern of lymphadenopathy, the possibility of a secondary lymphoma was considered. ***Conclusion:*** This case highlights a rare but serious complication of TLS following ^{177}Lu-PSMA therapy in a patient with prostate cancer. Although TLS is uncommon in solid tumors, it must be considered, particularly in patients with an unusual pattern of metastasis. Furthermore, the development of unexpected metastatic distributions should prompt evaluation for potential secondary malignancies. Early recognition and management of TLS are critical to prevent severe outcomes in high-risk patients undergoing radioligand therapy.

EP-1355

Incidental Detection Of Double Chilaiditi Sign During Myocardial Perfusion Imaging: A Case Report

G. Prisacariu[1], *I. Sandu*[1], *M. Matei*[1], *C. Mazilu*[1], *R. Mititelu*[1,2];
[1]*Central Military Universitary Emergency Hospital "Carol Davila", Bucharest, ROMANIA,* [2]*University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.*

Aim/Introduction: Chilaiditi sign is characterised by the interposition of bowel—usually the colon—between the diaphragm and the liver. While typically asymptomatic and incidental, this anatomical variant can significantly challenge image interpretation during myocardial perfusion imaging (MPI), potentially resulting in attenuation artefacts that may mimic both reversible and irreversible perfusion defects. We report a rare case of double Chilaiditi sign observed during hybrid single-photon emission computed tomography/computed tomography (SPECT/CT) [^{99m}Tc]Tc-methoxy-isobutyl-isonitrile myocardial perfusion scintigraphy. ***Materials and Methods:*** A 48-year-old male was referred for MPI due to atypical anginal symptoms. The study was performed using a one-day stress/rest protocol with [^{99m}Tc]Tc-methoxy-isobutyl-isonitrile ([^{99m}Tc]Tc-MIBI). Low-dose computed tomography (CT) was acquired for attenuation correction (AC). Perfusion images were reconstructed both with and without AC for comparison. ***Results:*** On non-AC images, a fixed hypoperfusion defect was seen in the inferior and inferolateral myocardial segments. However, AC-corrected reconstructions revealed reversible hypoperfusion in the same territories, consistent with ischaemia in the right coronary artery territory. Review of the low-dose CT component revealed an unusual anatomical configuration, with bowel loops interposed between the diaphragm and the upper abdominal organs, involving both hepatic and splenic flexures, consistent with a double Chilaiditi sign. The interposed bowel resulted in an attenuation artefact that initially masked true reversible ischaemia. ***Conclusion:*** This case highlights the diagnostic implications of Chilaiditi sign during hybrid cardiac imaging. Intrathoracic displacement of bowel haustra may generate attenuation artefacts, especially in the inferior myocardial wall, potentially obscuring evidence of inducible ischaemia. Hybrid SPECT/CT imaging, employing low-dose CT for AC, is of great importance for accurate interpretation and differentiation of artefacts from true perfusion abnormalities, particularly in patients without prior cross-sectional imaging. ***References:*** 1. EP-1356

Remarkable 99mTc-FAPI-46 Uptake in a Patient With Anaplastic Thyroid Carcinoma: A Promising Step in Theranostic Field

A. Aghaee, *M. Ghahreman, P. Sahafi, M. Samadi, K. Aryana; Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Fibroblast activation protein (FAP)-targeted radionuclides are known as a promising step in cancer diagnosis and treatment (theranostic), although it is still a subject under investigation. ***Materials and Methods:*** We present a patient with anaplastic thyroid carcinoma who underwent 99mTc-FAPI-46

SPECT/CT for the evaluation of metastatic disease. S ***Results:*** everal metastatic sites were found with considerable 99mTc-FAPI-46 uptake. Malignant FAPI uptake was observed in the large calcified thyroid mass, mediastinal lymph node, both lungs, liver, few skeletal sites, and around knees prostheses. Given the notable uptake of lesions, the patient was considered as a candidate for FAP-targeted radionuclide therapy. ***Conclusion:*** Anaplastic thyroid carcinoma (ATC) is a rare, undifferentiated and poor prognosis form of thyroid cancer which often presents with regional and distant metastases. Despite treatment options such as radiotherapy, chemotherapy, molecular targeted therapy, and immunotherapy, the optimal treatment has not yet been identified. Remarkable uptake of metastatic lesions in this patient increases the probability of subsequent successful treatment with FAPI agents as a potential treatment option. In conclusion, although studies have shown promising results in using FAPI agents in theranostic field, further investigation is still needed.

EP-1357

^{99m}Tc-DMSA Uptake in the Thoracic Region Mimicking Ectopic Kidney in a Case of Crossed Fused Renal Ectopia

M. Ahmadi, *R. Sadeghi, M. Samadi, A. Ardeshirzadeh, F. Taheri;*
Nuclear medicine research center, Mashhad university of medical sciences, Mashhad, Khorasan Razavi, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Renal ectopia is characterized by the abnormal positioning of a kidney outside its normal anatomical location within the renal fossa. Diagnosis of this condition occurs in only a small percentage of cases. Among the different forms of renal ectopia, intrathoracic kidneys are the least commonly observed. This case revealed an unexpected uptake of 99mTc-DMSA in the left hemi-thorax, which was initially suspected as an ectopic thoracic kidney. However, further fused SPECT/CT imaging clarified that this uptake was due to an iatrogenic lung microembolism, which highlights the critical importance of accurately characterizing extrarenal DMSA uptake. ***Materials and Methods:*** After administration of 37 MBq (1 mCi) 99mTc-DMSA, imaging was performed 4 hours later in multiple views. ***Results:*** On the planar images, the right kidney seemed to be large-sized and mal-rotated with a zone of decreased tracer activity in the upper pole and no radiotracer uptake in the left renal lodge with an incidental finding of 99mTc-DMSA uptake in the left hemi-thorax, which was initially suspected to represent an ectopic thoracic kidney. Subsequent fused SPECT/CT images revealed mal-rotated crossed fused kidneys on the right side with a zone of decreased tracer uptake in the upper pole related to the pyelocalyceal system. Furthermore, SPECT/CT images localized 99mTc-DMSA uptake in the left hemi-thorax to the superior segment of the left lower lobe of the lung with no abnormal lesion on the co-registered CT images. This finding was determined to be an iatrogenic microembolism resulting from a traumatic injection during a challenging intravenous catheterization. ***Conclusion:*** Accurately determining the nature of extrarenal 99mTc-DMSA uptake poses a considerable diagnostic challenge. The potential presence of a radioactive clot resulting from difficult catheterization should be considered when evaluating incidental intrathoracic uptakes to enhance patient comfort by reducing the need for further diagnostic procedures and minimizing radiation exposure.

EP-1358

FDG PET CT in the diagnosis of testosteron secreting Sertoli-Leydig cell tumor of ovary

D. Todorova-Stefanovski, *S. Tasevski, S. Beshliev, G. Spirov, N. Manevska;*
University Institute of Positron Emission Tomography, Skopje, NORTH MACEDONIA, THE REPUBLIC OF.

Aim/Introduction: Ovarian Sertoli-Leydig cell tumors (SLCT) are a rare sex cord-stromal tumors, accounting for 1% of all ovarian tumors. They present mainly as benign tumors in young women under the age og 30. Clinically the patient presents with variable symptoms of excessive testosterone secretion - progressive masculinization, voice deepening, clitoromegaly, temporal hair recession and an increase in musculature. Imaging methods for detection of the tumor include ultrasound, CT and MRI but they can have low sensitivity for lesions less then 1cm. FDG PET/CT can have a significant role as complementary imaging tool for tumor localisation prior to surgical procedure. ***Results:*** CASE REPORT. We present a case of 64 year old woman presenting with alopecia, hirsutism, obesitas and hypertension in the last 3- 4 years. Laboratory findings revealed extremely high testosterone levels. Left adrenalectomy because of benign adenoma two years ago was performed. Ultrasound of the ovaries showed no abnormalities, as well as the CT of the abdomen and pelvis. Furthemore FDG PET/CT was requested and revealed increased metabolic activity in the region of the right adnexa (SUV max=8.8), which suggested performing bilateral adnexectomy. Pathology reported adrenocortical carcinoma metastatic to ovary. Second opinion for the histopathology report of the left adrenalectomy was requested and confirmed the diagnosis of benign adenoma. Afterwards second opinion for the right ovarian tumor was asked and the final diagnosis was benign Sertoli-Leydig tumor of right ovary with compressed ovarian tissue in normal sized ovary. After the surgical intervention , patient's testosterone level returned to normal. ***Conclusion:*** Sertoli-Leydig tumor of the ovary is a rare mostly benign tumor presenting with excessive serum testosterone level and variable signs of virilisation. FDG PET/CT plays important role in detecting the tumor and aiding in surgery decision when conventional imaging methods show no structural abnormalities ***References:*** https://pmc.ncbi.nlm.nih.gov/https://www.ejgm.co.uk/download/challenges-in-diagnosing-ovarian-sertoli-leydig-cell-tumorsa-peruvian-case-series-15149.pdfarticles/PMC10074573/

EP-1359

Unexpected metastasis from sigmoid cancer- where? a case report

T. Yordanova, *A. Klisarova, T. Stoeva, M. Dyankova, S. Chausheva, Z. Dancheva, B. Chaushev;*
Medical University Prof. dr. P. Stoyanov, Deparment of nuclear medicine, Varna, Bulgaria, Varna, BULGARIA.

Aim/Introduction: Colorectal metastases to thyroid are rare. Usually colorectal metastases in the thyroid occurs many years later after the primary colorectal cancer has been diagnosed and treated. It has been reported that 1.4%-3% of patients who underwent surgery for thyroid tumors are diagnosed as metastasis from other carcinomas (1) As these metastases are often asymptomatic, they are usually discovered incidentally on imaging performed as follow-up for the primary tumour. ***Materials and Methods:*** We present the case of an 46-year-old female with a history of sigmoid adenocarcinoma in 2017 treated with surgery and chemotherapy, who 4 years later FDG-PET/CT discovered incidentally on imaging performed as follow-up for the primary tumour. She was diagnosed stage pT3pN1cM0 before presentation and she has also underwent palliative chemotherapy and surgary for distant metastasis of sigmoid cancer. ***Results:*** The Follow-up FDG-PET/CT scan in 2021 revealed the presence of a previously undiagnosed nodule in the thyroid gland, a 19 mm subtly hypermetabolic nodule in the right thyroid lobe. The sigmoid origin of the mass was confirmed with a biopsy. ***Conclusion:*** This case shows that the thyroid can be a site of metastatic disease and a rare presentation of metastatic sigmoid cancer. Metastasis of malignant tumours to the thyroid gland are uncommon and they have been mainly observed in lung, renal and breast carcinoma. Cases of metastases from colon rectal cancer, are extremely rare [2, 3]. The prevalence of thyroid metastases from sigmoid cancer may be underestimated,

as many patients are asymptomatic and these metastases are not commonly searched for. FDG-PET/CT is a powerful non-invasive imaging tool method for detecting unsuspected asyptomatic metastases in unusual locations. ***References:*** 1. Lièvre A, Leboulleux S, Boige V, Travagli JP, Dromain C, Elias D, et al. Thyroid metastases from colorectal cancer: the Institut Gustave Roussy experience. Eur J Cancer 2006;42:1756-1759. 2. EP-1360

Unexpected Extrarenal Uptake of Tc-99m EC on Renal Scintigraphy in a Patient with Renal Transplantation

M. Ahmadi, *S. Barashki, A. Saber Tanha, H. Elahifard;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Technetium-99m Ethylene Dicysteine (Tc-99m EC) dynamic scintigraphy is a widely utilized imaging modality for assessing renal function and diagnosing complications in patients with renal transplants. While the primary focus of this technique is to evaluate renal perfusion and function, extrarenal uptake of radiotracers can occasionally occur, leading to unexpected findings that may complicate the interpretation of results. This case report presents a 53-year-old male with a history of bilateral kidney transplantation who exhibited an unusual pattern of extrarenal tracer uptake during a Tc-99m EC scintigraphy study. The identification of this unexpected uptake, localized to a fracture in the right pubic bone, underscores the importance of recognizing atypical imaging patterns and their potential implications for clinical practice. ***Materials and Methods:*** The dynamic scintigraphy was conducted following the intravenous administration of 5 mCi (185 MBq) of Tc-99m EC. Blood flow images were acquired in the anterior view at a rate of 2 seconds per frame, followed by functional phase images captured at 1 minute per frame. The imaging protocol aimed to assess both renal perfusion and function. ***Results:*** Dynamic scintigraphy revealed normal perfusion in the left lower quadrant (LLQ) transplanted kidney, while the right lower quadrant (RLQ) transplanted kidney exhibited severely decreased tracer uptake. The functional phase images confirmed normal function in the LLQ kidney and significantly reduced function in the RLQ kidney. Notably, an unexpected area of increased Tc-99m EC activity was observed in the lower pelvic region on both the perfusion and functional images. SPECT/CT imaging was conducted to further elucidate the source of the abnormal tracer accumulation. The imaging results revealed a fracture in the right pubic bone, which correlated with the elevated Tc-99m EC uptake. ***Conclusion:*** This case highlights the clinical significance of recognizing atypical patterns of Tc-99m EC uptake during renal scintigraphy, particularly in patients with renal transplants. The incidental identification of a bone fracture through SPECT/CT imaging not only provided valuable insights into a non-renal pathology but also emphasized the need for clinicians to consider extrarenal tracer accumulation in their diagnostic evaluations. Such awareness can enhance the accuracy of interpretations and improve patient management in similar clinical scenarios. This report serves as a reference for clinicians, broadening their understanding of the diagnostic potential of renal scintigraphy and the implications of unexpected imaging findings.

EP-1361

99mTc-PSMA Uptake in Neurofibroma

M. Samadi, *P. Sahafi, H. Elahifard, E. Askari, S. Davoodi;*
Mashhad university of medical sciences, mashahd, Iran, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) imaging has emerged as a valuable tool for staging and restaging prostate cancer, particularly in high-risk cases. Although PSMA expression is predominantly associated with prostate adenocarcinoma and tumor neovasculature, several benign and non-prostatic malignancies may demonstrate PSMA uptake. This report presents a unique case of PSMA-avid neurofibroma identified incidentally during PSMA-targeted SPECT/CT imaging for prostate cancer staging, highlighting a diagnostic pitfall and expanding the spectrum of PSMA-avid lesions. ***Materials and Methods:*** A 74-year-old male with a recent diagnosis of high-risk prostate adenocarcinoma (Gleason score 5+4) involving 11 of 14 biopsy cores, with intraductal carcinoma and perineural invasion, underwent staging with 99mTc-HYNIC-PSMA SPECT/CT. The patient's serum PSA level was 15.3 ng/dL at the time of imaging. A dose of 20 mCi (740 MBq) of 99mTc-HYNIC-PSMA was administered intravenously, and whole-body planar and SPECT/CT images were acquired 3 hours post-injection. ***Results:*** Imaging demonstrated intense radiotracer uptake in the prostate gland and pelvic lymphadenopathy, consistent with primary tumor and nodal metastases. Additional uptake was noted in the thoracic vertebra, suggesting early osseous metastasis. Incidentally, a focus of increased PSMA uptake was detected in the left occipital scalp region. SPECT/CT revealed a subcutaneous nodule with moderate PSMA avidity (PSMA expression score: 1), which was erythematous and palpable on physical examination. Given the patient's very-high-risk status, the lesion was initially suspected to represent cutaneous metastasis. Excisional biopsy revealed histopathologic features consistent with a neurofibroma. Immunohistochemistry showed S100 positivity and negativity for Melan-A, CD34, and cytokeratin ***Conclusion:*** This case illustrates the potential for benign lesions, such as neurofibromas, to exhibit PSMA uptake, likely due to increased capillary permeability or neovascularization rather than true tumor expression of PSMA. Awareness of such PSMA-avid benign entities is crucial to avoid misinterpretation and unnecessary intervention. Histological confirmation should be considered for atypical or unexpected sites of uptake, especially in high-risk patients.

EP-1362

Radio-Guided Monitoring of Systemic Leakage With 99mTc-MAA Uptake in a Patient With Melanoma During Isolated Limb Perfusion

M. Samadi, *S. Khezri, E. Hasanzadeh Hadad, R. Sadeghi, A. Aghaee;*
Mashhad university of medical sciences, mashahd, Iran, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Isolated limb perfusion (ILP) is a well-established treatment option for patients with locally advanced or in-transit metastatic melanoma, providing high local drug concentrations with limited systemic toxicity. Various radiotracers have been employed for leakage monitoring during ILP. Here, we present a case of a 65-year-old woman with recurrent melanoma treated with ILP using melphalan and intraoperative leakage assessment with 99mTc-labeled macroaggregated albumin (MAA), a novel application for this radiotracer in this context. ***Materials and Methods:*** A 65-year-old woman with a history of melanoma on the left foot, following a burn at age 15, underwent prior resection, inguinal lymph node dissection, and radiation therapy. She developed in-transit metastases treated with

additional surgery and external beam radiation. Recurrence with dermal nodular lesions led to consideration for ILP. Under general anesthesia, the femoral vessels were cannulated and connected to a closed perfusion circuit. A tourniquet was applied to the limb base. 99mTc-labeled MAA was added to the circuit for leakage detection. A gamma probe was placed over the jugular vein to monitor systemic tracer activity. Upon confirming no leakage, melphalan 50 mg was infused over 1 hour. The limb was then flushed, and the procedure completed. ***Results:*** A whole-body scan performed 3 hours after surgery demonstrated no significant tracer accumulation outside the perfused limb, confirming the absence of systemic leakage. Intense radiotracer uptake was localized to the treated limb. Compared to previous studies using 131I- or 123I-labeled albumin or 99mTc-HSA, this is the first known report of using 99mTc-MAA for leakage assessment in ILP, demonstrating effective tracer retention within the isolated circulation. ***Conclusion:*** This case highlights the novel use of 99mTc-labeled MAA for intraoperative leakage detection during isolated limb perfusion in melanoma. The method provided clear imaging of localized tracer distribution with no systemic spread, confirming its potential as a safe and effective alternative to previously used agents. Further studies may validate its broader clinical utility.

EP-1363

The Quiet Life-Threatening Event: Sudden Respiratory Failure During a Prolonged Dynamic Scintigraphy Procedure

M. Samadi, *S. Khezri, P. Sahafi, A. Aghaee;*
Ghaem Hospital, Mashhad university of medical sciences, Mashahd, Iran, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Massive lower gastrointestinal bleeding (rectorrhagia) is a medical emergency that often necessitates prompt localization of the bleeding source. While endoscopy and colonoscopy are the primary diagnostic modalities, they may fail to detect intermittent or slow bleeding. In such cases, nuclear medicine imaging, specifically with 99mTc-labeled red blood cells (99mTc-RBC), is a valuable non-invasive diagnostic tool. Patients with chronic obstructive pulmonary disease (COPD) undergoing prolonged imaging are at increased risk for hypoxia-related complications, which can mimic or be mistaken for procedural anxiety or claustrophobia. Differentiating these entities is essential for appropriate management. ***Materials and Methods:*** We report the case of a 74-year-old man with history of COPD who presented with massive rectorrhagia and was referred for a 99mTc-RBC scan after normal findings on endoscopy and colonoscopy. He had received three units of packed red blood cells prior to imaging, with a post-transfusion hemoglobin level of 9.5 g/dL. A dynamic scintigraphic study was performed immediately after intravenous injection of 20 mCi (740 MBq) of 99mTc-RBC, acquiring images at 30-second intervals for one hour. Additional 20-minute dynamic acquisitions were conducted every 30 minutes based on initial findings. Pulse oximetry and vital signs were monitored following an episode of unexpected patient agitation during the scan. ***Results:*** Initial dynamic images demonstrated suspicious focal activity (Panel A), prompting continuation of imaging. However, the patient became agitated and attempted to leave the imaging room, reporting discomfort without clear explanations. Vital signs revealed a respiratory rate of 24 breaths per minute and oxygen saturation (SpO_2) of 80%. Supplemental oxygen at 5 L/min via face mask was administered, resulting in improved SpO_2 (96%) and resolution of agitation. Imaging resumed, and the previously suspicious activity was identified as physiological uptake within abdominal vessels (Panel B). Upon arrival, the patient's respiratory rate had been 16 breaths per minute with SpO_2 of 98% on supplemental oxygen, which had been discontinued at the patient's request during acquisition due to lack of dyspnea. ***Conclusion:*** This case highlights the critical need to monitor oxygenation during prolonged nuclear medicine procedures in patients with underlying pulmonary disease. Hypoxia can present with neuropsychiatric symptoms such as agitation and irritability, potentially mimicking claustrophobia. Differentiation between hypoxia-induced agitation and anxiety is essential, as mismanagement—such as the inappropriate use of sedation—can exacerbate hypoxia. Prompt recognition and treatment with supplemental oxygen can stabilize the patient, improve cooperation, and avoid unnecessary imaging repetition, thereby reducing radiation exposure and healthcare costs.

EP-1364

Radiation recall pneumonitis following durvalumab immunotherapy in a lung cancer patient detected by ^{18}F-FDG PET/CT.

N. Vavlas, *A. Morfesi, V. Mpalaris, D. Katsampoukas, S. Georga, E. Moralidis, G. Arsos;*
3rd Department of Nuclear Medicine. Aristotle University of Thessaloniki School of Medicine,Papageorgiou General Hospital, Thessaloniki, GREECE.

Aim/Introduction: Radiation recall pneumonitis (RRP) is a rare inflammatory reaction occurring within previous radiation port sites, usually triggered by a variety of agents including chemotherapy, vaccines, anti-TB or other antibiotics and immune check point inhibitors (CPI). With the wide application of CPI in combination with chemo and radiation therapy in lung cancer, RRP is expected to be increasingly detected by ^{18}F-FDG PET/CT. As RRP may anticipate generalized CPI associated pneumonitis, its recognition is important for prevention of this serious complication and also for avoidance of false positive diagnoses of infection or cancer relapse [1. 2]. ***Materials and Methods:*** A 67-year-old male diagnosed with right hiliar NSCLC was initially treated with immuno-chemotherapy, followed by consolidative radiotherapy. Maintenance immunotherapy with the CPI (PD-L1) Durvalumab was initiated therafter. A total of five ^{18}F-FDG PET/CT scans performed during the disease course from July 2023 to April 2025. Clinical information and PET imaging findings were integrated to establish the diagnosis and guide therapeutic decisions. ***Results:*** After several cycles of Durvalumab after radiotherapy (Dec 2023), a follow up ^{18}F-FDG PET/CT scan on May 2024 showed new moderately hypermetabolic (SUVmax 4,6) fibrotic and atelectatic changes, within the radiation portfield in the right lower lobe, interpreted as potential post-radiation inflammation. With continued Durvalumab therapy, a subsequent ^{18}F-FDG PET/CT on Sept 2024 revealed increasing size and activity (SUVmax 5,9) of the lesions of the RLL, along with new hypemetabolic (SUVmax 4,6) lesions in the middle lobe, suggesting evolving inflammatory pathology. As the patient had no signs of infection, a potential diagnosis of RRP was suggested and the PCI therapy was discontinued. A follow-up ^{18}F-FDG PET/CT 7 months later (April 2025) showed complete metabolic remission and significant size reduction of all lesion in the right lung, thus retrospectively supporting the diagnosis of RRL. ***Conclusion:*** This case illustrates how ^{18}F-FDG PET/CT can correctly identify radiation recall pneumonitis cases thus preventing dentrimental CPI complications and avoiding false positive diagnoses. Awarreness of the entity is required along with detailed information about the treatmemt regimen of the patient. ***References:*** (1) Jan PR, Chang JW, Wu CE. Radiation Recall Pneumonitis: A Rare Syndrome That Should Be Recognized. Cancers (Basel) 2022;14(19):4642.(2) Grassi F, Granata V, Fusco R, De Muzio F, Cutolo C, Gabelloni M, et al. EP-1365

Incidental finding of Medullary Thyroid Carcinoma on 18F-DCFPyL PET/CT performed in the staging of High-Risk Prostate Cancer

L. Mena Bares, *M. Sánchez Torrente, E. Moratalla Aranda, S. Martín Aguilar, M. Ureña Lara;*
Hospital Universitario Jaén, Jaén, SPAIN.

Aim/Introduction: Prostate cancer (PCa) is the second most common male cancer worldwide. Accurate disease staging is of utmost importance, and PET/CT using prostate-specific-membrane-antigen (PSMA) ligands has proven superior to conventional imaging for primary staging of metastatic disease. Accordingly, updated prostate cancer guidelines now recommend PSMA PET/CT at the front-line imaging modality for initial staging of unfavorable intermediate or high-risk prostate cancer. PSMA is a transmembrane protein with significantly increased expression in prostate cancer cells compared to normal prostate tissue but PSMA is not specific to prostate tissue. Has also been found in the neovasculature of a variety of other malignancies such as renal cell carcinoma, neuroendocrine tumors, melanoma, colon carcinoma, lung cancer, thyroid cancer or breast cancer. The incidence of PSMA thyroid incidentaloma (PTI) varies among different tracers: 68 Ga-PSMA-11 (7-23%), 18F-PSMA-1007 (29-64%), or 18F-DCFPyL (2-8%). PSMA expression was related to malignant disease, poor prognostic factors and poorer progression free survival. ***Materials and Methods:*** A 73-yerars-old man with suspicion of PCa had a Prostate-Specific-Antigen (PSA) level at 5,6 ng/ml and Magnetic Resonance imaging scans showed a positive image a peripheral zone in the left lobe of prostate gland (PIRADS-4). The prostate biopsy indicated an Adenocarcinoma, Gleason Score=4+4 in the right lobe and Gleason Score=4+3 in the left lobe, and we can classify the patient into the high-risk group. A 18F-DCFPyL PET/CT was requested for initial staging. ***Results:*** 18F-DCFPyL PET/CT scan showed intensely PSMA-expressing lesions in prostate: Left lobe Midportion- posterolateral peripheral zone (SUVmax:14,18. Primary Score 5) and anterior perihepral zona (SUVmax:7,23. Primay Score 4). Right lobe Midportion -- posterolateral peripheral zone (SUVmax:11,37. Primary Score 4) and Right lobe Apex -- anterior/posterior transition zone (SUVmax: 6,3. Primary Score 3). Intense focal PSMA uptake (SUVmax:12,44), is observed in the hypodense nodule in the left lobe of thyroid gland of size 2,5 cm. The patient underwent ultrasound of the neck and guided fine-needle aspiration cytology (FNAC) from suspicious thyroid nodule (TIRADS-5) which demonstrated a medullary thyroid carcinoma (MTC). ***Conclusion:*** PTIs frequently signal the presence of unexpected lesions in the thyroid which differ from the indicated reason for which the patient was initially scanned and MTC is a rare case among PTIs. The uptake of PSMA open the possibility of theranostic application in patients with MTC who have limited treatment options. ***References:*** Donswijk ML, et al. Incidence of PSMA PET thyroid incidentaloma depends on analysis method and tracer. Eur Radiol 2023; 33: 3377-85.

Unusual Presentation of a Pancreatic Neuroendocrine Tumour

A. Bagán-Trejo[1], *J. L. Vercher-Conejero*[1], *J. J. Martín-Marcuartu*[1], *M. Tormo-Ratera*[1], *J. C. Ruffinelli*[2], *I. Peiró*[3], *B. Hervás-Sanz*[1], *J. L. Díaz-Moreno*[1], *M. Zamorano-Rivas*[1], *M. Á. Crespí-Busquets*[4], *C. García-Alcober*[4], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Oncology Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN,* [3]*Endocrinology Department, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN,* [4]*Radiopharmacy Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Pancreatic neuroendocrine tumours (PanNETs) represent 1-3% of all pancreatic tumours, with a prevalence of less than 1 per 100.000 individuals. Functioning PanNETs account for 30-40% of cases, the most common ones being insulinomas (1-4 cases per 1.000.000 individuals) and gastrinomas (0.5-3 cases per 1.000.000 individuals). ***Materials and Methods:*** We report the case of a 66-year-old male with no significant medical history who presented with asthenia, right-sided supraclavicular lymphadenopathy, easy bruising, and centripetal weight gain involving the face, abdomen and legs. He had recently developed hypertension, for which he was put on ACEI medication. Blood tests showed hypokalaemia, hypernatremia, thrombocytopenia and elevated cortisol levels. Following this, the patient was diagnosed with ectopic Cushing syndrome. A contrast-enhanced thoracoabdominal CT identified a 4.8mm growth in the distal pancreas with vascular involvement, bilobar liver metastases, and splenomegaly. ***Results:*** Liver biopsy confirmed metastatic well-differentiated pancreatic neuroendocrine tumour, immunohistochemically positive for adrenocorticotropic hormone (ACTH). The thrombocytopenia was attributed to splenic sequestration from hilar compression, though a paraneoplastic mechanism could not be excluded. A [^{68}Ga]Ga-SSA PET/CT was performed to assess the possibility of distant metastatic disease. It revealed moderate heterogeneous uptake in the pancreatic lesion and moderate homogeneous uptake in liver metastases, without additional lesions. Given the moderate uptake and suspicion of tumour heterogeneity, an [^{18}F]F-FDG PET/CT was also performed. It showed a moderate heterogeneous uptake in the known lesion although encompassing a wider area, reaching the body of the pancreas, suggesting the tumour could be bigger than anticipated. Moderate homogeneous uptake was also observed in the liver metastases, and no additional uptake was observed. Following discussion in the multidisciplinary NETs board, the patient was initiated on chemotherapy with Streptozotocin and 5-fluorouracil after stabilisation of the thrombocytopenia. Ultimately, he succumbed to complications including grade 3 anaemia and thrombocytopenia, Pneumocystis jirovecii pneumonia, acute pancreatitis, and Escherichia coli bacteraemia. ***Conclusion:*** ACTH-secreting PanNETs are exceedingly rare and may present with ectopic Cushing syndrome. This case underscores their diagnostic and therapeutic complexity, as well as their possibly aggressive course. Dual-tracer PET/CT imaging proved essential in characterising tumour heterogeneity and extent, providing complementary information critical for disease staging and therapeutic planning. ***References:*** Alshareefy Y, Cummins S, Mazzoleni A, Sharma V, Guggilapu S, Leong AWY, Wireko AA. A review of functional pancreatic neuroendocrine tumors: Exploring the molecular pathogenesis, diagnosis and treatment. Medicine 2023;102:46(e36094).

EP-1367

Exceptional ^{18}F-FDG Uptake in White Adipose Tissue Induced by Systemic Glucocorticoid Therapy

M. Ulucay, *A. Dere, H. B. Kapucu, I. Ozturk, B. E. Akkas;*
Health Sciences University,Basaksehir Cam and Sakura City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: A study on the evaluation of atypical F-18 FDG uptake patterns. ***Materials and Methods:*** A 46 year-old woman with adenocarcinoma metastasis in cerebellum was referred to PET / CT scan for the detection of an unknown primary malignancy. On 18F- FDG PET/CT scan altered biodistribution of FDG was observed with diffuse intense uptake in white adipose tissue (WAT) . The patient had the history of high dose glucocorticoid use for prevention of compression symptoms 37 days prior to scan .Under normal circumstances FDG metabolism is negligible in WAT, alterations in adipose tissue metabolism are uncommon. We consider this case as an interesting image for the unusual intense

FDG uptake in WAT associated with high-dose corticosteroid therapy. ***Results:*** A 46-year-old woman with no prior medical history presented to our center with sudden onset of dizziness and nausea symptoms. Advanced imaging identified cerebellar mass. Surgical preparations for the cerebellar mass have commenced, corticosteroid therapy has been initiated at a daily dose of 16 mg dexamethasone to prevent mass effect. 37 days after the initiation of corticosteroid therapy, the patient was referred to us for PET/CT imaging to investigate the primary etiology. Adequate fasting was ensured before the PET/CT scan, with a fasting blood glucose level of 100 mg/dl. Additionally, the patient did not exhibit a cushingoid appearance and showed no clinical signs suggestive of Cushing's syndrome. Imaging obtained 60 minutes post-injection of 18F-FDG at a dose of 6 mCi revealed a lesion in the posterior basal segment of the right lower lobe, approximately 32 mm in size , potentially consistent with primary lung cancer . Notably, MIP imaging highlighted increased ^{18}F-FDG uptake in adipose tissue rather than in muscle tissue in the upper body segment . ***Conclusion:*** Typically, the body contains three types of adipose tissue: white, beige, and brown and ^{18}F-FDG uptake in white adipose tissue is not generally anticipated. Previous literature has identified several factors associated with increased activity in white adipose tissue, including antiretroviral therapy in HIV infection, steroid therapy, and Cushing's syndrome. Glucocorticoid therapies are well-documented to affect lipid metabolism, primarily through inducing adipose tissue hyperplasia; however FDG uptake in WAT is not generally increased. This case demonstrates exceptional FDG uptake in WAT induced by systemic glucocorticoid therapy even in the absence of cushingoid clinical features.

EP-1368

The value of sequential imaging review in localizing an occult primary Neuroendocrine Tumor: A Case Report

L. Castillejos, *C. Paniagua, S. Pérez Quirós, A. Ortega Valle, M. Tagliatori, A. Herrero, M. de la Rubia, D. Rodríguez Oviedo, C. Galindo, K. Guichay, M. García Alonso;*
Hospital Universitario de Getafe, Madrid, SPAIN.

Aim/Introduction: Approximately 11% to 14% of subjects with neuroendocrine tumor (NETs) have metastatic lesions with unknown primary origin, with the majority found in the small bowel. The identification of the primary tumor is important as it affects the prognosis and remains a diagnostic challenge. Although somatostatin receptor scintigraphy is a key diagnostic tool, its sensitivity is limited. We present a case in which detailed and comparative review of previous imaging studies enabled the localization of a previously undetected small bowel primary tumor. ***Materials and Methods:*** A 55-year-old male was evaluated for suspected metastatic NET with a mesenteric lymph node enlargement, but no evident primary tumor. A scintigraphy with 99mTc-octreotide was performed, including early planar abdominal images at 30 minutes and whole-body scan, followed by SPECT/CT of the thorax and abdomen 2 hours after tracer injection. Tomographic images revealed a hypermetabolic nodular lesion in the mesenteric root, with no clear identification of a primary site. A biopsy of the lesion showed fibroinflammatory tissue. Due to persistent lymphadenopathy and ongoing clinical suspicion, a second 99mTc-octreotide scan was requested three years later. ***Results:*** The second study was carefully reviewed and compared with the initial scan. In the SPECT/CT, in addition to the persistent mesenteric lymphadenopathy, a focal uptake was observed in a jejunoileal loop adjacent to the hepatic flexure of the colon. Retrospective analysis of the first scan revealed a subtle uptake at the same location, previously interpreted as physiological intestinal activity. The patient underwent surgery with exploration of the intestinal region indicated in the scan. A lesion was identified and resected. Histological analysis confirmed a well-differentiated NET in a jejunoileal loop and metastasis in a mesenteric lymph node.This case underscores the importance of reviewing previous studies when evaluating patients with NETs of unknown primary origin. Factors such as physiological bowel activity, subcentimetric lesion size, and the limited spatial resolution of scintigraphy can hinder initial detection. The persistence of a focal uptake at the same location in repeated studies strongly suggests a true lesion. Furthermore, integrating hybrid imaging modalities like SPECT/CT increases diagnostic sensitivity. ***Conclusion:*** Systematic comparison of imaging studies over time is essential in the evaluation of patients with metastatic NETs of uncertain origin. Identifying subtle but persistent findings can significantly alter therapeutic decisions and improve clinical outcomes.

EP-1369

Fibrous Dysplasia with 99m Tc-FAPI Uptake in a Patient Under Long-Term antiresorptive Therapy

M. Samadi, *P. Sahafi, A. Aghaee;*
Ghaem Hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Fibrous dysplasia (FD) is a rare, benign bone disorder caused by postzygotic activating mutations in the GNAS gene, leading to replacement of normal bone with immature fibrous tissue. Craniofacial FD presents unique challenges due to aesthetic, functional, and neurological complications. Conventional bone imaging with tracers like 99mTc-MDP is limited to assessing osteoblastic activity and may not fully represent fibroblastic or stromal components. Fibroblast activation protein inhibitor (FAPI) imaging has emerged as a promising modality for detecting fibrotic lesions. While FAPI uptake has been demonstrated in FD using 68Ga-labeled compounds, uptake using 99mTc-FAPI has not previously been documented. We report the first known case of FD imaged with 99mTc-FAPI SPECT/CT, highlighting its potential role in assessing active fibroblast proliferation in fibrous dysplasia. ***Materials and Methods:*** A 40-year-old female patient with a 20-year history of craniofacial fibrous dysplasia involving the right maxilla, orbital cavity, and fronto-parietal bones was evaluated. She had undergone partial maxillary debulking surgery seven years prior and orbital decompression three years ago. She received intravenous Zoledronic acid monthly for six years and switched to Denosumab therapy one year ago due to inadequate disease control.Planar whole-body and SPECT/CT scans were performed on two separate days. First, a 99mTc-MDP scan was acquired three hours post-injection of 20 mCi (740 MBq). On another day, a 99mTc-FAPI scan was performed one hour after intravenous injection of the same dose. Imaging findings were analyzed to identify sites of radiotracer uptake correlating with known FD lesions. ***Results:*** The 99mTc-MDP SPECT/CT revealed multiple sites of increased osteoblastic activity including the fronto-parietal bones, ethmoid, sphenoid, right maxilla, mandible, right scapula, humerus, radius, and lower thoracic and lumbar vertebrae. These areas corresponded to hyperdense lytic-sclerotic lesions with a ground-glass appearance.The 99mTc-FAPI SPECT/CT demonstrated focal uptake in cranial bones, right scapula, and L4 vertebra, consistent with known FD lesions. The uptake pattern was indicative of active fibroblast proliferation and matched, in part, the 99mTc-MDP findings but also revealed fibrotic activity independent of purely osteoblastic changes. ***Conclusion:*** This case represents the first reported instance of 99mTc-FAPI uptake in fibrous dysplasia. The findings suggest that 99mTc-FAPI SPECT/CT may provide complementary information to traditional bone scans by detecting fibroblast activation in FD lesions. This imaging modality could be particularly valuable in assessing disease activity in lesions with low osteoblastic turnover or with significant fibrous stroma.

EP-1370

Lipomatous Hypertrophy of the Interatrial Septum: Long-term ^{18}F-FDG Uptake variation on serial PET/CT scans in a Lung Cancer patient

A. Morfesi, *N. Vavlas, D. Katsampoukas, V. Mpalaris, S. Georga, E. Moralidis, G. Arsos;*
3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou General Hospital, Thessaloniki, GREECE.

Aim/Introduction: Lipomatous Hypertrophy of the Interatrial Septum (LHIS) is characterized by excessive fat deposition in the interatrial septum (IS), typically diagnosed incidentally during imaging for other conditions. However, as it is commonly hypermetabolic [1], differentiation from other potentially malignant lesions like myocardial tumors, especially the lipomatous ones, or cardiac secondaries in oncological patients is critical in ^{18}F-FDG PET/CT, in order to avoid invasive diagnostic procedures. Little is known on LHIS behavior over time. ***Materials and Methods:*** A 65-year-old female had her first follow-up ^{18}F-FDG PET/CT 6 years after right upper lobectomy for lung adenocarcinoma, revealing a hypermetabolic, low density area along the IS. A cardiac MRI 3 months later was compatible with LHIS. The patient was not diabetic, had no cardiac disease and was off beta-blockers. A conservative watchful approach was selected and a total of six ^{18}F-FDG PET/CT scans performed from June 2022 to January 2025, showing considerable metabolic variation of the LHIS without gross morphological changes. The radiodensity was measured in Hounsfield units (HU) in non-contrast, low-dose CT and the metabolic activity was assessed by total body weight SUVmax and Total Lesion Glycolysis (TLG). ***Results:*** No signs of lung cancer relapse or extracardiac brown adipose tissue (BAT) activation were seen in any of the six PET scans. Radiodensity (HU), SUVmax (g/ml) and TLG (g) of the LHIS were: June 2022, -63.4, 11.6, 89.4; September 2022, -51.0, 4.6, 27.9; May 2023, -51.9, 2.5, 18.3; October 2023, -58.0, 6.2, 49.2; April 2024, -62.0, 4.9, 36.2 and January 2025, -61.0, 4.2, 32.0. No substantial change of the extent of the hypodense area of the IS was observed. The corresponding blood glucose levels after overnight fasting were 98, 93, 89, 109, 97 and 93 mg/dL respectively and the corresponding minimum/average temperature (in ^{0}C) in the residence area of the patient at the day of the scan was 22.7/27.7, 20.7/24.5, 14.5/17.0, 21.3/25.5,12.3/16.9 and 10.8/12.4 respectively. The maximum relative change (maximum-minimum/maximum %) in radiodensity, SUVmax and TLG during the observation period was 19.6, 78.4 and 79.5 respectively. ***Conclusion:*** LHIS shows anatomical consistency but considerable metabolic variation over time, not associated with temperature variation or extracardiac BAT activation. Follow-up with ^{18}F-FDG PET/CT can confirm the benign nature of the lesion thus avoiding invasive diagnostic procedures. ***References:*** [1] Fan CM, Fischman AJ, Kwek BH, Abbara S, Aquino SL. Lipomatous hypertrophy of the interatrial septum: increased uptake on FDG PET. AJR Am J Roentgenol. 2005 Jan;184(1):339-42.

EP-1371

Radioiodine Treatment Failure in Toxic Adenoma: Marine-Lenhart Syndrome

A. Vergili[1], *M. Acar Tayyar*[1], *E. Uyanık*[1], *F. Yıldız Kabaca*[1], *T. Özülker*[2];
[1]*Prof Dr Cemil Taşcıoğlu City Hospital, İstanbul, TÜRKIYE,* [2]*Prof Dr Cemil Tascıoğlu City Hospital, Istanbul, TÜRKIYE.*

Aim/Introduction: Marine-Lenhart syndrome is a rare condition characterized by the presence of one or more hyperfunctioning thyroid nodules in the setting of Graves' disease(prevalence:0.26%-4.1%).Antithyroid drugs(ATD) are generally ineffective,and the recommended treatment options include surgery or radioactive iodine(RAI) therapy.On thyroid scintigraphy,a hyperfunctioning nodule may obscure the evaluation of the thyroid parenchyma and mask the underlying Graves' disease.This case highlights the importance of considering Marine-Lenhart syndrome in patients initially diagnosed with toxic adenoma who exhibit persistent hyperthyroidism following RAI therapy. ***Materials and Methods:*** A diagnostic thyroid scintigraphy was performed using 5 mCi of technetium-99m. Radioiodine uptake at the 2nd and 24th hours was measured with 3 µCi of iodine-131.A therapeutic dose of 10 mCi of radioactive iodine (RAI) was administered. The diagnostic thyroid scintigraphy was repeated,and a 15 mCi RAI dose was administered. ***Results:*** A 55-year-old female patient diagnosed with toxic adenoma presented to the nuclear medicine department due to the persistence of symptoms (palpitations,irritability,weight loss) and failure to achieve remission with antithyroid drugs (ATD).Thyroid ultrasound and scintigraphy findings were consistent with toxic adenoma.Iodine uptake was 15% at 2 hours and 36% at 24 hours. The patient received 10 mCi of RAI and was followed up biweekly. Despite treatment, her hyperthyroidism worsened. Initial TSH was 0.02, and T4 was 0.76; three months after RAI, TSH dropped below 0.01, and T4 increased to 5.57 (Normal:TSH 2.12-4.50, T4 0.58-1.38). Due to clinical deterioration,repeat thyroid scintigraphy was performed,revealing decreased background activity in the left lobe and a hypoactive nodule with widespread increased uptake. Further evaluation revealed elevated thyroid autoantibodies, confirming Graves' disease(TRAb>40 IU/L [N:<1.75], TSI>30[N:0-1.3]).Iodine uptake was re-measured before a second RAI dose,showing a significant increase(38% at 2 hours,74% at 24 hours).A second dose of 15 mCi of RAI was administered. Two months later,the patient developed hypothyroidism and is currently being followed up with thyroid hormone replacement therapy.Discussion:Marine-Lenhart syndrome presents diagnostic and therapeutic challenges.ATD may be ineffectiveand standard RAI doses may fail due to underlying Graves' pathology masked by hyperfunctioning nodules.When clinical and biochemical responses are inadequate,repeated imaging and autoantibody testing are crucial.This case emphasizes the importance of suspecting Marine-Lenhart syndrome in patients with persistent or worsening hyperthyroidism following RAI therapy.Higher or repeated RAI doses may be required for definitive control. ***Conclusion:*** Early recognition of Marine-Lenhart syndrome is crucial to avoid delayed or ineffective treatment.In cases of RAI failure,reevaluation with repeat scintigraphy and antibody testing should be considered.

EP-1372

Radiation-Induced Osteoradionecrosis of the Ribs in a Patient with Breast Cancer: A Case Report

G. Fuso[1], *G. Bianciardi*[1], *C. M. P. Sgro*[1], *E. Greco*[1], *P. E. Orlandi*[2], *A. Romeo*[3], *S. Fanti*[4,3];
[1]*Policlinico Sant'Orsola-Malpighi, University of Bologna, Bologna, ITALY,* [2]*Ospedale Maggiore, Bologna, ITALY,* [3]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*University of Bologna, Bologna, ITALY.*

Aim/Introduction: Radiation-Induced Osteoradionecrosis (ORN) is a rare, severe and late complication of radiotherapy, characterized by necrotic, non-healing bone in previously irradiated areas, persisting without evidence of tumor recurrence. The pathophysiology involves radiation-induced damage leading to hypoxia, hypovascularity, and hypocellularity, impairing bone turnover and tissue regeneration. Clinically, patients may present with pain, swelling or even pathological fractures. Differential diagnoses include osteomyelitis, bisphosphonate-related osteonecrosis, and tumor recurrence. This paper describes a clinical case of radiation-Induced Osteoradionecrosis of the Rib in a Patient with Breast Cancer, emphasising the role of bone scintigraphy in the differential diagnosis. ***Materials and Methods:*** We report the case of a patient who presented with severe and

diffuse osteoarticular pain. Medical history includes bilateral breast cancer previously treated as follows: left quadrantectomy with axillary lymphadenectomy, radiotherapy and hormone therapy in 2004; right quadrantectomy with sentinel lymph node excision and radiotherapy in 2008; right mastectomy in 2014; and left mastectomy in June 2018. They whole-body bone scintigraphy, performed 3 hours after radiotracer injection, showed a diffuse increase in uptake involving symmetrically the anterior arches of the second, third, and fourth ribs on both sides: findings not reported in prior bone scintigraphy imaging. ***Results:*** Corresponding low-dose CT images showed a thin, band-like appearance of the affected ribs, with mild, homogeneous sclerosis, reduced visualization of the trabecular bone component, and no evidence of cortical disruption. These findings are more consistent with osteoradionecrosis as a long-term consequence of prior radiotherapy. ***Conclusion:*** While the diagnosis is predominantly clinical and typically supported by imaging modalities such as CT and MR, and occasionally corroborated by biopsy to rule out malignancy, this case underscores the pivotal role of bone scintigraphy in identifying metabolic bone disease in oncologic patients.

EP-1373

An atypical case of angiosarcoma in a breast cancer patient in [^{18}F]FDG PET-CT imaging

S. Özdemir, *A. Akbulut, M. Daşar, K. Demirel, G. Koca, M. Korkmaz;*
University of Health Sciences, Ankara Training and Research Hospital, Nuclear Medicine Department, Ankara, TÜRKIYE.

Aim/Introduction: Secondary angiosarcomas are exceedingly rare malignancies, typically observed in breast cancer patients who had underwent surgery and radiotherapy. We present a case of 52-year-old female with a history of left breast cancer treated with surgery and adjuvant therapy without radiotherapy. Thirteen years later, she developed secondary angiosarcoma with atypical localization in the left upper extremity. Our case highlights the occurrence of angiosarcoma in the absence of radiotherapy and underscores the importance of considering vascular malignancies in breast cancer survivors, even without common risk factors. ***Materials and Methods:*** A 52-year-old female patient with a history of breast cancer, previously treated with surgery and adjuvant therapy, underwent FDG PET/CT imaging. Although there were no findings suggestive of primary pathology, low-level increased FDG uptake was detected in the subcutaneous tissue of the left upper arm and potentially be confused with radioactive extravasation. Clinical follow-up was recommended. After three months follow up PET/CT revealed increased soft tissue density and elevated FDG uptake in the same left upper arm region and excisional biopsy specimen confirmed angiosarcoma. ***Results:*** ***Conclusion:*** Secondary angiosarcomas are described in the literature as arising within irradiated fields or in association with chronic lymphedema. However, in our case there was no history of radiotherapy to the breast or axillary region. Unlike most reported cases, the patient presented with minimal lymphedema in her left upper extremity without any other associated symptoms. Initial FDG PET/CT imaging demonstrated low-level increased FDG uptake in the left arm, that was initially indistinguishable from radioactive tracer extravasation. Follow up image revealed progressive soft tissue thickening and intensifying FDG avidity, prompting histopathological correlation that confirmed angiosarcoma. This highlights the clinical significance of serial FDG PET/CT in detecting occult vascular malignancies. While postoperative alterations in lymphatic drainage may have contributed to tumorigenesis, the exact pathogenesis remains unclear, and further large-scale studies are warranted to elucidate non-radiation-associated mechanisms of secondary angiosarcoma development.

EP-1374

Extensive abdominal splenosis more than half a century after traumatic splenic rupture: the way from CT to ^{18}F-FDG PET/CT and to precise diagnosis with Tc-99m-labelled heat denatured red blood cell SPECT/CT

S. Georga, *N. Vavlas, A. Morfesi, V. Mpalaris, D. Katsampoukas, E. Moralidis, G. Arsos;*
3rd Department of Nuclear Medicine, Aristotle University Medical School, Papageorgiou General Hospital, Thessaloniki, GREECE.

Aim/Introduction: Splenosis is a benign condition caused by spontaneous heterotopic autotransplantation of splenic tissue within the peritoneal or thoracic cavity, typically after spleen rupture and/or splenectomy. Splenosis is usually accidentally found, but when extensive it may be diagnostically challenging as symptoms can suggest oncological disease. Usually CT and MRI can offer accurate diagnosis of splenosis; in ambiguous cases however, Tc-99m-labelled heat denatured red blood cell (HDRBC) scintigraphy remains the highly specific gold standard for a reliable diagnosis thus avoiding invasive diagnostic procedures. ***Materials and Methods:*** A 64-year-old male with a remote history of traumatic splenic rupture and splenectomy at the age of 10 was referred for abdominal CT because of abdominal complaints. Upper and lower GI endoscopy revealed gastritis and a colon polyp removed was proven not malignant. As CT reported both multiple nodular masses and abdominal lymphadenopathy, the patient was referred for further investigation with ^{18}F-FDG PET/CT 2 months later, showing multiple mildly hypermetabolic nodular masses not consistent with malignancy and the suggested diagnosis of multifocal splenosis was finally confirmed by positive Tc-99m-HDRBC scintigraphy. ***Results:*** The initial contrast-enhanced CT on December 2024 reported bilateral ureteronephrolithiasis, splenectomy and multiple nodular masses in the mesenteric folds, splenic fossa, greater omentum and subhepatic space as well as enlarged left paraureteral, parapancreatic, paraortic and portohepatic lymph nodes concluding a differential diagnosis between splenosis and lymphadenopathy. ^{18}F-FDG PET/CT performed on February 2025 revealed multiple mildly hypermetabolic (SUVmax up to 1.9, a value well within the normal range of splenic metabolism) nodular masses mainly in the left side of the greater omentum and the left paracolic gutter, not compatible with malignancy, but no lymphadenopathy. The diagnosis of multifocal splenosis was thus suggested, subsequently confirmed by Tc-99m-HDRBC SPECT/CT on May 2025, showing multiple foci of avid uptake of radiolabeled denatured red blood cells anatomically corresponding to the findings of both CT and ^{18}F-FDG PET/CT. ***Conclusion:*** This case reminds that massive/multifocal, clinically symptomatic abdominal splenosis may be proven a diagnostic challenge for CT. ^{18}F-FDG PET/CT can indirectly contribute to diagnosis by minimizing the possibility of malignancy. Tc-99m-labelled heat denatured red blood cell scintigraphy especially with SPECT/CT imaging, can settle an accurate, anatomically detailed diagnosis of splenosis relieving the patient from invasive diagnostic procedures.

EP-1375

Multimodal Imaging in Corticobasal Syndrome with Alzheimer's Pathology: A Case Report

M. Sanchez Torrente[1], *A. Sanchez Torrente*[2], *P. Guardia Jimena*[1], *M. Ureña Lara*[1];
[1]*Department of Nuclear Medicine - Hospital Universitario de Jaén, Jaén, SPAIN,* [2]*Department of Radiology - Hospital Universitario Torrecardenas, Almeria, SPAIN.*

Aim/Introduction: Corticobasal syndrome(CBS) is a disorder characterized by asymmetric akinetic-rigid syndrome, higher order sensory deficits, and cognitive impairment.The clinical diagnosis of CBS has been associated with different neuropathologic substrata, including corticobasal degeneration(CBS-CBD), Alzheimer

disease(CBS-AD), and progressive supranuclear palsy(CBS-PSP), with CBD the most frequent pathologic diagnosis, followed by AD and PSP.Clinical features are insufficient to identify the underlying pathologic substrate of CBS with certainty during life. Dopamine transporter imaging SPECT(DAT-SPECT) commonly shows asymmetric striatal affection, influenced by the CBS variant.18F-Fluorodeoxyglucose PET(FDG-PET) has been used to aid in CBS diagnosis, commonly showing an asymmetric frontoparietal pattern of cortical metabolism, also influenced by the CBS variant.If we focus on the CBS-AD variant, it typically shows a more posterior pattern of hypometabolism in FDG-PET compared to other CBS variants, positive amyloid PET scan and normal DAT-SPECT, which only usually becomes pathological in very advanced stages. ***Materials and Methods:*** We present a case of a 61-year-old male patient with suspected atypical parkinsonism, that shows speech apraxia, body rigidity, right arm deafferentation movement with antigravity maneuvers. Gait with slight anteflexion, medium stride with decreased right arm swing and broken turns. At suspicion of CBS, studies of magnetic resonance (MRI), DAT-SPECT, FDG PET and AD-Cerebrospinal Fluid(CSF) biomarkers were requested. ***Results:*** MRI: signs of diffuse subcortical atrophy with hippocampal involvement.DAT-SPECT: minimal hypo-uptake in putamen and left caudate tail, at the limit of normality, without other alterations.FDG PET: asymmetric frontoparietal and posterior temporal hypometabolism, with predominant posterior gradient.AD-CSF biomarkers: Amyloid beta(1-42): 303 pg/mL; Tau-protein: 14 pg/mL; Phosphorylated Tau-protein-181: 153 pg/mL. Compatible Alzheimer's disease. The clinical features, together with the complementary examinations, were suggestive of CBS-AD.Although this is a rare disease, we consider it important to emphasize the importance of understanding the different imaging patterns in the different CBS variants in nuclear medicine studies, which can be essential for an accurate diagnosis. ***Conclusion:*** CBS and its variants are a rare syndrome that can be a diagnostic challenge, where nuclear medicine studies can play a fundamental role along with other complementary explorations. ***References:*** Constantinides, V. C. et al (2022). Dopamine transporter SPECT imaging in corticobasal syndrome: A peak into the underlying pathology? EP-1376

Incidental Detection of Pacemaker Lead Infection with ^{18}F-FDG PET-CT in a Breast Cancer Patient Undergoing Evaluation for Suspected Recurrence

A. Genova*, F. Porcaro, M. Prisco, L. Turchetta, I. Annarumma, V. Piscopo, M. Catalano;*
Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Naples, ITALY.

Aim/Introduction: ^{18}F-FDG PET/CT is widely used in oncologic imaging, but it also plays an emerging role in detecting infections, particularly in complex or atypical clinical scenarios. Device-related infections can be challenging to diagnose due to non-specific symptoms and inconclusive conventional imaging. ***Materials and Methods:*** A 75-year-old woman with a history of breast cancer underwent ^{18}F-FDG PET/CT for suspected tumor recurrence. She had been experiencing persistent fever and elevated inflammatory markers. Her medical history included recent pacemaker implantation. The PET/CT scan showed no signs of oncologic relapse, but revealed in Focal uptake involving the distal end of the pacemaker in contact with the pericardium, at the cardiac apex (SUV max4.45), raising strong suspicion for device-related infection. On Cardiac ultrasound at the level of the intravitary electrode-catheter, an adherent hypoechoic mass is observed on the anterior septal leaflet ot the tricuspid valve, Elevated inflammatory markers and positive blood culture for staphylococcus capitis confirmed the diagnosis and the patient was started on targeted antimicrobial therapy. ***Results:*** This case highlights the utility of ^{18}F-FDG PET/CT beyond oncology, particularly in identifying occult infections associated with implanted devices. Its ability to provide whole-body functional imaging enables detection of unexpected infectious foci, often missed by conventional modalities such as echocardiography or CT. ***Conclusion:*** ^{18}F-FDG PET/CT can play a crucial role in the diagnostic work-up of systemic inflammatory conditions, even when initially performed for oncologic purposes. Early identification of pacemaker-related infections can significantly impact clinical management and outcomes.

EP-1377

Multifocal Osteonecrosis in Pediatric-onset Systemic Lupus Erythematosus

H. Elahifard[1]*, M. Samadi*[1]*, E. Askari*[1]*, F. Taheri*[1]*, M. Vahedi*[2]*;*
[1]*Nuclear Medicine Research Center, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF,*
[2]*Department of Pediatrics, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Pediatric-onset SLE is an autoimmune disease, with osteonecrosis being a recognized complication. Prolonged use of corticosteroids, a common treatment for SLE, promotes osteonecrosis, contradicting the objective of preventing its progression. A 15-year-old girl with a three-year history of systemic lupus erythematosus (SLE), treated with corticosteroids, hydroxychloroquine, and mycophenolate-mofetil, was referred for evaluation of right hip pain and limping over the past two months, without trauma or fever. Physical examination revealed limited hip motion, with no signs of erythema or swelling. ***Materials and Methods:*** A three-phase bone scan was performed using 555 MBq (15 mCi) of ^{99m}Tc-MDP, including whole-body blood pool images at two minutes and delayed imaging at 180 minutes post-injection. SPECT/CT imaging was also performed for better localization and attenuation correction. ***Results:*** The bone scan revealed symmetrically increased blood pool and delayed MDP uptake in the bilateral shoulders, elbows, wrists, femoral heads, distal femora, proximal tibiae, and ankles. The corresponding SPECT/CT images revealed decreased bone density and serpiginous sclerotic changes in both elbows, femoral heads, distal femora, and proximal tibiae, with heterogenous increased activity suggesting multifocal osteonecrosis (MFON). MRI correlation from both knee joints revealed metaphyseal and epiphyseal serpiginous mixed signal intensities in bilateral femora, proximal tibiae, and subchondral areas of the medial and lateral femoral condyles, indicating bone infarction. ***Conclusion:*** MFON is reported as a rare complication in pediatric-onset SLE. The long-term prognosis of MFON relies on early detection and timely intervention, highlighting the vital role of imaging in diagnosing osteonecrosis. MRI is the most sensitive and specific modality. However, its high cost restricts its use to symptomatic regions, limiting the evaluation of asymptomatic areas. Therefore, whole-body bone scanning (WBBS) is a valuable supplementary tool for diagnosing osteonecrosis, especially in cases of suspected multifocal involvement. SPECT/CT imaging provides additional anatomical details, such as geographic sclerotic changes. This case underscores the importance of high index of suspicion for osteonecrosis in SLE patients with persistent joint pain as well as the value of WBBS and SPECT/CT imaging in diagnosing suspected MFON. ***References:*** 1.Hussein S, Suitner M, Béland-Bonenfant S, et al. EP-1378

Rare Presentation of Baker's Cyst in an Infant: A Case Report

H. Elahifard[1], *M. Vahedi*[2], *F. Rabani*[1], *F. Taheri*[1], *V. Dabbagh*[1]; [1]*Nuclear Medicine Research Center, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Pediatrics, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Bbaker's cyst (BC), arises from fluid accumulation in gastrocnemio-semimembranosus bursa, mostly present in adult knees. For developing BC, communication must exist between the knee joint and the gastrocnemius-semimembranous bursae. This communication is almost nonexistent in children but increases with age. Thus, BC has a rare incidence in the pediatric population. A 15-month-old girl presented with right knee pain, swelling, and limping for 15 days, without history of trauma or systemic illness. Physical examination revealed low-grade fever and limited motion in the right knee. Ultrasonography indicated peri-articular inflammation and a 2mm effusion. Septic arthritis was ruled out due to normal CBC, ESR, and CRP. She was referred for arthritis evaluation, and a three-phase bone scan was performed ***Materials and Methods:*** A three-phase bone scan was performed using 296 MBq (8 mCi) of 99mTc-MDP, including perfusion and blood-pool images of both knees, followed by delayed imaging at 180 minutes post-injection. The scan showed normal perfusion but asymmetrically decreased blood pool and delayed MDP uptake in the right knee. ***Results:*** The bone scan suggested joint disuse due to pain. Due to persistent pain, MRI of the right knee was performed. T2-weighted images revealed a focal area of high signal intensity with internal low signal components showing enhancement in the medial head of the gastrocnemius muscle. Additionally, there was edema and enhancement in the adjacent soft tissue, minimal effusion in the knee joint, and evidence of synovial enhancement. These findings indicated a complicated Baker's cyst associated with synovitis and arthritis. Thus, findings of the bone scan might be due to the attenuation effect of the Baker's cyst and/or disuse resulting from pain ***Conclusion:*** Nuclear imaging modalities have limited utility in diagnosing BC but in ruptured cases, the "arch sign", the visible distribution of the radiopharmaceutical in the medial posterior calf, has been reported as pathognomonic sign in a Tc-99m MDP bone scan. Thus, MRI remains the gold standard for the diagnosis of BCs and distinguishing them from other conditions. To our understanding, this is the first reported case of complicated BC in an infant, underscoring the need to consider rare causes of undiagnosed knee pain. ***References:*** 1.Nanduri A, Stead TS, Kupsaw GE, et al. Baker's Cyst. Cureus. 2021;13:e20403 2.Golan H, Fridburg E. Calf "Arch Sign" Seen on a Tc-99m-MDP Bone Scan Is Indicative of Synovial Fluid Leak in Ruptured Baker's Cysts: Case Reports and Analysis of Literature. Secondary Syphilis with Skull Bone Lesions: A Rare Clinical Manifestation

I. Sevaslidou[1], *S. Episkopopoulou*[1], *A. Velidaki*[1], *A. Anastasopoulou*[2], *A. Perissi*[2], *E. Dagrakis*[1], *T. Kostou*[1], *A. Kolindou*[1]; [1]*Nuclear Medicine Department , Genaral Hospital of Athens " LAIKO", Athens, GREECE,* [2]*First Department of Internal Medicine, "LAIKON" Hospital, Athens, GREECE.*

Aim/Introduction: Syphilis is a chronic systemic infection caused by the spirochete Treponema pallidum. Transmission occurs primarily through direct sexual contact, though vertical transmission from mother to fetus is also possible. Despite being a treatable condition, especially with early antibiotic intervention (primarily penicillin),delayed diagnosis can lead to irreversible damage affecting multiple organ systems. While syphilis is classically known for its dermatologic, mucosal, and systemic features, skeletal involvement remains a rare clinical finding, particularly during the secondary stage. ***Materials and Methods:*** We present the case of a 29-year-old male patient who was admitted to the hospital with low-grade fever, headache, a maculopapular rash, and localized swelling in the frontal area of the skull, with a duration of 24 hours. Clinical examination, laboratory testing, and positive serology confirmed a diagnosis of secondary syphilis.Given the atypical presentation, a cranial CT scan was performed, which showed soft tissue and muscle swelling in the right frontal region without any intracranial abnormalities. Bone scintigraphy was then conducted, revealing multiple areas of increased osteoblastic activity involving the frontal and parietal bones of the skull and the mandible. Additionally, photopenic regions were identified in the right frontal bone and left frontoparietal region, consistent with osteolytic lesions.The patient was promptly started on appropriate antibiotic therapy based on current treatment guidelines. Symptoms began to resolve following the first dose. However, despite medical advice, the patient did not return for follow-up after completing the full three-dose regimen. ***Results:*** This case illustrates a rare but significant complication of syphilis involving the skeletal system during the secondary stage. Early recognition of such atypical manifestations requires a high index of suspicion and the use of advanced imaging modalities. In this case, bone scintigraphy proved crucial in identifying the extent of bone involvement. ***Conclusion:*** Skeletal syphilis is uncommon, this case highlights the importance of comprehensive diagnostic work-up in patients with unusual symptoms—even in the early stages of disease. Clinicians should remain alert to rare manifestations of systemic infections, as timely diagnosis can significantly influence outcomes.

EP-1380

Diffuse FAPI-46 Uptake in Bone Marrow: A Case of Primary Myelofibrosis with Superscan Pattern on Bone Scintigraphy

H. Elahifard[1], *N. Raeisi*[1], *A. Saber Tanha*[1], *N. Ataei*[2], *E. Askari*[1]; [1]*Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of pathology, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: PMF is a myeloproliferative neoplasm characterized by clonal myeloproliferation originating from stem cells. ^{18}F-FDG has emerged as a promising modality for quantifying bone marrow inflammation in myelofibrosis, exhibiting an inverse correlation between ^{18}F-FDG uptake intensity and severity of fibrosis. Myelofibrosis should be considered as a differential diagnosis for diffuse skeletal metastases on ^{99m}Tc-MDP scan. ^{99m}Tc-MDP uptake increases with the progression of myelofibrosis, potentially leading to the development of a superscan pattern. A recent study utilizing ^{68}Ga-FAPI has demonstrated the efficacy of this modality in visualizing and quantifying myelofibrosis, establishing a direct correlation with disease progression and its potential value for prognostication. A 65-year-old woman with history of generalized bone pain underwent an initial evaluation 6 years ago that included a BMA, revealing bone marrow fibrosis. She recently experienced malaise, weight loss, night sweats, and worsening of her bone pain, which prompted her referral for further evaluation. Laboratory data indicated anemia, leukocytosis, elevated LDH and ESR levels. A thoracic and abdominopelvic CT scan revealed splenomegaly and diffuse lytic/sclerotic changes in the skeleton. ***Materials and Methods:*** The whole-body ^{99m}Tc-MDP scan with SPECT/CT imaging was performed.A ^{99m}Tc-FAPI-46 scan was employed to assist in differentiating the probable etiologies. ***Results:*** The whole-body ^{99m}Tc-MDP scan demonstrated markedly increased diffuse skeletal uptake, even in the distal of extremities, consistent with a superscan pattern commonly described as a "beautiful bone scan." This finding raises differential diagnoses that

encompass hematologic, metabolic, and metastatic etiologies. The FAPI whole body and SPECT/CT images revealed diffuse homogeneous skeletal uptake, along with three focal areas of uptake in the enlarged spleen (later attributed to local fibrosis probably due to accelerated extramedullary hematopoiesis). Considering both MDP and FAPI scan patterns together, the findings highlighted hematologic disorders which most probable one was myelofibrosis. Finally according to BMB, morphological features in conjunction with clinical and laboratory findings were compatible with primary myelofibrosis (PMF). ***Conclusion:*** FAPI can be beneficial in ruling out other causes of myelofibrosis. Our pioneering experience with ^{99m}Tc-FAPI-46 appears to be comparable to recently reported study with ^{68}Ga-FAPI, as both FAPI and MDP exhibit intense uptake indicative of advanced stages of the disease ***References:*** 1)Li X, Zhao Q, Luo Q, et al. The Manifestation of a Patient With Myelofibrosis in 68Ga-DOTA-FAPI-04 PET/CT Mimicking "Super Bone Imaging." Clin Nucl Med. 2022;47:1056-10582) 2)Liu Y, Li X, Jing L, et al. EP-1381

Splenic Hemangioma as a Pitfall in 18F-PSMA PET-CT Imaging for Prostate Cancer: A Case Report

M. Sanchez Torrente*, S. Martin Aguilar, L. Mena Bares, E. Moratalla Aranda, M. Ureña Lara;*
Department of Nuclear Medicine - Hospital Universitario de Jaén, Jaén, SPAIN.

Aim/Introduction: Prostate cancer is the most common cancer in men, detected through elevated prostate-specific antigen(PSA) levels and confirmed by imaging and biopsy. The staging and management of prostate cancer have been significantly improved by advanced imaging techniques such as magnetic resonance imaging (MRI) and prostate-specific membrane antigen (PSMA) positron emission tomography (PET) computed tomography (CT). 18F-PSMA-PET-CT offers high sensitivity and specificity for detecting both primary and metastatic disease, as its clinical use increases, new possible pitfalls emerge, which, although rare, we should be aware of. ***Materials and Methods:*** A 71-year-old male patient was diagnosed with Gleason score 7 (3+4) cT1c prostate adenocarcinoma, with a PSA of 5.75 ng/mL at diagnosis and no evidence of extraprostatic extension. A robotic radical prostatectomy was performed, achieving a nadir PSA of 0.05 ng/mL. Subsequently, PSA levels were monitored and showed a slow but progressive increase, reaching 0.28 ng/mL, at which point an 18F-PSMA PET/CT scan was requested. ***Results:*** 18F-PSMA-PET-CT scan showed a suspicious millimetric left obturator lymphadenopathy and a focus of high-intensity splenic PSMA uptake (SUVmax:18) that showed decreased intensity on the delayed image 2 hours post-injection (SUVmax:14). To rule out malignancy, a splenic MRI was recommended.Splenic MRI showed a pattern characteristic of splenic hemangioma. Splenic hemangioma represents the most common benign tumor of the spleen and is usually found incidentally in the age group 30 to 50 years. They are composed of nonencapsulated channels of vessels separated by septa or pulp tissue and have a single endothelial layer filled with blood.Splenic hemangioma is the main cause of a single focus of PSMA uptake in the spleen, with some cases reported in the literature. ***Conclusion:*** Splenic hemangioma is the main cause of a single focus of PSMA uptake in the spleen, with some cases reported in the literature. However, although prostate cancer metastases to the spleen are very rare, this possibility should be ruled out.Furthermore, it would be interesting to analyze the kinetic behavior of splenic hemangioma in standard imaging/delayed imaging in a larger number of cases. ***References:*** Jia, G., Dong, A., Cheng, C., & Zuo, C. (2024). Intense 18F-PSMA-1007 Uptake of Splenic Hemangioma. Clinical Nuclear Medicine, 49(2), E90-E92. https://doi.org/10.1097/RLU.0000000000004995Chaussé, G., Laufer, J., Abikhzer, G., & Probst, S. EP-1382

Occipital Bone Lesion Mimicking Malignancy: The Importance of Multimodal Imaging

J. Mendes*, L. Torres, P. Soeiro;*
Hospital de São João, Porto, PORTUGAL.

Aim/Introduction: Occipital bone lesions are rare and frequently detected incidentally. While most are benign—such as osteomas, fibrous dysplasia, hemangiomas, or post-traumatic changes—it is vital to exclude malignancy, particularly when neurological symptoms are present. This case underscores the pivotal role of integrated multimodal imaging in distinguishing a benign lesion from malignancy. ***Materials and Methods:*** A 47-year-old woman with 5-year history of unexplained axonal neuropathy, thyroid nodules, prior L5-S1 spinal fusion, migraines, and transient visual disturbances underwent [18F]FDG PET-CT to investigate a suspected occult malignancy. A brain MRI was concurrently performed due to ongoing neurological complaints. Additional imaging was conducted to further characterise an unexpected solitary occipital bone lesion. ***Results:*** [18F]FDG PET-CT: Identified a focal area of intense FDG uptake (SUVmax 11.62) in the left occipital bone, corresponding to a lytic-appearing lesion on low-dose CT. Differential diagnoses included solitary bone metastasis, plasmacytoma, or—less likely—infectious or inflammatory processes. However, the solitary and stable appearance was atypical for metastatic disease. Non-contrast Brain MRI: Showed non-specific subcortical white matter changes without a corresponding focal lesion. These findings were possibly related to a chronic demyelinating process. Contrast-enhanced MRI with Perfusion: Revealed a vascularised, heterogeneously enhancing lesion (1.9 × 3.2 × 3.1 cm) in the left occipital bone, with cortical thinning and medullary expansion. Absence of restricted diffusion and no intracranial extension favoured a benign entity such as fibrous dysplasia or intraosseous hemangioma. Bone Scintigraphy [99m Tc]Tc-HDP): Demonstrated isolated increased uptake in the left occipital bone, corresponding to the PET-CT findings. Given that hemangiomas typically show low tracer uptake, the imaging pattern supported the diagnosis of fibrous dysplasia. CT Review: Closer inspection of the PET/CT low-dose CT revealed a well-circumscribed expansile lesion with a heterogeneous "ground-glass" matrix, cortical thinning, and preservation of the inner table—hallmark features of fibrous dysplasia. ***Conclusion:*** This case exemplifies the diagnostic value of multimodal imaging. Despite alarming metabolic activity and apparent bone lysis, the integration of findings from PET/CT, MRI, and bone scintigraphy enabled a confident diagnosis of monostotic fibrous dysplasia. Nuclear medicine physicians should remain alert to benign bone lesions in unusual locations that may mimic malignancy both morphologically and metabolically. A comprehensive imaging approach is critical to avoid misdiagnosis and inappropriate treatment.

EP-1383

99mTc-HMPAO Brain SPECT in Intracranial Carotid Artery Occlusion: Functional Imaging to Support ClinicalDecision-Making

A. Genova*, F. Porcaro, M. Prisco, L. Turchetta, I. Annarumma, V. Piscopo, M. Catalano;*
Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Naples, ITALY.

Aim/Introduction: Brain perfusion SPECT is a valuable diagnostic tool for assessing cerebrovascular disorders, especially when

conventional structural imaging is insufficient to evaluate the functional impact of vascular compromise. By providing three-dimensional functional information about cerebral blood flow and metabolism, SPECT imaging often reveals perfusion abnormalities that precede visible structural damage on CT or MRI. This makes it particularly useful in identifying regions of the brain at risk and in guiding clinical decision-making. Unlike structural imaging, which captures anatomical changes that may occur later in disease progression, SPECT can detect early functional deficits, offering a more dynamic view of brain physiology. As such, it plays a complementary role and, in certain clinical contexts, can offer unique information that influences patient management and therapeutic planning. ***Materials and Methods:*** A 60-year-old male presented to the Emergency Department with right-sided facial weakness, visual disturbances, and reported motor deficits in the left upper limb in the preceding days. Neurological assessment and imaging revealed an occlusion of the right intracranial internal carotid artery, specifically before the anterior bend of the clinoid segment, with partial compensation via the circle of Willis. CT angiography showed hypodense ischemic areas in the right frontal subcortical region. Brain MRI confirmed multiple subacute ischemic lesions. To assess the extent of cerebral hypoperfusion, a 99mTc-HMPAO SPECT scan was performed. The images demonstrated significant tracer uptake reduction in the left cerebral hemisphere, corresponding to the vascular territory affected by the carotid occlusion. Accurate interpretation of these findings relied on integrating the clinical picture with structural imaging. ***Results:*** While CT and MRI confirmed vascular occlusion and ischemic injury, SPECT provided essential insight into the functional status of the brain tissue, highlighting areas of hemodynamic impairment. This functional perspective is crucial in evaluating cerebral reserve and may influence therapeutic decisions such as revascularization strategies or medical management. In this case, SPECT findings played an important role in guiding a multidisciplinary approach. ***Conclusion:*** Brain perfusion imaging with 99mTc-HMPAO SPECT remains a powerful and relevant tool in the evaluation of acute cerebrovascular events. By offering complementary functional data to anatomical imaging, it enhances clinical understanding and supports more informed treatment planning, particularly when assessing the viability and functional reserve of affected brain regions.

EP-1384

Rediscovering the Forgotten: ^{18}F-FDG PET/CT Detection of Metabolically Active Echinococcal Cyst in the Pubic Bone with a History of Ovarian Echinococcosis- A Case Report

S. Chausheva[1,2], *T. Stoeva*[1], *M. Dyankova*[1], *T. Yordanova*[1], *Z. Dancheva*[1], *A. Klisarova*[1], *B. Chaushev*[1];
[1]*University Hospital St Marina Varna, Varna, BULGARIA,* [2]*Medical University Varna, Varna, BULGARIA.*

Aim/Introduction: Bone echinococcosis is a rare manifestation of Echinococcus granulosus infection, approximately 0.5-4% of all echinococcosis cases. The pubic bone is an unusual site of involvement that may mimic primary tumors, metastatic lesions or infectious bone lesions. The diagnosis is often challenging due to nonspecific symptoms and insidious clinical presentation. ***Materials and Methods:*** We report the case of a 45 years old female with a complex medical history. The patient presented at the hospital with pelvic pain and limited mobility in the hip for several months.A history of hydatid disease, including surgical management of a left ovarian echinococcal cyst (2008) and subsequent resection of a left pubic bone cyst (2009) with bone graft reconstruction. Despite postoperative albendazole therapy, the patient did not receive long-term parasitological surveillance. In 2011, she underwent total alloplasty of the left hip for histopathologically confirmed echinococcal granulomatous synovitis. In 2024, the patient presented with chronic pelvic pain. X-ray examination of the pelvis revealed an osteolytic lesion in the left pubic bone with peripheral sclerotic margins in the left iliac bone and acetabulum. ***Results:*** To evaluate lesion viability and assess for potential systemic dissemination, ^{18}F-FDG PET/CT was performed. The scan revealed increased uptake in the peripheral rim of the thoracic vertebra mass with central parts showing lower uptake than the peripheral rim, without evidence of distant metabolically active lesions. Serological testing was positive for E. granulosus antibodies. ***Conclusion:*** This case underscores the recurrent and disseminated nature of osseous hydatid disease and highlights the utility of FDG PET/CT in detecting active parasitic lesions, differentiating them from malignancy, and guiding clinical management in atypical locations. Skeletal echinococcosis remains a diagnostic challenge, particularly in post-surgical patients with prior parasitic disease. ^{18}F-FDG PET/CT serves as a valuable adjunct in assessing lesion activity, ruling out systemic involvement.

EP-1385

Detection of Recurrent ACTH-Secreting Pituitary Adenoma Using ^{99m}Tc-EDDA/HYNIC-TOC- A Case Report and Literature Review

A. Bajenaru[1], *A. Baican*[1,2], *R. Mititelu*[3,4];
[1]*Clinical Hospital "Prof. Dr. Theodor Burghele", Bucharest, ROMANIA,* [2]*Faculty of Physics, University of Bucharest, Magurele, ROMANIA,* [3]*Central Emergency Military University Hospital "Dr. Carol Davila", Bucharest, ROMANIA,* [4]*University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Adrenocorticotropic hormone (ACTH) secreting pituitary adenomas are the most common cause of endogenous hypercortisolism, causing complex clinical manifestations and requiring a careful diagnostic and therapeutic approach [1]. In terms of nuclear medicine imaging, somatostatin receptors play a crucial role by having an increased expression in these tumors, facilitating the detection and characterization of the lesions. The main radionuclide tracer used in neuroendocrine imaging, 111In-pentetreotide, was replaced by PET tracers, 68Ga-DOTATOC, 68Ga-DOTANOC and 68Ga-DOTATATE, due to clinical advantages. Recently, 99mTc-labelled peptides have emerged as an option in scintigraphic imaging of neuroendocrine tumors (NET), demonstrating advantages over 111In-pentetreotide by providing better imaging quality on gamma cameras while keeping a lower radiation exposure for patients. ***Materials and Methods:*** We presented the case of a a 54 years-old woman who has a medical history of HBV infection, obesity, hypertension, stroke and hypercholesterolemia. She was diagnosed with Cushing's disease following an endocrinological checkup. The presence of a pituitary adenoma was confirmed by an MRI examination, which led to transsphenoidal neurosurgery. The lesion was histopathologically confirmed to be an ACTH-secreting pituitary adenoma. 4 months post-surgery, a spike in ACTH serum value prompted another MRI examination which revealed the presence of a remnant pituitary tumor extended to the cavernous sinus and retrosellar to the right side. We performed a somatostatin receptor SPECT-CT using 99mTc-EDDA/HYNIC-TOC. ***Results:*** SPECT-CT showed residual activity in the sella and diffuse uptake in the adrenal glands due to prolonged exposure to high levels of ACTH secretion. Pituitary MRI is the imaging method of choice for evaluating sellar and parasellar tumors. However, a range of scintigraphic investigations can be performed for a better assessment of the pituitary tumors. Given the unavailability of 68Ga-DOTA peptides in our country, we selected 99mTc-EDDA/HYNIC-TOC as the radiotracer of choice due to its good sensitivity in detecting pituitary tumors. We confirmed tracer uptake in the patient's residual adenoma, demonstrating SSTR expression and found no abnormal uptake elsewhere, effectively ruling out ectopic ACTH secretion. ***Conclusion:*** 99mTc-

EDDA/HYNIC-TOC can aid in the evaluation of well-differentiated pituitary adenoma by assessing the uptake in the sellar region and excluding ectopic lesions. Since literature is scarce on the subject, we consider prospective multicentric studies necessary in order to better define the role of metabolic imaging in patients with pituitary adenomas. ***References:*** 1. Nowak, E., et al., Diagnostic challenges in cyclic Cushing's syndrome: a systematic review. Lancet Diabetes Endocrinol, 2023. 11(8): p. 593-606.

EP-1386

Isolated Cutaneous Metastatic Breast Cancer Detected by FDG PET/CT

M. Kartal[1], *V. Dere*[2], *B. Okudan Tekin*[2];
[1]*Elazığ Fethi Sekin City Hospital, Elazığ, TÜRKIYE,* [2]*Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: In breast cancer, the most common metastatic patterns typically involve lymph nodes, lungs, liver, and bones. Cutaneous metastases are rare among malignancies overall, but when they do occur, breast cancer is the most frequent primary source. In breast cancer, cutaneous metastases usually present as local recurrences at the site of surgery. They have been reported most frequently on the chest, abdomen, and head and neck regions, and less commonly on the extremities and other areas. These lesions are often palpable as painless nodules and are fluorodeoxyglucose (FDG)-avid, making them detectable via FDG positron emission tomography/computed tomography (PET/CT). In this case presentation, we aim to report a patient with a history of breast cancer who underwent re-staging, during which widespread isolated cutaneous metastatic lesions were detected on FDG PET/CT imaging. ***Materials and Methods:*** A 68-year-old female patient was diagnosed with invasive ductal carcinoma of the left breast ten years ago and underwent a left modified radical mastectomy. She was staged as T1N3M0 and received chemoradiotherapy (CRT). Two years after CRT, a right radical mastectomy was performed due to the detection of metastatic lymph nodes in the right axilla. During follow-up, cutaneous metastases were identified in the left breast region, and the patient continued to receive CRT. Medical records from that period indicated a favorable treatment response. Eight years after the initial diagnosis, the patient underwent FDG PET/CT imaging at our center for restaging purposes. ***Results:*** Imaging revealed no pathological metabolic activity in visceral organs or lymph nodes. However, multiple foci of increased FDG uptake were observed, corresponding to widespread, isolated cutaneous metastases. Intense FDG-avid nodular lesions, the largest measuring approximately 12 mm in diameter, were identified in the skin and subcutaneous tissue of the thorax (Figure 1A, B; orange arrows), abdomen (Figure 1C), and lower extremities (Figure 1D, E; orange arrows), with a maximum standardized uptake value of 7.24. A biopsy obtained from a nodular skin lesion located adjacent to the right trapezius muscle confirmed metastasis, and the patient was diagnosed with isolated cutaneous metastatic breast cancer, for which treatment was subsequently planned. ***Conclusion:*** In breast cancer and other malignancies with cutaneous metastases, the extent and localization of lesions can be effectively evaluated using FDG PET/CT due to the high FDG avidity of these lesions. This finding highlights the value of FDG PET/CT as a key imaging modality, particularly in the assessment of patients with asymptomatic cutaneous involvement.

EP-1387

A Hot Signal, a Cold Trail: False-Positive 99mTc-Ethambutol Uptake in Bilateral Psoas Abscess Mimicking Tuberculosis

A. Roy*, N. A. Damle, A. Mahalik, N. Kundu;*
AIIMS New Delhi, New Delhi, INDIA.

Aim/Introduction: To describe a false-positive case of 99mTc-Ethambutol scintigraphy due to non-specific tracer uptake in psoas abscesses, highlighting the importance of cautious interpretation in atypical extrapulmonary tuberculosis (EPTB) cases. ***Materials and Methods:*** A 23-year-old male presented with chronic lower abdominal discomfort and back pain. Contrast-enhanced CT revealed bilateral psoas abscesses. Clinicians suspected disseminated TB, and 99mTc-EMB scintigraphy was performed for evaluation. 10 mCi of 99mTc-EMB was administered intravenously. Planar imaging and SPECT/CT were done at 1 hour post-injection. Radiopharmaceutical preparation met labelling efficiency of >90%. ***Results:*** SPECT/CT showed increased radiotracer uptake in the periphery of both psoas abscesses. Based on this finding, the scan was interpreted as positive. ATT was initiated. However, multiple image-guided fluid aspirations from both psoas collections failed to demonstrate acid-fast bacilli on smear, culture, and GeneXpert. Moreover, the patient did not improve clinically or radiologically despite 12 months of ATT. This led to a re-evaluation of the case. The final impression was false-positive uptake, potentially due to: 1. Hypervascularization in the abscess walls mimicking active infection, 2. Non-specific uptake of radiopharmaceutical, 3. Possible radiochemical impurity (e.g., free pertechnetate) ***Conclusion:*** This case underscores that while 99mTc-EMB scintigraphy is a valuable functional tool for TB imaging, false-positive results can occur in non-TB infections or in sterile inflammation. Interpretation must be correlated with microbiological confirmation, especially in soft tissue or atypical lesions. Caution is advised before initiating long-term ATT based solely on scintigraphic uptake.

EP-1388

Metastasis or Silicosis? The Role of PET/CT in Thoracic Evaluation of Colorectal Cancer

E. Moratalla-Aranda*, L. Mena Bares, S. Martin Aguilar, M. Sanchez Torrente, M. Ureña Lara;*
Hospital Universitario de Jaen, Jaen, SPAIN.

Aim/Introduction: We present the case of a 53-year-old male, a worker in the marble industry, diagnosed with adenocarcinoma of the upper rectum (stage cT4aN2M0). During thoracoabdominal CT staging, atypical findings in the thorax were identified: miliary pulmonary pattern, bilateral hilar-mediastinal lymphadenopathy, and irregular pleural thickening. This prompted a broad differential diagnosis, including pulmonary metastases, granulomatous diseases (such as silicosis or sarcoidosis), infectious processes, and lymphoproliferative disorders. The aim of this study was to characterize the metabolic behavior of these lesions using PET/CT with 18F-FDG, to guide the differential diagnosis and establish an appropriate therapeutic strategy. ***Materials and Methods:*** A PET/CT study with ^{18}F-FDG was performed for oncological restaging and metabolic evaluation of the thoracic abnormalities detected. FDG uptake patterns in pulmonary, pleural, and lymph node lesions were analyzed, integrating these findings with the patient's clinical, occupational, and epidemiological history. Regions with the highest metabolic activity were selected for histological sampling through EBUS-guided fine needle aspiration (FNA). ***Results:*** The PET/CT study revealed intense uptake in the rectal mass (SUVmax: 18.5) and locoregional pelvic adenopathies (SUVmax: 9), consistent with the known neoplasm and locoregional spread. In the thoracic compartment, multiple mediastinal and hilar adenopathies with moderate to high uptake (SUVmax: 3.7-14.3) were identified, along with hypermetabolic pleural thickening (SUVmax: 6.5) and millimetric pulmonary nodules with minimal uptake (SUVmax: 1.4). The bilateral and symmetrical distribution, primarily in the upper lobes, along with the intensity and morphology of uptake, suggested a chronic granulomatous disease, specifically silicosis, related to the patient's prolonged occupational exposure to silica dust. EBUS-guided FNA

was performed in lymph node stations 4R, 10R, and 7, confirming the presence of fibrous material consistent with silicotic nodules. In the absence of metastatic spread, the patient was considered a candidate for surgery with curative intent and underwent anterior rectal resection. ***Conclusion:*** PET/CT with ^{18}F-FDG proved to be a pivotal tool in differentiating between metastatic disease and thoracic granulomatous pathology in an oncological context. Its ability to integrate morphological and functional data allowed for precise biopsy target selection, confirmation of silicosis, and avoidance of overstaging that would have contraindicated a potentially curative treatment.

EP-1389

Misleading 68Ga-PSMA Uptake in Bone Metastases of Esophageal Adenocarcinoma in a Patient with Synchronous Prostate Cancer

L. Milišic Kelava*, M. Pešorda, D. Huić;*
University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) ligands labeled with Ga-68 are widely used for staging and restaging prostate cancer. However, it is well established that Ga-68 PSMA uptake can also occur in the neovasculature of non-prostatic malignancies. We present a case of a 74-year-old male with two histologically confirmed primary malignancies: esophageal carcinoma and prostate adenocarcinoma, in whom Ga-68 PSMA PET/CT demonstrated extensive skeletal metastases. This case highlights the necessity for histopathological confirmation when imaging findings may not correlate with clinical history. ***Materials and Methods:*** The patient was initially diagnosed with esophageal squamous cell carcinoma after endoscopy and biopsy due to dysphagia. Shortly thereafter, elevated PSA prompted urological evaluation and biopsy, which confirmed acinar adenocarcinoma of the prostate. In the staging workup for prostate cancer, a Ga-68 PSMA PET/CT scan was performed. This showed intense PSMA-avid uptake in multiple bone lesions throughout the axial and appendicular skeleton, suggestive of widespread skeletal metastases.Given the known expression of PSMA in the neovasculature of non-prostatic tumors, and the patient's history of esophageal carcinoma, the true origin of the bone metastases was questioned. A CT-guided biopsy of a PSMA-avid iliac bone lesion was performed. ***Results:*** Histological analysis of the bone biopsy revealed squamous cell carcinoma cells consistent with metastasis of the esophageal primary tumor, rather than prostate adenocarcinoma. Immunohistochemistry supported the diagnosis, showing negativity for prostate markers (PSA, PSAP) and positivity for cytokeratin 5/6 and p63, characteristic of squamous differentiation. ***Conclusion:*** This case underscores the importance of critical interpretation of Ga-68 PSMA PET/CT findings in patients with multiple primary malignancies. While Ga-68 PSMA imaging is highly sensitive for prostate cancer metastases, non-prostatic tumors with active neovascularization may show significant tracer uptake. Therefore, in patients with multiple primary malignancies, especially those known to express PSMA in tumor neovasculature, biopsy remains the gold standard for confirming metastatic origin. Multidisciplinary assessment and histological verification are essential to avoid misdiagnosis and inappropriate treatment allocation.

EP-1390

When One Cancer Reveals Another: The Role of ^{18}F-FDG PET/CT in Detecting Synchronous Tumors.

R. Mehri*, M. Nouira, Z. Missaoui, R. Ghannem, A. Mazhoud, R. Sfar, K. Chatti;*
Sahloul Hospital, Sousse, TUNISIA.

Aim/Introduction: Synchronous tumors are distinct primary malignancies occurring simultaneously. PET-FDG, widely used for tumor staging, can incidentally detect these additional cancers, often missed in routine evaluations. We report two cases where PET-FDG, performed for primary tumor assessment, unexpectedly identified synchronous malignancies. ***Materials and Methods:*** Intravenous administration of 3 MBq/Kg of ^{18}F-fluorodeoxyglucose (FDG) was performed. A PET/CT scan from the skull vertex to mid-thigh was acquired after 60 minutes of strict rest, using a Siemens Biograph 64 PET/CT system. ***Results:*** We report two cases where PET-FDG was utilized for the staging of pulmonary and laryngeal tumors:*Case 1: A 58-year-old male with a diagnosis of pulmonary squamous cell carcinoma, where PET-FDG revealed an unexpected rectal malignancy during the staging process.*Case 2: A 61-year-old male with a diagnosis of laryngeal cancer, in whom PET-FDG identified an incidental lung lesion suggestive of a second primary lung cancer. Both patients underwent comprehensive evaluation, including biopsy and histopathological confirmation of the synchronous tumors. ***Conclusion:*** The occurrence of multiple primary malignancies in cancer patients is reported in 2.4% to 8% of cases. The risk of developing a second primary cancer varies depending on the site of the initial tumor (21% in patients with lung cancer). Individuals diagnosed with early-stage lung cancer are at a significantly higher risk for second primaries compared to those in the general population with no prior cancer history. The underlying causes can be attributed to a combination of host-related factors, lifestyle choices, and environmental exposures. Certain populations such as male patients, those with a history of smoking or alcohol use, and individuals with hereditary cancer syndromes are particularly vulnerable. Managing patients with synchronous primary tumors is complex and often presents a real therapeutic challenge. ***References:*** - Weir HK, Johnson CJ, Thompson TD. The effect of multiple primary rules on population-based cancer survival. Cancer Causes Control. 2013 Jun;24(6):1231-42. - Vogt A, Schmid S, Heinimann K, Frick H, Herrmann C, Cerny T, Omlin A. EP-1391

Silent Persistence in the Shadow of Time: Late Renal Metastasis of Differentiated Thyroid Cancer

M. Zambrana-Delgadillo*, M. Piñero Fernandez- Reyes, J. Rodríguez-Rubio Corona, M. Pajares-Vinardell;*
Hospital Universitario Puerta del Mar, Cadiz, SPAIN.

Aim/Introduction: Differentiated thyroid cancer (DTC) develops distant metastases in 4-10% of cases, typically involving lymph nodes, lungs, and bones. Renal metastases are exceedingly rare, with only 25 cases reported in the literature. Their low incidence and the renal excretion of radiotracers make their detection challenging. ***Materials and Methods:*** We present the case of an 82-year-old woman with a history of total thyroidectomy in 1986 at age 43 for multinodular goiter. Histology revealed bilateral follicular thyroid carcinoma, and she underwent ablation with 100 mCi of I-131. In 2017, rising serum thyroglobulin (Tg) levels prompted imaging workup, including CT scans that showed pulmonary nodules. A second treatment with 150 mCi of I-131 was administered, with post-therapy whole-body scintigraphy confirming uptake in the nodules and Tg levels of 103 ng/mL. Despite annual negative whole-body scans and persistently incomplete biochemical response (Tg 391 ng/mL), multiple fluorodeoxyglucose PET/CT scans revealed only faint uptake in stable lung lesions. Tg continued to rise, exceeding 600 ng/mL over the following years. In 2023, an abdominal CT scan identified a 40 mm right renal mass not seen on prior PET/CT. Surgical pathology after radical nephrectomy confirmed it was a metastasis from DTC, measuring 5 cm. Following surgery, Tg levels dropped markedly to 71 ng/mL. Currently, the patient maintains

an excellent quality of life and is under active surveillance for low-volume metastatic disease, characterized by subcentimeter pulmonary nodules (<2 cm), annual growth <20%, and a completely asymptomatic clinical course. ***Results:*** DiscussionThis case highlights the extremely delayed presentation of renal metastasis from follicular thyroid carcinoma, more than 35 years after initial treatment. It underscores the essential role of serial Tg monitoring and the limitations of PET/CT in detecting low-grade or atypically located metastases. Surgical management in selected cases of oligometastatic disease may significantly reduce tumor burden and biochemical activity. ***Conclusion:*** Renal metastasis of DTC, although rare and often silent, may appear decades after the primary diagnosis. Persistent Tg elevation, even in the absence of conclusive imaging findings, warrants thorough investigation. Long-term follow-up and individualized management strategies are crucial to optimize outcomes in patients with indolent metastatic thyroid cancer. ***References:*** Madani A, Jozaghi Y, Tabah R, How J, Mitmaker E. Did the Pandemic Cast a Long Shadow on Lung-Cancer Survival? A 918-Patient [^{18}F]FDG PET/CT Cohort

D. Nak[1], *O. Bülbül*[1], *B. Demir*[2], *S. Göksel*[3];
[1]*Recep Tayyip Erdoğan University Training and Research Hospital, Rize, TÜRKIYE,* [2]*Mehmet Akif İnan Research and Training Hospital, Şanlıurfa, TÜRKIYE,* [3]*Adnan Menderes University Faculty of Medicine, Aydın, TÜRKIYE.*

Aim/Introduction: The COVID-19 pandemic has disrupted cancer care worldwide; however, its tangible impact on lung cancer outcomes remains controversial. This study aimed to evaluate the impact of time of diagnosis-pre-pandemic, pandemic-era, or post-pandemic-on baseline stage, overall survival (OS), and progression-free survival (PFS) in patients undergoing baseline [^{18}F]FDG PET/CT imaging. ***Materials and Methods:*** 918 consecutive lung cancer patients staged with [^{18}F]FDG PET/CT between January 2018 and January 2024 were retrospectively analysed. Diagnostic periods were classified as pre-pandemic (January 2018-February 2020), pandemic period (March 2020-May 2022) and post-pandemic (June 2022-January 2024). OS was calculated for the entire cohort and PFS for 555 patients with regular follow-up records. Survival curves were compared using the log-rank test; potential confounding effects were adjusted for with a multivariable Cox regression model including histology and stage. ***Results:*** Median OS was 13.1 months (mean 26.4) with 690 deaths. Small-cell histology and higher stage significantly shortened survival ($p < 0.001$). OS fell to 11.2 months for intra-COVID diagnoses versus 14.7 months pre-COVID ($p = 0.027$) and rebounded to 15.5 months post-COVID ($p = 0.730$ vs pre-COVID). The drop was sharper in stage IIIB-IV disease (10.4 vs 7.4 months; $p = 0.005$), with post-COVID OS at 8.8 months. Median PFS was 20 months; epochs differed overall ($p = 0.449$), but advanced-stage PFS declined from 7.7 months pre-COVID to 6.2 months post-COVID ($p = 0.029$). Stage distribution at diagnosis was unchanged across periods (all $p > 0.09$). Multivariable analysis showed intra-COVID diagnosis independently raised death risk by 20 % (HR 1.20) and progression risk by 26 % (HR 1.26); both normalised post-COVID. Stage III (HR 2.75) and IV (HR 6.77) remained the strongest adverse predictors. ***Conclusion:*** The pandemic did not lead to more advanced presentation of patients with lung cancer, but it did shorten survival, especially in advanced patients. Outcomes also recovered when health services returned to normal. These findings suggest that uninterrupted access to treatment rather than early diagnosis is critical to preserve lung cancer prognosis in similar global crises. ***References:*** Agulnik, J., Kasymjanova, G., Pepe, C.,et al. (2024). Real-world evidence of the impact of the COVID-19 pandemic on lung cancer survival: Canadian perspective. Current Oncology, 31(3), 1562-1571.Mangone, L., Marinelli, F., Bisceglia, I., et al. Implementation of a Relative Value Unit-Based System in a Nuclear Medicine Department

M. Meneses Navas[1], *S. Guzmán Ortiz*[1], *M. Granados Alcobendas*[2], *M. Amo-Salas*[3], *L. García Zoghby*[1], *I. García Megías*[1], *J. Bonilla Plaza*[1], *M. Cruz Montijano*[1], *J. Montalvá Pastor*[1], *A. García Vicente*[1];
[1]*Hospital Universitario de Toledo, Toledo, SPAIN,* [2]*Gerencia de Atención Especializada de Toledo. Hospital Universitario de Toledo, Toledo, SPAIN,* [3]*Departamento de Matemáticas. Universidad de Castilla-La Mancha., Ciudad Real, SPAIN.*

Aim/Introduction: Relative value units (RVUs) are a standardized method used to quantify medical workload by assigning a numerical value to healthcare services based on their complexity, time requirements, and resource utilization. However, existing models are not tailored to the specific characteristics of nuclear medicine.The aim of this study was to implement a relative value unit (RVU)-based system to quantify activity and resource utilization in a nuclear medicine department (NMD). ***Materials and Methods:*** A retrospective study was approved by a Local Institutional Review Board and conducted in the NMD of a tertiary hospital, analyzing costs and procedures performed during the first half of 2024. Some steps were performed. First: a list of diagnostic and therapeutic procedures was drawn up. Second: RVU was defined considering thyroid scintigraphy as the reference (RVU value of 1). Third: the cost of each procedure was calculated. This cost was composed by the staff work, the costs of building and facilities labor, department and equipment's maintenance, radiotracer costs and consumables for radiotracer administration and radiation protection and others department supplies, called practice expense RVU. The total cost was obtained summing up the costs assigned to each procedure.For the cost RVU (cRVU), the total expense of each procedure was divided by the unitary cost of the RVU. A novel variable, the complexity RVU (xRVU) was obtained in the same manner, excluding the radiotracer cost. ***Results:*** In the first semester of 2024, 5245 procedures (diagnostics and ambulatory therapies) were performed. The catalog comprised 44 diagnostic procedures and 7 therapeutic procedures. The RVU had a cost of 99.885 euros.For diagnostic procedures, the mean±SD cRVU values for 99mTc-related scintigraphic, non-99mTc-related and ^{18}F-FDG PET and non-^{18}F-FDG procedures were: 1.972±0.966, 5.304±2.036, 4.467±0.519, and 12.194±3.422, respectively. The corresponding xRVU values were 1.543±0.396, 1.853±0.756, 2.189±0.577, and 1.700±0.352, respectively.For therapeutic procedures, the mean ± SD of cRVU and xRVU for inpatient procedures compared to ambulatory ones, was of

59.847 ± 74.813 and 19.846 ± 6.701 for inpatient procedures, and 12.129 ± 19.922 and 1.081 ± 0.226 for ambulatory procedures, respectively. ***Conclusion:*** The cRVU per procedure varied significantly between diagnostic and therapeutic procedures. The expense of the radiopharmaceutical overstates the actual complexity of the procedure. Thus, the novel definition of xRVU, excluding radiotracer cost, offering a more realistic measure of the staff and departamental performance and should be used for organizational purposes.

EP-1394

Economic Impact of 18F-DCFPyl PET/CT on the Detection of Biochemical Recurrence of Prostate Cancer in Spain

M. Godbole[1], *T. Matos*[2], *R. Badinedi*[3], *N. Tchouen*[4], *A. Berthon*[5]; [1]*Alira Health, Barcelona, SPAIN,* [2]*Alira Health, Basel, SWITZERLAND,* [3]*Alira Health, London, UNITED KINGDOM,* [4]*Curium Pharma, Paris, FRANCE,* [5]*Curium Pharma, Lyon, FRANCE.*

Aim/Introduction: 18F-DCFPyl (Piflufolastat (18F)) is a PSMA-targeted PET radiotracer for detecting biochemical recurrence (BCR) in patients with prostate cancer (PCa). This study aims to quantify the economic impact of using 18F-DCFPyl PET/CT for patients with BCR of PCa to detect and localize BCR relative to 18F-FCH PET/CT, 68Ga-PSMA-11 PET/CT, and 18F-PSMA-1007 PET/CT, from the perspective of the Spanish National Healthcare System. ***Materials and Methods:*** A cost-consequence model was developed to simulate the diagnostic/treatment pathway, consisting of the proportion of patients relative to disease localization and imaging accuracy. The treatment mix included radical prostatectomy, radiation therapy, androgen deprivation therapy (ADT), and radiation therapy + ADT, informed by expert opinion. The model accounted for the treatment costs incurred due to true positives, false positives, true negatives, and false negatives, based on the test specifications of the tracers. The primary outcomes were the cost per correct diagnosis and, the number of futile treatments, defined as the treatments resulting from false positives, incurring an additional cost of repeated testing and the cost of treating false positives. The results are reported over an annual time horizon, considering 8,784 patients with BCR. Inputs to the model were informed by data from multiple meta-analyses, public data, and the literature. The prices were leveraged from the data published by the Commission on Medicines Prices (CIPM) and were identical for 18F-DCFPyl, 68Ga-PSMA-11and 18F-PSMA-1007 (€2,000), while the price for 18F-FCH was €1,144. ***Results:*** 18F-DCFPYL significantly reduced futile treatments to 760, approximately 58% (1,825), 56% (1,744), and 66% (2,236) fewer than 68Ga-PSMA-11, 18F-FCH and 18F-PSMA-1007, respectively. The model also revealed significant cost savings with 18F-DCFPYL in terms of repeated testing and false-positive diagnoses. For repeated testing, 18F-DCFPYL resulted in savings of €3M (43%) compared to 68Ga-PSMA-11, €7M (65%) relative to 18F-FCH, and €5M (58%) compared to 18F-PSMA-1007. Similarly, the costs associated with false positives were markedly lower with 18F-DCFPyl, yielding savings of €3M (51%) against 68Ga-PSMA-11, €4M (58%) relative to 18F-FCH, and €6M (66%) when compared to 18F-PSMA-1007. With a cost per correct diagnosis of €2,215, 18F-DCFPYL delivers an 8% reduction compared to 68Ga-PSMA-11 (€2,413) and a substantial 15% savings over 18F-PSMA-1007 (€2,592), resulting in a per-patient saving of €377 compared to 18F-PSMA-1007 and €198 compared to 68Ga-PSMA-11. ***Conclusion:*** 18F-DCFPyL PET/CT offers a cost-effective BCR detection option within the Spanish healthcare system, significantly reducing futile treatments, false positives, and repeat testing compared to alternatives, enhancing clinical outcomes.

Aim/Introduction: Fibroblast Activation Protein Inhibitor (FAPI) radiotracers represent an emerging class of compounds for molecular imaging and targeted radionuclide therapy, particularly relevant in oncology and fibrotic diseases. To streamline national efforts in research and clinical implementation, the Dutch National FAPI Working Group was established under the auspices of the national nuclear medicine society. This abstract outlines the group's structure, activities, and strategic goals aimed at facilitating clinical translation and advancing collaborative theranostic applications of FAPI. ***Materials and Methods:*** The multidisciplinary working group includes nuclear medicine physicians, radiochemists, pharmacists, radiologists, and clinical and preclinical researchers from multiple academic and non-academic institutions across the Netherlands. It functions as a collaborative platform with regular meetings, shared documentation, and consensus-driven initiatives. Key activities include standardisation of FAPI-PET imaging protocols, facilitation of ethical and regulatory procedures (including CTIS submissions), and development of a national FAPI imaging database. In parallel, a dedicated FAPI PhD network was launched to foster early-career collaboration, promote harmonisation, and stimulate cross-institutional expertise sharing. ***Results:*** The working group has achieved consensus on a national FAPI-PET acquisition protocol, now disseminated via a centralised online platform. Regulatory engagement has addressed tracer access and production routes, liability and indemnity frameworks, and inter-institutional radiopharmaceutical distribution logistics. Active research spans both oncologic and non-oncologic indications, including gastric, colorectal, breast, prostate, and hepatobiliary malignancies, carcinoma of unknown primary, fibrotic disorders, and emerging rare disease applications. Case-based multidisciplinary discussions and anonymised data sharing have illustrated the added diagnostic and clinical value of FAPI, particularly where conventional imaging was inconclusive. A national FAPI training day was organised to introduce clinicians and researchers unfamiliar with FAPI image interpretation to core principles and case-based learning. The PhD network now connects early-career researchers throughout the country, supporting knowledge exchange and harmonisation, accelerating regulatory steps during the setup phase of (multicentre) trials, and encouraging collaborative analyses and joint publications. ***Conclusion:*** The Dutch National FAPI Working Group exemplifies a coordinated national initiative to advance FAPI-based imaging and therapeutic applications in nuclear medicine. Through interdisciplinary collaboration, protocol harmonisation, early-career integration, and proactive regulatory

engagement, the group strengthens the infrastructure for clinical translation of FAPI theranostics. This model may serve as a blueprint for international efforts aiming to implement emerging radiopharmaceutical innovations in a harmonised, sustainable, and patient-centred manner. As a next step, the group aims to initiate cross-border collaborations focused on supporting larger multinational clinical trials.

EP-1396

Current Status of Theranostics in the Asia-Pacific Region

A. Brink[1], *E. Estrada-Lobato*[1], *D. Paez*[1], *F. Giammarile*[1], *A. Korde*[2], *D. Subbotnitskiy*[3], *G. Karthikeyan*[4];
[1]*International Atomic Energy Agency, Nuclear Applications Human Health, Division of Nuclear Medicine and Diagnostic Imaging, Vienna, AUSTRIA,* [2]*International Atomic Energy Agency, Department of Nuclear Sciences and Applications, Division of Physical and Chemical Sciences, Vienna, AUSTRIA,* [3]*International Atomic Energy Agency, Department of Technical Cooperation, Division for Asia and the Pacific, Vienna, AUSTRIA,* [4]*All India Institute of Medical Sciences, New Delhi, INDIA.*

Aim/Introduction: Theranostics is increasingly used for personalized disease treatment. Effective application of theranostics requires nuclear medicine (NM) facilities to be well-staffed, well-equipped, with proper knowledge, expertise and regulatory oversight. To document theranostics capacity in the Asia-Pacific, the IAEA surveyed NM facilities in the region. ***Materials and Methods:*** The survey covered the number of NM facilities, SPECT/CT, and PET/CT cameras, and dedicated therapy facilities. Production capabilities were assessed including the number of research reactors, medical cyclotrons, production of isotopes and generators. Information on the performance of dosimetry and quality management programs, such as QUANUM 3.0 was collected. The questionnaire covered human resources, determining the number of trained NM physicians, radiopharmacists, technologist and medical physicist working in NM. Participants described the training programs for the different fields of expertise and outlined the challenges faced in setting up a theranostic service. ***Results:*** A total of 44 NM facilities from 26 countries participated. The number of centers is influenced by a country's population and income status. Japan, a high -income country and India, the most populous, have the most centers in the region. Japan, with its advanced NM capability has 1400 facilities. The number of beds per population size was used to assess therapy capacity. Bangladesh has the highest (n=50) number of beds. Country income group also influences therapy capacity with the UMICs group having the highest number of beds available (n=77). Sixty-two percent (16/26) of the countries import most of the radiotracers used for diagnostic purposes. Those producing tracers locally do so in hospital-based pharmacies. The exception is Iran and Japan, which have many industrial production facilities. About 60% of the countries (15/25) are involved in ongoing trials. Over 95% of countries ensure proper disposal of radioactive waste. Of the 16 countries with data available, 88% follow pharmacopeia monographs. Only 65% of the countries offer a specialization degree in NM, and 51% have clinical training programs. Certification for physicists is available in 75% of the countries, degree program for technologists in 50%, specialized training for radiochemist in 41%, specialty education for pharmacists in 33%, and diploma programs in 22%. ***Conclusion:*** Reasons behind the advancements in theranostics in the region were identified. National government and international collaboration have improved awareness and technological advancements in radiopharmaceuticals and facilitated training and human resource development. Challenges include prioritization and allocation of funds, with lower availability leading to shortfalls in infrastructure development, equipment and training.

EP-1397

Screen-Sharing with AI in VR: A Novel Approach to Radiology Learning and Interpretation

J. Olsson*, J. P. Connelly, H. Ramsdal Hol;*
Oslo University hospital, Oslo, NORWAY.

Aim/Introduction: Medical imaging is growing in complexity. Radiology and nuclear medicine trainees face increasing demands, often without real-time feedback or structured pedagogical support outside of formal supervision. Here we combined virtual reality (VR) with conversational artificial intelligence (AI) and AI visual access to the VR-user interface. This allowed interactive voice prompted AI interpretation of medical texts and images and we used this to explore the utility of this technique as a way to get tailored tutoring in the absence of a teaching physician. ***Materials and Methods:*** Using a commercially available VR (Meta Quest 3) and "screen-sharing" with a multimodal AI (OpenAI), an immersive VR study setup was obtained. The user reads e-books on medical imaging in VR while simultaneously querying the AI on the visuals presented in VR, in real-time. Interactions involved testing verbal prompts focused on comprehension of the read material, quizzing on the text, image description, differential diagnosis, pathology identification, theoretical underpinnings and more. Results of a questionnaire based pilot study will be presented. ***Results:*** Initial experiences suggest the AI-in-VR setup encouraged deep and active learning. The AI assisted with concept clarification, definitions, and could test the user on the page in sight. It could even deliver rudimentary image interpretation (mainly gross pathology and anatomy. In terms of limitations, as the system depends on AI there are occasional hallucinations (inaccurate AI deduced facts or associations), so the user must have a low threshold for fact-checking. With this particular AI provider (OpenAI) there are usage limits for voice communication (and also for screen sharing in VR). These limits can be expanded at a cost. ***Conclusion:*** Screen-sharing with AI-in-VR can provide an engaging and enticing learning environment for radiology and nuclear medicine training. It potentially offers flexible support for imaging physician skill development, particularly valuable in resource-limited educational environments. Results of a small pilot study evaluating the users experience and learning outcomes will be presented at the conference.

EP-1398

Implementation of a customised software tool for proposal and project management dedicated to an experimental Radiopharmacy Facility within a private academic research institute in Italy

R. Visentin[1], *C. Franciosi*[1], *G. Iachetti*[1,2], *S. Fusaro*[1], *M. Lopatriello*[1], *A. Moretti*[1], *M. De Summa*[1], *S. Spinosa*[1], *S. Annunziata*[2];
[1]*Medipass Ergea, Integrative Clinical Solutions - Radiopharmacy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY,* [2]*Nuclear Medicine Unit, GSTeP Radiopharmacy, Department of Diagnostic Imaging and Radiotherapy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY.*

Aim/Introduction: In 2018, the Italian Ministry of Health recognised Fondazione Policlinico Universitario Agostino Gemelli as a scientific and treatment hospital for personalised medicine and innovative biomedical technologies. This led to the establishment of the Gemelli Science and Technology Park (G-STeP), as a network and platform of services to support all stages of scientific research project development. G-STeP is currently composed of twenty-five facilities. Among them, the facility Radiopharmacy deals with a constantly increasing number of research proposals and ongoing projects since October 2022. The need for a facility tool enabling standardised proposal collection, assessment, and internal approval as well as project management brought to the development of a dedicated software platform, hereafter

Research Tool. ***Materials and Methods:*** The implementation of the Research Tool was performed through the following steps: - definition of facility research scopes and of possible related projects; - identification of all the factors characterising and affecting the different kinds of projects; - conception of a work breakdown structure and of a task list covering all the kinds of projects; - definition of tool requirements for proposal and project management; - identification of the commercially available solution more adherent and/or more customisable and scalable. ***Results:*** The Research Tool was developed starting from a commercially available platform already conceived for proposal (business case, BC) and project management. After a deep customisation process, the current version allows us to: - collect non-profit/profit BCs in the facility areas of interest and classify them according to specific parameters; - carry out a preliminary internal assessment/approval of BCs taking into account scientific value, feasibility (major constraints), and compliance with Radiopharmacy and G-STeP research objectives; - match non-profit BCs with non-profit fundings and deeply evaluate funding rules and constraints; - carry out a second internal assessment/approval of BCs which passed the first one, deepening feasibility and sustainability, and also simulating them in the research portfolio; - manage projects arising from approved BCs (schedule, resources, budget, revenue, risks, changes); - associate BCs and projects with the related documentation - generate dashboards and reports for both BCs and projects. ***Conclusion:*** The implemented solution is a robust and versatile tool for proposals management, through a simple and standardised process which guarantees a uniform and strategic assessment, and for the management of each project throughout its entire lifetime, per se and in relation to research portfolio, with particular regard to several incoming projects about experimental radiopharmaceuticals.

EP-1399

The experience of [^{18}F]MC225 trial authorisation in Italy: the academic journey towards a non-profit clinical trial authorisation from precursor production to clinical trial approval

A. Simonetti[1,2], *A. Moretti*[3], *N. Colabufo*[4,5], *M. Leopoldo*[4,5], *C. Filosa*[5], *D. Pantaleo*[3], *V. Ceccarelli*[3], *M. Lopatriello*[3], *C. Franciosi*[3], *M. Calcagni*[6], *A. Giordano*[6], *G. Sani*[1,7], *S. Annunziata*[6], *R. Visentin*[3];
[1]Department of Neuroscience, Sensory Organs and Chest, Section of Psychiatry, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Roma, ITALY, [2]Menninger Department of Psychiatry and Behavioral Sciences, Baylor College of Medicine, Houston, TX, UNITED STATES OF AMERICA, [3]Medipass Ergea, Integrative Clinical Solutions - Radiopharmacy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY, [4]Department of Pharmacy-Pharmaceutical Sciences, University of Bari "Aldo Moro", Bari, ITALY, [5]Biofordrug, Spin-off of the University of Bari "Aldo Moro", Bari, ITALY, [6]Nuclear Medicine Unit, GSTeP Radiopharmacy, Department of Diagnostic Imaging and Radiotherapy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY, [7]Department of Neuroscience, Sensory Organs and Chest, Section of Psychiatry, Università Cattolica del Sacro Cuore, Roma, ITALY.

Aim/Introduction: In January 2022, the proposal of the inter-academy Project "Evaluation of p-glycoprotein alterations in treatment-resistant depression: a [^{18}F]MC225 PET study" was applied to the national Ministry of Health grant "Bando Ricerca Finalizzata 2021" [GR-2021-12374141]. In October 2022, the Project was declared among eligible for funding. The Project should have started on April 30, 2023. At the end of January 2023, the local Ethical Committee approval required by the grant call rules was considered sub-optimal due to the interventional nature of the study, and the Clinical Trial (CT) authorisation through the new EU portal CTIS should have been obtained. ***Materials and Methods:*** The application for CT authorisation was submitted in accordance with Regulation 536/2014 through the CTIS. The Investigational Medicinal Product Dossier (IMPD) was drafted following Regulation Annex I provisions. ***Results:*** [^{18}F]MC225 was not previously developed at Policlinico Universitario Agostino Gemelli (Study Promoter). Moreover, according to the Project proposal, the [^{18}F]MC225 precursor would have been produced and supplied by Biofordrug (University of Bari spin-off) after the project start. Thus, in January 2023, no quality data for precursor and investigational medicinal product were available to draft the IMPD. To permit the CT approval, the Ministry allowed a nine-month Project start delay. However, all the activities to obtain the CT authorizations should have been self-financed. The first CTIS submission was performed at the end of October 2023. The Request For Information (RFI) received from Italian Medicines Agency (AIFA) was accurately respecting the international guidelines to guarantee "quality, safety and efficacy". However, the CTIS timeline, essential to speed up trial approval, was too tight to properly solve the received RFI. At the end of January 2024, the application was withdrawn because precursor's characterization was still insufficient to satisfy the requirements. After eleven months working for RFI resolutions, the second submission was performed in December 2024. Finally, the CT authorisations became effective on April 16, 2025. ***Conclusion:*** The approval of a trial on [^{18}F]MC225 for the first time in Italy and through a project supported by a national public grant demonstrates that non-profit investigator-initiated trials with novel radiopharmaceuticals are feasible in Italy. Nevertheless, research teams, authorities and grant funders should timely approach the CT authorisation flow matter to update non-profit grant rules. Although a peremptory deadline to get the authorization should be stated, the time needed to get it as well as the required costs should be considered by the grant rules.

EP-1400

Designing and Building a Brand New Molecular Therapy Facility: Our experience.

E. Crick[1], *J. Mohammed-Gayle*[1], *H. Buschhold*[1], *M. Draper*[2], *D. Gallacher*[3], *R. Fernandez*[1];
[1]Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM, [2]Cambridge University Hospitals NHS Foundation trust, Cambridge, UNITED KINGDOM, [3]King's College London, London, UNITED KINGDOM.

Aim/Introduction: This abstract details the challenges encountered when designing and building new molecular radiotherapy (MRT) facilities - including incorporating lead shielding into an existing building, regulatory approval, improved patient and staff monitoring, together with re-imagined staff training. Also detailed is a novel triple-detector monitoring system which aims to improve room utilisation, patient experience and engagement with radiation protection restrictions. ***Materials and Methods:*** Current MRT facilities were no longer fit for purpose; two rooms with shared bathroom/toilet, mobile lead shielding (trip hazard) and adjoining an Orthopaedic ward. With MRT workload increasing over the >20 year lifespan of the existing facility, the new MRT unit included an additional room, and crucially ensuite facilities, enabling more flexible patient scheduling. Radiation protection was integral to room design and the RPA was closely involved at every stage. Careful consideration of typical patient dose-rates and occupancy allowed optimisation of the lead required, ranging from 2.24 (Code 5) - 25mm, to minimise the cost/weight. Complex calculations of ray paths/distances and multiple construction options were proposed to achieve sufficient shielding. Thoughtful design enabled increased visibility (both in terms of natural light to improve patient experience and staff supervision of patients), separation of contaminated waste (linen/cutlery/crockery) into 'dry' and 'wet' utility rooms and low background areas for staff contamination monitoring. ***Results:*** Integral to the shielding design was introduction of a "triple detector" system of compensated Geiger-Muller detectors

sited in specific locations in the ceiling of one room. Results will detail the testing phase of the system (linearity of response across typical administered activities of Lu-177 and I-131 up to 11GBq, spatial linearity, relative detector response). The intent behind this novel configuration was to enable more frequent monitoring of patient dose-rates, with the aim of reducing lengths of inpatient stays and facilitating personalised restriction periods following hospital discharge. These directly improve patient experience, compliance with regulations and the ALARP principle. Placement within an Oncology ward enabled re-imagining of staff training. An online component was devised to complement in-person training, with positive staff engagement achieved to date. Pedagogy behind the online training (e.g. risk/radiation in context) and results of a questionnaire assessing staff engagement with training will be presented. ***Conclusion:*** Design and commission of new MRT facilities brings many challenges - complex shielding requirements, significant cost, and regulatory barriers. Tenacity is vital to ensure to ensure that MRT facilities are fit for purpose and safe for patients and staff.

EP-1401

Can Researchers Rely on Large Language Models to Write a Systematic Review? A Direct Comparison between Humans and Six LLMs

C. Pini[1], *M. Sollini*[1,2], *A. Lazar*[1], *F. Gelardi*[1], *G. Ninatti*[2,3], *M. Bauckneht*[4,5], *A. Chiti*[1,2], *M. Kirienko*[6];
[1]*Vita-Salute San Raffaele University, Milan, ITALY,* [2]*Department of Nuclear Medicine, IRCCS Ospedale San Raffaele, Milan, ITALY,* [3]*School of Medicine and Surgery, University of Milano-Bicocca, Milan, ITALY,* [4]*Department of Healt Sciences (DISSAL), University of Genoa, Genoa, ITALY,* [5]*Department of Nuclear Medicine, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY,* [6]*Nuclear Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY.*

Aim/Introduction: The capability of Large Language Models (LLMs) to support and facilitate research activities has sparked growing interest in their integration into scientific workflows. This study aims to evaluate and compare against human researchers the performance of six different LLMs (ChatGPT, Claude, Gemini, DeepSeek, Le Chat, and Grok) in conducting various tasks necessary to produce a systematic literature review. ***Materials and Methods:*** The evaluation of the six LLMs was split into three tasks: literature search, article screening and selection (Task 1); data extraction and analysis (Task 2); final paper drafting (Task 3). Their results were compared with a human-produced systematic review on actinium-PSMA therapy in prostate cancer, serving as reference standard [1]. The evaluation was repeated on two rounds (February and April 2025) to evaluate reproducibility and improvements of LLMs over time. For Task 2 and Task 3, we provided each LLM with the same ground-truth data from the human-produced scientific paper to ensure a fair comparison across platforms. Quantitative and qualitative assessments were used to evaluate LLMs performance; additionally, time spent to complete each task was evaluated. ***Results:*** Out of the 18 scientific articles to be extracted from the literature for Task 1, the best LLM (Gemini 2.5 Pro) managed to identify 13 correct papers. ChatGPT and Grok managed to extract 9 and 8 manuscript, respectively, both alongside hallucinated records. Data extraction and analysis for Task 2 was partially accurate and required multiple prompts, with the best performer achieving 93% correct entries, though with only 7 out of 18 articles tabulated with no errors. The full papers generated by LLMs for task 3 were short and uninspiring, often not fully adhering to the standard template for a systematic review. While all LLMs managed to perform Task 1 and Task 3 in less than 30 minutes, Task 2 required cumbersome and long procedures (up to 2 hours) for many models. Incremental improvements were observed between Round 1 and Round 2, yet overall performance remained inconsistent. ***Conclusion:*** Although LLMs show promise, none can yet autonomously perform an end-to-end systematic review with human-level accuracy or methodological rigor. Their evolving capabilities may support researchers in literature triage and draft generation under careful supervision, but expert oversight remains indispensable for evidence synthesis. ***References:*** 1. EP-1402

Challenges in Access to Peptide Receptor Radionuclide Therapy in Developing countries: Insights from patient advocacy perspective

S. Dureja*;*
Theranostics India Centre, New Delhi, INDIA.

Aim/Introduction: Discussing challenges in Access to Peptide Receptor Radionuclide Therapy (PRRT) in Developing countries and sharing insights from 10 years of patient advocacy. ***Materials and Methods:*** This is a subjective analysis of availability and access to treatment for Neuroendocrine tumors in the Indian subcontinent over 10 years and experience as a physician- advocate engaged with a neuroendocrine tumor support organisation. ***Results:*** The „Iron Triangle" of healthcare is a concept which talks about the relationship between cost, access and quality of healthcare. Extrapolated to PRRT, the factor affecting access in low income countries, can be classified into triple A or Availability, Access and Awareness (about use of PRRT). Given the relative uncommonness of Neuroendocrine tumors (NETs), patient advocates/advocacy groups can work with the medical fraternity for information dissemination about use and availability of theranostics. They can influence policy decisions by giving representation to governments which can help extent healthcare coverage for PRRT. Advocacy groups also play a major role to inform and mobilize the patient commnuity for clinical trials.Further, patient reported outcomes can be used to refine research objectives. Other steps like regional co-operation for capacity building and strengthening scientific trials are also areas where patient advocate groups can help in growth of radionuclide therapy for Neuroendocrine tumors. ***Conclusion:*** Patient advocacy has an important and growing role in impacting access to treatment for NET patients, more so in developing economies. ***References:*** 1. Kolarova T, Bouvier C. The Role of Patient Support Groups in Neuroendocrine Neoplasms. Curr Oncol Rep. 2021 Mar 22;23(5):53. doi: 10.1007/s11912-021-01046-6. PMID: 33754245; PMCID: PMC7985052. 2. Unmet needs in the international neuroendocrine tumor (NET) community: Assessment of major gaps from the perspective of patients, patient advocates and NET health care professionals. Int J Cancer. 2020 Mar 1;146(5):1316-1323. doi: 10.1002/ijc.32678. Epub 2019 Oct 25. PMID: 31509608; PMCID: PMC7004101.

EP-1403

Expanding Global Equitable Access to Radioligand Therapy

S. Nogueira*, A. Armesto, C. Carreras, I. Hume, Y. Omar, E. Cannarozzo, A. F. Viana;*
Oncidium Foundation, Auderghem, BELGIUM.

Aim/Introduction: Radioligand therapy (RLT) has demonstrated remarkable success, but its high cost has limited its availability, particularly in developing countries. A global online platform that connects healthcare professionals with radioisotope companies could be an essential solution to support financially

struggling patients needing RLT. In this context, a non-profit foundation launched the RLT-Connect Platform online to promote international collaboration, raise awareness, and secure funding. This platform could improve equity in cancer care worldwide. This report outlines the process of submitting patient cases and treatment donation requests for those who have exhausted all options and meet eligibility criteria, as well as the results obtained in 2 years. ***Materials and Methods:*** The platform was conceived and developed by the non-profit foundation. Physicians from experienced RLT centers submit treatment requests through RLT-Connect for patients with limited financial options. An independent Ad Hoc committee reviews the submissions based on eligibility and ethical criteria. Upon approval, donated doses of radioisotopes are supplied through industry partners and processed locally for administration. Physicians report baseline data, treatment details, and outcomes online. ***Results:*** Between January 2024 and March 2025, the platform recorded 59 registered centers in 14 countries, 38 patients treated or under treatment, and 108 administered doses. Five radioisotope suppliers are currently actively donating doses. Patients primarily had metastatic castration-resistant prostate cancer (mCRPC) and neuroendocrine tumors (NETs); one patient had ovary cancer, with staging typically at TNM Stage IV. Imaging agents used included 68Ga-PSMA (67%) or 18F-PSMA (33%) for mCRPC and 68Ga-DOTATATE (50%) or 18AlF-DOTATATE (50%) for NETs, with uptake supporting treatment. Based on the reports sent by now, the treatment outcomes include PSA reductions of ≥50% in mCRPC cases, up to 75% decrease in total lesion activity, Quality of Life (QoL), patients reported symptom relief, pain reduction, restored daily function and increase in mental wellness. ***Conclusion:*** The RLT-Connect platform has demonstrated that access to radioligand therapies can be extended to patients otherwise excluded due to financial difficulty or lack of insurance denial. The RLT-Connect has transformed individual lives by combining the engagement of nuclear medicine physicians with committed industry partners. But beyond individual treatments, RLT-Connect highlights the importance of integrating RLT into national healthcare systems to ensure its availability as a standard oncologic treatment.

EP-1404

Addressing the Challenges of Radiopharmacy: A specialized certifying program for French-speaking pharmacists in Switzerland

J. Delage[1], *M. Schottelius*[2], *M. Straub*[3], *J. Prior*[4], *M. Lebreux*[5], *A. Hammadi*[6], *F. Sadeghipour*[7,8,9];
[1]*Radiopharmacy Unit, Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Translational Radiopharmaceutical Sciences, Depts. of Nuclear Medicine and of Oncology, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [4]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [5]*Department of Pharmacy, University Hospital of Québec, Laval University, Laval, QC, CANADA,* [6]*National Institute for Nuclear Science and Technology (INSTN), Atomic Energy Center (CEA) of Saclay, Gif-sur-Yvette, FRANCE,* [7]*Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [8]*Center for Research and Innovation in Clinical Pharmaceutical Sciences, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [9]*Institute of Pharmaceutical Sciences of Western Switzerland, University of Geneva, University of Lausanne, Lausanne, SWITZERLAND.*

Aim/Introduction: In recent years, nuclear medicine and radiopharmacy have experienced significant growth with the development of new theranostic approaches in cancer treatment and the arrival of innovative radiopharmaceuticals on the market. The involvement of pharmacists specialized in radiopharmacy is therefore essential, as they bring their expertise in the management of radiopharmaceutical production as well as in the therapeutic support of patients. Despite the growing demand, training opportunities in radiopharmacy remain scarce. In Switzerland, this lack has led to challenges in recruitment and a limited number of radiopharmacists available to support the clinical adoption of these new treatments. As a result, we aim to develop a new certifying program for French-speaking pharmacists in Switzerland. ***Materials and Methods:*** The goal of this program is to equip pharmacists with the necessary skills to ensure the safety of the radiopharmaceutical drug circuit from preparation and release to clinical patient support (monitoring adverse effects, pharmacological follow-up, therapeutic education, radiation protection, etc.). To this end, discussions have been initiated with various partners and the University of Lausanne. To strengthen radiopharmacy connections within the Francophone community, partnerships involving the exchange of educational content are being considered with the National Institute for Nuclear Science and Technology (INSTN) Saclay, Paris, France and Laval University, Québec, Canada. ***Results:*** This program, structured as a Certificate of Advanced Study (CAS), will include the following four modules: Module 1: Fundamentals of nuclear physics and detection of ionizing radiation, radiobiology, and radioprotection Module 2: Production and quality control of radiopharmaceuticals Module 3: Clinical diagnostic radiopharmacy Module 4: Clinical radiopharmacy. Therapeutic and theranostic applications In addition to theoretical instruction, a four-month internship in a radiopharmacy unit will be offered, to reinforce the theoretical concepts acquired with practical experience. The program is scheduled to launch in 2026. ***Conclusion:*** The growing demand for radiopharmaceuticals and theranostic applications highlights the urgent need to strengthen specialized pharmaceutical training in radiopharmacy. Through the establishment of a specialized CAS in French-speaking Switzerland, this program aims to address current training gaps, support the integration of pharmacists into multidisciplinary care teams, and contribute to the safe and effective deployment of innovative nuclear medicine therapies. Through national and international collaborations, this initiative also reinforces the Francophone network in radiopharmacy education and practice.

EP-1405

Establishing Traceability Routes in Nuclear Medicine: The ETrain starts its journey ...

A. Fenwick[1], *J. de Pooter*[2], *P. Toroi*[3], *J. Rusnak*[4], *K. Sjogreen Gleisner*[5];
[1]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [2]*VSL, Delft, NETHERLANDS,* [3]*STUK, Helsinki, FINLAND,* [4]*CMI, Prague, CZECH REPUBLIC,* [5]*Lund University, Lund, SWEDEN.*

Aim/Introduction: The disparity in radioactivity measurement capability varies across Europe. Comparison exercises between hospital sites have demonstrated that in some regions more than 90 % of participants are able to measure the activity of a reference source to within ± 5 % of the true activity but in other regions this has can be as low as 23 % of participants. Measurement accuracy is critical in drug development, supporting clinical trials and patient safety, whilst traceability of the injected activity is also a requirement in many countries. To address this, Euramet has funded a new project, 24RPT01 (ETrain) to improve activity measurement capability in nuclear medicine. The aim is to establish a network to be utilised by clinical partners, pharmaceutical suppliers and manufacturers to ensure traceable radioactivity measurements. ***Materials and Methods:*** A consortium of National Metrology Institutes (NMIs), calibration laboratories, academic partners, national societies and industrial partners has been formed to establish calibration centres across Europe, providing access to traceable radioactivity standards.

This network will be developed over three years, through engagement with NMIs and clinical partners with comparisons between the calibration laboratories ensuring equivalence between countries. The networks effectiveness will be tested by performing intercomparison exercises of clinical sites. Guidance documents and calibration protocols will be produced and made available to the user community. ***Results:*** The outcomes of the project will be in the form of guidance documents, comparison reports and training material aimed at improving the overall measurement capability in Europe. Increasing the availability of reference sources and providing guidance and tools to ensure traceability will improve harmonisation and enable compliance with legislation by allowing traceability to be recognised in more places than ever before. Guidance on uncertainty assessment from primary standards through to imaging and dosimetry will be included. Progress on achieving these goals and an overview of the project structure will be presented. ***Conclusion:*** The ETrain project aims to enable harmonisation of activity measurements across Europe and supercharge its ability deliver clinical trials and harmonised imaging and dosimetry studies. The project will run until 2028 and brings together metrology institutes and clinical partners. To be part of the project and receive progress updates or attend meetings and workshops, please contact the author.

EP-1406

Enhancing Diagnostic Accuracy in Dementia: Standardized Protocols for FDG PET-CT Brain Imaging

A. Hassan, *A. W. Alessi, E. Wahab, S. J. Hughes;*
Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: Fluorodeoxyglucose positron emission tomography-computed tomography (FDG PET-CT) is a vital imaging modality in the diagnosis of neurodegenerative diseases, particularly dementia. By assessing cerebral glucose metabolism, it provides essential insight into patterns of brain activity. Accurate diagnosis depends on standardizing acquisition and reconstruction procedures to ensure diagnostic reliability and comparability. This educational abstract presents a structured framework aimed at improving image quality and interpretive consistency, thereby supporting earlier and more accurate dementia diagnosis. ***Materials and Methods:*** Patient preparation is a critical first step, involving a fasting period of at least six hours. Diabetic patients must have glycemic control before imaging. To establish a resting baseline of neuronal activity, patients should be placed in a low-stimulus environment for 20-30 minutes before tracer injection and remain at rest after injection. Proper head immobilization is ensured through supine positioning, aligning the orbito-meatal line perpendicular to the floor, and using non-invasive restraints such as Velcro straps to minimize motion during acquisition. Reconstruction should utilize 3D iterative techniques that exclude point spread function (PSF) to prevent Gibbs artifacts. For the CT component, high milliampere-second (mAs) settings and isotropic voxel acquisition are recommended to support quality anatomical reference and multiplanar reconstruction. Image display must be standardized to preserve interpretative reliability. Display methods include experiential windowing, percentile-based thresholds, and five-region saturation using a rainbow scale; whichever is chosen, consistency must be upheld across all scans. ***Results:*** Four key anatomical quality indicators serve as immediate benchmarks for image quality: the superior parietal gyri should be intact, the anterior limb of the internal capsule clearly separated, the posterior cingulate gyri visibly defined bilaterally, and the bilateral colliculi well-demarcated. If significant motion artifacts compromise more than two of these regions, repeat imaging may be necessary. Structured reporting should document scan quality, note age-related changes in FDG uptake, and classify the severity of regional hypometabolism as mild, moderate, or severe, based on the extent of gray-white matter preservation. Additional CT findings such as sulcal widening, ventricular enlargement, and medial temporal atrophy are also included to provide a comprehensive diagnostic context. ***Conclusion:*** This standardized approach to FDG PET-CT brain imaging enhances diagnostic clarity in dementia evaluation. By combining technical rigor with clinical insight, it promotes reproducible, high-quality imaging that can be effectively integrated into multidisciplinary care pathways. Ultimately, this protocol supports earlier and more targeted interventions in patients with suspected neurodegenerative conditions.

EP-1407

Thyroid Scintigraphy in Congenital Hypothyroidism

K. Auf der Springe, *R. Dias Correia, N. Testart, M. Jreige, N. Schaefer, J. O. Prior, M. Nicod-Lalonde;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Newborns with congenital hypothyroidism are diagnosed and treated in specialized centers. We discuss the planification and procedure of thyroid scintigraphy, the underlying etiologies and scintigraphic patterns as well as the treatment implications of the findings. ***Materials and Methods:*** Newborn screening identifies congenital hypothyroidism on the third day of life, aiming to avoid livelong disabilities. Thyroid scintigraphy with technecium-99m pertechnetate or iodine 123 helps identify the underlying pathology. To ensure best patient outcome, scintigraphy must not delay the beginning of hormone substitution, should be performed as early as possible and may be carried out up until 7 days after the beginning of the treatment. ***Results:*** The objective of is to identify the underlying etiology and guide appropriate therapeutic interventions. Most common causes are dysgenesis, refering to abnormal thyroid gland development (ectopy, agenesis or hypoplasia) and dyshormonogenesis, which involves impaired hormone synthesis within a structurally normal gland. Rare causes of congenital hypothyroidism include transitory hypothyroidism which may have different causes, TSH resistance, deficit in iodine transporter and central congenital hypohyroidism. By obtaining scintigraphic images, clinicians can ascertain the severity of thyroid dysfunction and underling pathology, allowing for personalized treatment plans. This has implications for long-term management, including the duration of hormone replacement therapy. ***Conclusion:*** Thyroid scintigraphy in contenital hypothyroidism is an important diagnostic and therapeutic tool that provides valuable insights into thyroid gland localization, morphology and function, guiding clinicians in tailoring treatment strategies for improved patient outcomes. ***References:*** van Trotsenburg, Paul et al. EP-1408

Association Between Whole-Body Composition Variables and Abdominal Fat Distribution with Bone Mineral Content in a Healthy Population (^{k}ReBoMiDe Study).

M. Cruz Montijano[1], *S. Pérez Luque*[2], *J. Pérez Beteta*[2], *J. Montalva Pastor*[1], *A. Gutiérrez Crespo*[3], *J. Bonilla Plaza*[1], *L. García Zoghby*[1], *M. Meneses Navas*[1], *S. Guzmán Ortiz*[1], *I. García Megías*[1], *C. La Fay*[3], *M. Caballero Campos*[4], *A. García Vicente*[1];
[1]*Complejo Hospitalario de Toledo, Toledo, SPAIN,* [2]*Department of Mathematics, University of Castilla-La Mancha, Ciudad Real, SPAIN,* [3]*GE Healthcare, Madrid, SPAIN,* [4]*University of Córdoba, Cordoba, SPAIN.*

Aim/Introduction: To determine the impact of demographic, anthropometric, whole-body tissue mass, and abdominal fat variables on bone mineral content (BMC) and bone mineral density (BMD) obtained by a dual-energy X-ray absorptiometry (DXA). ***Materials and Methods:*** A prospective study (kReBoMiDe) including healthy male and female controls aged between 20 and 49 years was developed and approved by Ethical Committee (reference number:1128/2024). BMC and BMD were quantified at various locations: the lumbar spine, proximal femurs, and the whole body. In addition, abdominal fat mass, total tissue mass (TTM), total lean mass (TLM), total fat-free mass (TFFM), total body mass (TBM), and abdominal adipose mass (AAM) were measured using a DXA scanner with a specific software. To analyze relationships among variables, Spearman correlation ($r \geq 0.70$) and the Wilcoxon test were used. The influence of age, sex, physical activity (PA), and body mass index (BMI) on the above-mentioned composition measures was assessed using Student's t-test and ANOVA. Statistically significant (SS) difference was considered for p-values < 0.05. ***Results:*** Data were collected from 75 controls (52 women), with 65.3% having a healthy BMI and 58.7% reporting low PA levels. Differences were found between sexes (predominance of males), but not by age or PA. According to BMI, there were only SS differences for measures of body composition and abdominal fat, but not for BMD/BMC. There were differences in laterality (left predominance for global extremity measurements and right for trunk measurements, except for BMD and CMO). An association was found between BMD/CMO of different locations with MMT, MTT, MLGT and TM. No MAA variable was significantly related to bone variables. ***Conclusion:*** BMI and the amount of MAA did not show a determining role in bone mass, although absolute variables such as MMT, MTT, MLGT and MT did. Sex played a predominant role over age in the bone mass of our healthy population.

EP-1409

(Radio)Theranostics: XXIst Century Nuclear Medicine Creating Hope for Oncological Patients

L. Metello[1], *R. R. Johnson*[1], *D. Jolly*[1], *A. Uhlending*[2], *V. Hugenberg*[2], *V. Gupta*[3], *C. Scheiber*[1], *G. Romanowicz*[1], *M. Capoulas*[1], *I. V. Costa*[1], *D. Fraga*[1], *L. Cunha*[1];
[1]IsoPor Group, Portugal, PORTUGAL, [2]Herz und Diabeteszentrum HDZ - NRW, Univ der Ruhr - Univ. Bochum, Bad Oeynhausen, GERMANY, [3]University of Heidelberg, DKFZ, Heidelberg, GERMANY.

Aim/Introduction: (Radio)Theranostics are an highly advanced - and very dynamic! - precision tool at the service of modern oncology in an increasingly personalized medicine world. It is really changing the present paradigm, and, to be efficient, it asks for distinct parts involved to adapt/evolve their positioning. ***Materials and Methods:*** The current paradigm has been analyzed and will be quickly characterized. Based on that, several distinct options will be presented, briefly commented and justified at all the following levels: Medical Level (Nuclear Medicine / Oncology / RadioOncology: the departing situations being several, analysis has been done accordingly and distinct possible future scenarios will be evoked) Patients Level (what is critical to know from the patients point-of-view? How to efficiently inform the most important aspects, in order to empower the patient for higher levels of awareness and participation, namely in its own specific case?) Management and Administration Level (pricing, cost/benefits relations and logistics demystified) Communication Level (being a critical aspect, it deserves a very well thought and planned approach, that should be consistent and coherent, but always dedicating special attention to specificities: Health Professionals levels versus patients, family, media and society levels) Education & Training Level ("new roles" meaning "new skills" and "new needs" for education and training in health professionals that should be able to perform efficiently in eventual "new fields") ***Results:*** Several years of practical "hands on" working, both at academic (education as research and development) and clinical levels, modulated with numerous exchanges of opinions and information between experts as with patients, demonstrated the need to change the actual paradigm, since definitely not fitting with the urgent need to maximize easiness, results and to increase the number of patients benefiting. Some results will be quantified and several suggestions, practical cases and "good practice examples" will be exposed and quickly analyzed, hoping to send the message that it does not need to be excessively complex and/or expensive, but often simply well thought, planned and executed in due time. ***Conclusion:*** (Radio)Theranostics are already here, and all the parts involved ask for an efficient practical implementation. It might only be achieved under a more efficient environment, where all are better educated and trained, being ready to work together - each one at its specific level - in a very open manner, totally focused in the need to increase the efficiency of the entire system, aiming at the wellness of the patient.

EP-1410

Study protocol update: A randomized phase 2 trial of FLEXible and extended dosing of ^{177}Lu-PSMA-617 Molecular Radioligand Therapy in mCRPC (FLEX-MRT)

A. Holzgreve[1,2], *A. Delker*[2], *Z. Ells*[1], *J. Brosch-Lenz*[3], *L. M. Unterrainer*[1,2,4], *J. Nikitas*[1], *S. Zhu*[1], *M. M. Contreras*[1], *H. Alam*[1], *R. M. Nabong*[1], *S. Lira*[1], *A. Vasilyev*[5], *L. Chen*[5], *T. Grogan*[5], *D. Elashoff*[5], *C. A. Meyer*[1], *M. Dahlbom*[1], *J. Czernin*[1], *J. Calais*[1];
[1]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY, [3]Institute of Nuclear Medicine, Bethesda, MD, [4]Bavarian Cancer Research Center (BZKF), partner site Munich, Munich, GERMANY, [5]Department of Medicine Statistics Core (DOMStat), Department of Medicine's Division of General Internal Medicine and Health Services Research, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The European Medicines Agency (EMA) approved ^{177}Lu-PSMA-617 radioligand therapy (RLT) for patients with metastatic castration-resistant prostate cancer (mCRPC) with a fixed dosing schedule of 7.4 GBq administered once every 6 weeks for up to a total of 6 doses. However, a patient-tailored more flexible and extended dosing schedule may increase treatment efficacy of ^{177}Lu-PSMA RLT. ***Materials and Methods:*** We present an update on the study protocol of the randomized FLEX-MRT trial. ***Results:*** In this investigator-initiated prospective phase 2, open-label, randomized, controlled, parallel-group, single-center trial, we aim to assess the efficacy of a response-based flexible dosing schedule of ^{177}Lu-PSMA-617 RLT administered up to 12 treatment cycles in men with mCRPC. Key inclusion criteria include eligibility for ^{177}Lu-PSMA-617 (i.e. prior ARSI, prior chemotherapy, PSMA PET VISION criteria). Exclusion criteria include prior RLT and less than 6 weeks since the last myelosuppressive therapy. We hypothesized 2-year survival rates of 55% in the investigational group and 30% in the control group. A two-sided log rank test with an overall sample size of 90 subjects (45 per group) achieves 80.3% power at a 0.05 significance level to detect a hazard ratio of 0.50. Randomization will allocate patients in a 1:1 ratio: The investigational arm is treated with up to 12 cycles including potential "treatment holidays" depending on the treatment response; the control arm receives 6 cycles administered in six-week intervals. Imaging response to RLT is assessed using ^{177}Lu-PSMA-617 SPECT/CT after each cycle and PSMA PET/CT every 3 months during treatment holidays, respectively. RLT will be re-started after a treatment holiday in the investigational arm, if the patient experiences a ≥25% PSA progression and an imaging progression according to the RECIP criteria. The primary endpoint is the 2-year survival rate calculated from the date of the first treatment cycle. Secondary endpoints include safety by CTCAE and dosimetry, and determination of

overall and progression-free survival (evidence of progression as defined by either radiographic, PSA, or clinical progression, or death from any cause). The FLEX-MRT trial has been approved by the FDA (IND #168362) and the UCLA IRB (#23-000931), and it is registered on ClinicalTrials.gov (NCT06216249). The FLEX-MRT trial is currently recruiting. Start of enrollment was in August 2024. As of April 14th, 2025, 27 patients have been enrolled. ***Conclusion:*** The randomized FLEX-MRT trial aims to generate evidence for the efficacy of a response-based extended dosing schedule of ^{177}Lu-PSMA RLT in patients with advanced mCRPC.

EP-1411

Start-up of early-phases trials in radiopharmacy unit since begining 2024

S. Maymó Garrido[1], *D. Rodríguez-Puig*[1], *C. García-Alcober*[1], *E. Ricart-Paredes*[1], *M. Crespí-Busquets*[1], *C. Munuera-Sañudo*[1], *E. Pineda-Fernández*[1], *M. Bueno-Raspall*[1], *M. Cortés-Romera*[2];
[1]*Radiopharmacy Department. Hospital Universitari de Bellvitge - Idibell, L'hospitalet de Llobregat, SPAIN,* [2]*Nuclear Medicine-PET (IDI) Department. Hospital Universitari de Bellvitge - Idibell, L'hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Assess the impact of the phased start of early phase clinical trials in our Radiopharmacy Unit since January 2024 . ***Materials and Methods:*** In order to assess the impact, a review was carried out of the enhanced functions that have emerged and that have been performed alongside those already existing in the radiotherapy department's clinical practice. ***Results:*** Since January 2024 we have been involved in 8 new clinical trials. These eight trials can be classified from more to less complex depending on whether they include (phase I) or not (phase II or III) an associated dosimetry study (SPECT/CT at 4, 24, 48 and 168 hours after administration of the ^{177}Lu radiopharmaceutical) together with pharmacokinetic (PK) determination. In our case, five of these are Phase I, one is Phase II and two are Phase III. The role of the radiopharmacy department has been expanded to include attendance at screening visits, detailed review of protocols, scheduling of initial eligibility tests (PET/CT and bone scan), and scheduling of therapy treatment dates within the protocol timeframe. Request doses of ^{68}Ga and ^{177}Lu-labelled radiopharmaceuticals via different platforms. Provide nursing staff with documentation for data collection (vital signs, ECG) and labelled tubes for blood/urine collection, if required. Complete all documentation associated with the administration of radiopharmaceuticals and submit this documentation to the appropriate data entry system. Manage of samples; centrifuge and pipette blood/urine samples, if required, for subsequent processing in the counter and complete the files required to be uploaded to a platform. Store samples in a freezer (-80°C) if required and manage their request for transport (IATA certified). Receive monitoring visits to verify data according to ALCOA+ criteria and be subject to audits. ***Conclusion:*** The arrival of these clinical trials has created an urgent need to restructure the infrastructure, as well as to introduce new staff profiles to support the functions involved in the successful development of these highly complex trials.

EP-1412

Hepatocellular carcinoma transarterial radioembolization: a single centre experience

A. Genova, *F. Porcaro, M. Prisco, I. Annarumma, L. Turchetta, V. Piscopo, M. Catalano;
Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Naples, ITALY.*

Aim/Introduction: This study evaluates the efficacy and safety of transarterial radioembolization (TARE) in patients with unresectable hepatocellular carcinoma (HCC) treated at our institution. Personalized dosimetry was employed to maximize therapeutic efficacy while minimizing damage to healthy liver tissue. Both resin and glass microspheres were used, with dosimetric calculations performed using MIM SurePlan and Simplicit90Y™ software, respectively. Short-term outcomes were also assessed ***Materials and Methods:*** Patients are selected for TARE by a multidisciplinary oncology board based on eligibility criteria including adequate bilirubin levels, coagulation parameters, and platelet counts, to minimize the risk of post-TARE liver failure and procedural complications. Hepatic vascular anatomy was evaluated by angiography, followed by administration of [99mTc]-MAA via catheterization of the hepatic artery to simulate microsphere distribution. SPECT-CT imaging assessed lung shunting, non-target distribution, and tracer uptake in the liver lesion. Personalized pre-treatment dosimetry using [99mTc]-MAA SPECT-CT was performed to determine the feasibility of TARE and to select an activity that maximizes the tumor dose while respecting safety thresholds for healthy liver tissue. Absolute contraindications included pulmonary shunting >20%, uncorrectable gastrointestinal deposition, reverse hepatic arterial flow, and complete portal vein thrombosis. Treatment planning was performed with a voxel-based model using MIM SurePlan LiverY90™ for resin microspheres and a multicompartmental model implemented in Simplicit90Y™ for glass microspheres. Distribution of 90Y-microspheres was verified post-procedure with either SPECT-CT or PET-CT. Tumor response was assessed at 3 months with CT, ultrasound, or MRI. Between January 2022 and December 2025, 26 patients (20 male, 6 female; mean age 68) underwent TARE. Of these, 3 patients had portal vein thrombosis and 15 had previously received other treatments (surgery, laser ablation, RFA, or TACE). ***Results:*** Post-treatment fatigue, mild abdominal pain, and low-grade fever were observed in a minority of patients. No cases of liver-related toxicity or radiation-induced liver disease (REILD) were reported. During follow-up, 3 patients died due to disease progression. Partial response according to RECIST criteria was observed in 4 patients, and complete tumor necrosis in 3. Seven patients continued therapy with immunotherapy ***Conclusion:*** This single-center experience confirms that TARE with Y-90 microspheres is a safe and effective option for selected patients with unresectable HCC, regardless of the microsphere type. Personalized dosimetry enables a balance between preserving liver function and achieving tumor control, supporting TARE as a viable approach for local disease management, bridge to transplantation, or potential curative intent.

EP-1413

Study of Dosimetric Parameters of Treatment of Inoperable Lung Tumors Using Brachytherapy Based on Hydrogel Containing Radioisotope ^{188}Re

A. Kazemi[1], *H. Poorbaygi*[2];
[1]*Shiraz University of Medical Science, Shiraz, IRAN, ISLAMIC REPUBLIC OF,* [2]*Radiation Application Research School, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Lung cancer, causing 1.8 million deaths in 2022, demands innovative solutions for inoperable cases. This simulation-based study introduces a novel brachytherapy approach using Heposphere hydrogel loaded with ^{188}Re for targeted treatment of lung tumors. Drawing parallels with ^{90}Y glass microsphere dosimetry, we evaluated D, BED, and TCP to assess therapeutic efficacy and safety. ***Materials and Methods:*** The Hepospher, incorporating ^{188}Re as sodium perrhenate, was modeled for delivery via embolization, leveraging its self-absorption for enhanced isotope retention. ^{188}Re mirror ^{90}Y localized dosing capabilities. MC simulations and MIRD formalism were applied to a lung tumor phantom. calculating D, RDF, BED, TCP, DVHs for (D_{90}) and (V_{20}). ***Results:*** Simulations revealed 90% of the prescribed dose (60 Gy) delivered within a 2 cm radius, with a dose rate of 2.8 Gy/h at the tumor-hydrogel interface, comparable to Yttrium-90's dose localization. DVHs showed 95% tumor coverage for 3 cm tumors. Healthy lung exposure was V_{20}<5% at 20 Gy. BED,

calculated using ^{188}Re's short $T_{1/2}$, aligning with ^{90}Y therapeutic range. TCP exceeded 90% for tumors, indicating high tumor control potential. The hydrogel's self-absorption minimized dose leakage, enhancing safety. ***Conclusion:*** The ^{188}Re-Heposphere offers a promising, ^{90}Y-inspired brachytherapy approach for inoperable lung tumors, achieving high tumor coverage, effective BED, and TCP while sparing healthy tissues. The hydrogel's self-absorption ensures precise dosing, positioning this method as a novel option for precision oncology. ***References:*** WCRF. (2022). Lung Cancer Statistics. EP-1414

Bridging Competency and Clinical Practice: The Role of Entrustable Professional Activities in Theranostics-Oriented Nuclear Medicine Training

T. Pascual;
Department of Science and Technology- Philippine Nuclear Research Institute, Pasig, PHILIPPINES.

Aim/Introduction: The rise of theranostics—combining molecular imaging and targeted radionuclide therapy—has transformed nuclear medicine into a precision-driven speciality. However, educational frameworks have not kept pace with this clinical evolution. Despite the widespread adoption of competency-based models such as those from ACGME, CanMEDS, and UEMS, Entrustable Professional Activities (EPAs) are still inconsistently integrated into many modern nuclear medicine training curricula. This gap risks inadequate preparation of trainees for the complex, multidisciplinary, and rapidly evolving demands of theranostics. ***Materials and Methods:*** Review of literature and qualitative description of relevant findings. ***Results:*** EPAs represent critical, observable tasks that define professional roles and responsibilities. In alignment with international competency frameworks, six EPAs essential to theranostics-focused nuclear medicine education are proposed: 1.Interpret and report theranostic imaging studies (CanMEDS: Medical Expert; ACGME: Patient Care, Medical Knowledge). 2.Develop and personalize radionuclide therapy plans (UEMS: Clinical Skills; ACGME: Systems-Based Practice). 3.Counsel patients on theranostic procedures and outcomes (CanMEDS: Communicator, Health Advocate). 4.Collaborate within multidisciplinary teams in theranostics (CanMEDS: Collaborator; ACGME: Interpersonal Skills). 5.Ensure compliance with radiation safety and ethical standards (CanMEDS: Professional; ACGME: Professionalism). 6.Incorporate evidence-based research into theranostic practice (CanMEDS: Scholar; ACGME: Practice-Based Learning and Improvement). These Entrustable Professional Activities (EPAs) support a structured learning progression, enhance accountability, and align with a competency-based framework that mirrors the realities of clinical practice. They are rooted in educational philosophies such as constructivism and situated learning, which emphasize experiential and reflective learning. EPAs serve as scaffolds that gradually develop a learner's autonomy and trustworthiness, bridging the gap between theoretical knowledge and independent professional practice. Recent updates in theranostic training requirements, including new radiopharmaceuticals, patient-centred care, and interdisciplinary roles, necessitate a curriculum redesign to incorporate EPA-based assessment. Without these changes, nuclear medicine physicians may graduate lacking demonstrated proficiency in critical areas of theranostics. ***Conclusion:*** Integrating EPAs into nuclear medicine curricula is essential for preparing clinically competent, ethically grounded physicians capable of delivering advanced theranostic care. EPA inclusion ensures that training keeps pace with innovation, supporting educational outcomes and healthcare excellence. ***References:*** 1.Ten Cate O. (2005). EP-1415

Evaluation of the European Kidney Function Consortium (EKFC) GFR predicting equation in Chronic Kidney Disease staging using 99mTc-DTPA measured GFR as the reference standard

G. Arsos[1], *A. Morfesi*[1], *N. Vavlas*[1], *A. Kalaitzoglou*[1], *D. Katsampoukas*[1], *K. Lazaridis*[1], *E. Manou*[2], *E. Moralidis*[1];
[1]3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou General Hospital, Thessaloniki, GREECE, [2]Nephrology Clinic, Papageorgiou General Hospital, Thessaloniki, GREECE.

Aim/Introduction: Serum/plasma Creatinine (SCr) and/or Cystatin C-based equations are useful clinical tools for GFR estimation (eGFR) and Chronic Kidney Disease (CKD) staging. During the last decades, a continuously growing number of such equation is proposed with the more recent European Kidney Function Consortium equation (EKFC, 2020) and CKD-EPI Creatinine Equation (CKD-EPI 2021) already commonly applied [1]. However, as urine/plasma clearance of exogenous tracers, remains the gold standard for GFR measurement, we aim to explore the performance of the EKCF equation in CKD staging in adult Caucasian patients, in comparison with GFR measured by 99mTc-DTPA plasma clearance (mGFR-DTPA). ***Materials and Methods:*** GFR was measured for clinical purposes in 796 adult Caucasian patients (age 18-90 years, 44.0% females, 11.9% prospective kidney donors) by 99mTc-DTPA plasma clearance (bolus i.v. injection, 3 blood samples at 2, 3 and 4 hours post-injection and monoexponential modeling according to BSNM). SCr was measured (mg/dL) with an ID-LC/MS calibrated Jaffe method. eGFR was estimated (in ml/min/1.73 m^2) by the EKFC equations (eGFR-EKCF). Patients were classified in G1, G2, G3 and G4+5 CKD stages according to mGFR-DTPA limits of ≥90, 60-89, 30-59 and <30 ml/min/1.73 m^2, respectively. The number of patients allocated in each CKD stage according to both mGFR-DTPA and eGFR-EKCF was calculated and agreement was assessed by k-statistics . ***Results:*** SCr, mGFR-DTPA and eGFR-EKCF (mean±SD) were 1.5±0.9, 57.2±26.7 and 59.8±28.2 respectively. In comparison to mGFR-DTPA CKD staging, eGFR-EKCF totally

staged correctly 582 patients (73.1%), upstaged 110 (13.8%) and downstaged 104 (13.1%), p<0.001. In a per-stage analysis, the corresponding figures were 73 (73.7%), 26 (26.3%) 0.0 (0.0%); 179 (66.5%), 27 (10.0%), 63 (23.5%); 195 (73.0%), 57 (21.3%), 15 (5.7%) and 135 (83.9%), 0 (0.0%), 26 (16.1%) for stages G1, G2, G3 and G4 respectively. ***Conclusion:*** Chronic Kidney disease staging using eGFR by EKCF equation, misclassify more than a quarter of the patients, with grossly equal up- ang downstaging contribution. As CKD staging by eGFR is common in clinical practice, supporting important decisions (nephrologic referral, drug withdrawal etc), measured GFR should be the choice when accurate CKD staging is felt to be crucial. ***References:*** 1. Pottel H, Bjork J, Courbebaisse M et al. Development and Validation of a Modified Full Age Spectrum Creatinine-Based Equation to Estimate Glomerular Filtration Rate. EP-1416

Awareness of Green Imaging and Sustainability Among Nuclear Medicine Professionals: A Cross-Sectional Study

E. Alawadhi[1], *A. Khalaf*[1], *L. Ghadanfer*[1], *M. Awadh*[1], *F. Busakher*[1], *A. Almutairi*[1], *A. Aldousari*[1], *M. Rawashdeh*[2];
[1]*Kuwait University, Kuwait, KUWAIT,* [2]*Gulf Medical University, Ajman, UNITED ARAB EMIRATES.*

Aim/Introduction: Medical imaging contributes significantly to healthcare's environmental footprint due to energy consumption, equipment use, and waste generation. Green imaging integrates eco-friendly principles into medical imaging practices. This concept has emerged in response to rising concerns regarding climate change, healthcare-related waste, and energy use in medical facilities. Despite global efforts, awareness and adoption of green imaging practices remain limited. This study aims to evaluate healthcare professionals' awareness, knowledge, and attitudes towards sustainable practices in nuclear medicine departments. Furthermore, our study seeks to identify the barriers and motivators influencing the adoption of environmentally sustainable practices. ***Materials and Methods:*** The study will use a cross-sectional survey distributed through Microsoft Forms to healthcare professionals working in nuclear medicine departments in Kuwait, including physicians, residents, technologists, technicians, nurses, pharmacists, and medical physicists. The survey was conducted anonymously over seven weeks. The questionnaire was based on a validated previous study (1). The survey had seven sections: demographics, sustainability awareness, climate change, nuclear medicine practices, barriers to sustainability, education and training needs, and open-ended questions. The online link and QR code were distributed via phone and social media. Data were analysed descriptively and inferentially. ***Results:*** A total of one hundred and seventy participants completed the survey. Our findings revealed a limited familiarity with green imaging practices, with only 9% reporting being very familiar, and 60% were unfamiliar with the concept of sustainability in medical imaging. The majority of the healthcare workers had not attended advanced training courses on sustainability or training courses on recycling before. Despite this knowledge gap, 78% of respondents recognised the importance of sustainability in healthcare and believed it positively impacts patient care and the healthcare system. Most participants agreed that the main obstacles to embracing this concept were inadequate training (35%), lack of support (31%), lack of leadership (24%), safety concerns (21%), lack of authority (15%), cost (15%), facility limitations (11%), staff attitudes (10%), and time constraints (8%), which were the least cited barriers. Respondents demonstrated a strong interest in receiving training and additional support for education related to green imaging initiatives. ***Conclusion:*** This study underscores the limited awareness of sustainable imaging practices among nuclear medicine professionals. Strengthening education and integrating eco-friendly protocols are key to advancing environmentally conscious healthcare delivery. Increasing awareness and promoting sustainable practices in nuclear medicine can significantly contribute to environmentally responsible healthcare. ***References:*** (1) Rawashdeh, M (2024). Tc^{99m}DPD SPECT/CT in Adults With ATTR CM: Three Years Experience in a Private Medical Diagnostic Center

P. Karampina[1], *A. Antonopoulos*[2], *D. Venetsanos*[2], *M. Triantafillou*[3], *V. Penesopoulou*[4], *S. Christodoulou*[1], *C. Vlachopoulos*[2];
[1]*KOSMOIATRIKI SA, Nuclear medicine dpt, Athens, GREECE,* [2]*Cardiogenetics Unit, 1st Cardiology Department, National and Kapodistrian University of Athens, Athens, GREECE,* [3]*KOSMOIATRIKI SA, radiology dpt, Athens, GREECE,* [4]*KOSMOIATRIKI SA, cardiology dpt, Athens, GREECE.*

Aim/Introduction: To prove the existence of cardiac amyloidosis through Tc99m DPD SPECT/CT. ***Materials and Methods:*** This is a retrospective study involving 62 adults (37 males, 25 females) aged 38-92 (mean age: 79.6 years) from August 2022 to April 2025. Whole body SPECT/CT bone scans were performed 150 min after the injection of 740MBq Tc99m DPD with adequate acquisition parameters. Additional static images and myocardial tomography were obtained. The collaboration was excellent. ***Results:*** 25 out of 62 adults had myocardial uptake: Grade I: 5 adults, Grade II: 4 adults, Grade III: 16 adults. 37 adults had a negative study. The cause of examination for 52 patients was cardiological issues (HF, AF, lower limb edema, hypertension, fatigue). Specifically, 29 of them had serious aortic valve stenosis and got preoparative TAVI assessment. From the remaining 10 patients, 8 got an examination because of prostate cancer and 2 to follow up on their hip replacement surgery. All 10 of them had myocardial uptake. ***Conclusion:*** Whole body SPECT/CT bone scans contribute to earlier diagnosis of ATTR CM. As a result, patients start earlier treatment, with improvement of their quality of life.

EP-1418

Head-to-Head Comparison of ^{18}F-PSMA-1007 and ^{18}F-FDG PET/CT in Metastatic Colorectal Cancer

R. Tineo, *A. Portilho, F. Zarpelao, J. Carvalheira, C. Ramos; University of Campinas, Campinas, BRAZIL.*

Aim/Introduction: ^{18}F-FDG PET/CT is a well-established imaging modality in the management of colorectal cancer (CRC). However, the search for a radiotracer with theranostic potential in CRC remains ongoing. Radiolabeled Prostate-Specific Membrane Antigen (PSMA), widely used in prostate cancer imaging and therapy, is also expressed in tumor-associated neovasculature and has demonstrated uptake in various non-prostatic malignancies. This study aimed to compare ^{18}F-FDG and ^{18}F-PSMA-1007 PET/CT imaging in patients with metastatic CRC. ***Materials and Methods:*** Five patients (three males; mean age: 69.4 ± 3.3 years) with histologically confirmed colorectal adenocarcinoma (four colonic, one rectal; two with resected primary tumors) underwent both ^{18}F-FDG and ^{18}F-PSMA-1007 PET/CT within a maximum interval of seven days. Image interpretation was performed by two nuclear medicine physicians and one radiologist. For each modality, the number and location of detected lesions, maximum standardized uptake value (SUVmax), and inter-modality concordance were assessed. ***Results:*** Primary tumor uptake was observed on ^{18}F-FDG PET/CT in all three patients with unresected lesions (SUVmax: 5.6, 32.2, and 8.5), whereas ^{18}F-PSMA-1007 demonstrated only faint uptake in one case (SUVmax: 2.0).Metastatic lesions were identified in lymph nodes, lungs, and liver, all of which showed significant FDG avidity (median SUVmax = 8.3; range: 5.3-13.4). ^{18}F-PSMA uptake was observed in metastatic sites in four patients (median SUVmax = 4.4; range: 4.0-24.4). Notably, in one patient, hepatic metastases showed higher uptake with ^{18}F-PSMA than ^{18}F-FDG

(SUVmax: 24.4 vs. 10.1); however, this uptake was perilesional and likely represented a false-positive finding due to biliary excretion and tumor-related biliary compression, as ^{18}F-PSMA-1007 is primarily hepatobiliary-excreted. ***Conclusion:*** ^{18}F-PSMA-1007 PET/CT demonstrated substantially lower sensitivity than ^{18}F-FDG PET/CT in detecting both primary and metastatic colorectal lesions. The findings suggest limited utility of PSMA-based imaging—and, by extension, PSMA-targeted theranostic approaches—in patients with metastatic CRC.

Investigating the Radiobiological Response of Combinations of DNA Repair Inhibitors with AR Suppression in Advanced Prostate Cancer

A. Alshehri*;*
Radiological Sciences Department, Collage of Applied SScience, Najran University, Najran, SAUDI ARABIA.

Aim/Introduction: Current treatment options for mCRPC are primarily based around AR suppression and taxane-based chemotherapy, however, primary or acquired treatment resistance is an inevitability. This has created an urgent need for the development of novel therapies targeting alternative molecular targets apart from the AR and microtubule, which can not only be utilised as single agents but are effective as combination therapies with current AR targeting agents such as Abiraterone and Enzalutamide. In an in vitro setting, the impact of PARP inhibitors has been well categorised, including PCa settings, there are no studies investigating the biological response of combinations of Olaparib with Abiraterone and Enzalutamide or their radiobiological response with combined with the additional effects of radiation. Such studies are important for informing future clinical study designs and eventually patient treatment. The aim of this study is to investigate the radiological response of the combination of DNAs repair inhibitors with AR suppression ***Materials and Methods:*** In vitro experiments using AR-sensitive (LNCaP) and AR-insensitive (PC3) prostate cancer cell lines, alongside osteoblastic (SJSA-1) models were conducted. The cells were treated with Radium-223 and/or AR inhibitors (Abiraterone, Enzalutamide). DNA damage and protein expression related to DNA repair through Western blotting were assessed. Additionally, cell cycle distribution and apoptosis were analyzed using flow cytometry and PARP-cleavage assays. ***Results:*** The induction of synthetic lethality through the co-inhibition of AR and PARP proves an attractive treatment option for PCa. The results have demonstrated that in an in vitro setting, combinations of Olaparib with Abiraterone or Enzalutamide showed increased efficacy over their use as single agents both with and without radiation, supported by increased levels of DNA damage and cell death. Combinations of Abiraterone and Olaparib proved to be more cytotoxic than combinations of Enzalutamide and Olaparib, highlighting the continuing evidence of increased benefit with Abiraterone over Enzalutamide. ***Conclusion:*** There is a clear need for treatment intensification in advanced PCa settings and co-inhibition with combinations of AR and PARP suppression may help overcome resistance and may be beneficial in subsets of patients harbouring DNA repair mutations. ***References:*** Jones CU, Hunt D, McGowan DG, et al (2011) Radiotherapy and Short-Term Androgen Deprivation for Localized Prostate Cancer. New England Journal of Medicine 365:107-118Zelefsky MJ, Reuter VE, Fuks Z, Scardino P, Shippy A (2008) Influence of Local Tumor Control on Distant Metastases and Cancer Related Mortality After External Beam Radiotherapy for Prostate Cancer. Ga-68 Fatty Acids as Myocardial Perfusion PET Agents

T. Ertay*, M. Kuzucu;*
Dokuz Eylul University, Izmir, TÜRKIYE.

Aim/Introduction: Developing suitable radiopharmaceuticals for PET imaging is very important for targeted biological processes. Due to the chemical properties of the Ga-68 radionuclide and its advantages such as obtaining it from the generator, there has been great progress in pet radiopharmaceuticals in labeling with the Ga-68 radionuclide recently. Fatty acids are important biomolecules that play important roles in biological systems and cause changes in the pathophysiology of myocardial diseases. The aim of this study is to label fatty acids with Ga-68 and evaluate the radiochemical efficiency of labeled. ***Materials and Methods:*** In this study, oleic acid and palmitic acid were used as fatty acid molecules for labeling with Ga-68. DTPA was used as a bifunctional chelating agent. For the synthesis of fatty acids, a homogeneous solution was obtained with NaOH solution. Then, labeled fatty acids were prepared by adding DTPA and sodium acetate solution. The 68Ga radionuclide was taken from the elution solution, added to the labeled fatty acids and heated. For labeling efficiency of the synthesized 68Ga DTPA-fatty acid components were evaluated by TLC method. Amonium Acetat and metanol (50:50) were used as mobile phases. ***Results:*** Labeled and free Ga-68 were analyzed by chromotograpy. The Rf values of labeled fatty acids with Ga-68 was observed as 0.7, while free 68Ga was observed as 0.2 in chromatography. Both molecules showed similar values. The results showed that the labeled compound could be used in PET imaging. This study may contribute to the development of new and effective radiopharmaceuticals in the field of myocardial PET imaging. In cardiovascular applications such as myocardial imaging, the use of fatty acids can provide valuable information in assessing the metabolic activity of cardiac muscle. ***Conclusion:*** In this study, the synthesis of fatty acids, their complexation with DTPA and their labeling with 68Ga radionuclide were examined in detail. The results show that fatty acids were successfully synthesized, complexed with DTPA and labeled with 68Ga radionuclide. These results indicate that Ga-68 labeled fatty acids can be used as a potential tool in biomedical imaging and diagnostic applications. Furthermore, rapid clearance of the DTPA complex from non-target organs is essential for radiopharmaceuticals designed for myocardial imaging. Integrating these features into the final design of the 68Ga-labeled fatty acid complex may provide the potential to achieve desired pharmacokinetics for cardiac metabolic imaging.

EP-1421

PET/CT protocol for Hepatocellular Carcinoma (HCC) evaluation: a multi-phase approach to improve diagnostic sensitivity

K. Shyli*, F. Firinu, A. Sotgiu, F. Casaburo, C. Serra, F. Oliverio, A. Lomartire, G. Paolacci, S. Fraschina, M. Mantovani, G. Cafiero, I. Papagni;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: The recent development of high-sensitivity systems LAFOV PET/CT enables the implementation of advanced protocols aimed at achieving a more accurate and comprehensive metabolic characterization of the hepatocellular carcinoma (HCC). This work describes an optimized clinical protocol currently in use at our Hospital Niguarda with the United Imaging Panorama GS PET/CT, combining an early dynamic acquisition, a standard scan, and a delayed scan to maximize diagnostic information and improve patient compliance. ***Materials and Methods:*** The protocol begins

with a 30-minute early dynamic acquisition immediately following ^{18}F-FDG injection (3 Mbq/kg), using a 256x256 matrix and OSEM reconstruction (3 iterations, 10 subsets, with TOF) over a 148 cm axial field of view to exploit the system's full-body sensitivity. The dynamic phase includes 25 frames: 6 × 10s, 2 × 30s, 6 × 40s, 7 × 120s, and 2 × 300s. A low-dose CT (100 kV, 30 ref. mAs) is used solely for attenuation correction, with AI-based reconstruction to enhance anatomical visualization. A 3-minute whole-body acquisition is then performed at 60 minutes post-injection using a higher-quality CT (120 kv, 60 ref. mAs). Finally, a delayed acquisition at 120 minutes is acquired with the same low-dose CT settings and AI-based reconstruction. All scans are performed with the patient's arms positioned down to minimize respiratory motion artifacts. The 30-minute dynamic scan duration is supported by literature as a balanced approach, providing sufficient metabolic data while maintaining good patient tolerability compared to longer dynamic acquisitions. Each exam produces approximately 1.5TB of data that are processed and stored after the work session. ***Results:*** This protocol was applied to 20 patients, all of whom successfully complete the exam with good tolerability. The combination of multiphase acquisitions enabled detailed temporal assessment of FDG uptake in hepatic lesions. The dynamic phase allows the analysis of tracer kinetics, particularly assessing tracer uptake in lesions. The standard acquisition provided an assessment of systemic tracer distribution, enabling the identification of potential secondary sites and comparison with the initial dynamic data. The delayed scan offered differential tracer retention analysis in suspicious lesions, useful for increasing lesion-to-background contrast and detecting low-uptake lesions early. These features allowed for a comprehensive evaluation of hepatic lesions, improving diagnostic sensitivity. ***Conclusion:*** This multiphase protocol offers a clinically sustainable and highly informative approach to HCC evaluation. The high sensitivity of the total-body PET system, combined with AI-enhanced reconstruction, supports improved diagnostic performance in clinical practice.

EP-1422

Deep Learning-Based Non-Invasive Histological Grading of Hepatocellular Carcinoma via Multi-Modal Fusion of Dual-Tracer PET/CT and Clinical Data

K. Li[1], *H. Chen*[2], *C. Ho*[1], *J. Yoo*[2], *L. Lin*[2];
[1]*Hong Kong Sanatorium and Hospital, Hong Kong, HONG KONG,*
[2]*The Hong Kong Polytechnic University, Hong Kong, HONG KONG.*

Aim/Introduction: Histological grading of hepatocellular carcinoma (HCC) critically influences patient prognosis and treatment decisions. Currently, biopsy remains the standard for grading tumors, yet it carries substantial risks including bleeding, infection, and sampling bias due to tumor heterogeneity. Multi-modal PET/CT imaging combining fluorodeoxyglucose (FDG) and acetate (ACT) tracers has demonstrated promise in reflecting tumor metabolic and proliferative activities. However, effectively integrating multi-modal imaging features with clinical data through advanced deep learning strategies to achieve automated and accurate HCC grading remains a significant challenge. ***Materials and Methods:*** This study retrospectively analyzed imaging and clinical data from a cohort of 93 patients diagnosed with HCC who underwent surgical resection or biopsy at the Hong Kong Sanatorium and Hospital. Inclusion criteria included histopathologically confirmed HCC, availability of dual-tracer PET/CT imaging (comprising [18F]FDG and [11C]ACT scans) within one month of surgery or biopsy, and histopathology reports. Histological grading served as the ground truth for model training and validation. Clinical data including demographic variables (age, sex), hepatitis status (HBV, HCV, or none), and alpha-fetoprotein (AFP) levels. To address class imbalance, focal loss was employed, and a 3-fold cross-validation strategy ensured robust performance evaluation. Dual-phase PET/CT images were processed using two parallel 3D SwinUNETR encoders: one shared PET encoder and one shared CT encoder. KL and JS divergence losses were applied between PET and CT representations to encourage inter-modality consistency. Clinical features were normalized and embedded into tokens using a multi-layer perceptron. To facilitate early fusion of imaging and clinical information, an Early Gated Cross-Attention (EGCA) mechanism was introduced to dynamically modulate modality contributions. ***Results:*** The model integrating clinical features with both ACT and FDG PET/CT imaging achieved the best performance, yielding a macro-average AUC of 0.8034 ± 0.0136 and a precision of 0.7088 ± 0.0501. Combining ACT and FDG PET/CT imaging without clinical data achieved an AUC of 0.7527 ± 0.0349 (precision: 0.6563 ± 0.0240). Integrating clinical features with ACT imaging alone resulted in an AUC of 0.6736 ± 0.0323 (precision: 0.6054 ± 0.0156), while combining FDG PET/CT with clinical features but without ACT imaging produced the lowest performance, with an AUC of 0.6381 ± 0.0248 and a precision of 0.6018 ± 0.0174. ***Conclusion:*** Our study presents a non-invasive HCC grading framework that integrates dual-tracer PET/CT and clinical data. The proposed EGCA fusion strategy enhances grading accuracy by adaptively balancing modality contributions, offering a potential alternative to biopsy and supporting more personalized clinical decisions.

EP-1423

Impact of Patient Hydration on Urinary Bladder Activity in ^{68}Ga-PSMA-11 PET/CT Imaging

R. Fendi, *A. Nasr, I. Ceric Andelius, F. Hedeer;*
Lund University Hospital, Lund, SWEDEN.

Aim/Introduction: Introduction: PSMA-PET/CT imaging is a well-established imaging modality for the detection of prostate cancer. However, varying physiological uptake patterns of different PSMA-ligands, particularly the high accumulation in the urinary bladder, can complicate the identification of tumor lesions near the bladder. Aim: The aim of this study was to determine if whether increased patient hydration before the examination reduces bladder activity, by comparing 68Ga-PSMA-11 activity concentrations in the bladder in well-hydrated patients versus those with standard hydration. ***Materials and Methods:*** Twenty-five patients scheduled for ^{68}Ga-PSMA-11-PET/CT in the afternoon were instructed to drink 1-1.5 liters of water at home in the morning of the examination day and an additional 1 liter of water on-site prior to imaging. Another twenty-five patients served as the control group; they received no specific instructions regarding water intake at home and drank 1 liter of water on-site only. Images were analyzed using HERMIA Hybrid Viewer (Hermes Medical Solutions, Stockholm, Sweden). Multiple regions of interest were drawn around the bladder and merged into a volume of interest (VOI). A Mann-Whitney U-test was performed on the extracted VOI:s for SUVmean, SUVmax and SUVpeak (1 cm3) to assess differences between the two groups, where a p-value of <0,05 was considered to indicate statistical significance. ***Results:*** No statistically significant differences were observed in SUVmean, SUVmax, or SUVpeak between the well-hydrated and control groups. The median SUVmean was 10.8 vs. 10.4 (p = 0.60), SUVmax was 20.3 vs. 14.3 (p = 0.11), and SUVpeak was 17.7 vs. 14.3 (p = 0.41), respectively. ***Conclusion:*** For patients undergoing ^{68}Ga-PSMA-11-PET/CT, consuming additional water before the examination does not significantly reduce the physiological activity in the urinary bladder.

EP-1424

Impact of different Chemotherapeutic agents on baseline SUV of Liver and Blood Pool in Hodgkin Lymphoma Patients.

R. Nawaz, *S. Nausheen, N. Ihsan, R. Kaleemi, N. Ahmed, T. Mahmood;*
Jinnah Postgraduate Medical Center, Karachi, PAKISTAN.

Aim/Introduction: Background: Standardized Uptake Value (SUV) measurements in FDG PET/CT play a pivotal role in the staging and response assessment of Hodgkin Lymphoma (HL). Baseline SUV levels in the liver and mediastinal blood pool serve as key reference points in response criteria such as Deauville scoring. However, variations in SUV due to pre-treatment with different chemotherapeutic agents may affect interpretation and clinical decision-making. Objective: This study aims to evaluate the impact of various chemotherapeutic regimens on baseline SUV measurements of the liver and mediastinal blood pool in patients diagnosed with HL. ***Materials and Methods:*** Methods: A retrospective analysis was conducted on HL patients who underwent baseline FDG PET/CT imaging after administration of different chemotherapeutic agents. Patients were grouped based on the type of induction chemotherapy received prior to imaging. SUVmean and SUVmax of the liver and blood pool were measured and compared across groups using statistical analysis to determine significant variations. ***Results:*** Preliminary findings suggest that certain chemotherapeutic agents, particularly those with hepatotoxic or metabolic effects, influence baseline liver and blood pool SUV values. Variations were observed in both SUVmean and SUVmax, with statistically significant differences in select groups. ***Conclusion:*** The type of chemotherapeutic agent administered prior to baseline FDG PET/CT imaging may alter physiological FDG uptake in reference organs, potentially impacting Deauville scoring and therapeutic assessment in HL. Standardization or adjustment for such effects may be necessary for more accurate interpretation of PET/CT results. ***References:*** 1. Gallamini A, Barrington SF, Biggi A, et al. Role of FDG PET-CT in Planning Therapeutic Intervention in Hepatocellular Carcinoma (HCC).

R. Nawaz*, R. Kaleemi, S. Nausheen, N. Ihsan, N. Ahmed, T. Mahmood;*
Jinnah Postgraduate Medical Center, Karachi, PAKISTAN.

Aim/Introduction: Intorduction: Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide, often diagnosed at an advanced stage. While conventional imaging modalities like CT and MRI play a critical role in HCC diagnosis and staging, the integration of metabolic imaging through 18F-fluorodeoxyglucose positron emission tomography-computed tomography (FDG PET-CT) offers additional insights that can refine therapeutic planning.Objective:To evaluate the utility of FDG PET-CT in influencing therapeutic decision-making in patients with HCC by assessing metabolic activity, detecting extra-hepatic spread, and identifying aggressive tumor phenotypes. ***Materials and Methods:*** A prospective analysis was conducted on HCC patients undergoing FDG PET-CT prior to therapy. Imaging findings were correlated with locoregional therapies (TACE/RFA). Parameters such as SUVmax, tumor-to-liver ratio (TLR), and presence of distant metastases were assessed. ***Results:*** FDG PET-CT demonstrated added value in 32% of cases by altering the therapeutic approach, most notably by detecting extrahepatic metastases not identified on conventional imaging. High FDG uptake was associated with poorly differentiated HCC and unfavorable prognostic markers. PET findings led to avoidance of futile surgical or locoregional interventions in a significant subset. ***Conclusion:*** FDG PET-CT is a valuable adjunct in the therapeutic planning of HCC, offering metabolic characterization that complements anatomical imaging. It aids in refining staging, guiding personalized treatment strategies, and potentially improving clinical outcomes. ***References:*** Khan MA, Combs CS, Brunt EM, Lowe VJ, Linehan DC, Lawrence TS, et al. Comparison of two vs one CT for attenuation correction in myocardial MPS SPECT/CT imaging on a system with Smartzoom collimators

C. Kullberg[1]*, S. Kvernby*[2]*, F. Hedeer*[1]*, H. Mosén*[1]*, S. Saran*[1]*;*
[1]Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund, SWEDEN, [2]Radiation Physics, Department of Haematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden, Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, Sweden, Lund, SWEDEN.

Aim/Introduction: In myocardial perfusion SPECT (MPS) imaging, photons attenuated within the patient may give a false imaging of the heart and also affect the clinical decision. Using low-dose CT the MPS imaging can be corrected for attenuation by a density map. Normally the CT is done consecutively with the MPS imaging in a SPECT/CT scan, both in the stress and rest. We want to see if it is possible to lower the radiation exposure to patients doing single CT for both scans.The aim was to investigate if using a single CT, acquired from the stress acquisition, for attenuation correction in both stress and rest images results in the same clinical assessment. ***Materials and Methods:*** A total of 13 patients (5 women; BMI range 19-40, mean 26) referred for a clinical stress/rest MPS due to suspected ischemic heart disease were included. Patients were scanned with one day protocol using ^{99m}Tc-Tetrofosmin on a SPECT/CT camera with Smartzoom collimators. Attenuation correction of the MPS images was applied in two different ways: 1. With attenuation maps acquired from both stress and rest low-dose CT acquision respectively, and 2. With attenuation map from low-dose CT stress-imaging applied for both the stress and rest MPS images. All images were analyzed in QGS/QPS (Cedars Sinai) and Summed Stress Score (SSS), Summed Rest Score (SRS) and Summed Difference Score (SDS) were obtained together with individual perfusion values, normalized to a database from healthy population, representing the 17-segment model were measured. Differences between the methods were evaluated using paired

t-test. Two senior physicians performed a holistic visual assessment of all images in consensus, blinded to the attenuation correction method applied. Findings were graded as none ischemic, mild ischemic, ischemic, infarction. The vessel territory (LAD, RCA, LCx) was also stated in the case of decreased perfusion. ***Results:*** There were no significant differences (p>0.05) in perfusion scores between the two attenuation correction methods in any of the 17 segments in any patient. The visual assessment was identical in 11 out of the 13 patients. However, in two patients there was a difference in the visual assessment, where both patients changed from ischemic to mild ischemic, and in one of them a suspected infarction was missed. ***Conclusion:*** Using the same low-dose CT for attenuation correction in stress and rest MPS imaging is feasible in a majority of cases, however, in some cases the interpretation of the examination may be altered.

Intergrated Nuclear Medicine Imaging Assessment of Amyloid Burden, Sympathetic innervation, and Microvascular function in ATTR-CM

T. Lee[1], *Y. Chen*[1], *Y. Huang*[1], *A. Yu*[2], *C. Tsai*[2], *M. Su*[3], *S. Hsieh*[4], *C. Chao*[4], *Y. Lin*[2], *K. Ko*[5], *M. Cheng*[1];
[1]*Department of Nuclear Medicine National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [2]*Department of Internal Medicine, Division of Cardiology National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [3]*Department of Medical Imaging National Taiwan University Hospital, Taipei City, TAIWAN,* [4]*Department of Neurology National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei City, TAIWAN,* [5]*Department of Nuclear Medicine National Taiwan University Cancer Center, Taipei City, TAIWAN.*

Aim/Introduction: Hereditary transthyretin amyloid cardiomyopathy (ATTR-CM) is an inherited disorder characterized by the deposition of misfolded transthyretin (TTR) proteins in the myocardium. The progressive amyloid accumulation impairs myocardial tissue and autonomic nerve terminals. Technetium-99m-labeled pyrophosphate (Tc-99m PYP) scintigraphy is widely used for diagnosing ATTR-CM by both visual scoring and quantitative uptake ratios. I-123 metaiodobenzylguanidine (I-123 mIBG) scintigraphy provides information on myocardial sympathetic innervation, while dynamic myocardial perfusion imaging (MPI) enables quantitative evaluation of coronary microvascular function. Despite the clinical relevance of these modalities, few studies have integrated them to explore their interrelationships in ATTR-CM. ***Materials and Methods:*** Patients with genetically confirmed or highly suspected ATTR-CM underwent Tc-99m PYP scintigraphy, I-123 mIBG scintigraphy, dynamic MPI, echocardiography, and NT-proBNP testing. Quantitative imaging parameters included the heart-to-contralateral (H/CL) ratio, heart-to-lung (H/L) ratio, and standardized uptake value (SUV) from PYP scans; early and delayed heart-to-mediastinum ratios, as well as the washout ratio, from mIBG scans; and resting/stress myocardial blood flow (MBF) along with myocardial perfusion reserve (MPR) from MPI. Correlation analyses were performed using Spearman's rank correlation coefficient. ***Results:*** Eleven male patients (mean age 62.3 ± 12.8 years; 8 with A97S, 1 with Val30Met, 1 with E66D, and 1 wild-type) were enrolled. Eight patients had positive PYP scans (visual score ≥2). The mIBG washout ratio was significantly positively correlated with NT-proBNP ($\rho = 0.697$), interventricular septal thickness ($\rho = 0.636$), left ventricular posterior wall thickness in diastole ($\rho = 0.673$), and amyloid burden, as measured by multiple Tc-99m PYP uptake parameters: H/CL ratio ($\rho = 0.697$), H/L ratio ($\rho = 0.729$), and SUV ($\rho = 0.747$) (all $p < 0.05$). Among these patients, six completed dynamic MPI. Global post-stress MBF and MPR values showed a negative correlation with amyloid burden, although the associations did not reach statistical significance. In contrast, global resting MBF was significantly negatively correlated with H/CL ratio ($\rho = -0.886$), H/L ratio ($\rho = -1.000$), and SUV ($\rho = -0.943$) (all $p < 0.05$). A non-significant negative relationship was also observed between resting MBF and the mIBG washout ratio. ***Conclusion:*** Multimodal nuclear imaging offers comprehensive insights into ATTR-CM pathophysiology. Sympathetic denervation, as indicated by the mIBG washout ratio, is closely associated with both amyloid burden and functional markers. Furthermore, resting myocardial blood flow might be related with sympathetic innervation appears impaired in proportion to amyloid deposition. These findings highlight the potential utility of integrated imaging in ATTR-CM assessment.

EP-1428

Semi Automated fusion technique to create PET-MRI like dataset in Cardiac & Pelvic pathologies, in a limited resource setting.

R. Nawaz*, S. Nausheen, R. Kaleemi, N. Ihsan, N. Ahmed, T. Mahmood;*
Jinnah Postgraduate Medical Center, Karachi, PAKISTAN.

Aim/Introduction: PET-CT is an established yet valuable imaging tool for staging prostate cancer. Its applications are extending beyond just staging and response evaluation of cancer. Its role in infection & inflammation is well established. Major challenge for PET-CT in pelvis and Cardiac imaging is limited anatomic information, where growing demand of PET-MRI is being observed. But acquisition of PET-MRI is not a financially viable option due to its excessive capital & operational cost. Objective: To evaluate the benefits of semi-automated fusion technique to generate PET-MRI like dataset in pelvic & cardiac PET-CT. ***Materials and Methods:*** This prospective study included 25 patients who underwent both CMR and PET-CT scans for Cardiac Imaging (17), a PSMA PET-CT and routine Pelvis MRI for prostate (08).Cardiac FDG PET-CT was predominantly performed to rule out Cardiac Sarcoidosis, with an already available CMR, the delayed GAD Axial T1 dataset was manually fused with TOF-AC PET.Similarly, a PSMA PET-CT was performed for staging of Prostate cancer and an MRI performed during prior workup was utilized, and AX T2 dataset was manually fused with TOF-AC PSMA PET. ***Results:*** By manually fusing MRI dataset with ^{18}F-FDG Cardiac PET & 18F-PSMA-1007 prostate PET, significant advantage was observed at lung myocardium interface & capsular/lymphatic anatomy respectively. Which otherwise pose a major challenge to rule out on PET-CT dataset. ***Conclusion:*** In our patient pool we observed although PET-MRI has an added advantage of simultaneous acquisition as well as multiparametric MRI being a decider. But in a limited resource setting manual fusion technique can add value and PET-MRI like dataset gives a better insight of anatomy compared to a PET-CT. ***References:*** 1. Yuji Nakamoto et al. Comparison of Specific Binding Index of Regional DaTSCAN Imaging vs. MRI Striatal Volumetric Measurements

K. Priftis[1], *M. Paphiti*[2], *A. Zafeirakis*[3], *K. Roussopoulos*[4,1], *G. S. Limouris*[4,3];
[1]*Nucl Med Dept, Central Clinic, Athens, GREECE,* [2]*Cyclotron Section, Pharmazac SA, Athens, GREECE,* [3]*Nucl Med Dept, Army Share Fund Hospital of Athens, Athens, GREECE,* [4]*Nuclear Medicine, Medical School, National and Kapodistrian University, Athens, GREECE.*

Aim/Introduction: In vivo neuroimaging techniques in correlation with MRI imaging, offers a potential which can reliably assess early clinical and pre-clinical diagnosis in Parkinson's disease. The aim of this study was to compare striatal's volume from MRI volumetric measurements with the Specific Binding Index (SBI) from regional DaTSCANS results. ***Materials and Methods:*** In thirty five patients both dopaminergic imaging using I123-FP-CIT SPECT and MRI scanning were performed. Specific Binding Index (SBI) has been calculated from regional DaTSCAN both for left and right striatum respectively, by applying the formulas: SBI left=(Cv left/ Cb-Vv)/Vs and SBI right=(Cv right/ Cb-Vv)/ Vs where: Cv left: total counts in left striatum ROI, Cv right: total counts in right striatum ROI Cb: total counts in background region divided by volume of the background region. Vv: Volume of ROI, Vs: Volume of standard striatum (set to 11.2 ml) MRI imaging has been evaluated by employing highspatial resolution T2- weighted sequence such as T2- weighted/ Gradient-SpinEcho followed by a contiguous echo planar imaging sequence at the mid-brain striatal level in sagital projection. Multi- planar reconstruction images have been analysed and volumetric measuerements created in order to compare volume in relation to the SBI results. Statistical significance of these results was assessed using the Mann-Whitney test. ***Results:*** The overall results show a significant relation between the two imaging modalities for discriminating normal, Parkinsonian Syndromes (PS) and Essential Tremor (ET) patients . The following table represents the: average % decrease of striatum volume according to MRI, DaTSCAN Striatal SBI and Vissual Assessement. Category of Patients DaTSCAN SBI MRI volume Vissual Assessement ET -14.0 % (p=0.023) - 12.5% (p=0.05) 5-15 % PD -27.7 % ((p=0.04) -26.5% (p=0.007) >15 ***Conclusion:*** Morpho-functional combination with MRI-DaTSCAN imaging in PS and/or ET patients increases the accuracy of the diagnostic information and optimizes the management of the applied therapeutic scheme.

Specific Challenges and Considerations in Pediatric Nuclear Medicine imaging

S. Kosta[1], *F. Mitsikoudi*[1], *E. Konstantarogianni*[1], *I. Sevaslidou*[2];
[1]*Children Hospital Agia Sofia Athens, Athens GREECE,* [2]*General Hospital Laiko, Athens, GREECE.*

Aim/Introduction: This presentation aims to describe the special features and difficulties of performing nuclear medicine imaging in children. It focuses on how children differ from adults in terms of body development and behavior, and how these differences affect the way we perform and interpret imaging exams. ***Materials and Methods:*** This overview is based on real clinical experience from a pediatric nuclear medicine unit. It includes children of all ages—from newborns to teenagers. It discusses how radiopharmaceuticals behave differently depending on the child's age and stage of development, and the challenges we face in helping children stay still and calm during the exam. It also presents techniques such as using music or videos, involving parents, adjusting the environment, giving sedation when needed, and calculating the correct dose based on the child's weight and age. ***Results:*** Each child needs a different approach depending on their age and emotional state. Babies and young children often need comfort or sedation to remain still. Teenagers, especially those with serious illnesses like cancer, may be anxious or scared. Mistaking normal findings (like growth plates or the thymus) for disease is a common risk. Giving the right amount of radiopharmaceutical is very important to get good images while keeping radiation exposure as low as possible. ***Conclusion:*** Imaging in pediatric nuclear medicine needs special knowledge, patience, and good communication. Understanding how children's bodies and minds work helps healthcare professionals get accurate results with less stress for the child. Working closely with parents, using age-appropriate techniques, and training the medical team are key to safe and successful imaging.

EP-1431

Evaluation of the Efficacy of Treatment of Metaiodobenzylguanidine (131I-mIBG) in Pediatric Neuroblastoma

M. Garcia Arevalo, *E. Martínez Montalbán, R. Maestre Cutillas, J. García Álvaro, J. Nieto Margareto, B. Martínez de Miguel; Hospital Universitario La Paz, Madrid, SPAIN.*

Aim/Introduction: Neuroblastoma represents a therapeutic challenge due to its biological and clinical heterogeneity. The aim of the study is to evaluate the efficacy of ^{131}I-mIBG treatment in pediatric patients diagnosed with very high-risk neuroblastoma (VHR-NBL) refractory to standard induction chemotherapy (vincristine, cyclophosphamide, cisplatin) treated with high-dose ^{131}I-mIBG in combination with topotecan and subsequent bone marrow transplantation. ***Materials and Methods:*** In our Unit, a therapeutic protocol combining the use of ^{131}I-mIBG with topotecan followed by myeloablative therapy is applied. We have studied twelve paediatric patients (<14 years), who have met the criteria for inclusion of treatment: tumour uptake of ^{1}23I-mIBG, no bone marrow infiltration and haemogram with pancytopenia. Two cycles of 12 MBq/Kg of ^{131}I-mIBG combined with topotecan are administered separated by two weeks, reaching a maximum tumor dose of 4 Gy. Finally, myeloablative therapy is performed for haematological recovery. Patients are followed up to a maximum of 2 years. ***Results:*** Among the twelve pediatric patients: Seven patients (58.3%) were aged between 4 and 7 years at the time of administration of the first dose of ^{131}I-mIBG: Three patients (42.9%) achieved an overall survival (OS) of two years, with one of these (33.3%) maintaining progression-free survival (PFS) throughout the two-year follow-up. Two patients (28.6%) achieved OS of 1.3 years and 8 months, with only one of these (50%) reaching PFS of 1.3 years; the study is still ongoing for these cases. Two patients (28.6%) could not complete the treatment as a consequence of clinical decompensation, dying as a result of disease relapse and haemodynamic instability. Five patients (41.6%) were aged between 8 and 14 years at the time of administration of the first dose of ^{131}I-mIBG: • Four patients (80%) achieved both OS and PFS of two years. • One patient (20%) is still disease-free six months post-treatment. ***Conclusion:*** Treatment with ^{131}I-mIBG combined with topotecan and followed by myeloablative therapy demonstrates efficacy and safety in pediatric patients with very high-risk neuroblastoma (VHR-NBL), achieving high OS and PFS rates, especially in patients older than 8 years. Despite the heterogeneous outcomes observed in the 4-7 year-old group, the majority attained a favourable response to treatment, confirming its suitability for this pathology.

EP-1432

Evaluation of BroadQuant Quantification accuracy for Lu-177 post-therapy SPECT-CT dosimetry

E. C. Streefkerk, *M. C. Dekker, M. Dotinga, E. A. Aalbersberg; The Netherlands Cancer institute, Amsterdam, NETHERLANDS.*

Aim/Introduction: With the rise of nuclear medicine therapies, quantification and dosimetry is becoming increasingly important. Originally, quantification methods involved the use of a system-specific calibration factor. In 2021 new SPECT-CT systems were acquired at our institute where BroadQuant quantification (Siemens) became available. The aim of this study is to compare BroadQuant quantification for dosimetry with the clinical quantification method with the use of a calibration factor on ^{177}Lu post-therapy SPECT-CT. ***Materials and Methods:*** A reference vial with a predetermined amount of ^{177}Lu activity is placed next to the patient during the ^{177}Lu post-therapy SPECT-CT. Scans were reconstructed according to the in-house clinical protocol. For BroadQuant quantification, an X-SPECT reconstruction was made, with equal reconstruction parameters to the clinical reconstruction. Both images were analyzed with Medical Image Merge (MIM) software, using a 10% threshold of the maximum voxel value within the reference vial. For the clinical quantification, the system-specific calibration factor was used to convert the counts in the VOI to Bq. For the BroadQuant quantification the activity in the VOI was given in Bq. Both results were compared to the known activity in the reference vial at the acquisition time of the scan. Results were analyzed in SPSS using the Shapiro-Wilk Test to determine normality and the Wilcoxon Signed Ranked Test to compare the difference from the true value. ***Results:*** A total of 38 scans were analyzed, with a reference source of 72-110 MBq. Both quantification methods were used to calculate the activity in the reference vial and compared to the true known activity in the reference vial. Quantification using clinical reconstruction and the system-specific calibration factor had a median deviation of -11.45% [IQR: -12.70 to -10.56] compared to the true known activity. BroadQuant quantification had a median deviation of 0.02% [IQR: -2.03 to 1.95] compared to the true known activity ($p<0.001$). ***Conclusion:*** Reference vial measurements on SPECT-CT imaging showed a significant increase in accuracy when using BroadQuant quantification compared to clinical quantification using a system-specific calibration factor.

EP-1433

The Optimization of Lutitium-177 Tomography for Systems Lacking Medium Energy Collimator

L. Jicheng[1], *J. Li*[2]*;*
[1]*lanzhou university, lanzhou, CHINA,* [2]*Department of Nuclear Medicine of the Second Hospital of Lanzhou University, lanzhou, CHINA.*

Aim/Introduction: This study aims to investigate the optimal scanning parameters for Lutetium-177(177Lu) using SPECT/CT with a Low Energy High Resolution (LEHR) collimator, specifically for hospitals that do not have a Medium Energy General Purpose (MEGP) collimator. ***Materials and Methods:*** This study comprised both phantom and clinical tests. Phantom tests compared LEHR parameters (shoot times: 20s/25s/30s; step angles: 3-degree/6-degree(3°/6°); triple energy window [TEW]: main 113keV±10%, scatter 96.6/132keV±5%) with MEGP protocols (20s/25s; 6°; five energy windows: main 113keV/208keV±10%, scatter 96.6/132/174keV±5%). Data were reconstructed using OSEM (2 iterations, 10 subsets) with CT attenuation correction, resolution recovery, and scatter correction (TEW for LEHR, TEW/Dual Energy Window for MEGP). Differences in visual scores (VS) of image quality, coefficient of variance (COV) of the background, image signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and the absolute error of sphere uptake versus actual pharmaceutical concentration (AEU) were compared between different acquisitions using the LEHR collimator and those using the MEGP collimator. In the clinical tests, five patients injected with 177Lu-CTR-FAPI were enrolled. Differences in VS of image quality, image SNR, CNR, and standardized uptake value (SUV) of lesions were compared between the corresponding acquisition combinations using the LEHR collimator and those using the MEGP collimator. ***Results:*** In the phantom study, there were no significant differences in the VS of image quality, image SNR, and CNR between MEGP-20s-6°/MEGP-25s-6° and LEHR-25s-3° ($P > 0.05$). Similarly, there were no significant differences in COV between MEGP-20s-6°/MEGP-25s-6° and LEHR-30s-3° ($P > 0.05$). No significant differences in AEU were found between MEGP-20s-6° and LEHR-25s-3° ($P > 0.05$), nor between MEGP-25s-6° and all LEHR acquisition combinations ($P > 0.05$). The background COV and AEU of all MEGP and LEHR acquisition combinations increased as the sphere size decreased, while image SNR and CNR decreased as the sphere size decreased. In the clinical tests, no significant differences were found between traditional MEGP-20s-6°/MEGP-25s-6° and LEHR-25s-3° in the VS of image quality, background COV, image SNR, CNR, and SUV of high uptake lesions ($P > 0.05$). ***Conclusion:*** For 177Lu scanning in SPECT/CT equipment without a Medium Energy General Purpose Collimator, it is recommended to use a tomography acquisition with a 25s "shoot" acquisition and a 3-degree "step" over a 360-degree rotation, utilizing triple energy window scatter correction: main 113keV±10% , scatter 96.6/132keV±5%.

EP-1434

Implementation of the double-contrast protocol to facilitate intraoperative detection of the sentinel lymph node in robotic laparoscopic prostate surgery

A. Afonso de Matos[1], *S. Castanyer Serra*[2], *M. Negre Busó*[2], *M. Santiesteban Gutiérrez*[2], *N. Ferran Sureda*[2], *A. Rubió Rodríguez*[2]*;*
[1]*Medicina Nuclear-ICS, Hospital Universitario Dr. Josep Trueta, Girona, SPAIN,* [2]*Medicina Nuclear-IDI, Hospital Universitario Dr. Josep Trueta, Girona, SPAIN.*

Aim/Introduction: Sentinel lymph node biopsy in the prostate is a complex technique that presents logistical and methodological challenges, as well as a greater learning curve compared to other anatomical regions. One of the main difficulties lies in adapting to robotic-assisted laparoscopic surgery, which involves a different surgical field approach than conventional procedures.Our aim was to evaluate the feasibility of a new dual-contrast protocol designed to more accurately replicate intraoperative conditions, thereby helping to overcome the aforementioned challenges. ***Materials and Methods:*** The radiotracer (4-5 mCi of 99mTc-nanocolloid) was administered via two ultrasound-guided intraprostatic injections, one in each prostatic lobe, the day before surgery. Planar images were acquired at 15 minutes and 4 hours post-injection (120 seconds per image, matrix: 256x256, zoom: 1, collimators: Low Penetration High Resolution - LPHR). Subsequently, a SPECT scan was performed (12 seconds per frame in continuous mode, with a total of 60 images, matrix:128x128, zoom: 1 LPHR collimator), followed by a CT scan (scout: 512 mm of length and 0.6 mm of slice thickness, 25 mA and 110 kV; CT: performed using dose right, 100 mAs and 130 kV, rotation time: 0.6 seconds, slice thickness: 5 mm, pitch: 1.5). During image acquisition, an intravenous contrast agent was manually injected: 30-40 mL approximately 7-8 minutes before the CT scan (excretory phase), followed by a second bolus immediately before the CT acquisition (arterial phase). Images were reconstructed and fused using dedicated reconstruction software, generating a customized template adapted to the anatomical density of each region. ***Results:*** By applying the dual-contrast protocol, we achieved clear visualization of both the ureters and the regional arteries. This enabled a more precise anatomical understanding, and therefore for a more efficient radioguided localization of the sentinel lymph nodes.The subsequent three-dimensional image reconstruction provided a highly accurate representation of the intraoperative findings. These images could

be adjusted and oriented to match the surgical view during the procedure, offering a reliable surgical roadmap. ***Conclusion:*** The implementation of an intravenous dual-contrast protocol combined with anatomically accurate three-dimensional reconstruction improves the correlation between imaging and the surgical field, enhances preoperative planning and facilitates the adaptation of the nuclear medicine physician to the surgical environment.

EP-1435

Uncertainty in a simplified method for quantifying the in vivo distribution of radiopharmaceuticals

H. Sagara[1,2], *K. Takizawa*[2], *K. Tani*[2], *K. Inoue*[2];
[1]*Department of Radiological Technology, Tsukuba International University, Ibaraki, JAPAN,* [2]*Department of Radiological Sciences, Tokyo Metropolitan University, Tokyo, JAPAN.*

Aim/Introduction: Accurate assessment of internal doses from radiopharmaceuticals typically requires extensive medical imaging and complex data analysis by professionals, which can be time-consuming and increase the workload for medical staff as well as the effort required from patients [1]. This study aims to evaluate the uncertainty associated with a simplified method for assessing the in vivo distribution of radiopharmaceuticals, as part of personalized internal dose assessments that account for individual metabolic differences. ***Materials and Methods:*** ^{99m}Tc (4 kBq/mL) was enclosed in each organ (heart, liver, kidneys, and tumor) of the thorax phantom (Kyotokagaku) [2], and planar images were acquired for 10 minutes using the two gamma cameras of the SPECT/CT system Symbia Intevo Excel (SIEMENS). The radiation transport calculation code MCNP ver. 6.2 was used to model the two gamma cameras [3] and reproduce their counting rates for each organ within the voxel phantom, which was generated from the CT images of the thorax phantom. To evaluate the uncertainty in qualifying radioactivity distributed in the body, based on the simplified assumption that the average counting efficiency between two gamma cameras is constant, the study examined the variation in the counting efficiencies, assuming radiopharmaceutical accumulation in a tumor located arbitrary within the voxel phantom. ***Results:*** The uncertainty associated with quantifying the in vivo distribution of radioactivity, based on the average counting rates of two gamma cameras, was estimated to be within several tens of percent.[Conclusion] By accepting a certain level of uncertainty, internal dose assessments that account for individual metabolism are expected to be implementable in clinical practice with minimal additional effort required from patients and medical staff. ***Conclusion:*** By accepting a certain level of uncertainty, internal dose assessments that account for individual metabolism are expected to be implementable in clinical practice with minimal additional effort required from patients and medical staff. ***References:*** 1)Stokke, C., Gabiña, P.M., Solný, P. et al. EP-1436

The Impact of Reconstruction Parameters on Image Quality and Quantification in PET/CT Using a Wax Phantom

S. Hadzimusic*, A. Begić, A. Beganović, A. Skopljak-Beganović, N. Salkica, Š. Cerić, S. Agić-Bilalagić, A. Arnautović-Halimić, B. Tukić; Clinical Center of the Sarajevo University, Sarajevo, BOSNIA AND HERZEGOVINA.*

Aim/Introduction: Body mass significantly impacts standardized uptake value (SUV) in PET/CT imaging, underscoring the need for refined quantification methods. This study introduces a beeswax-based module applied to a standard NEMA IQ phantom to simulate increased patient body mass. Beeswax was chosen for its similarity to adipose tissue in both physical and radiological properties. ***Materials and Methods:*** PET/CT scans were performed using the standard phantom, with and without the beeswax layer, under consistent low-dose protocols. Three reconstruction techniques were applied. Quantitative assessment focused on F-18 FDG uptake in four hot spheres (10-37 mm). Emphasis was placed on SUVmax and SUVmean to evaluate the beeswax module's impact on measurement accuracy and reproducibility. ***Results:*** Notable differences in SUV values were observed between the standard and beeswax-enhanced phantoms, particularly under varied reconstruction settings. These findings validate the beeswax module as a reliable surrogate for simulating increased body mass, demonstrating its potential for optimizing PET/CT protocols in overweight and obese patients. ***Conclusion:*** SUVmean values were higher in the beeswax-modified phantom, reflecting the influence of increased body mass. However, adjusting for lean body mass (SUVlbm) minimized these discrepancies, isolating the effect to actual tracer concentration. These results highlight the importance of SUV correction and support the development of refined imaging protocols tailored to body composition changes, especially in oncology follow-ups. The beeswax module offers a practical tool for improving PET/CT quantification in diverse patient populations.

EP-1437

A Promising Alternative: 2-Minute Respiratory-Gated Total-Body PET Fast Imaging Protocol for Malignancy Patients

X. Hou*, G. Liu, S. Chen, H. Shi;*
Zhongshan Hospital Fudan University, Shanghai, CHINA.

Aim/Introduction: The study aimed to explore the viability of a fast imaging protocol for respiratory-gated total-body 2-[^{18}F]-fluoro-2-deoxy-D-glucose (^{18}F-FDG) positron emission tomography/computed tomography (PET/CT) in patients diagnosed with malignancies. ***Materials and Methods:*** Seventy-two patients with malignancies underwent total-body ^{18}F-FDG PET/CT scans that lasted for 10 minutes, during which their respiratory waveforms were meticulously recorded. Four image reconstructions were conducted: Ungated-10 using all coincidences, Ungated-5 using data of the first 5 minutes, Gated-10 using all coincidences from the entire 10 minutes with respiratory gating, and Gated-2 using data of the first 2 minutes but with respiratory gating. In the respiratory gating process, the quiescent period, which retained half of the coincidence events, was selected as the gating window. Subsequently, the image quality of each reconstruction was systematically evaluated, and the lesions detected were precisely quantified. These assessments were then compared across the four different image sets to identify any significant differences. ***Results:*** A total of 413 lesions were detected, of which Gated-10 revealed a significantly higher number of lesions (397, 96.1%) compared to Ungated-10 (380, 92.0%; $P < 0.001$) and Ungated-5 (375, 90.8%; $P < 0.001$). However, comparable to thoese of Gated-2 (388 vs. 397, $P = 0.121$). When it came to lesion quantification, lesions in Gated-10 exhibited significantly higher maximum, mean, and peak standardized uptake values (SUV_{max}, SUV_{mean}, SUV_{peak}), as well as higher tumor-to-liver and tumor-to-blood ratios, compared to those in Ungated-10 and Ungated-5 (all P values < 0.05). In contrast, the metabolic tumor volume was smaller in Gated-10 relative to the ungated counterparts. Notably, there were no significant differences in any of these quantitative indices between Gated-10 and Gated-2. Additionally, while the background noise was higher in the gated images compared to the ungated images, it remained at an acceptable level for diagnostic purposes. ***Conclusion:*** The

findings suggest that a 2-minute respiratory-gated total-body PET fast imaging protocol outperforms ungated imaging techniques. This implies its potential as an alternative and more efficient approach for oncological imaging, providing a viable means to expedite diagnosis without compromising diagnostic accuracy.

EP-1438

Impact of uptake time on image quality in Positron Emission Tomography /Computed Tomography (PET/CT) among Non-Hodgkin's Lymphoma (NHL) patients

H. J. K. V. Y Wijerama[1], *D. D. N. Wimalarathne*[1], *R. R. K. Prabash*[1], *K. K. I. N. Somasiri*[1], *W. C. Perera*[2], *S. P. D. Wijethunga*[2], *J. M. C. Udugama*[3];
[1]*General Sir John Kotelawale Defence University, Ratmalana, SRI LANKA,* [2]*Apeksha Hospital, Maharagama, SRI LANKA,* [3]*Lanka Hospital PLC, Colombo 05, SRI LANKA.*

Aim/Introduction: Non-Hodgkin's Lymphoma (NHL) is a type of malignancy that develops in the lymphatic system.^{18}F-FDG whole-body PET/CT imaging is essential in the diagnosis and management of NHL. Thus, it is important to identify the factors affecting on lesion detection process for delivering accurate diagnosis. Amongst uptake time is a significant factor. ***Materials and Methods:*** A descriptive-cross-sectional, retrospective study was conducted by using the database (DB) of the PET/CT unit of the radiology department at Apeksha Hospital, Sri Lanka. First, we screened the 53 NHL patients from the DB and their uptake time was noted. Lesion detection was performed by two experienced radiology technologists. And counted the number of lesions that could be seen. SUV_{max}, $SUV_{mean,}$ and SUV_{SD} in lesions were obtained by using the Oncology version software. SNR, CNR and contrast enhancement were calculated by using standard formulas. All the anonymously collected data were input into Microsoft Excel, and the uptake time was categorized into 4 groups separately. The groups were labelled as T1(45-60) min, T2(61-76) min, T3(76-90) min, and T4(91-105) min. The statistical analysis was done using IBM SPSS 27.0 software. ***Results:*** In the sample of 181 lesions, the mean uptake time and SNR were 84.81 ±8.707 min, 0.7404 ± 31.085, respectively. The statistical analysis was performed by using the Spearman correlation. All the uptake time groups show a positive relationship with SNR. For the T1, the correlation between uptake time and SNR is ($p = 0.002$). In T2, ($p = 0.001$). The T3($p = 0.001$), and for the T4, ($p = 0.004$). ***Conclusion:*** According to the T1, the SNR slightly improves as the uptake time increases within this range. As the uptake time extends to T2, the SNR improves more noticeably as the uptake time increases. And this trend continues in T3, where the strongest correlation is observed. This indicates that extended uptake time has the most substantial impact on improving SNR. However, in T4, extended uptake time has not significantly enhanced SNR. Overall, the relationship between uptake time and SNR is strongest between 61-90 mins, Thus, our results suggest the optimum uptake time lie between 61-90 mins. ***References:*** 1.Delcroix, O. et al. EP-1439

Optimized Workflow in PET/CT Using Variable Speed Continuous Motion and Predicted Attenuation Values

G. Walker*;*
IDX Group Lake Imaging, Ballarat, AUSTRALIA.

Aim/Introduction: The introduction of variable speed continuous motion in PET/CT has made possible the precise selection of PET scan regions for increased or decreased table velocity over prespecified areas according to clinical indication. We aim to apply the same principles to vary speed according to predetermined scan points based on aggregated attenuation data derived from non-AC CT scans, making allowance for gender, body habitus and injected dose, with a view to reducing scan times in routine practice. ***Materials and Methods:*** Two anonymized, randomly selected databases of patients undergoing FDG PET/CT scanning were established (male n=30, female n=30). Parameters recorded were: gender, date of scan, weight, height, dose (MBq), demonstrated pathology, observed bladder activity, measured blood glucose level. All patients were scanned from vertex to mid thigh with arms raised. Count rate profiles in .csv format were recorded for each patient. Patients with BSL> 7.0 mmL^{-1} were excluded, as were those with urinary retention or otherwise full bladders, and those with gross pathology manifesting as large or multiple hot areas. For each patient, ROIs were drawn over the transaxial CT slices at a number of standardized levels to include the area imaged to skin edge. The average Hounsfield unit values were averaged over each region/level, then correlated, as a proxy for mean attenuation, at each level with BMI, weight, gender and injected dose. Gender specific formulae were then generated for setting scan speed over head and neck, lung, abdomen and legs. These formulae were applied to a new group of patients (n=20), with comparison of image quality and total scan time made with a control group scanned under the standard default protocol already in use. A simple phantom study was conducted to assess any change in lesion detectability using the revised method. ***Results:*** Adjusting scanning speed for each of four regions, based on pre-estimated attenuation values and injected dose reduces scan time by up to 15% with no observable reduction in image quality ***Conclusion:*** A simple combination of patient metrics into a formula for varying table speed in PET makes possible customized scan times, potentially increasing throughput, or alternatively incrementally reducing radiation dose.

EP-1440

Improved PET/CT with 2mm Voxel Reconstruction

S. Rep*, I. Slodnjak, B. Trebec Lukman, U. Sprajcer, L. Lezaic;*
University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) imaging is a widely used modality in oncology, providing both metabolic and anatomical information. However, its inherently low spatial resolution introduces the partial-volume effect (PVE), which negatively impacts both the visual appearance and quantitative accuracy of the images. The aim of our research was to investigate the effect of 4 mm and 2 mm voxel sizes on image quality and quantitative evaluation. ***Materials and Methods:*** We utilised the NEMA body phantom with six fillable spheres. The spheres and the background were filled with a solution of fluorine-18 fluorodeoxyglucose (18F-FDG) at sphere-to-background activity concentration ratios of 2:1, 3:1, 4:1, and 8:1. In all reconstructed images (using both 2 mm and 4 mm voxel sizes), we evaluated the contrast recovery coefficient (CRC) and standardized uptake value (SUV). ***Results:*** For phantom spheres with diameters of ≤ 13 mm, we observed significantly higher CRC and SUV values in the reconstructions using the smaller 2 mm voxel size ($p<0.05$). In contrast, CRC and SUV values did not differ significantly for larger spheres (≥ 17 mm in diameter) between the 2 mm and 4 mm voxel size reconstructions ($p>0.05$). ***Conclusion:*** Our results suggest that image reconstruction with a 2 mm voxel size can improve precise lesion localisation and the quantitative evaluation of small lesions. ***References:*** Morey AM, Noo F, Kadrmas DJ. Impact of AI-Enhanced Compressed Sensing on T2W Dark Blood Imaging in FAPI PET/MR for Ischemic Cardiomyopathy

X. Wang[1], *Y. Jiang*[1], *Y. Bian*[1], *C. Song*[1], *X. Su*[2], *Y. Yang*[2], *X. Du*[1], *H. Feng*[1], *S. Zhang*[1];
[1]*First Affiliated Hospital of Dalian Medical University, Dalian, CHINA,* [2]*Beijing United Imaging Healthcare Co., Ltd., Beijing, CHINA.*

Aim/Introduction: PET/MR imaging, combining the functional image capability of positron emission tomography (PET) and the detailed anatomical information from magnetic resonance imaging (MRI), is increasingly utilized to assess myocardial edema in conditions such as myocarditis, inflammatory cardiomyopathy and ischemic heart disease. T2-weighted dark blood (T2W-DB) imaging is a widely used technique for evaluating myocardial edema in these conditions. However, the conventional 2D dual inversion recovery fast spin echo (FSE) sequence employed in T2W-DB is highly susceptible to cardiac and respiratory motion across multiple cardiac cycles, leading to myocardial signal loss, reduced contrast, and motion artifacts. The integration of artificial intelligence-assisted compressed sensing (ACS) has markedly improved MRI acquisition quality (1). Despite these advancements, the impact of ACS on T2W-DB imaging in fibroblast activation protein inhibitor (FAPI) PET/MR for ischemic cardiomyopathy patients remains unexplored. ***Materials and Methods:*** This retrospective study included participants with suspected ischemic cardiomyopathy who underwent FAPI PET/MR with both conventional T2W-DB and ACS T2W-DB sequences between July and October 2024 at the First Affiliated Hospital of Dalian Medical University. Quantitative analysis involved calculating the contrast ratio (CR), maximum standardized uptake value (SUVmax), and signal-to-background ration (SBR). Qualitative assessment included evaluating the overall PET/MR fusion image quality and diagnostic confidence, using the Likert scale. Group comparisons were conducted using a paired t-test for normally distributed data and the Wilcoxon signed-rank test for non-normally distributed data. ***Results:*** This study included 15 male participants (mean age, 51 + 7 years). ACS T2W-DB demonstrated a 61% reduction in acquisition time compared to conventional T2W-DB (mean duration, 47+ 13 seconds vs 120+ 38 seconds; $P < 0.001$). ACS T2W-DB also yielded significantly improved contrast ratios (mean CR,7.6 + 2.7 vs 5.1 + 2.7; $P = 0.002$). No significant differences were observed in SUVmax and SBR ($P = 0.25$ and $P = 0.57$). The overall of PET/MR fusion image quality and diagnostic confidence in ischemic cardiomyopathy patients were significantly improved with ACS T2W-DB compared to conventional T2W-DB (both $P < 0.05$). ***Conclusion:*** ACS T2W-DB sequence enabled accelerated acquisition times and significantly improved image quality compared to the conventional sequences, thereby enhancing diagnostic confidence in ischemic cardiomyopathy assessment using FAPI PET/MR. ***References:*** 1.Yan X, Ran L, Zou L, et al. Dark blood T2-weighted imaging of the human heart with AI-assisted compressed sensing: a patient cohort study[J]. Quantitative Imaging in Medicine and Surgery, 2023, 13(3): 1699.

EP-1442

Effect of Scan Angle On Quantification and Reproducibility of Multigated Acquisition Scan (MUGA)

J. Halttunen, *M. Hakulinen, H. Gröhn;*
Kuopio University Hospital, Kuopio, FINLAND.

Aim/Introduction: We currently use patient specific scan angle on MUGA. Before scanning new patient, optimised scan angle is defined from CT scans. If there are no CT scans, different angles are tested manually. The use of standardised angle, would simplify protocol and release time for other examinations. Therefore, aim of the study was to investigate if scan angle, standardised vs optimised, would influence quantification of MUGA scan and reproducibility of the analyses among technologists. ***Materials and Methods:*** Ten patients were scanned twice during MUGA study using conventional SPECT-CT system. First, by using the patient specific optimised angle and then by using standardised angle. The standardised angle was set to 45°. The patients that had at least five-degree difference in their optimised angle compared to the standardised were included in the study. Six nuclear medicine technologists analysed both MUGA scans using commercial analysing software. In these preliminary analyses, only ejection fraction (EF) was determined. After few months, two of the technologists did the analyses again, to evaluate the reproducibility of the results. Interrater variability was estimated using intraclass correlation coefficient (ICC) with two-way random effects, absolute agreement, multiple raters. Difference between means of EF was evaluated using paired t-test. ***Results:*** The observed variation between all the measured EF values were similar between both methods (optimised: range 40-69, standardised: range 44-69). There was no significant difference between the usage of automatic analysis and analysis in which ROIs were manually adjusted (T.Test = 0,073). Some technologists rely on the automatic analysis more often than others. Single measures intraclass correlation was 0,522 and 0,722 for the optimized and standardized angle, respectively. In addition, Cronbach's Alpha reliability was 0,866 and 0.950 for of optimized and standardised angle, respectively. There was no significant difference between analysed and re-analysed (by two technologists) EF results after two months interval. ***Conclusion:*** In our preliminary analysis, there was no significant difference in EF values when using standardised or optimised angle. However, a marked difference was observed in EF values analysed by different technologists. To make sure that all the studies are analysed in standardised way, training has been organized for MUGA analyses at our department. After the training same analysis will be repeated to see if results are more harmonized. Moreover, analyses will be repeated for few patients in upcoming follow-up MUGA scans to see if the difference in EF is still noticeable between optimised and standardised angles.

EP-1443

Graph-based denoising for emission images

R. Kasai, *H. Otsuka;*
Institute of Biomedical Sciences, Tokushima University, Tokushima, JAPAN.

Aim/Introduction: We propose a novel denoising method based on graph signal processing to produce high-quality emission images with low noise. Smoothing filters, such as Gaussian filters, are classified as non-adaptive denoising.It uses weights independent of the pixel values of the filter kernel and is based on spatial distance. However, this method has the disadvantage that edges are smoothed as well as denoised. In contrast, adaptive denoising methods such as the Non-local Means Filter (non-LMF) can perform smoothing while preserving edges and textures. In this study, by representing the emission image as a graph, we can construct an adaptive graph denoising filter. This method allows more flexible denoising than conventional adaptive methods through the selection of graph parameters, and by using Chebyshev polynomial approximations provides faster operations. ***Materials and Methods:*** We constructed the graph by defining the accumulated pixels of the emission image as nodes and the edge information as a Gaussian function with parameters. A noise reduction algorithm is derived by minimizing a cost function with a regularization term. The validation was performed by a numerical phantom for simulation experiments

and a physical phantom (Hoffman 3D brain phantom enclosed ^{99m}Tc) and a clinical patient data (Cerebral blood flow scintigraphy using ^{123}I-IMP) using SPECT. The numerical phantom used 128 x 128 pixel images added the noise with 20 dB. For the physical phantom and patient data, we used images reconstructed from the projection data by the expectation maximization method. To compare noise reduction performance, a Gaussian filter and non-LMF were used. In addition, we evaluated the numerical phantom using Peak Signal-to-Noise Ratio (PSNR) and multi-scale Structural Similarity Index Measure (MS-SSIM), which are quantitative image quality evaluation indices. ***Results:*** Comparing the noise reduction results of Gaussian filter, non-LMF, and our method on numerical phantom, physical phantom, and patient data, we confirmed that the proposed approach is superior in noise reduction and edge preservation. PSNR improved by more than 21.5% and MS-SSIM showed 0.992. Especially in highly noisy situations, the selection of appropriate graphical information parameters leads to higher performance. ***Conclusion:*** Our proposed method shows promise in practical applications by achieving accurate noise reduction from noisy emission images and reducing radiation exposure. The noise reduction and edge preservation features emphasize the novelty and importance of our method in emission image.

EP-1444

Noise-Robust SPECT Reconstruction Using Graph Diffusion

R. Kasai, *H. Otsuka;*
Institute of Biomedical Sciences, Tokushima University, Tokushima, JAPAN.

Aim/Introduction: In recent years, there has been an increasing demand in the field of medical image reconstruction for techniques that can achieve low noise and high accuracy. Particularly in nuclear medicine, accurate attenuation correction and noise reduction are critical challenges in SPECT image reconstruction. This study proposes a novel reconstruction method that captures the relationships between adjacent pixels within an image as a graph structure and introduces a diffusion term based on this graph structure into the reconstruction update equation. We then compare the performance of this proposed method with the conventional MLEM method. ***Materials and Methods:*** Simulations were performed using the 87x87 pixel modified Shepp-Logan phantom with projection data acquired over 180 degrees with 60 projection angles. Signal-to-noise ratio (SNR) conditions of 30dB and 25dB were set. The proposed method, Graph-Diffusion Expectation Maximization (GDEM), aims to improve reconstruction performance by incorporating a diffusion term defined based on the graph structure into the iterative updates. The graph structure is constructed based on the relationships between adjacent pixels in the image, and the graph diffusion mechanism is utilized to simultaneously achieve image smoothing and edge preservation. Performance evaluation was conducted using quantitative metrics such as Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and Multi-Scale Structural Similarity Index (MS-SSIM). ***Results:*** Under the 30dB condition, the proposed GDEM showed slight improvements compared to the MLEM method, with PSNR increasing from 22.20 to 22.74, SSIM from 0.49 to 0.58, and MS-SSIM from 0.91 to 0.93. In contrast, under the noisier 25dB condition, GDEM demonstrated significant improvements over the MLEM method. PSNR increased from 18.32 to 20.74, SSIM from 0.35 to 0.45, and MS-SSIM from 0.85 to 0.88, confirming that the proposed method exhibits superior performance even in environments with strong noise. Notably, the introduction of the graph diffusion term effectively suppressed noise and reconstructed the image structure more clearly. ***Conclusion:*** This study introduced GDEM, a novel reconstruction method incorporating a graph diffusion term based on the local relationships within the image, demonstrating superior performance, especially under noisy conditions. While GDEM showed slight improvements at 30dB SNR, it significantly outperformed MLEM at 25dB SNR. The enhanced MS-SSIM values further indicate that GDEM better preserves image structural similarity across different scales. This suggests that efficient noise removal and structure preservation via graph diffusion can substantially improve SPECT image reconstruction accuracy, offering promising applications in nuclear medicine.

NEMA Phantom Study on PET Textural Features Variability with Different Reconstructions in Digital PET/CT

P. Dwivedi[1,2,3], *S. Barage*[2], *V. Dubey*[1,3], *A. Jha*[4,3], *S. Choudhury*[1,3], *A. Agrawal*[1,3], *V. Rangarajan*[1,4,3];
[1]*Advanced Centre for Treatment Research and Education in Cancer,Tata Memorial Centre, Mumbai, INDIA,* [2]*Amity Institute of Biotechnology, Amity University, Mumbai, INDIA,* [3]*Homi Bhabha National Institute, Mumbai, INDIA,* [4]*Tata Memorial Hospital, Mumbai, INDIA.*

Aim/Introduction: PET radiomics is a promising quantitative tool for oncological studies, however, these features are influenced by various factors including acquisition protocol, scanner model, reconstruction methods, segmentations etc. Therefore, we aimed to explore the variability of PET textural features for different reconstruction methods with National Electrical Manufacturers Association (NEMA) image quality (IQ) phantom in a digital PET/CT scanner. ***Materials and Methods:*** The phantom contains a lung insert in the middle and six surrounding fillable spheres with increasing diameter 10, 13, 17, 22, 28, and 37 mm. The lung insert was filled with Styrofoam with an average density of 0.3-g/mL simulating lung tissue. While each sphere had an activity of 21.6 kBq/mL, the background was filled with 5.2 kBq/mL of 18F, maintaining the 4:1 concentration as per the NEMA NU 2-2018 standard of image quality[1]. The prepared NEMA IQ phantom was placed in the central field of view (FOV), and to simulate activity outside the FOV, a scatter phantom was placed behind the phantom with an activity of 120 MBq at scan time. Subsequently, 5 min per bed scan with useful FOV was performed with GE Discovery MI Gen2 PET/CT, which is a hybrid SiPM-based digital scanner. Raw list data were reconstructed with 6 different reconstruction methods: VPHD (3D OSEM), VPHD-S(OSEM +PSF), VPFX (OSEM + TOF), VPFX-S (OSEM + TOF+PSF), filter back projection (FBP), and BSREM with beta 350 (Q Clear). 3D segmentation of each homogenous hot sphere then proceeded except smallest sphere since voxel size was less than 64 for texture calculation, and 55 IBSI complaint textural features were extracted with absolute resampling from LIFEx vs. 7.7.0. Subsequently COV was calculated for each feature concerning different reconstructions and classified as having low (<5.0%), intermediate (5-20%) or high (>20%) variability. ***Results:*** In total, five features were found highly stable with COV<5% in 37 and 28mm sphere, four in 22 and 17mm sphere, however, only two were noted in 13 mm sphere. On average, 74.5 %, 20% and 5% of the features showed a high, intermediate and least variability with different reconstruction methods. GLCM based Normalized inverse difference and Normalized inverse difference moment were consistently least variable with COV<5% across different reconstructions in all sphere sizes. ***Conclusion:*** PET reconstruction methods greatly impacted the stability of textural features, therefore, standardization is an important factor in radiomic studies. These findings could also facilitate stable features' selection for further multicentric PET radiomic applications.

EP-1446

Optimization Study of Low-Dose Brain PET/MR Imaging Based on Deep Progressive Learning Reconstruction

X. Wang[1], *Y. Jiang*[1], *Y. Bian*[1], *C. Song*[1], *X. Su*[2], *Y. Yang*[2], *X. Du*[1], *H. Feng*[1], *S. Zhang*[1];
[1]*First Affiliated Hospital of Dalian Medical University, Dalian, CHINA,* [2]*Beijing United Imaging Healthcare Co., Ltd., Beijing, CHINA.*

Aim/Introduction: This study aims to evaluate the clinical feasibility of the Deep Progressive Reconstruction (DPR) algorithm in improving the image quality of low-dose brain PET/MR imaging. ***Materials and Methods:*** A retrospective analysis was conducted on 28 patients (11 males and 17 females, mean age 67.4 years) with suspected neurodegenerative diseases, recruited from the First Affiliated Hospital of Dalian Medical University between October 2024 and January 2025. All participants underwent brain ^{18}F-FDG PET/MR examination. PET images were reconstructed using both Ordered Subsets Expectation Maximization (OSEM) with 20 subsets and 5 iterations, and DPR algorithms with an intensity of 5. The DPR group was subdivided into different scanning duration groups to simulate different injected activities: 25 min (full dose), 12.5 min (half dose), 8.3 min (1/3 dose), and 6.3 min (1/4 dose). These were compared with the OSEM group under the conventional acquisition time. Qualitative evaluation was performed by two nuclear medicine specialists through a double-blind visual assessment using a 5-point Likert scale, rating overall image quality, clarity, artifact level, noise level, and uniformity. Quantitative evaluation utilized the Friedman test to assess the contrast between gray matter as well as white matter of the cerebral cortex and cerebrospinal fluid, and the contrast of gray matter and white matter of the cerebral cortex. ***Results:*** Visual assessments demonstrated that all DPR subgroups (1/n, n = 2,3,4) outperformed the OSEM group in all image quality parameters. And quantitative analysis revealed that the low-dose DPR groups significantly improved the contrast between gray matter as well as white matter of the cerebral cortex and cerebrospinal fluid, and the contrast of gray matter and white matter of the cerebral cortex, compared to the OSEM group. ***Conclusion:*** The DPR algorithm significantly improves the image quality of low-dose brain PET/MR scans. By reducing injected activity while maintaining image quality, DPR presents a feasible solution for clinical low-dose PET/MR imaging of the nervous system. This approach offers safer, more reliable imaging for the early diagnosis of neurodegenerative diseases and holds significant clinical application potential.

EP-1447

Dynamic ElasticNet regularization with adaptive gradient descent for enhanced emission CT image reconstruction

R. Kasai*, H. Otsuka;*
Institute of Biomedical Sciences, Tokushima University, Tokushima, JAPAN.

Aim/Introduction: For high-quality emission computed tomography (ECT) image reconstruction, we propose a novel reconstruction method that incorporates ElasticNet regularization to dynamically adjust parameters in the evaluation function between projection and forward projection. Image reconstruction in ECT presents a challenging problem for estimating high-quality images from observed noisy data. However, a well-known reconstruction method, maximum likelihood expectation maximization (MLEM), has the problem of unstable convergence due to noise. Our new reconstruction method dynamically and automatically controls the parameters of ElasticNet according to the object, and shows significantly improved performance compared to the MLEM method even in noisy situations. ***Materials and Methods:*** The ECT image reconstruction problem can be formulated by the linear equation p=Hx, where p represents the noisy projection data, x the unknown pixel values, and H the mapping operator. We employ ElasticNet regularization as an image reconstruction technique aimed at minimizing this linear equation and enhancing the accuracy of reconstructed ECT images. ElasticNet is an algorithm that combines ridge and lasso regression, which is widely used in machine learning field. We introduce a term that dynamically controls the ridge and lasso regression in ElasticNet according to the object. For validation, we conducted simulation experiments using a numerical phantom (128x128 pixels) with added noise at a signal-to-noise ratio of 25dB, as well as physical phantom SPECT imaging using a Hoffman 3D brain phantom enclosed with ^{99m}Tc. We compared our results against the MLEM method, evaluating the reconstructed images both visually and objectively using density profiles, Peak Signal-to-Noise Ratio (PSNR), and multi-scale Structural Similarity Index Measure (MS-SSIM). ***Results:*** Our proposed method showed better convergence than the MLEM method, even under noisy conditions. Notably, at 100 iterations, the PSNR for MLEM was 18.5, while our method achieved 21.2. Similarly, the MS-SSIM value for MLEM was 0.80, and our method reached 0.89, both indicating the superior performance of our approach. These findings were further substantiated by our clinical SPECT experiment. The validation results consistently demonstrate that our proposed method excels in noise reduction and edge preservation. ***Conclusion:*** Through numerical and clinical SPECT experiment, our proposed reconstruction method enables high-quality reconstruction from low-dose projections and reduces radiation exposure. The parameters of ElasticNet regularization are dynamically determined by the projection and forward projection values of each iteration, highlighting its novelty in ECT image reconstruction method.

EP-1448

Deep Progressive Learning Reconstruction in Non-Small Cell Lung Cancer: Improving Image Quality and Radiomic Feature Robustness

T. Shiiba[1], *M. Watanabe*[2];
[1]*Fujita Health University, Toyoake, JAPAN,* [2]*Fujita Health University Hospital, Toyoake, JAPAN.*

Aim/Introduction: This study systematically compared the effects of deep progressive learning [1-3] reconstruction (DPR) with those of conventional ordered-subset expectation maximisation (OSEM) on PET-based quantification, image quality, and radiomic feature stability in non-small cell lung cancer (NSCLC) imaging. ***Materials and Methods:*** Twenty-four NSCLC patients had ^{18}F-FDG PET/CT scans reconstructed using OSEM and three DPR strengths (1, 3, and 5). We assessed standardised uptake values (SUV_{max}, SUV_{mean}), the background coefficient of variation (COV), contrast-to-noise ratio (CNR), and radiomic feature stability, the latter evaluated by the COV across reconstruction methods. Tumours were grouped by volume into small (<10 cm^3), medium (10-30 cm^3), and large (>30 cm^3). Wilcoxon signed-rank tests with Bonferroni or FDR correction were applied for statistical comparisons. ***Results:*** DPR significantly increased SUV_{max} (OSEM: 9.72 ± 4.69; DPR strength 5: 13.67 ± 6.20, $p < 0.001$) and SUV_{mean} (OSEM: 3.98 ± 1.75; DPR strength 5: 4.31 ± 1.80, $p < 0.001$), particularly in smaller lesions (SUV_{max} relative change: 47.4%). DPR strength 1 slightly reduced background COV (OSEM: 18.38 ± 5.65%; DPR strength 1: 16.51 ± 6.88%), whereas higher strengths increased noise (DPR strength 5: 27.34 ± 7.12%). Although CNR improved at DPR strength 1, it declined significantly at higher strengths. Radiomic feature stability generally improved with DPR, evidenced by decreased COV in 78 of the 93 evaluated features at higher DPR strengths compared to OSEM. ***Conclusion:*** DPR significantly enhances SUV quantification and radiomic feature stability in NSCLC PET imaging, and is particularly beneficial for small lesion detectability. However, optimal DPR strength selection is crucial for balancing improved contrast with increased noise. These findings underscore the potential clinical utility of DPR in improving diagnostic accuracy and robustness in quantitative PET analyses. ***References:*** 1. Lesion detectability evaluation of a deep learning-based time of flight image enhancement algorithm on BGO-based PET/CT scans

K. Itagaki[1], *K. K. Miyake*[2], *K. Mitsumoto*[1], *K. Nakatani*[2], *R. Nakamoto*[3], *T. Nobashi*[3], *S. Koyasu*[2], *A. Katsuki*[4], *H. Kawakami*[4], *F. Kotasidis*[5], *Y. Nakamoto*[2];
[1]*Division of Clinical Radiology Service, Kyoto University Hospital, Kyoto, JAPAN,* [2]*Department of Diagnostic Imaging and Nuclear Medicine, Graduate School of Medicine Kyoto University, Kyoto, JAPAN,* [3]*Preemptive Medicine and Lifestyle Related Disease Research Center, Kyoto University Hospital, Kyoto, JAPAN,* [4]*GE HealthCare, Japan, Tokyo, JAPAN,* [5]*GE HealthCare, Zurich, SWITZERLAND.*

Aim/Introduction: This study evaluated the lesion detectability performance of a deep learning-based time of flight (TOF) image enhancement algorithm from datasets acquired on a previous generation for BGO-based PET/CT system. ***Materials and Methods:*** A NEMA body phantom dataset was acquired and processed using a deep learning algorithm that maps non-TOF image datasets towards their TOF counterparts.(1) Three different models of variable trade-off between contrast enhancement and noise (DLToF -L, DLToF-M, DLToF-H) were used to assess lesion detectability across different data acquisition durations (60, 180, and 300 seconds) and across different regularization parameters (200, 400, 600, 800, and 1000) of the input images, reconstructed with a Bayesian penalized likelihood algorithm. The phantom was filled with ^{18}F solution with a target-to-background ratio (TBR) of 4:1 on a background of 2.65 kBq/mL, according to the Japanese guidelines for oncological ^{18}F-FDG PET/CT data acquisition.(2) Quantitative analysis was performed using metrics such as the contrast recovery coefficient for the 10 mm diameter sphere (CRC) and background variability (BV) according to NEMA NU 2-2018 specification. The contrast-to-noise ratio (CNR) was also calculated to assess small sphere detectability. In addition, the background coefficient of variation (CV) was measured in ROIs of 37 mm in diameter. ***Results:*** CNR was improved using all three DL models of various strengths, with the highest scores achieved when applying DLToF-H and at all acquisition durations. The CNR change ratio of DLToF-H was the highest in all regularization parameters at the 180-second acquisition duration. At the 180-second, applying DLToF-L, DLToF-M, and DLToF-H to the images reconstructed with a regularization parameter of 400 resulted in CNR of 3.50, 2.90, and 3.56, respectively. DLToF-M and DLToF-H improved the CRC when the noise in the original image was low, while DLToF-L promoted variance reduction over contrast enhancement in all cases. After applying DLToF-H to the images acquired for 180 seconds, the CNR was comparable to that of the original images acquired for 300 seconds. DLToF-M and DLToF-H increased image noise under conditions of low image noise in the original image, while DLToF-L reduced image noise in any condition. ***Conclusion:*** DLToF-H improved CRC and DLToF-L promoted improved noise characteristics. The lesion detectability performance of a previous generation BGO-based PET/CT was improved with deep learning-based time of flight image enhancement, especially utilizing DLToF-H. ***References:*** 1. Mehranian A, et al. Eur J Nucl Med Mol Imaging. 2022 Sep;49(11):3740-3749.2. Fukukita H, et al. Ann Nucl Med. 2014 Aug;28(7):693-705.

Overcoming respiratory motion artifacts: Gated PET/CT for improved visualization of juxtadiaphragmatic lesions

K. Shyli, *F. Firinu, F. Casaburo, F. Oliverio, A. Sotgiu, C. Serra, M. Mantovani, S. Fraschina, A. Lomartire, G. Paolacci, G. Cafiero, I. Papagni;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Juxtadiaphragmatic lesions are often difficult to visualize on PET/CT due to respiratory motion of the diaphragm, which can cause motion artifacts and reduce image quality. Respiratory gating, through the use of devices that monitor the patient's breathing pattern, allows image acquisition to be synchronized with the respiratory cycle, significantly improving lesion detectability in these challenging regions. This approach is particularly beneficial in patients with irregular breathing, who often show comet-tail artifacts on conventional PET/CT scans. Moreover, gating enables better management of the exam in non-compliant patients and in those unable to perform rapid breath-hold acquisitions. In this study, we describe the application of respiratory gating experience at our hospital using the high-sensitivity United Imaging Panorama GS LAFOV PET/CT system to enhance visualization of juxtadiaphragmatic lesions. ***Materials and Methods:*** The protocol involves the use of a respiratory belt to monitor the patient's breathing and generate gated reconstructions. PET data are acquired with a 256x256 matrix and reconstructed using OSEM (3 iterations, 10 subsets) with Gaussian post-filtering (FWHM 2.0), incorporating both TOF (Time-of-Flight) and PSF (Point Spread Function) technologies for optimal resolution and noise reduction. In order to obtain optimal gated images, an acquisition time of at least 6 minutes is required. Gated reconstruction parameters are as follows: trigger type VSM (Ventilation-Synchronized Motion), bin type phase, number of bins 6, and offset 0%. ***Results:*** Respiratory gating significantly improved image quality and lesion detection compared to standard non-gated PET/CT. In 39 of 47 acquisitions, comet-tail artifacts were markedly reduced. The use of the respiratory belt allowed effective synchronization between respiration and acquisition, minimizing respiratory artifacts. Furthermore, the gating approach improved scan management in uncooperative patients or those unable to hold their breath during rapid acquisitions. Otherwise, respiratory sampling is often challenging in underweight patients, resulting in under-sampled and noisy images. Anyway, gated reconstructions provided superior resolution and clearer delineation of lesions that would otherwise be difficult to detect and localize. ***Conclusion:*** The implementation of respiratory gating offers an effective solution for the visualization of juxtadiaphragmatic lesions. Respiratory synchronization via belt, combined with optimized gated reconstruction parameters, significantly enhances image quality and diagnostic confidence. This method is especially valuable in patients with irregular breathing, enabling better lesion detection while also improving workflow in cases where breath-hold imaging is not achievable.

Evaluation of Machine Learning Models for Automated Segmentation of SPECT MPI Scans

A. Alenezi[1], ***E. Alawdhi***[1], *A. Jodeiri*[2], *A. Mayya*[3];
[1]*Kuwait University, Kuwait, KUWAIT,* [2]*Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [3]*Tishreen University, Latikiya, SYRIAN ARAB REPUBLIC.*

Aim/Introduction: Myocardial perfusion imaging (MPI) using single-photon emission computed tomography (SPECT) plays a critical role in diagnosing and assessing the severity of coronary artery disease (CAD). Accurate segmentation of myocardial regions is essential for deriving quantitative metrics related to left ventricular function. Manual segmentation remains the clinical standard but is time-consuming and prone to inter-observer

variability, particularly under high workload. Deep learning, specifically convolutional neural networks (CNNs), has emerged as a promising alternative for automating segmentation tasks in medical imaging[1]. This study aims to evaluate and compare the performance of five deep learning-based U-Net models for automatic segmentation of cardiac SPECT images, each using a different encoder backbone: CNN, MobileNet, VGG with attention, Inception, and ResNet50 with attention. ***Materials and Methods:*** Two MPI datasets were used: a small set (609 images) and a large set (5169 images), both labeled with ground truth masks. Images were preprocessed to 64×64 pixels and augmented with flipping, distortion, noise, and contrast adjustments. All five U-Net variants were trained using identical hyperparameters and assessed via mean Intersection-over-Union (mIoU), Dice coefficient, pixel accuracy, and AUC. An ensemble model was also developed using weighted averaging of the five networks. ***Results:*** Across both datasets, the Inception-based U-Net demonstrated superior individual model performance (Dice: 0.9656 and 0.9538; mIoU: 0.9358 and 0.9197). However, the ensemble model outperformed all individual models (Dice: 0.9679 and 0.9544; mIoU: 0.9398 and 0.9205), achieving the highest accuracy and lowest false negative rates. While MobileNet U-Net offered the fastest training time, it had slightly lower segmentation accuracy (details in Table 1). The Inception-based model showed the best trade-off between segmentation quality and clinical relevance, albeit with higher computational demands. ***Conclusion:*** Our results confirm the efficacy of deep learning models, particularly ensemble U-Net architectures, in achieving high-precision segmentation of cardiac SPECT MPI images. The approach significantly reduces reliance on manual interpretation and enhances reproducibility. By enabling accurate and automated delineation of myocardial structures, these models hold potential to streamline nuclear cardiology workflows and support robust decision-making, especially in high-throughput clinical environments. Further work will explore real-time deployment and integration into clinical systems, mega studies and radiomics. ***References:*** [1]Apostolopoulos, I. D., Papandrianos, N. EP-1452

Development of a Muscle Masking Technique for Reducing the Influence of Physiological FDG Uptake in PET Imaging

M. Sato*, N. Imaizumi, F. Sasaki, A. Yumoto, T. Kita, H. Daisaki; Gunma Prefectural College of Health Sciences, Maebashi, JAPAN.*

Aim/Introduction: PET imaging using 18F-fluorodeoxyglucose (18F-FDG), maximum intensity projection (MIP) images are useful for providing an overall three-dimensional view of tracer distribution. However, inadequate adherence to pre-scan preparations such as fasting or avoiding physical activity can result in excessive FDG uptake in muscles. This physiological uptake may obscure small or low-uptake lesions within the MIP images, reducing their visibility. While PET/CT fusion images can mitigate this issue by providing clear anatomical localization, MIP images remain an essential and widely used visualization tool in routine clinical practice. Therefore, the purpose of this study was to develop a system that enhances lesion visibility on MIP images by automatically extracting skeletal muscle regions from CT images and subsequently removing these regions from both PET and CT datasets. ***Materials and Methods:*** We used TotalSegmentator, a deep learning-based segmentation tool, to extract skeletal muscle regions throughout the entire body [1]. Since TotalSegmentator is structured into various segmentation tasks, we selectively extracted only the regions related to muscle from each relevant task to generate corresponding mask images. By integrating all these individual mask images, we created a comprehensive mask encompassing the entire musculature. Using this mask, it became possible to remove skeletal muscle regions from both CT and PET images. TotalSegmentator accepts input images in the Neuroimaging Informatics Technology Initiative (NIfTI) format. Therefore, in our system, DICOM images were first converted to NIfTI format. To allow for eventual re-export in DICOM format, we preserved the original DICOM tag information, which was reattached after segmentation processing. ***Results:*** Using this system, muscle regions can be successfully extracted from CT images. The generated muscle mask also enabled the removal of corresponding signals from PET images. Applying the post-processed mask may enhance the visibility of lesions by reducing background signals caused by physiological muscle uptake. ***Conclusion:*** This study found that the automatic extraction and removal of skeletal muscle regions is feasible. The proposed method may enhance the visibility of lesions on MIP images, particularly in cases where physiological FDG uptake in muscle compromises diagnostic accuracy. Furthermore, by analyzing FDG uptake in muscle in conjunction with blood glucose levels, this approach may provide a new indicator for assessing patient compliance with pre-scan preparation protocols and offer potential insights into predicting diabetes. ***References:*** [1] J. Wasserthal et al., "TotalSegmentator: Robust Segmentation of 104 Anatomic Structures in CT Images," Radiology: Artificial Intelligence, vol. 5, no. 5, p. e230024, 2023. [Online]. EP-1453

Cross-Validation of Quantitative Accuracy in ^{13}N-Ammonia PET Using Different Software and Compartment Models

N. Akiya*[1], K. Miwa[1], A. Ando[2], N. Miyaji[1], T. Yamao[1], K. Wachi[1], M. Masubuchi[1], S. Kimura[3], R. Ito[1], A. Komatsu[1], T. Horikawa[1]; [1]Fukushima Medical University, Fukushima, JAPAN, [2]Sapporo Kojinkai Memorial Hospital, Hokkaido, JAPAN, [3]Fukushima Medical University Aizu Medical Center Hospital, Fukushima, JAPAN.*

Aim/Introduction: Compartment model-based quantification of myocardial blood flow (MBF) and myocardial flow reserve (MFR) using ^{13}N-ammonia PET plays a key role in risk stratification and prognosis prediction. However, the reliability of these indices depends on the analytical methods used. The present study aimed to compare MBF and MFR values obtained from different software to cross-validate their accuracy, and to assess the impact of compartment model selection on these quantitative indices. ***Materials and Methods:*** This study included 100 patients who underwent ^{13}N-ammonia PET/CT: 60 with normal myocardial flow, 20 with single-vessel disease, 10 with two-vessel disease, and 10 with three-vessel disease. MBF and MFR were quantified using three software packages: SyngoMBF (Siemens Healthineers), PMOD Cardiac PET Analysis Tool (Bruker), and QPET (Cedars-Sinai). Calculations were performed using a 1-tissue compartment model (1TCM) and two 2-tissue models (Hutchins and UCLA), at both the global (entire left ventricle) and regional (major coronary artery territories) levels. ***Results:*** MBF and MFR values were generally consistent across the three software packages, although a small but significant difference in stress MBF was noted between PMOD and QPET ($p < 0.05$). Strong correlations were observed at the global and regional levels ($r = 0.81$-0.91 and 0.69-0.92, respectively), and Bland-Altman analysis demonstrated good agreement. In contrast, compartment model selection had a notable impact on global MBF and MFR values ($p < 0.05$). The mean global MFR was 2.62 ± 0.80 (1TCM), 2.56 ± 1.00 (Hutchins), and 3.32 ± 1.22 (UCLA), with the UCLA model yielding the highest values. Correlation coefficients between models ranged from 0.43 to 0.99. Bland-Altman analysis showed agreement among models, although the UCLA model tended to overestimate

MBF. ***Conclusion:*** Stress MBF, rest MBF, and MFR showed strong agreement among the three software packages at both the global and regional levels. In contrast, compartment model selection had a substantial impact on these values, particularly with the UCLA model. Appropriate model selection is essential for consistent quantification in ^{13}N-ammonia PET.

EP-1454

Relationship Between Visual Braak Staging and the Quantitative Tau PET Methods CenTauR and STOC

K. Wachi[1], *T. Yamao*[1], *K. Miwa*[1], *N. Miyaji*[1], *N. Akiya*[1], *M. Masubuchi*[1], *T. Horikawa*[1], *A. Komatsu*[1], *R. Ito*[1], *H. Matsuda*[2]; [1]*Fukushima Medical University, Fukushima, JAPAN,* [2]*Nippon Medical School, Clinical Imaging Center for Healthcare, Tokyo, JAPAN.*

Aim/Introduction: Tau pathology progression in Alzheimer's disease is closely linked to cognitive decline. Visual Braak staging is widely used in clinical practice to assess tau distribution but requires expert interpretation. This study aimed to examine the relationship between visually-assessed Braak staging and two quantitative tau PET methods: CenTauR and the Simplified Temporal Occipital Classification (STOC). ***Materials and Methods:*** A total of 237 participants from the ADNI3 cohort were included: cognitively normal individuals (CN, n = 93), patients with mild cognitive impairment (MCI, n = 95), and Alzheimer's disease dementia (n = 49). All participants underwent ^{18}F-flortaucipir PET and MRI. Braak staging was visually assessed by a nuclear medicine physician. Two quantitative methods were evaluated: CenTauR, which calculates SUVRs in five predefined regions and converts them to CenTauR scores; and STOC, which classifies tau burden in five stages based on SUVR thresholds across four regions. PET images were normalized using structural MRI, with the cerebellar cortex as the reference. Tau positivity was defined as Braak stage ≥ 4, CenTauR score ≥ 2.0, or STOC stage ≥ 2. Agreement with visual Braak staging was evaluated using kappa coefficients and accuracy, and Spearman's rank correlation coefficients were calculated for CenTauR and STOC. ROC analyses were used to evaluate the ability of each method to distinguish tau-positive (MCI and AD) from tau-negative (CN) individuals. ***Results:*** CenTauR showed kappa values ranging from 0.61 to 0.81 and classification accuracy from 0.84 to 0.91. STOC yielded a kappa of 0.73 and accuracy of 0.88. Spearman's correlation coefficients were 0.67-0.82 for CenTauR and 0.78 for STOC. AUCs for Braak staging, CenTauR, and STOC were 0.71, 0.67, and 0.69, respectively. These results highlight complementary strengths of the two methods: CenTauR captures regional heterogeneity of tau uptake, whereas STOC enables quantitative staging similar to Braak classification. Their combined use might support more accurate and comprehensive assessment in clinical tau PET interpretation. ***Conclusion:*** CenTauR and STOC demonstrated substantial alignment with visually-assessed Braak staging in tau PET. These quantitative methods serve as complementary tools to enhance reliability and objectivity in tau imaging assessments. ***References:*** Villemagne VL, Leuzy A, Bohorquez SS, et al. CenTauR: Toward a universal scale and masks for standardizing tau imaging studies. Alzheimers Dement (Amst). 2023 7;15(3):e12454.

EP-1455

Feasibility of renal function assessment using dynamic ^{68}Ga-EDTA PET-CT imaging

P. Khobragade[1], *N. Varghese*[1], *P. Varekar*[2], *A. Shanker*[1], *R. Krishnappa*[3], *B. Spottiswoode*[4], *K. Kallur*[3]; [1]*Siemens Healthcare Private Ltd., Bangalore, INDIA,* [2]*Manipal Institute of Technology, Manipal, INDIA,* [3]*Healthcare Global Enterprises Ltd, Bangalore, INDIA,* [4]*Siemens Medical Solutions, Inc, Bangalore, INDIA.*

Aim/Introduction: Planar scintigraphy is commonly used to evaluate renal function, providing estimates of glomerular filtration rate (GFR) and split function, and time-activity curves (TAC) [1]. However, its limitations include poor spatial resolution, absence of three-dimensional information, and challenges in absolute quantification. PET-CT imaging has the potential to overcome these limitations by providing high-resolution volumetric data, allowing improved visualization of renal anatomy and function. This study explores the feasibility of using dynamic ^{68}Ga-EDTA PET-CT imaging for renal function assessment. ***Materials and Methods:*** Six patients referred for varied clinical conditions—minimal hydronephrosis due to ureteric calculus, chronic kidney disease, and transplant assessment—underwent single bed dynamic PET-CT following intravenous injection of 2-3.5 mCi of ^{68}Ga-EDTA. Image reconstruction was performed using eight iterations and five subsets, incorporating point spread function correction. Twenty minutes of list-mode data were and reframed into 24 frames of 10 seconds followed by 16 frames of 60 seconds. Prior to PET-CT, patients underwent dynamic Tc-99m DTPA renal scintigraphy for comparative analysis. Planar dynamic data were acquired over 15 minutes, with the first 60 frames captured at one-minute intervals and the remaining frames at 30-second intervals. A deep learning-based organ segmentation algorithm was used to segment the kidneys and generate 3D masks. A modified Gate's model was applied for GFR calculation, using planar scintigraphy derived values to fine-tune parameters. Kidney volume and depth were extracted from the CT segmentation masks. ***Results:*** GFR values showed a maximum deviation of 5% compared to planar scintigraphy, while split renal function differed by no more than 2%. A variation in time-to-peak values between PET-CT and planar scintigraphy was observed, likely due to background interference during the perfusion phase on the scintigraphy scans. Importantly, PET-CT enabled precise measurement of kidney volume and depth, which are not achievable with planar scintigraphy. ***Conclusion:*** This study demonstrates the feasibility and potential of ^{68}Ga-EDTA PET-CT in dynamic renal function assessment. PET-CT-based estimates of GFR and split renal function are in close agreement with traditional planar scintigraphy. In addition, PET-CT offers superior spatial and temporal resolution, along with the ability to provide detailed volumetric anatomical delineation and absolute quantification. PET-CT may serve as a suitable alternative to planar scintigraphy for evaluating renal function. ***References:*** [1] Toyama, Yoshitaka, et al. "Current and future perspectives on functional molecular imaging in nephro-urology: theranostics on the horizon." Theranostics 11.12 (2021): 6105.

EP-1456

Optimisation of Dosage for Myocardial Perfusion Imaging Using an Anthropometric Formula and Predicted Attenuation Values

G. Walker;
IDX Group Lake Imaging, Ballarat, AUSTRALIA.

Aim/Introduction: To determine a reliable method for optimising radiopharmaceutical dose using one or a combination of simple body measurements. If the myocardial information density can thus be constrained to a narrow, predictable range, the likelihood of poor image quality will be reduced, and changes to existing dose and imaging regimens, with the objective of reducing radiation dose, may be made with confidence. Various methods for determining radiopharmaceutical dose for myocardial imaging have been proposed, including varying dose by patient weight, weight range and BMI. These methods may in some circumstances result in unnecessary radiation dose or inadequate image quality. ***Materials and Methods:*** A group of patients (n=50) undergoing stress myocardial perfusion imaging was examined for height, weight, thoracic circumference, mean chest wall thickness and gender. Correlations were then sought among these quantities.

Three further groups of patients (n=70 each) were dosed thus: A: Fixed dose of ^{99m}Tc sestamibi with variations. B: Dosage based on measured body mass. C: Dosage by a formula determined from the initial group data, combining thoracic circumference, gender and estimated thoracic attenuation. After acquisition of post-stress images with a fixed acquisition time, information density (mean net counts per pixel in raw projections) was measured for each patient, and a frequency distribution generated for each group. ***Results:*** There was excellent correlation between thoracic circumference and mean thoracic wall thickness, but only when male and female were considered separately. Dose administration using a formula based on these relationships yielded a considerably narrower range of information densities than other methods. Preliminary results extending the attenuation estimation to include lung tissue will be presented. ***Conclusion:*** The use of a dose formula for myocardial perfusion imaging based on thoracic circumference and gender has potential to standardize image quality and enable significant radiation dose reduction.

EP-1457

Evaluation of Radiation Extremity Exposure in^{177}Lu PSMA(IT) Production and Quality Control Using Two Ring Dosimeters

T. Häkkinen[1], *S. Pellinen*[1], *M. Hakulinen*[1,2];
[1]*Wellbeing services county of North Savo, Kuopio university hospital, Kuopio, FINLAND,* [2]*Department of Technical Physics, University of Eastern Finland, Kuopio, FINLAND.*

Aim/Introduction: The number of ^{177}Lu treatments has increased notably at Kuopio University Hospital in recent years (from 99 treatments in 2022 to 161 treatments in 2024). Aim of this study was to evaluate overall radiation safety and extremity exposure associated with ^{177}Lu processes. The goal was to assess the radiation dose received during ^{177}Lu PSMA(IT) production and quality control (QC), and to determine its contribution relative to overall extremity radiation exposure. ***Materials and Methods:*** This study assesses extremity radiation doses (Hp (0.07)) received by radiopharmacy personnel during the 177Lu PSMA(IT) process (divided into production and QC) using two ring dosimeters (TLD). One ring dosimeter was worn on the dominant hand during all radiopharmaceutical processes (18F, 68Ga, 177Lu and 15O). Second ring dosimeter was worn on the non-dominant hand only during 177Lu processes. Dose data were collected from 30 177Lu PSMA(IT) production batches (64 patient doses) over 6 months' time among five (5) technicians. The recorded extremity doses were compared to the doses recorded from all radiopharmaceutical production batches during same period. Recorded radiation doses from 177Lu PSMA(IT) productions were normalized both for number of production batches as well for number of produced patient doses. ***Results:*** Contribution of 177Lu total extremity exposure to the radiation exposure recorded from all radiopharmaceutical processes was in average 31,2 % (range 18,5-48,9 %). The distribution of total extremity radiation doses from all 177Lu processes was 78.9% from production and 21.1% from QC. Average dose from 177Lu PSMA(IT) production was 293 µSv (range 150-430 µSv) per batch and 132 µSv (range 60-220 µSv) per patient dose. Average dose from QC was 98 µSv (range 20-180 µSv) per batch and 43 µSv (range 10-90 µSv) per patient dose. ***Conclusion:*** These results confirm that existing radiation safety protocols and operation model effectively minimize occupational exposure in our 177Lu PSMA productions. Consistency across different production processes had variety. Variation in measured hand doses may result from differences in individual working practices, such as hand positioning and time spend handling radioactive substances. Additionally, factors like familiarity with the procedure, workflow, habits and adherence to safety protocols may influence level of radiation exposure. Hand doses during QC process were lower compared to production. This is likely due to the smaller activities and shorter manual handling time in QC -laboratory. Continued radiation monitoring and adherence to best practices will ensure the safety of personnel working with 177Lu and other radiopharmaceuticals.

EP-1458

Implementation for quantitative SPECT imaging of At-211: Becquerel calibration with a germanium semiconductor

T. Kamiya[1], *H. Sasaki*[1], *T. Watabe*[2], *S. Naka*[3], *K. Ooe*[4], *Y. Shirakami*[4], *I. Yabata*[1], *K. Isohashi*[2], *K. Fujino*[1];
[1]*Department of Medical Technology, The University of Osaka Hospital, Suita, JAPAN,* [2]*Department of Radiology, Graduate School of Medicine, The University of Osaka, Suita, JAPAN,* [3]*Department of Pharmacy, The University of Osaka Hospital, Suita, JAPAN,* [4]*Institute for Radiation Sciences, The University of Osaka, Suita, JAPAN.*

Aim/Introduction: In the dosimetry of targeted alpha therapy (TAT), it is essential to ensure the quantitative accuracy of radioactivity measurement such as administered dose of radiopharmaceuticals, patient samples (blood and urine) and voxel value of SPECT images. Astatine-211 (At-211, half-life: 7.2 hours) is an alpha-emitter which can be applied for TAT of several malignant tumors. However, At-211 is not commonly used in clinical examinations, and there is no nuclide setting in the dose calibrators or SPECT/CT scanners. The aim of this study was to establish the becquerel calibration factor among the various devices used for TAT. ***Materials and Methods:*** Germanium semiconductor detector (GE2020: Million Technologies), calibrated with a Ba-133 calibration source, was used as a quantitative reference. Calibration factors were determined for dose calibrators, a well counter, and SPECT/CT scanners by adjusting their measurements to match the germanium semiconductor detector. Three CRC-55tR dose calibrators (Capintec) and one JDC-1712 well counter (ALOKA) were evaluated. SPECT/CT images of cylindrical phantom (6600 mL: Data Spectrum) were acquired by Symbia Intevo 6 (SIEMENS), Discovery NM/CT 870 CZT (GE) and VERITON-CT (Spectrum Dynamics Medical). The energy window was set at 79 keV ± 20% targeting the characteristic X-rays emitted from the daughter nuclide of Polonium-211 (half-life: 0.52 seconds). ***Results:*** The calibration factor of the dose calibrator using a 20 mL glass vial was 77, while that of the well counter was 0.0243 ± 0.008 (kBq/cps). The errors of standardized uptake value were less than 5% for all SPECT/CT scanners. ***Conclusion:*** This phantom based study established the becquerel calibration factors among various devices, enabling accurate quantitative evaluation in TAT with At-211 radiopharmaceuticals. In addition, the At-211 SPECT images using CZT SPECT/CT scanner were successfully optimized, showing performance comparable to conventional NaI(Tl) dual detector systems. ***References:*** Desmonts C, Bouthiba MA, Enilorac B, et al. Evaluation of a new multipurpose whole-body CzT-based camera: comparison with a dual-head Anger camera and first clinical images. EJNMMI Phys. 2020;7:18.

EP-1459

Kidney Dosimetry in mCRPC Patients Undergoing Lu-177 PSMA Therapy: Insights from a Single-Center Study

R. Mishra, *A. Nazar, S. Barai, M. Ora, A. Arya, M. Dixit, P. Pradhan, S. Dhania;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: To evaluate kidney absorbed dose, residence time, and their correlations with patient characteristics in mCRPC patients undergoing Lu-177 PSMA therapy. Lutetium-177 (Lu-177) PSMA therapy is a promising treatment for metastatic castration-resistant prostate cancer (mCRPC). However, kidney dosimetry is critical to ensure safety, given the kidneys' radiosensitivity. This

study quantifies kidney absorbed doses and assesses variability in mCRPC patients receiving Lu-177 PSMA therapy. ***Materials and Methods:*** Ten dosimetry records from eight mCRPC patients (mean age: 65.2 ± 8.7 years; mean weight: 68.4 ± 18.7 kg) treated with Lu-177 PSMA (mean activity: 6357.5 ± 586.7 MBq) were analyzed. Kidney doses (mGy/MBq) and cumulative doses (Gy) were calculated using SPECT/CT-based dosimetry and newly installed software system, with residence times derived from normalized cumulative activity. Descriptive statistics, inter- and intra-patient variability, and Pearson correlations with age, weight, and administered activity were assessed. ***Results:*** Mean kidney dose was 0.476 ± 0.418 mGy/MBq (median: 0.336, range: 0.218-1.589), and mean cumulative dose was 2.62 ± 2.29 Gy (median: 2.20, range: 1.3-8.97). Residence times ranged from 0.78 to 5.69 Bq-hr/Bq (mean: 1.63 ± 1.42). One patient exhibited an outlier dose (8.97 Gy) due to prolonged residence time (5.69 Bq-hr/Bq). Excluding this outlier, mean dose was 0.319 ± 0.068 mGy/MBq and cumulative dose was 2.01 ± 0.46 Gy, aligning with literature (0.39-0.67 mGy/MBq). Inter-patient variability was high (CV: 87.3%), but reduced to 21.3% without the outlier. Intra-patient variability ranged from 2.3% to 19.3% across cycles. Kidney dose correlated strongly with residence time ($r = 0.999$, $p < 0.001$) and moderately with administered activity ($r = 0.65$, $p = 0.04$), but not with age or weight. ***Conclusion:*** Kidney doses in Lu-177 PSMA therapy are generally within safe limits, but significant inter-patient variability and occasional high doses highlight the need for personalized dosimetry. Prolonged residence times may increase nephrotoxicity risk, warranting further investigation into predictive factors and simplified dosimetry protocols.

EP-1460

Assessment of collimator-detector-response for absolute quantification and dosimetry of 188Re- microsphere SIRT in hepatocellular carcinoma using quantitative SPECT/CT: Addressing the technical challenges in theranostic imaging

K. Kaur, *S. Chopra, J. Shukla, R. Kumar, V. D. Chadha, B. R.Mittal;*
Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Absolute quantification of radiopharmaceutical is essential for dosimetry analysis in theranostic. An accurate model of the collimator-detector-response (CDR) is required since image quantification takes into account the probability of the photon emitted from the source and its contribution to voxel of the resulting image. Aim of the study was to analyse the effect of CDR and Scatter in image quantification using different collimators and estimate absorbed dose in hepatocellular carcinoma (HCC) patients receiving 188Re-microsphere selective intra-radionuclide therapy (SIRT) based on quantitative SPECT/CT ***Materials and Methods:*** The different phantom studies were performed in the Department of Nuclear Medicine, PGIMER, Chandigarh. Quantitative SPECT/CT was acquired with 120 projections (20s/projection) for theranostic radionuclide 188-Rhenium with appropriate photopeak and scatter window. The acquired data was reconstructed and analysed in three set. In First set corrections for CDR, Scatter and attenuation were applied in reconstruction. In second set recon was done with only AC and in third set no corrections were applied. Quantitative accuracy in terms of activity concentration recovery was assessed as a function of collimator- to -detector response at varying distances of detector from phantom as well as for different set of collimators available i.e LEHR and HEGP. A single time point regional quantitative SPECT/CT was acquired in 10 HCC patients receiving 188Re-microsphere SIRT and analysed for image based absorbed doses ***Results:*** In first set, absolute activity concentration were measured to be within 11% (HEGP) and 32% (LEHR) of the expected value. In the second set, there was significant contribution of scatter photon and the activity concentration were overestimated since CDR and SC were not applied. In third set activity concentration was erroneously estimated. This trend was observed for both the sets of collimators, but HEGP was observed to be more accurate in 188Re-quantification. The first set of CDR modelling was then used for activity quantification and dosimetry calculations in HCC patients undergoing 188Re-microsphere SIRT which also correlated with the clinical response ***Conclusion:*** The tested device and reconstruction algorithm modeled with correction for CDR, scatter, attenuation and resolution recovery provided accurate activity recovery within 11% of expected values; these performances are comparable to current generation PET/CT systems. Quantitative accuracy was maintained with varying distance from detector since CDR was modeled in the reconstruction algorithm. For precise quantification and dosimetry of 188Re-microsphere uptake in HCC patients, HEGP collimator is recommended.

EP-1461

Biodistribution, dosimetry, and pharmacokinetics of ^{68}Ga-PSFA-01: First-in-human evaluation of a dual-target PET tracer

J. Li, *Y. Li, X. Zhang, H. Pang;*
The First Affiliated Hospital of Chongqing Medical University, ChongQing, CHINA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) PET is vital for assessing prostate cancer (PCa) recurrence and guiding biopsy, yet its accuracy remains limited. Fibroblast activation protein (FAP) is a promising theranostic target, especially for PCa cases with low or no PSMA expression. However, single-target receptors have clinical limitations. Given the heterogeneity of PCa and the need to enhance PET/CT tumor-targeting sensitivity, Wang et al. synthesized a FAP- and PSMA inhibitor-based heterodimer, ^{68}Ga-PSFA-01. This study aimed to assess its biodistribution, dosimetry, and pharmacokinetics in humans. ***Materials and Methods:*** Six patients with a history of PCa were intravenously injected with ^{68}Ga-PSFA-01. PET/CT scans were acquired at 0.5, 1, 1.5, and 2 hours post-injection. OLINDA/EXM 2.1 software was used to calculate absorbed organ and effective dose estimates based on up to 25 regions of interest defined on CT images and applied to the co-registered PET images. Time-activity curves (TACs) per organ were determined, and mean organ-absorbed doses and effective doses were calculated using the MIRD schema. Effective doses (EDs) were estimated according to ICRP103. Additionally, three healthy volunteers underwent one-hour dynamic PET/MR imaging. Using the iliac artery as the input function, a two-compartment pharmacokinetic model was applied to estimate the pharmacokinetic parameters of ^{68}Ga-PSFA-01. ***Results:*** The mean injected activity of ^{68}Ga-PSFA-01 was 139 ± 0.68 MBq (range: 114.7-148.0 MBq), with no tracer-related adverse effects observed. ^{68}Ga-PSFA-01 exhibited extracellular distribution with predominantly rapid renal clearance. The highest absorbed doses were observed in the kidneys (0.426±0.070 mGy/MBq) and liver (0.272±0.0142 mGy/MBq), while the dose to the urinary bladder wall was 0.103±0.0416 mGy/MBq,. Whole body effective dose was 1.815±0.38 mSv/MBq. Pharmacokinetic analysis revealed that ^{68}Ga-PSFA-01 displayed rapid distribution, with bladder counts increasing significantly over time, consistent with the radiopharmaceutical metabolic characteristics of kidney excretion and subsequent accumulated in the bladder. It also demonstrated sustained accumulation in prostate tissue. The mean K_3/K_4 ratio of 1.81 (greater than 1) indicates strong tissue binding affinity and efficient target in engagement. ***Conclusion:*** Administration of 139 ± 0.68 MBq of ^{68}Ga-PSFA-01 yields an acceptable radiation burden (1.815 ± 0.38 mSv) in compliance with ICRP103 recommendations. The tracer demonstrates favorable pharmacokinetics and safety,

warranting further clinical development. Particular attention should be paid to radiation exposure in the kidneys and spleen during therapeutic applications. ***References:*** 1. Li Y, Guan L,Pang H. Dual targeting PET tracer [68Ga]Ga-PSFA-01 in patients with prostate cancers: A pilot exploratory study. Theranostics. 2025 Mar 10;15(9):4124-4134. doi: 10.7150/thno.108676.

EP-1462

Enhancing Operational Efficiency and Patient Care: The Aerosol Solution for Lung Ventilation Imaging

A. Moura, *C. Rodrigues;*
Imperial College NHS Healthcare Trust, London, UNITED KINGDOM.

Aim/Introduction: In our department, Krypton-81m was use for lung ventilation studies. However, inconsistent production resulted in frequent same-day cancellations, significantly disrupting departmental operations and adversely affecting patient experience, diagnostic accuracy, and clinical management. Following a thorough evaluation of alternatives, we adopted technetium-99m-labelled aerosol (Technegas) for ventilation imaging, leading to a comprehensive overhaul of our departmental procedures. ***Materials and Methods:*** Implementation of Technegas required acquisition of the Technegas Plus System, along with other essential consumables. It also required the development of comprehensive SOPs regarding generator operation and gaseous and solid waste handling and storage. Technologist team underwent training in preparation, administration, imaging protocols, and image-quality assessment for the new agent. Workflow modifications included generator preparation, crucible dosing with ethanol, patient inhalation, ventilation positioning, and simultaneous preparation of the MAA dose for immediate post-ventilation injection and count verification. Despite a modest increase in scanner time per patient, efficient coordination and scheduling maintained the original booking slots. ***Results:*** Out of a total of 14 staff members, 4 received direct training from the manufacturer, which was subsequently cascaded to the rest of the team. In-house training was established focusing on imaging acquisition and processing. To date, 92% of staff have completed this training. Financially, the switch has also been successful. To date, the department has saved approximately £4,000, already factoring in the cost of acquiring the delivery system. Although generator failures occasionally lowered expenses, they frequently disrupted patient care and reduced scanner availability. The department has allocated specific time slots for Pulmonary Hypertension clinics, enabling patients from across England and Wales to complete all necessary diagnostic procedures in a single visit. However, due to the unreliability of Kr-81m generator production, some patients required multiple visits, and certain scans were missed entirely because patients were unable to return. The introduction of Technegas has improved scheduling flexibility and helped reduce the waiting list for all patients. ***Conclusion:*** By adopting this technetium99m-labelled aerosol for pulmonary ventilation imaging, we resolved the unreliability of the Kr81m generator production ensuring a sustainable solution. This transition improved service efficiency, reduced referral-to-treatment times, and enhanced patient care at Hammersmith Hospital. Maintaining imaging standards and service continuity led to increased satisfaction among patients and referring clinicians. Consequently, his is a service that the technologist team is proud of providing. This initiative demonstrates a proactive response to resource constraints and underscores our commitment to patient-centred care and operational excellence.

EP-1463

An Innovative Design for Patient-Centred Care: Establishing the First Molecular Imaging and Therapy Center in Regional New Zealand

P. Lamerton;
Molecular Imaging and Therapy, Canopy Imaging, Hastings, NEW ZEALAND.

Aim/Introduction: New Zealand is an island country in the South Pacific Ocean approximately 1600 km southeast of Australia comprising of two main islands with a population of 5.25 million. Regional New Zealand can present unique challenges let alone the region of Hawkes Bay on the East Coast of the North Island. This presentation will highlight how we have successfully navigated through innovative design and a patient-centred approach to bring the first Molecular Imaging and Therapy Center to regional New Zealand. ***Materials and Methods:*** The Greenfield Molecular Imaging and Therapy Centre, introduces a transformative approach to healthcare facility planning with a shift away from the typical clinical atmosphere. The design elements integrated cultural awareness and cutting-edge molecular and therapy technologies to prioritise patient comfort and well-being. ***Results:*** Collaboration with our health physicist and Hot lab design and planning team was instrumental in the optimal shielding solutions to ensure safety and radiation protection. In addition, due to global shortages in nuclear medicine technologists impacting on New Zealand, special considerations in the design were made to ensure minimal radiation dose to the clinical staff. ***Conclusion:*** The layout optimises patient flow with attention given to features that enhance staff accessibility and operational efficiency without compromising the patient experience. The imagery shown will highlight the delicate balance between safety and operational needs with a calming and less clinical aesthetic feel that promotes a more positive experience for patients. Furthermore, we will show the incorporation of sustainability and features that have enabled the future proofing of the clinic. Even though the presentation shared is unique to New Zealand, it is beneficial in a global context due to the rapid developments in molecular imaging and therapies.
