Prognostiv Value of F-18 FDG PET/CT-Derived TLG and Radiomics Features in Breast Cancer Patients

F. Görtan[1], *M. Kartal*[2], *A. Kartal*[2];
[1]*Turkish Ministry of Heath, Ankara Bilkent City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Elazıg Fethi Sekin City Hospital, Department of Nuclear Medicine, Elazıg, TÜRKIYE.*

Aim/Introduction: This study aimed to evaluate the prognostic utility of radiomics features and total lesion glycolysis (TLG) derived from baseline [^{18}F]FDG PET/CT imaging in predicting metastasis development and metastasis-free survival (MFS) in patients with breast cancer. ***Materials and Methods:*** A retrospective analysis was conducted on 37 female patients (median age: 50 years) with histologically confirmed breast carcinoma who underwent staging FDG PET/CT. Quantitative imaging features including conventional metabolic parameters (SUVmin, SUVmean, SUVmax, SUVpeak, TLG) and radiomics texture features extracted from GLCM, GLRLM, NGLDM, and GLZLM matrices were evaluated. The relationship between these features and metastasis development during follow-up was assessed using ROC curve analysis and Cox regression models. ***Results:*** Among the patients, 86.5% had invasive carcinoma, and molecular subtyping revealed 62.2% luminal A, 27.0% luminal B, and 8.1% triple-negative breast cancer. During a median follow-up of 56 months, metastasis occurred in 6 patients (16.2%). ROC analysis identified five parameters significantly associated with metastasis: TLG (AUC=0.801), GLCM-Correlation, NGLDM-Coarseness, GLZLM-LZHGE, and GLZLM-GLNU (all $p < 0.05$). TLG >56.8 g was the most powerful predictor, yielding 83.3% specificity and 77.4% sensitivity. Univariate Cox regression revealed that high TLG, GLZLM-LZHGE >8820, and GLZLM-GLNU >4.96 were significantly associated with shorter MFS ($p < 0.05$), while age and receptor status were not. In multivariate analysis, only TLG >56.8 g remained statistically significant (HR: 12.034, 95% CI: 1.398-103.605, $p = 0.024$). Kaplan-Meier analysis confirmed significantly shorter MFS in patients with high TLG values (mean MFS: 47.4 vs. 63.25 months, Log Rank $p = 0.004$). ***Conclusion:*** TLG measured from staging FDG PET/CT emerged as an independent predictor of metastasis and reduced MFS in breast cancer patients. Selected radiomics features, particularly GLZLM-derived metrics, may offer additional prognostic value. Integration of metabolic and radiomic biomarkers from FDG PET/CT into clinical decision-making may enhance early risk stratification and guide treatment strategies.

EP-0295

Contribution of 68Ga-DOTA-cyclo (RGDfK) [Integrin αvβ3 Inhibitor] PET/CT Imaging in Staging and Restaging of Breast Cancer: Preliminary Findings

Z. Tosunoglu*, Ö. F. Şahin, A. E. Öztürk, G. Alçın, E. Akgün, E. Arslan; Istanbul Training and Research Hospital, Nuclear Medicine Clinic, Istanbul, TÜRKIYE.*

Aim/Introduction: Integrin αvβ3 is heterodimeric transmembrane glycoprotein expressed in activated endothelial cells, newly formed blood vessels, various tumor cells. It plays crucial role in angiogenesis and distant metastasis development, making it a target for early detection and treatment management of tumors such as breast and lung cancer. This prospective study aims to evaluate the role and contribution of 68Ga-DOTA-cyclo(RGDfK) [integrin αvβ3 inhibitor] PET/CT in staging and restaging breast cancer patients. ***Materials and Methods:*** In this prospective study, conducted between September 2024 and January 2025, 18 F diagnosed breast cancer underwent 68Ga-DOTA-cyclo(RGDfK) [integrin αvβ3 inhibitor] PET/CT within maximum 2 weeks after ^{18}F-FDG PET/CT.Written and verbal informed consent obtained from all patients. VOI drawn to include the entire lesion. SUV recorded for primary and metastatic lesions. Highest SUVmax lesion in each organ was reported. Relationship between SUVmax parameters and histopathological features was analyzed. Angiogenesis imaging using 68Ga-DOTA-cyclo(RGDfK) [integrin αvβ3 inhibitor] PET/CT was compared to metabolic imaging using ^{18}F-FDG PET/CT. ***Results:*** Mean age 56.2 ± 13.6 years .Imaging purposes: 12 staging 5 treatment response evaluation, 1 restaging after recurrence Histopathological distribution: 15 (83.3%) invasive ductal carcinoma 2 (11.1%) invasive lobular carcinoma 1 (5.6%) mixed-type tumor Physiological radiotracer uptake was observed in the liver, spleen, ventricles, thyroid, and intestines, with renal

excretion. Primary tumor uptake comparison: FDG SUVmax: 13.35 ± 8.56 Integrin SUVmax: 5.38 ± 1.61 FDG SUVmax was significantly higher than Integrin SUVmax (p=0.005). Moderate correlation was found between FDG SUVmax and Integrin SUVmax (r=0.514, p=0.05). ALN uptake comparison: FDG SUVmax: 12.72 ± 5.22 Integrin SUVmax: 5.18 ± 2.45 FDG SUVmax was significantly higher than Integrin SUVmax (p=0.007). Bone metastases (n=7): FDG SUVmax: 11.61 ± 5.86 Integrin SUVmax: 6.01 ± 2.84 FDG SUVmax was significantly higher than Integrin SUVmax (p=0.018). Distant LN metastases (n=5): FDG SUVmax: 14.58 ± 8.84 Integrin SUVmax: 4.83 ± 1.85 FDG SUVmax was significantly higher than Integrin SUVmax (p=0.043). Lung and liver metastases: FDG SUVmax was higher than Integrin SUVmax, but the difference was not statistically significant (p>0.05). ***Conclusion:*** 68Ga-DOTA-cyclo(RGDfK) [integrin αvβ3 inhibitor] PET/CT is promising imaging method for the early detection of patients suitable for neovascularization-targeted therapies and monitoring emerging drug resistance. Our results indicate that ^{18}F-FDG PET/CT remains superior for tumor staging and restaging, while 68Ga-DOTA-cyclo(RGDfK) [integrin αvβ3 inhibitor] PET/CT provides complementary rather than equivalent information. Additionally, our findings suggest that Lu-177-labeled integrin analogs may be considered for breast cancer treatment in the future.

EP-0296

Novel spatial PET parameters NHOC and NHOP Predict Pathological Complete Response to Neoadjuvant Therapy in HER2-Positive Breast Cancer

O. Vezir[1], *A. Aksu*[1], *Z. Guc*[2], *K. Kucuker*[1], *A. Alacacioglu*[2], *B. Turgut*[1];
[1]Izmir Katip Celebi University Faculty of Medicine, Department of Nuclear Medicine, Izmir, TÜRKIYE, [2]Izmir Katip Celebi University Faculty of Medicine, Department of Oncology, Izmir, TÜRKIYE.

Aim/Introduction: Accurate prediction of pathological complete response (pCR) following neoadjuvant therapy remains a critical challenge in HER2-positive breast cancer management. We investigated whether spatial metabolic parameters—particularly the novel Normalized Hotspot-to-Centroid (NHOC) and Normalized Hotspot-to-Perimeter (NHOP) from baseline ^{18}F-FDG PET/CT—could improve pCR prediction beyond conventional PET metrics. ***Materials and Methods:*** We retrospectively analyzed female patients with diagnosed HER2+ invasive breast carcinoma, who underwent baseline ^{18}F-FDG PET/CT, completed neoadjuvant therapy, and had subsequent surgery. Primary tumors were manually segmented using LIFEx software. NHOP, NHOC, SUVmax, SUVmean, metabolic tumor volume (MTV), and total lesion glycolysis (TLG) values were calculated for each lesion. The NHOC defined as the normalized distance between the SUVmax voxel and tumor centroid, while NHOP represented the minimum normalized distance between the SUVmax voxel and tumor perimeter. Differences in these parameters between patients with and without pCR were assessed using the Mann-Whitney U test. Statistically significant variables were further analyzed using multivariate logistic regression to identify independent predictors. ***Results:*** A total of 96 HER2+ breast cancer patients were included; 45 achieved pCR. The pCR rate was significantly higher in the non-luminal group (65.6%) compared to the luminal group (37.5%) (p = 0.009). NHOPmax (p = 0.039), NHOCmax (p = 0.022), and SUVmax (p = 0.016) were significantly associated with pCR. NHOPmax and SUVmax were higher in the pCR group, while NHOCmax was lower. The cut-off values were determined as 0.386 (AUC: 0.636) for NHOCmax, 0.141 (AUC: 0.623) for NHOPmax and 11.0 (AUC: 0.643) for SUVmax. In multivariate analysis, NHOPmax (p<0.001, OR: 7.522), NHOCmax (p = 0.047, OR: 2.701), SUVmax (p = 0.005, OR: 4.563) and luminal subtype (p = 0.044, OR: 2.953) emerged as independent predictors of pCR. The spatial parameters showed no correlation with SUVmax (p>0.05), suggesting complementary predictive value. ***Conclusion:*** In addition to SUVmax, the novel PET-derived spatial distribution metrics NHOP and NHOC emerged as independent predictors of pCR in HER2-positive breast cancer. Interestingly, higher NHOP and lower NHOC values were associated with pCR, suggesting that tumors with more homogeneous intratumoral FDG uptake may be more likely to respond completely to neoadjuvant therapy. These readily quantifiable PET biomarkers may help personalize neoadjuvant therapy strategies, particularly for luminal-HER2 tumors where conventional predictors underperform. Further prospective validation in larger cohorts is warranted. ***References:*** J. Jiménez-Sánchez, J.J. Bosque, G.A. Jiménez Londoño et al. [1]Institut Curie, Inserm, Orsay, FRANCE, [2]Unité Chimie Biologie des Cancers, Institut Curie, PSL University, Inserm, CNRS, Paris, FRANCE, [3]Dpt of Nuclear Medicine, Institut Curie, Saint-Cloud, FRANCE, [4]Dpt of Nuclear Medicine, Institut Curie, Paris, FRANCE, [5]Dpt of Pharmacy, Institut Curie, Saint-Cloud, FRANCE, [6]Dpt of Medical Oncology, Institut Curie, Saint-Cloud, FRANCE, [7]Dpt of Medical Oncology, Institut Curie, Paris, FRANCE, [8]Department of Diagnostic and Theranostic Medicine, Institut Curie, PSL University, Paris, FRANCE.

Aim/Introduction: Fibroblast Activation Proteins (FAP) are detected at the surface of Cancer Associated Fibroblasts (CAF) in many cancer types of poor prognosis, including Triple Negative Breast Cancer (TNBC). As part of the Skyline trial (NCT06175390), we are exploring the expression of FAP using a multi-scale imaging approach, involving [68Ga]FAPI-46 PET/CT, histopathology and spatial transcriptomics, to shed new lights into the role of FAP in early and advanced TNBC. ***Materials and Methods:*** Skyline is an ongoing prospective phase 2 trial enrolling 160 TNBC patients to explore the use of an anti-TIGIT therapy combined with anti PD-L1 and chemotherapy in patients undergoing neoadjuvant therapy or first line treatment. All patients undergo an [18F]FDG and [68Ga] FAPI-46 PET/CT before treatment and after 2 cycles. PET-guided biopsies are performed from which immunohistochemistry (IHC) is used to rate the expression of FAP, ANTXR1 and SDC1, which are three markers of immunosuppressive FAP-positive CAF denoted as CAF-S1 [1]. Spatial transcriptomics is also performed for a subsample of subjects to identify CAF subpopulations. SUVmax and Total Tumor Signal (TTS) defined as mean SUV multiplied by the tumor volume on the corresponding PET images were calculated in the biopsied lesions and compared with the FAP, ANTXR1 and SDC1 h-scores from IHC and with the CAF subpopulations identified using spatial transcriptomics. ***Results:*** 50 patients have already been enrolled and 77 biopsied lesions have been analyzed, including 23 with spatial transcriptomic results. For these lesions, the Pearson correlation coefficients (rho) between [68Ga]FAPI SUVmax and h-scores were 0.52 for FAP, 0.69 for ANTXR1 and 0.59 for SDC1. The correlations between [68Ga]FAPI TTS and h-scores were 0.52 for FAP, 0.63 for ANTXR1 and 0.61 for SDC1. There was also a substantial correlation between [18F]FDG SUVmax and h-scores: 0.43 for FAP, 0.53 for ANTXR1 and 0.31 for SDC1 and between [18F]FDG TTS (=Total Lesion Glycolysis) and h-scores: 0.51 for FAP, 0.60 for ANTXR1 and 0.47 for SDC1, confirming that CAF-S1 are located close to tumor cells. Spatial transcriptomics showed that [68Ga]FAPI SUVmax and TTS best correlated with myofibroblastic (my) CAF involved in immunosuppression as opposed to inflammatory CAF (iCAF) (rho= 0.52 with myCAF against -0.33 with iCAF for SUVmax ; rho=0.55 with myCAF against

-0.36 with iCAF for TTS). ***Conclusion:*** [68Ga]FAPI-46 PET signal primary reflects the expression of immunosuppressive CAF and might play a key role for identifying TNBC patients who will benefit most from immunotherapy. ***References:*** Peltier et al. Semin Cancer Biol 2022:262-272.

EP-0298

A study to evaluate the heterogeneity of estrogenreceptor (ER) expression in breast cancer using^{18}F Fluoroestradiol (FES) and^{18}F FDG PET/CT

A. Mahalik, *N. Kundu, A. Roy, M. Tripathi, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: In-vivo assessment of estrogen receptor plays an important role in assessing the tumor heterogeneity and to select patients for hormonal therapy. The main objective of our study was to evaluate the role ofFES PET in estrogen receptor positive invasive ductal breast carcinoma patients and to compare with FDG PET/CT. ***Materials and Methods:*** A prospective cross sectional pilot study done at a tertiary care institute in India from July 2021 to December 2022. Patients with invasive ductal carcinoma and ER positive immunophenotype were included in the study. Patients with age </=18years and who didn't give consent were excluded. The study was conducted after obtaining institutional ethical committee approval. ^{18}F- FES PET/CT and ^{18}F-FDG PET/CT were performed with 7 to 10 days interval on dedicated PET/CT scanner (GE Discovery710). Visual analysis of ^{18}F-FES and ^{18}F-FDG PET/CT studies were performed by two experienced Nuclear Medicine physicians. Any uptake above background intensity was interpreted as positive.Lesions were analysed under four groups; primary, lymph node, osseous metastases and soft tissue metastases. Wilcoxon signed-rank tests were used to assess difference in distribution of number of lesions between 18F-FES and 18F- FDG PET/CT. p value <0.05 were considered significant. ***Results:*** A total of 15 patients were included in the study. Primary breast lesions were evaluated in eleven patients (four patients underwent mastectomy). Ten patients had lymph nodal metastases. Five patients had osseous metastases. Six patients had soft tissue metastases. In primary breast lesion group, alleleven patients (100%) showed 18F FDG avidity whereas only five (45.5%) showed 18F FES avidity (p=0.014). In lymph node group, ten patients showed 18F FDG avidity, but only five patients (50%) showed 18F FES avidity (p =0.034). In osseous metastases group, all seven patients showed 18F FDG avidity; but only five patients (71.4%) showed 18F FES avidity (p =1). In soft tissue metastases group, all six patients showed 18F FDG; only three patients (50%) showed 18F FES avidity (p value 0.02). In per lesion analysis out of total 82 evaluable lesions, FDGdetected 78(95.12%) lesions and FES detected 51(62.19%) lesions (P value <0.01). ***Conclusion:*** FES and FDG uptake in ER positive invasive ductal cancer patients is variable mainly due to tumor heterogeneity. Thus FES can play a main role in-vivo assessment of ER expression in local as well as metastatic sites thereby helping in selecting appropriate treatment. However, studies with large sample size with stringent selection criteria is needed to confirm our findings.

EP-0299

Outperforming FDG? Evaluating the Diagnostic Superiority of ^{68}Ga-FAPI-46 PET/CT in Breast Cancer Staging

S. Patel, *P. Sundaram, P. Subramanyam;*
Amrita Institute of Medical Sciences & Research Center, Kochi, INDIA.

Aim/Introduction: To compare the diagnostic performance of ^{68}Ga-FAPI-46 PET/CT and ^{18}F-FDG PET/CT in the initial staging of breast cancer; to assess metabolic parameters (SUV, MTV) of primary and metastatic lesions; and to evaluate their correlation with histopathological and IHC markers (ER, PR, HER2, Ki-67). ***Materials and Methods:*** A diagnostic cohort study was conducted from 2022 to 2025 with ethical approval. 63 newly diagnosed breast cancer patients were included. Inclusion Criteria 63: FNAC-confirmed breast cancer cases undergoing initial ^{18}F-FDG PET/CT. Exclusion Criteria: History of prior/synchronous malignancy, treatment, pregnancy, or unwillingness to complete both scans. Imaging Protocol: Day 1: Patients fasted ≥6 hours, injected with 0.1 mCi/kg of ^{18}F-FDG, and scanned after 60 minutes on a 16-slice PET/CT with contrast. Day 2: Patients were injected with 2-3 mCi of ^{68}Ga-FAPI and scanned 30 minutes post-injection using the same system. ***Results:*** FAPI PET/CT showed superior tumor delineation in 55 patients, detecting 4 retroareolar and 3 multifocal lesions missed by FDG. Quantitatively, FAPI showed significantly higher SUVmax (13.2 ± 5.4 vs 8.3 ± 4.2; p < 0.001), TBR (10.4 ± 3.4 vs 8.3 ± 3.6; p < 0.001), and larger MTV. Sensitivity (98.55% vs 95.52%), NPV (98.59% vs 95.89%), and accuracy (97.87% vs 96.40%) were higher for FAPI; specificity was identical (97.22%). Histologically, invasive lobular carcinoma showed SUVmax of 11.8 (FAPI) vs 3.9 (FDG); invasive ductal carcinoma: 14.1 vs 9.8. FAPI showed superior uptake across all IHC subtypes except TNBC and high-grade Luminal B, where FDG was better in 6 cases. FAPI had no significant correlation with Ki-67 or grade, unlike FDG. FAPI detected 8 satellite nodules and showed better axillary node assessment (289 vs 218 nodes), with higher SUVmax (11.4 vs 8.1) and greater sensitivity (90.4% vs 83.6%) and accuracy (94.1% vs 84.8%). For internal mammary nodes, FAPI outperformed FDG in sensitivity (94.7% vs 77.3%) and accuracy (94.0% vs 78.0%). Distant metastasis detection was better with FAPI in skeletal (287 vs 194), hepatic (28 vs 27), pleural, muscular, and pulmonary lesions with higher SUV Max values. ***Conclusion:*** ^{68}Ga-FAPI PET/CT demonstrated superior diagnostic performance over ^{18}F-FDG PET/CT in staging breast cancer, with better lesion conspicuity, higher uptake metrics, and improved detection across various sites, particularly in low-FDG-avid subtypes.

EP-0300

Diagnostic Performance of ^{68}Ga-FAPI-46 PET/CT in Metastatic Breast Cancer: A Prospective Comparative Pilot Study

Y. Khandelwal, *B. Jain, P. Baberwal, S. Rastogi, S. Shamim;*
AIIMS, New Delhi, INDIA.

Aim/Introduction: Fibroblast activation protein (FAP) is overexpressed in cancer-associated fibroblasts (CAFs) within the tumor microenvironment of many solid tumors, including breast carcinoma. ^{68}Ga-FAPI-46, a novel radiotracer targeting FAP, has shown encouraging results in oncologic imaging due to its high tumor-to-background contrast and low physiological uptake. This prospective study aimed to evaluate the diagnostic utility of ^{68}Ga-FAPI-46 PET/CT in patients with metastatic breast cancer and compare its imaging performance to that of the standard ^{18}F-FDG PET/CT. ***Materials and Methods:*** Twenty patients (median age: 52 years; range: 34-71) with histologically confirmed metastatic breast cancer were enrolled in this single-center pilot study. All participants underwent both ^{18}F-FDG PET/CT and ^{68}Ga-FAPI-46 PET/CT within one week, using either Siemens Biograph mCT or GE Discovery 710 scanners. Image interpretation included both visual and semi-quantitative assessment. For each modality, the number and distribution of metastatic lesions were recorded, alongside maximum standardized uptake values (SUVmax) and tumor-to-background ratios (TBR). Statistical comparison between the two imaging modalities was conducted using the Wilcoxon signed-rank test for SUVmax and TBR, and the McNemar test for lesion detection rate. ***Results:*** ^{68}Ga-FAPI-46 PET/CT detected a total of 145 metastatic lesions, compared to 116 lesions identified on ^{18}F-FDG PET/CT. FAPI imaging showed superior detection particularly in bone and liver metastases. While the mean SUVmax was slightly higher for ^{68}Ga-FAPI-46 (6.2 ± 2.4) compared to ^{18}F-FDG (5.8 ± 2.1), this difference was not statistically significant (p > 0.05). However, TBRs were significantly elevated in ^{68}Ga-FAPI-46 PET/CT images (p < 0.01). Subtype-specific analysis suggested improved

imaging performance of FAPI in hormone receptor-positive, HER2-negative tumors. ***Conclusion:*** This preliminary study demonstrates that ^{68}Ga-FAPI-46 PET/CT offers excellent diagnostic potential in the evaluation of metastatic breast cancer, with higher lesion detection and superior contrast in certain molecular subtypes and metastatic sites. The enhanced lesion visibility and favorable biodistribution profile of ^{68}Ga-FAPI-46 suggest its utility as a complementary imaging modality to ^{18}F-FDG, particularly in FDG-inconspicuous disease. ***References:*** Li T, Zhang J, Yan Y, Tan M, Chen Y. Applications of FAPI PET/CT in the diagnosis and treatment of breast and the most common gynecologic malignancies: a literature review. Front Oncol. 2024 Mar 5;14:1358070. doi: 10.3389/fonc.2024.1358070. PMID: 38505595; PMCID: PMC10949888.

EP-0301

Prospective Evaluation of ^{68}Ga-FAPi PET/CT Imaging to guide ^{177}Lu-FAPi therapy in patients with metastatic Breast Cancer (mBC)

N. Kumar, *S. Shamim, G. Arora, A. Batra;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Fibroblast Activation Protein (FAP), a type II membrane-bound glycoprotein, is selectively overexpressed on cancer-associated fibroblasts (CAFs) within the tumor microenvironment of various solid tumors, including breast carcinoma. This characteristic has made FAP an attractive theranostic target for in mBC patients. Thus, the present prospective study is designed to evaluate the role of ^{68}Ga-FAPi PET/CT imaging in identifying suitable candidates for ^{177}Lu-FAPi therapy among mBC patients who have exhausted conventional treatment modalities, thereby exploring a new avenue for precision-targeted radioligand therapy in this difficult-to-treat population. ***Materials and Methods:*** All histopathologically proven mBC patients underwent ^{68}Ga-FAPi-46 PET/CT before recruited for ^{177}Lu-FAPi therapy to see expression of FAPi-46 in the treating lesions. Acquired whole body PET/CTs were analyzed both visually and quantitatively. The patients showing good uptake [tumor to background (TBR) with respect to liver >3] on ^{68}Ga-FAPi scan were suitable for ^{177}Lu-FAPi therapy. ***Results:*** A total of 12 mBC patients, age ranged from 33 to 65 years (Median age = 42 years) were recruited for 68Ga-FAPi -46 PET/CT scan. Of 12 mBC patients, 4/12 patients (33%) were triple-negative (TNBC), while others exhibited varying expressions of ER, PR, and HER2neu, indicating differences in tumor biology and aggressiveness. Nine patients (75%) had high Ki-67 indices (60-95%), reflecting active disease proliferation, except for 3 patients (25%) with Ki-67 levels below 40%. All patients demonstrated significant heterogeneity in SUVmax values of primary lesion and metastatic sites. Based on the imaging findings, 11 out of 12 patients demonstrated high FAP expression (SUVmax >4.0, TBR with respect to liver >3.0) and were potential candidates for ^{177}Lu-FAPi radioligand therapy. The mean value of SUVmax of primary lesion and metastatic sites was 6.16 ± 3.0 (range 3.3-14.11), SUVmax of liver = 0.84 ± 0.39 (range 0.4-1.6) and tumor-to-background ratios (TBR) with respect to liver was 8.07 ± 2.97 (range 2.54-12.71). Higher uptake was observed in patients with TNBC, HER2-positive resistant disease, and those with high Ki-67 indices. Tracer avidity was evident across metastatic sites, including the lungs, liver, bones, brain, and lymph nodes. ***Conclusion:*** The high tumor-to-background ratios and SUVmax values observed, particularly in patients with elevated Ki-67 indices, support the potential utility of FAPi-based imaging in identifying suitable candidates for targeted ^{177}Lu-FAPi radioligand therapy.

EP-0302

[^{18}F]PSMA-1007 and [^{18}F]FDG PET/CT in patients with triple-negative breast cancer: a head-to-head comparative assessment study

T. Lazutina, *A. Khalimon, S. Urtaev, A. Lokhova, M. Khodzhibekova, D. Khodakova, G. Khamadeeva, I. Pylova, A. Leontev;*
P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: This study aimed to compare [^{18}F]FDG and [^{18}F]PSMA-1007 PET/CT head-to-head in patients with triple-negative breast cancer (TNBC). ***Materials and Methods:*** This prospective single-center study included 11 patients with histologically confirmed TNBC: 2 at initial staging, 6 with recurrence after treatment, and 3 with disease progression during therapy. [^{18}F]FDG and [^{18}F]PSMA-1007 PET/CT were performed within a 2-13 day interval between the studies. [^{18}F]FDG PET/CT included contrast-enhancement CT (CECT) from vertex to mid-thigh. For each tracer, the number and localization of detected lesions were determined using PET alone, PET/non-contrast CT (NCCT), and PET/CECT. Visual and semi-quantitative assessments of tracer uptake in tumor lesions were performed. SUVmax was measured for target lesions ≥15mm. ***Results:*** A total of 144 lesions were identified: chest wall (n=11), lymph nodes (n=58), bones (n=48), lungs (n=17), liver (n=7), peritoneum (n=2), brain (n=1). Concordant lesions between [^{18}F]FDG and [^{18}F]PSMA-1007 were found in 77.1% (n=111) using PET alone, in 86.8% (n=125) using PET/NCCT, in 93.8% (n=135) using PET/CECT. Nine discordant lesions (6.3%) were observed in four patients: 6 (66.7%) - using [^{18}F]PSMA-1007 PET (only bone lesions), 3 (33,3%) - using [^{18}F]FDG PET (only lymph nodes). Higher [^{18}F]FDG uptake was observed in 81 lesions (73%) across 10 patients: chest wall (n=10), lymph nodes (n=30), bones (n=32), lungs (n=8), peritoneum (n=1). [^{18}F]PSMA-1007 uptake predominated in 25 lesions (22.5%) across 6 patients: chest wall (n=1), lymph nodes (n=13), bones (n=3), lungs (n=6), liver (n=2). Comparable uptake of both tracers was noted in 5 lesions (4.5%) across 4 patients: lymph nodes (n=4), bones (n=1). 72 target lesions (50%) were identified. The median SUVmax for [^{18}F]FDG and [^{18}F]PSMA-1007 were as follows: for all lesions - 5.9[3.9;8.3] and 2.9[2.1;4.7]; for chest wall lesions - 6.8[4.4;9.5] and 2.1[1.5;2.9],(p=0.001); for lymph nodes - 5.2[4.6;6.95] and 3.0[2.2;5.6],(p=0.007); for bone lesions - 7.4[6.2;11.0] and 3.2[2.6;5.1],(p<0.0001); for lung lesions - 3.4[2.2;5.5] and 2.9[1.6;4.6],(p=0.535); for liver lesions - 7.6[6.0;9.6] and 9.5[8.6;10.4]. Total [^{18}F]PSMA-1007 uptake predominated in two patients, while [^{18}F]FDG uptake predominated in eight patients, one patient showed comparable uptake of the tracers across lesions. No target lesions with [^{18}F]PSMA-1007 SUVmax≥10.0 were observed. ***Conclusion:*** The additional use of CECT allows for an increase in the number of tumor lesions detected by both [^{18}F]FDG and [^{18}F]PSMA-1007 PET/CT to similar values. In general, the level of lesional [^{18}F]FDG uptake was higher than that of [^{18}F]PSMA-1007 uptake. No patient demonstrated PSMA-ligand uptake that met the current criteria for PSMA-positivity for radioligand therapy.

EP-0303

Evaluation of Treatment Response Using Post-^{131}I-MIBG Scintigraphy in Patients with unresectable or metastatic PPGL: Correlation with Prognosis and Clinical Factors

J. Takenaka[1,2,3], *S. Watanabe*[1,2,4], *T. Abe*[5], *S. Takeuchi*[6,7], *K. Hirata*[1,2,8], *R. Kimura*[1,9], *H. Ishii*[1,2], *N. Wakabayashi*[1,2], *M. Majigsuren*[1,10], *K. Kudo*[1,8,9];

University Hospital, Sapporo, JAPAN, [9]Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN, [10]Department of Radiology, Diagnostic Imaging Center, Second State Central Hospital, Ulaanbaatar, MONGOLIA.

Aim/Introduction: Pheochromocytomas and paragangliomas (PPGLs) are rare catecholamine-producing neuroendocrine tumors. Approximately 10-30% of PPGLs are unresectable or metastatic (umPPGLs), leading to both tumor- and catecholamine-related morbidity and mortality. Radionuclide therapy using ^{131}I-metaiodobenzylguanidine (^{131}I-MIBG) is an established treatment for umPPGLs, with demonstrated reductions in tumor burden and catecholamine levels. Post-therapy scintigraphy (PTS) using administered ^{131}I-MIBG enables imaging without additional tracers, but its role in evaluating therapeutic response remains uncertain. This study aimed to investigate the relationship between treatment response assessed by PTS and changes in tumor size, prognosis, and clinical factors. ***Materials and Methods:*** We retrospectively reviewed patients who underwent multiple sessions of ^{131}I-MIBG therapy at our institution between 2001 and 2024. The first post-therapy scintigraphy was compared with the latest post-therapy scintigraphy among a series of consecutive treatments administered within a one-year interval. Patients without MIBG-avid lesions were excluded. Visual assessment of PTS was performed by J.T. (a radiologist and nuclear medicine physician) and classified as partial response (PR_{PTS}), stable disease (SD_{PTS}), or progressive disease (PD_{PTS}). Compared to the first PTS, the latest PTS was categorized as PR_{PTS} if lesion uptake had decreased, SD_{PTS} if there was no change, and PD_{PTS} if uptake had increased. Tumor diameter was measured on CT scans obtained closest to each scintigraphy, the patients were categorized to PR_{CT}, SD_{CT}, PD_{CT} according to RECIST criteria. Concordance between PTS and CT responses was assessed using the kappa coefficient. Treatment responses evaluated by PTS were compared with overall survival since the first ^{131}I-MIBG therapy using the log-rank test, and with clinical factors using univariate logistic regression. ***Results:*** Twenty-one patients (age 24-69 years; 12 females) were included. PTS showed PR_{PTS} in 14 (66.7%), SD_{PTS} in 6 (28.6%), and PD_{PTS} in 1 (4.8%) patient. CT showed PR_{CT} in 6 (28.6%), SD_{CT} in 14 (66.7%), and PD_{CT} in 1 (4.8%). The concordance between PTS and CT was moderate ($\kappa = 0.382$). When patients were divided into PR and non-PR groups, overall survival did not significantly differ between PR and non-PR groups based on either PTS ($p = 0.65$) or CT ($p = 0.66$). The PR_{PTS} group was significantly associated with lower urinary dopamine levels ($p = 0.04$), absence of prior chemotherapy ($p = 0.04$), and the presence of lymph node or peritoneal lesions ($p = 0.001$). ***Conclusion:*** PTS-based treatment response does not correlate with prognosis and may have limited utility in assessing disease status in umPPGL patients.

EP-0304

Progression and characterization of intracardiac metastases from gastroenteropancreatic neuroendocrine tumors.

I. Scalia[1], *A. F. Yang*[2], *F. E. Abdelfattah*[1], *O. H. Ibrahim*[1], *J. M. Farina*[1], *R. Arsanjani*[1], *C. Ayoub*[1], *M. Yang*[1];
[1]*Mayo Clinic Arizona, Phoenix, AZ, UNITED STATES OF AMERICA,* [2]*Wayne State Medical School, Detroit, MI, UNITED STATES OF AMERICA.*

Aim/Introduction: Cardiac metastases from primary gastroenteropancreatic neuroendocrine tumors (NET) are rare and not well described. Significantly, little is known about the rate of progression or therapeutic effect of targeted therapies on cardiac metastases. ***Materials and Methods:*** All adult patients with primary NETs from three tertiary institutions between 2011 and 2023 were reviewed. Confirmation of cardiac metastatic involvement was determined on ^{68}Ga-DOTATATE positron emission tomography (PET), and patients were required to have at least one follow-up ^{68}Ga-DOTATATE PET scan. The maximal dimension and maximal standard uptake value (SUV_{max}) of lesions were measured. If patients had multiple intracardiac lesions, the largest was recorded. Patients were reviewed for baseline characteristics and treatment with Lu-177 DOTATATE. ***Results:*** Overall, 23 patients (M: F = 14: 9) with 32 intracardiac metastases had serial ^{68}Ga-DOTATATE PET imaging. The mean age of this cohort was 63.8 ± 10.8 years. The intracardiac metastases were located in the ventricular myocardium (43.5%), followed by the pericardium (30.4%) and the interventricular septum (26.1%). The median time between initial and follow-up ^{68}Ga-DOTATATE PET imaging was 2.2 [IQR 1.1-4.9] years. There was no significant difference in the median maximal dimension of cardiac metastases on initial imaging compared to follow-up imaging; 12.0mm [IQR 8.0-16.0] vs 11.0mm [IQR 9.0-15.0], p=0.322 (Figure A). Similarly, there was no significant change in SUV_{max} on serial PET-DOTATATE scans; 7.8 [IQR 3.9-14.7] compared to 7.1 [IQR 4.3-14.6], p=0.456 (Figure B). Within the cohort, 11 (47.8%) patients received Lu-177 DOTATATE therapy. There was no significant difference in age between patients who did and did not receive Lu-117 DOTATATE (64.1 years vs 63.5 years, p=0.896). Of the patients who received Lu-177 DOTATATE therapy, there was a median reduction in metastasis dimension of 1.0mm [IQR -3.0-0.0] on serial imaging (Figure C), and only four patients (36.4%) observed progression in metastasis burden (characterized as increase in either metastatic dimension or SUV_{max}). In comparison, there was a median increase in median metastatic dimension by 0.5mm [IQR -2.0-2.0] in patients who did not receive Lu-177 therapy, and 10 patients (83.3%) had progression of either diameter or SUV_{max}. ***Conclusion:*** Over approximately two years follow-up, intracardiac metastases from primary gastroenteropancreatic NETs did not demonstrate significant progression in either maximal dimension or SUVmax. Patients who received Lu-177 DOTATATE therapy were observed to have some regression in metastatic dimension and were less likely to have progression of intracardiac metastases compared to those who did not receive Lu-177 DOTATATE therapy.

EP-0305

Pancreatic Metastases in Small Intestinal Neuroendocrine Tumors: An Underestimated Occurrence?

Q. Wang[1], *A. Rinke*[2], *F. Eilsberger*[1], *M. Luster*[1], *B. Hooshyar Yousefi*[1], *D. Librizzi*[1,3];
[1]*Department of Nuclear Medicine, University Hospital Marburg, Philipps University of Marburg, Marburg, GERMANY,* [2]*Department of Internal Medicine, Division of Gastroenterology and Endocrinology, University Hospital Marburg, Philipps University Marburg, Marburg, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital OWL, Evangelical Hospital Bethel, Bielefeld, GERMANY.*

Aim/Introduction: Small intestinal neuroendocrine tumors (siNETs) are among the most common malignancies of the small intestine; however, their pancreatic metastases are rare. [^{68}Ga]Ga-DOTATOC, a well-established diagnostic tool for neuroendocrine tumors, has been utilized in clinical practice for over two decades. Despite its widespread use, a standardized SUVmax reference for pancreatic metastases has not yet been established. Pancreatic metastases are difficult to diagnose and may be underdiagnosed. This study aims to provide an SUVmax reference value for the clinical diagnosis of pancreatic metastases by measuring the SUVmax of pancreatic metastatic lesions in siNET patients, and assess the potential under-diagnosis of pancreatic metastases. ***Materials and Methods:*** A retrospective study was conducted, analyzing patient-based SUVmax data for Group A and Group B. Group A: Includes patients with pancreatic metastatic lesions confirmed by pathology, or clinical follow-up including MRI, physician review, or repeated [^{68}Ga]Ga-DOTATOC examinations. The number of patients in this group is 10. Group B: Includes patients with pancreatic metastatic lesions reported by a single [^{68}Ga]Ga-DOTATOC examination without further validation. This group contains 7 patients. SUVmax mean values were calculated using bootstrap resampling, extended to 10,000 data points. Comparisons were made between the SUVmax mean of Groups A and B, estimating the difference between the two. Group C:

Secondary assessment by the nuclear medicine specialist to assess possible missed diagnoses. ***Results:*** Group A: SUVmax mean = 24.4 (95% CI: 16.50, 34.00). Group B: SUVmax mean = 20.8 (95% CI: 14.60, 27.91). While Group A showed a higher SUVmax mean than Group B, the overlapping 95% confidence intervals indicated no statistically significant difference. The mean difference in SUVmax between Groups A and B was 3.6 (95% CI: -6.97, 15.36), confirming no significant difference. Pancreatic metastasis are highly suspected from SUVmax, although patients in group B have not been reconfirmed by other methods. Group C: Expert Secondary Evaluation. An experienced nuclear medicine specialist re-reviewed the [^{68}Ga]Ga-DOTATOC images that were first reported as negative for pancreatic metastases and identified 31 new cases that were highly suspicious to be positive for pancreatic metastases. ***Conclusion:*** This study offers validated SUVmax reference values for the diagnosis of pancreatic metastases from small intestinal neuroendocrine tumors, a rare metastatic site. The incidence of pancreatic metastases from small intestinal neuroendocrine tumors may be underestimated and further studies are needed to confirm this.

Aim/Introduction: Treatment of pancreatic neuroendocrine tumors (pNETs) relies on several options: somatostatin analogs, chemotherapy, multikinase inhibitors (MKIs), and peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE. Among these options, SSTR PET is used to monitor response and to select patients for PRRT. The aim of this study is to report the impact of lenvatinib treatment on somatostatin receptor expression as measured by 68Ga-DOTATOC PET in patients with metastatic pancreatic NETs. ***Materials and Methods:*** A total of 20 patients treated with lenvatinib were retrospectively evaluated. Patients were selected according to the following criteria: 1) confirmed metastatic pancreatic NET, 2) lenvatinib treatment administration, 3) DOTATOC PET performed within 12 months before starting treatment and at least once during or at the end of lenvatinib treatment, and 4) CT scans or MRI performed at the same time as the PET evaluation. Response was assessed according to RECIST-1.1 criteria. Semiquantitative PET analysis (SUVmax) was performed on the same target lesions considered for RECIST-1.1 using dedicated software (Syngo.via, Siemens). ***Results:*** Six patients (median age 55 years, range: 48-59 years, 2F, 4M) with pancreatic NET (5 G2 and 1 G3) who received lenvatinib treatment were finally selected. On-treatment DOTATOC PET was performed at 1 month (n=1), 3 months (n=2), 6 months (n=1), and 12 months (n=2) after treatment initiation. A total of 17 target lesions (12 liver lesions and 5 abdominal lymph nodes) were analyzed. Median baseline SUVmax was 33.4 (range: 7.3-97.6). On 68Ga-DOTATOC PET, ΔSUVmax was -100% at 1 month (patient 1) with RECIST 1.1 response of -42% (PR); -80% and -88% at 3 months (patients 2 and 3) with RECIST 1.1 responses of -2% and -27% (SD), respectively; -41.5% at 6 months (patient 4) with RECIST 1.1 response of -2% (SD); and -61% and -87.5% at 12 months with RECIST 1.1 responses of -2% and -68% (SD and PR, respectively; patients 5 and 6). Complete or near-complete negativation of somatostatin receptor expression in vivo was observed in 5 patients despite stable or only partial response by RECIST 1.1 criteria. These five patients remain under treatment without evidence of disease progression. ***Conclusion:*** These preliminary results suggest that, under MKI treatment, the loss of uptake to SSTR PET without RECIST 1.1 complete response occur. This phenomenon may theoretically affect patients eligibility for PRRT as next line treatment. A prospective study is planned to better understand the mechanism and prognostic impact of this finding (Tolerate study).

EP-0307

Prognostic Value of [^{68}Ga]Ga-SSA PET/CT After [^{177}Lu]Lu-DOTATATE Therapy in Neuroendocrine Tumours

A. Bagán-Trejo[1], *J. L. Vercher-Conejero*[1], *J. J. Martín-Marcuartu*[1], *G. Reynés-Llompart*[2], *M. Tormo-Ratera*[1], *J. C. Ruffinelli*[3], *D. Rodríguez-Puig*[4], *C. García-Alcober*[4], *B. Hervás-Sanz*[1], *D. J. Tamayo-Ossa*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine-PET (IDI) Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Medical Physics and Radiation Protection Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN,* [3]*Oncology Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN,* [4]*Radiopharmacy Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) using [^{177}Lu]Lu-DOTATATE has been widely used as an effective treatment for neuroendocrine tumours (NETs), particularly gastroenteropancreatic NETs (GEP-NETs). Assessing therapeutic effectiveness early is crucial to guide subsequent clinical management decisions. This study aimed to evaluate the prognostic value of the first response assessment using PET/CT with [^{68}Ga]Ga-somatostatin receptor analogues ([^{68}Ga]Ga-SSA) in predicting progression-free survival (PFS) and overall survival (OS) following PRRT. ***Materials and Methods:*** 96 patients were included in the study, with the majority diagnosed with GEP-NETs (83%). Other NET subtypes included pheochromocytomas/paragangliomas (7%) and lung carcinoids (5%). Most patients (83%) received four cycles of [^{177}Lu]Lu-DOTATATE, spaced 8 weeks apart. Clinical responses were assessed based on symptom improvement, with biochemical response defined as a decrease in chromogranin A or 5-Hydroxyndoleacetic acid (5-HIAA) levels by more than 50%. Adverse effects were monitored via standard criteria such as CTCAE, including haematological (anaemia, leukopenia, thrombocytopenia, or pancytopenia), gastrointestinal (nausea/vomiting, diarrhoea/constipation), and renal (glomerular filtrate and creatinine) toxicities. PET/CT scans with [^{68}Ga]Ga-SSA were performed 3 months after the final PRRT cycle, categorising outcomes into partial response (PR), stable disease (SD), and progressive disease (PD). Kaplan-Meier curves were used to analyse PFS and OS, and Cox regression was employed to evaluate the hazard ratio (HR) for response. ***Results:*** A favourable clinical response was observed in 49 patients (51%), with 16% showing a positive biochemical response. Observed adverse effects included gastrointestinal issues (25%), haematological (36%), and renal (3%) toxicity. In relation to PET/CT scans, PR was observed in 44% of patients; 42% showed SD; and 13% had PD. Overall survival was significantly improved in patients achieving PR or SD on PET/CT compared to PD (median OS: 53.17 vs. 8.5 months; p<0.0001). Progression-free survival also differed significantly (median PFS: 31 vs. 5.5 months; p<0.0001). Multivariate Cox regression identified PET/CT response as a strong predictor (HR=22.61 for OS, HR=12.38 for PFS; p<0.001). ***Conclusion:*** Evaluation with [^{68}Ga]Ga-SSA PET/CT after treatment with PRRT for NETs significantly correlates with long-term clinical outcomes, providing significant information for assessing therapeutic effectiveness and anticipating disease trajectory. The response evaluation using [^{68}Ga]Ga-SSA PET/CT represents a robust prognostic biomarker, enabling better patient stratification, informed clinical decisions, and tailored therapeutic

approaches. Future prospective studies may help refine the timing and interpretation of such assessments and explore their role in adaptive treatment strategies.

EP-0308

Peptide receptor radionuclide therapy (PRRT) in high-grade neuroendocrine neoplasms: a systematic review and metanalysis

E. Zampella, *F. Volpe, L. Piscopo, V. Gaudieri, c. Nappi, V. Cantoni, R. Green, E. Caiazzo, A. Cuocolo, M. Klain;*
University Federico II, Naples, ITALY.

Aim/Introduction: In patients with neuroendocrine neoplasms (NEN), tumor's aggressiveness and prognosis are strongly associated to the tumor grading. Peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE is a well validated treatment in patients with G1 and G2 gastro-entero-pancreatic (GEP) NENs. Previous studies investigated the potential role of 177Lu-DOTATATE in patients with G3 GEP-NENs. However, the efficacy of PRRT in these patients remains to be fully addressed. We conducted a systematic review and meta-analysis to evaluate the efficacy of PRRT by 177Lu-DOTATATE in patients with high GEP-NENs. ***Materials and Methods:*** All clinical studies published up to March 2025, including patients with G3 GEP-NENs treated with 177Lu-DOTATATE, were identified based on systematic searches in the PubMed, Cochrane Library and Web of Science. We included all the studies where disease control rate (DCR) and disease response rate (DRR), according to RECIST criteria, were reported. Moreover, in order to evaluate the therapeutic efficacy of PRRT, progression free survival (PFS) and overall survival (OS) were also considered. ***Results:*** We identified 12 studies, including a total of 374 participants. According to RECIST criteria, the pooled effect was 63% (95% confidence interval (CI) 54-73%) for the DCR and 32% (95% CI 21-44%) for the DRR. The PFS and OS were considered in 9 studies, with a median follow-up of 29 months. The pooled PFS and OS resulted to be 13.88 [95% CI 10.33-18.64] and 29.95 [95% CI 19.8-45.3] months, respectively. ***Conclusion:*** For patients with high grade GEP-NENs, 177Lu-DOTATATE is promising treatment providing substantial disease control and response rates. Moreover, PRRT seems to be able to delay the progression of the disease, improving patient's outcome. However, further multicenter randomized controlled trials are needed in order to assess the safety and efficacy of PRRT in these patients.

EP-0309

Optimal scan time for [18F]SiTATE PET/CT imaging of patients with neuroendocrine tumors

R. Ebner, *F. Herr, M. Zacherl, F. Eckenweber, K. Klimek, J. Ricke, C. C. Cyran, R. A. Werner, G. T. Sheikh;*
University Hospital LMU Munich, Munich, GERMANY.

Aim/Introduction: The fluorine-18-labelled, somatostatin receptor (SSR)-targeting tracer [^{18}F]SiTATE is gaining momentum in clinical use as a promising alternative to commonly used gallium-68-labelled SSR-targeting compounds, demonstrating excellent image quality and clinical utility. Currently, imaging with SITATE-PET/CT is performed 90 minutes after tracer injection, complicating integration into a multi-tracer PET environment, in which most tracers are imaged 60 minutes after tracer injection. We therefore investigated whether comparable image quality and quantification can be achieved at other time points, that integrate better into clinical routine. ***Materials and Methods:*** Eight NET patients with histologically confirmed metastasized GEP-NET received a [18F]SiTATE-PET/CT (250 ± 66 MBq) with repeated emission scans 60-, 90-, and 120-minutes post-injection. SUVmax, SUVpeak and SUVmean was measured in visceral organs and a total of 49 SSR-positive lymph node, liver and bone and tumor-to-background ratios were calculated. Statistical comparison of tumor-to-background ratios across the three time points was performed. Additionally, scans were visually evaluated for clinically noticeable differences by four individual readers of different experience levels. ***Results:*** No significant differences in tumor-to-background ratios were observed across timepoints for liver (p=0.6613), lymph nodes (p=0.5413), bone (p=0.8478), or overall lesion assessment (p=0.7248). Post hoc multiple comparisons using Tukey's test revealed no significant differences between the time points, with p-values ranging from 0.5103 to 0.999. Individual readers did not report any relevant qualitative visual difference between the time points; all lesions could be clearly identified against the surrounding background. ***Conclusion:*** The results demonstrate a consistent tracer uptake pattern over time, with minimal variation in tumor-to-background contrast across different metastatic sites. Imaging at 60 minutes post-injection yields equivalent lesion detectability and quantitative contrast compared to later time points at 90 and 120 minutes. These findings underscore the clinical utility of early imaging with [^{18}F] SiTATE for NET patients, offering the potential to facilitate workflow and enhance patient comfort without sacrificing diagnostic accuracy.

[68Ga]68Ga-DOTANOC LAFOV PET/CT in NET: are HYPER and OSEM semiquantitative parameters comparable?

G. Bianciardi[1], *E. Fortunati*[2], *M. Di Franco*[1], *C. Malizia*[2], *M. Assenza*[3], *D. Campana*[4], *E. Andrini*[4], *E. Tabacchi*[2], *V. Allegri*[2], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Professional Development and Implementation of Research in Health Professional Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Medical and Surgical Sciences (DIMEC), Medical Oncology Unit, Alma Mater Studiorum-University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: The introduction of long axial field-of-view (LAFOV) PET/CT has enabled significant improvements in visual image quality and increased sensitivity. It is well-known that different image reconstructions may impact both the visual-perceived overall image quality and the absolute values of functional semiquantitative PET parameters. HYPER is a bayesian penalized likelihood reconstruction algorithm which incorporates a pre-trained Computer Neural Network into the PET reconstruction to produce both high-contrast and low-noise PET images. Aim:to compare 68Ga-DOTANOC-PET/CT semiquantitative parameters obtained from the OSEM and HYPER reconstructions in NET patients. ***Materials and Methods:*** Among NET patients followed at the local Oncology Unit, those consequently imaged with 68Ga-DOTANOC uExplorer LAFOV PET/CT (October 2024-March 2025) were retrospectively included (mean injected dose [1.4±0.3MBq/kg]; acquisition time:5min). Images were reconstructed using both OSEM and HYPER. CNR ((⟦SUVmean⟧_ROI-⟦SUVmean⟧_background)/⟦SD⟧_(SUVmean background)) and SUVmax were measured in a maximum of 3 target lesions per-patient: the most avid lesion at any site >1cm (T); most avid liver lesion <1cm (t_L);the most avid extra-hepatic lesion <1cm (t). Wilcoxon-test and Bland-Altman test were used to compare SUVmax and CNR obtained from OSEM and HYPER in both the total number of paired target lesions and in each of the above-mentioned sub-categories (defined by lesions' dimensions and site). ***Results:*** Overall, 45 NET patients were included (primary tumour site: pancreas=21/45,47%;gastro-intestinal=18/45,40%; lung= 2/45,4%; other sites=4/45,9%).Indications to PET/CT were staging (7/45,16%), restaging (20/45,44%), follow-up (20/45,40%). PET was positive in 28/45(63%) and negative in 17/45(4%). A total of 40 target lesions were assessed: T=18, t_L=8, t=14. HYPER-SUVmax was higher than OSEM-SUVmax either when considering all target lesions (HYPERmedian=16.1vsOSEMmedian=14.4,p<0.01)

and within each target lesion's subgroup: T(33.1vs30.4,p<0.01); t_L(14.2vs11.8,p=0.016), t (14.4vs10.3,p<0.01). CNR values were also significantly higher when using the HYPER reconstruction regardless of target lesions' dimensions and site (T: p<0.001;t_L:p =0.031;t:p=0.007;all target lesions:p<0.01). Bland-Altman analysis showed a systematic bias in favour of HYPER, with mean negative differences for SUVmax in all target lesions cathegories (all target lesions: 95%CI=-4.65,-1.93;p<0.01;T:95%CI=-6.28,-0.53,p= 0.02;t_L:95%CI=0.66,4.44;p=0.02;t:95%CI=-5.11,-2.03;p<0.01). All comparisons showed statistically significant bias, indicating limited agreement between the two reconstruction methods. ***Conclusion:*** HYPER- SUVmax and CNR were higher compared to OSEM-SUVmax and OSEM-CNR. The presence of systematic bias suggests that 68Ga-DOTANOC-PET/CT HYPER and OSEM reconstructions are not directly comparable. Although these data were derived form a limited cohort, these preliminary results indicate the need to extend the sample size and to evaluate the impact of the use of different reconstructions in the routine workflow of PET centre with different camera technologies.

EP-0311

Preliminary experience on the use of [68Ga]68Ga-DOTANOC LAFOV PET/CT in NET patients

G. Bianciardi[1], *E. Fortunati*[2], *M. Di Franco*[1], *C. Malizia*[2], *M. Assenza*[3], *D. Campana*[4], *E. Andrini*[4], *V. Allegri*[2], *E. Tabacchi*[2], *S. Fanti*[1,2], *V. Ambrosini*[1,2];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Professional Development and Implementation of Research in Health Professional Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Medical and Surgical Sciences (DIMEC), Medical Oncology Unit, Alma Mater Studiorum-University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Long axial field-of-view (LAFOV) PET/CT ensures significant improvements in image quality and increased sensitivity, offering the advantage of reduced scanning time and possibility to use reduced injected activity. Aim: to describe the preliminary experience on the use of 68Ga-DOTANOC LAFOV PET/CT in NET patients and compare functional images with standard diagnostic imaging. ***Materials and Methods:*** Among the NET patients followed at the local Oncology Unit, those imagined with 68Ga-DOTANOC acquired on a uExplorer LAFOV-PET/CT (October 2024-March 2025; mean 68Ga-DOTANOC dose of 1.4±0.3MBq/kg; acquisition time=5min). Considering the higher sensitivity expected from LAFOV, results of PET were compared with standard morphologic diagnostic procedures, when available (contract-enhanced-CT, ceCT; MRI).ceCT/MRI vs LAFOV-PET/CT lesions by lesions analysis was performed when available (within 6months) and concordance/discordance was recorded. Lesions were classified as concordant (when visible on both PET and diagnostic imaging) or discordant (visible on one modality only). ***Results:*** Overall, 57 patients were studied (primary tumour site: pancreas=26/57,46%;other-GEP=20/57,35%;lung=4/57,7%;other-site=7/57.12%; grade: G1=26/57,46%;G2=31/57,54%).Overall, the procedure was well tolerated notwithstanding the extended FOV. Image visual-quality was overall good despite the injected activity in the lower recommended range. PET was positive in 34/57(60%) and negative in 23/57(40%). Metastatic lesions were mostly at liver and nodal level. ceCT/MRI was available in 27/57 (47.7%): ceCT in 24/27 (88.9%), liver-MRI in 3/27 (11.1%). Concordance was observed in 19/27 cases (70.4%), discordance in 8/27 cases (29.6%). In 4/8 discordant cases, PET identified additional findings undetected by ceCT/MRI: mesenteric nodules (n=1), ileal uptake (n=1), bone lesions without morphological correlates (n=2). In the remaining 4/8 cases, ceCT or MRI identified additional lesions undetected by PET: liver lesions on MRI (n=2; millimetric), pancreatic and liver lesions on ceCT (n=1), and small hepatic lesions on ceCT (n=1). ***Conclusion:*** 68Ga-DOTANOC LAFOV PET/CT was well-tolerated and resulted in high image visual-quality, notwithstanding the administration of mean doses in the lower range of the recommend injected activity and reduced acquisition times. In most cases, PET was concordant with ceCT/MRI (70%). Larger cohorts of NET patients are needed to fully understand the advantages of LAFOV in clinical practise and to optimise the comparison with images acquired on SAFOV cameras (a frequent issue in NET patients often scanned at different centers over time).

EP-0312

Functional vs. morphological imaging in Well-Differentiated Neuroendocrine Tumors: how ^{68}Ga-DOTATOC PET/CT can influence treatment decision-making

C. Battisti[1], *C. Ferrari*[1], *A. Pisani*[1], *D. Candido*[1], *E. Lauricella*[2], *M. Bacalim*[2], *D. Rubini*[3], *M. Cives*[2], *G. Rubini*[1];
[1]*Nuclear Medicine Unit, DIM, University "Aldo Moro", Bari, ITALY,* [2]*University of Bari Aldo Moro, Interdisciplinary Department of Medicine, Bari, ITALY,* [3]*Radiotherapy, Precision Medicine Department, University of Campania "Luigi Vanvitelli", Naples, ITALY.*

Aim/Introduction: to compare the ^{68}Ga-DOTATOC-PET/CT and morphological imaging (MI) detection rate in patients with well-differentiated neuroendocrine tumors (NETs) and their impact on changes in treatment strategy (CTS). ***Materials and Methods:*** 61 NETs patients who performed ^{68}Ga-DOTATOC-PET/CT and MI for staging/restaging purpose, between November 2023 and December 2024, were retrospectively analyzed. All ^{68}Ga-DOTATOC-avid lesions were compared with those detected by MI, in relation to primary site, lymph node involvement and metastatic locations (liver, bone, lung). MI was represented by TC in 37 patients, MRI in 11 and both modalities in 13 patients. All ^{68}Ga-DOTATOC-avid lesions were semiautomatically segmented and SUVmax, SUVmean, somatostatin-receptor-expressing tumor volume (SRETV) and total lesion somatostatin-receptor-expression (TLSRE) were extracted. Then, whole-body SRETV (SRETVwb) and TLSRE (TLSREwb) were defined as the sum of SRETV and TLSRE. After PET imaging, clinical follow-up was assessed in terms of CTS. The agreement between PET/CT and MI results was evaluated by Cohen's kappa-coefficient for each specific site of disease involved. Chi-square, Fisher's exact and Mann-Whitney tests were employed to assess the correlation between PET parameters and CTS. ***Results:*** Detection rate was 90% in MI and 87% in PET/CT. Median SRETVwb and TLSREwb was 46.64cm^3 and 303.67g/mLxcm^3, respectively. Both modalities were almost concordant in the assessment of primary site (p=0.000 k=0.630), while a slight agreement was observed in lymph nodes involvement (p=0.213 k=0.156, 15 patients MI-/PET+). On secondary lesion-based analysis, a substantial agreement was achieved in the liver (p=0.000 k=0.640), moderate agreement in the lung (p=0.000 k=0.504) and a fair agreement in the bone (p=0.001 k=0.387). PET/CT revealed more lesions in the bone (9 patients MI-/PET+), while MI in the lung (4 patients MI+/PET-). Regarding CTS, the absence of secondary sites (p=0.001), in particular of liver involvement (p=0.005), significantly correlated with no therapeutic modifications; conversely, higher SRETVwb values were significantly associated with CTS (p=0.028). CTS was confirmed in 27 patients (44%), and in 20/27 PET and MI showed discordant results. Out of 15/20 patients (75%), PET/CT revealed more lesions than MI, with a high tumor burden (median SRETVwb:392.23cm^3). ***Conclusion:*** The two methods confirm a reliable and complementary role in the management of NETs. In particular, MI remains the gold standard for lung assessment, while PET provides additional information on lymph node status and bone involvement. Furthermore, the tumor burden evaluation, using semiquantitative volumetric ^{68}Ga-

DOTATOC-PET/CT parameters, could represent a useful clinical tool for influence treatment decision-making in the perspective of personalized medicine.

EP-0313

Molecular Mechanisms of SSTR2-Mediated Regulation of Glucose Metabolism in Neuroendocrine Neoplasms

L. Hao;
Central South University, Changsha, Hunan, CHINA.

Aim/Introduction: Neuroendocrine neoplasms (NENs) exhibit clinical and pathological heterogeneity, with some patients harboring concurrent neuroendocrine tumors (NETs) and carcinomas (NECs) or progressing from NETs to NECs. The regulatory mechanisms driving this progression remain unclear. Combined [^{18}F]F-AlF-NOTA-octreotide ([^{18}F]F-OC) and [^{18}F]F-FDG PET/CT imaging delineates distinct metabolic phenotypes: NETs show high SSTR2 expression and low glucose metabolism, whereas NECs exhibit reduced SSTR2 and elevated glucose uptake. Prior studies have demonstrated somatostatin analogs suppress HIF-1α, a master regulator of glycolysis, thereby reducing GLUT1 expression and tumor proliferation. Therefore, this study aims to investigate the interplay between SSTR2 and glucose metabolism in NENs progression, providing insights for precision monitoring and targeted therapy. ***Materials and Methods:*** 67 histologically confirmed NEN patients undergoing both [^{18}F]F-OC PET/CT and [^{18}F]F-FDG PET/CT were retrospectively enrolled. Clinical data, follow-up outcomes, PET parameters and immunohistochemical markers (SSTR2, HIF-1α, GLUT1, Ki-67) were collected to analyze. In vitro validation was performed using NEN cell lines via gene interference or overexpression. ***Results:*** According to the World Health Organization (2022) classification, 53 (79.1%) patients had NETs (G1: 26.9%, G2: 37.3%, G3: 14.9%) and 14 (20.9%) had (NECs). Among NETs G1, median [^{18}F]F-FDG SUVmax was 3.63 (IQR: 2.84-6.21), [^{18}F]F-OC SUVmax was 35.45 ((IQR: 17.33-73.79), with 33.3% progressive disease (PD) versus 66.7% stable disease (SD). NETs G2 showed [^{18}F]F-FDG SUVmax was 5.45 (IQR: 2.84-8.94), [^{18}F]F-OC SUVmax was 29.75 ((IQR: 20.14-52.33), and 40% PD versus 60% SD. NETs G3 exhibited [^{18}F]F-FDG SUVmax was 9.78 (IQR: 7.20-13.63), [^{18}F]F-OC SUVmax was 6.76 ((IQR: 3.39-13.76) with 100% PD. NECs demonstrated [^{18}F]F-FDG SUVmax was 13.94 (IQR: 5.21-18.34), [^{18}F]F-OC SUVmax was 7.18 ((IQR: 5.18-16.0), and 71.4% PD versus 28.6% SD. In total cases, low ^{18}F-OC SUVmax (HR=0.41, 95% CI: 0.20-0.84, P=0.01) and low SSTR2 expression (HR=0.09, 95% CI: 0.02-0.37, P<0.001) independently predicted adverse outcomes. Histopathological analysis showed NENs pathological grade escalated with Ki-67 expression (NET G1:2.26% vs NEC:9.93%, P<0.001), contrary to SSTR2 expression (NET G1:21.9% vs NEC:1.40%, P<0.001). Besides, SSTR2 inversely correlated with HIF-1α (r=-0.25, P=0.04), while both HIF-1α (NET G1:2.19% vs NEC:9.17%, P<0.001) and GLUT1 (NET G1:2.14% vs NEC:7.76%, P<0.001) showed grade-dependent elevation (r=0.66, P<0.001). Further in vitro validation is pending. ***Conclusion:*** Our study demonstrated that the increase of NENs pathological grade was accompanied by the gradual loss of SSTR2 expression and gradual upregulation of HIF1-α and GLUT1, which suggesting that SSTR2 may play a crucial role in glucose metabolism, and facilitate the transformation of "NET-NEC".

EP-0314

Neuroendocrine carcinoma and NET grade 3: uptake of ^{18}FDG and ^{68}DOTATOC in lesions in relation to SSTR2 expression and survival

D. Truong, *Z. Ankers, A. Stenman, D. Granberg, J. Zedenius, C. C. Juhlin, A. Kistner;*
Karolinska Institute, Stockholm, SWEDEN.

Aim/Introduction: PET with ^{18}F-FDG has been shown to be of particular value in neuroendocrine carcinoma (NEC), while somatostatin-receptor-PET with ^{68}Ga-DOTATOC is standard in well-differentiated neuroendocrine tumours (NET). Recent data suggest that even some NEC-patients with somatostatin-receptor (SSTR) expression may benefit from radiolabeled somatostatin analogue treatment (1). In an ongoing retrospective study, we aim to investigate SSTR-expression and isotope uptake in a cohort of NEC patients, with a few included NET grade 3 cases, and to assess how ^{18}F-FDG PET/CT and 68Ga-DOTATOC PET/CT tumor uptake relate to survival time. ***Materials and Methods:*** 48 patients were investigated, 23 patients had undergone baseline PET/CT using intravenous ^{18}FDG, 32 patients performed ^{68}Ga-DOTATOC; and in 7 patients both modalities were done. Primary tumor location, size (by RECIST), clinical data as well as survival time from diagnosis were collected. In 41 cases, SSTR2 immunohistochemistry data was available. In addition, ^{18}FDG-SUV_{max} and ^{68}Ga-DOTATOC-SUV_{max} also in relation to non-metastatic liver uptake (tumor-to-liver ratio [TLR]) in primary tumors and metastases (lymph node, liver, skeletal) were estimated. ***Results:*** The cohort consisted of 29 men and 19 women, with a mean age of 64 years (95% CI: 60-68). The main primary tumor locations were the pancreas (17 patients), cancer of unknown origin (CUP) (9), rectum (6), and colon (4). At the time of PET/CT, 32 out of 48 patients (67%) had liver metastases, and 4 patients (8%) had skeletal metastases. The mean size of the primary tumor was 55 mm (95% CI:43-67 ;n=29). Among those who underwent 68Ga-DOTATOC PET/CT (n=32), 56% demonstrated uptake in metastatic lesions greater than that of the liver (tumor-to-liver ratio [TLR] > 1, corresponding to Krenning Score 3). Of those with histopathology available 73% (n=30) had SSTR2 expression in tumor lesions. In this group a tendency to lower ^{18}FDG-SUV_{max} in tumor lesions (p=0.07) as well as higher TLR at ^{68}Ga-DOTATOC (p=0.01) were present. Mean survival time was 34 (26-42) months. In regression analysis ^{18}FDG-SUV_{max} in tumor lesions was inversely correlated to survival time (r=-0.44, p=0.04, one outlier excluded). ***Conclusion:*** Despite being classified as NEC or NET grade 3, the majority of the cohort had tumors showing SSTR2 expression and isotope uptake on 68Ga-DOTATOC PET/CT (among those who underwent the scan). Higher ^{18}F-FDG uptake in lesions was associated with shorter survival time. Nonetheless, these findings suggest a potential therapeutic effect of Lutetium-177-DOTATATE treatment even in NEC and NET grade 3 cases. ***References:*** 1. Nilica B et al,EJNMMI 2016:43(9);1585-1592.

EP-0315

Compare the diagnostic value of [^{18}F]AlF-NOTA octreotide ([^{18}F]-OC) PET/CT and enhanced CT for suspected pheochromocytoma/paraganglioma (PPGL)

L. Huang, *J. Liu, Z. Cui, W. Ma, Y. Li;*
The Second Hospital & Clinical Medical School, Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: [^{18}F]AlF-NOTA octreotide ([^{18}F]-OC) shows a higher lesion detection rate in gastroenteropancreatic neuroendocrine tumors and lower uptake in the liver. However, there are few research reports on its imaging in pheochromocytoma/paraganglioma (PPGL). The aim of this study is to compare the diagnostic value of [^{18}F]-OC PET/CT and enhanced CT for suspected PPGL. ***Materials and Methods:*** A retrospective analysis was conducted on 31 patients with suspected PPGL. [^{18}F]-OC PET/CT images, enhanced CT images, and clinical data (age, gender, hematuria catecholamine assay) were collected. Postoperative pathology served as the "gold standard" for diagnosis, dividing patients into PPGL and non-PPGL groups. PET/CT image features (location, longest diameter, shortest diameter, CT value, SUVmax, SUVmean, metabolic tumor volume (MTV), ratio of lesion SUVmax to liver SUVmean (SUVR), visual score (VS), calcification, necrosis, metastasis) were analyzed. Logistic regression identified independent predictive factors for PPGL (P≤0.05), forming diagnostic model one. Enhanced CT image features (location, longest diameter, shortest diameter, CT value, degree and pattern of enhancement, calcification,

necrosis) were similarly analyzed to form diagnostic model two. A combined PET/CT and enhanced CT model (model three) was also created. Model performance was assessed using area under the receiver operating characteristic curve (AUC), sensitivity, specificity and accuracy. The Delong test compared the efficacy of the three models. ***Results:*** Among the 31 patients (9 males, 22 females; mean age 52.35±9.78 years, range 9-70 years), 17 were diagnosed with PPGL and 14 with non-PPGL (13 adrenal cortical adenomas, 1 retroperitoneal Castleman disease). Multivariate logistic regression based on PET/CT features identified high SUVR and necrosis as independent predictive factors for PPGL. The AUC, sensitivity, specificity, and accuracy of SUVR and necrosis alone for diagnosing PPGL were 0.840 (95% CI: 0.665-0.946), 0.647, 1.000, 0.806 and 0.687 (95% CI: 0.496-0.841), 0.588, 0.786, and 0.677, respectively. When used in combination, the AUC, sensitivity, specificity, and accuracy for diagnosing PPGL were 0.891 (95% CI: 0.726-0.974), 0.824, 0.929, and 0.871, respectively. For enhanced CT, only necrosis was a significant predictor (P=0.04). The Delong test showed no statistical difference in AUC between combined SUVR and necrosis versus SUVR alone (P=0.307), but a significant difference versus necrosis alone (P=0.012). No statistical difference was found between SUVR and necrosis alone (P=0.172). ***Conclusion:*** [^{18}F]-OC PET/CT demonstrates superior diagnostic value for suspected PPGL compared to enhanced CT. The SUVR metric exhibits the highest diagnostic efficacy, which can be further enhanced by combining it with necrosis.

EP-0316

Diagnostic accuracy of [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT in patients with pheochromocytomas and paragangliomas:a single-center experience

B. Li, *J. Zhang, X. Wu, Y. Gao;*
Department of Nuclear Medicine, Henan Key Laboratory of Novel Molecular Probes and Clinical Translation in Nuclear Medicine, Henan Provincial People's Hospital; Zhengzhou University People's Hospital, Henan University People's Hospital, Zhengzhou, CHINA.

Aim/Introduction: Pheochromocytomas and paragangliomas (PPGLs) present diagnostic challenges due to their diverse clinical manifestations. This study aims to evaluate the diagnostic accuracy of [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT in patients with clinically suspected PPGLs. ***Materials and Methods:*** A retrospective analysis was conducted on 75 patients (36 males, 39 females, mean age 47.7 ± 14.9 years) with suspected PPGLs. All patients underwent [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT imaging, and the results were compared with histopathological findings. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy of the imaging modality were calculated. Additionally, visual and semiquantitative evaluations were performed using Krenning score (KS) and tumor-to-background ratio (TBR), and their diagnostic performances were analyzed. ***Results:*** Of the 75 patients, 54 had PPGLs (40 pheochromocytomas, 7 paragangliomas, and 7 metastatic PPGLs), and 21 had non-PPGL tumors. [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT showed positive imaging in 63 patients, of whom 51 were confirmed as PPGLs and 12 as non-PPGLs. The sensitivity, specificity, PPV, NPV, and overall accuracy were 94.4% (51/54), 42.9% (9/21), 80.9% (51/63), 75.0% (9/12), and 80.0% (60/75), respectively. Visual and semiquantitative evaluations indicated higher KS and TBR values in PPGLs compared to non-PPGLs (median KS: 3.0 vs. 1.0, P<0.001; median TBR: 2.10 vs. 0.92, P<0.001). The Receiver operating characteristic (ROC) analysis revealed AUCs of 0.803 for KS and 0.791 for TBR, with no significant difference in their diagnostic performance (P=0.710). Metastatic PPGLs were detected in 7 cases, with metastases observed in multiple organs. ***Conclusion:*** [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT is a highly sensitive diagnostic tool for detecting PPGLs, providing effective differentiation between PPGL and non-PPGL tumors. Its ability to identify metastatic PPGLs with metastatic spread further underscores its potential in clinical practice. These findings highlight the potential of [^{99m}Tc]Tc-HYNIC-TOC SPECT/CT as a reliable imaging modality for suspected PPGLs, with implications for patient management and treatment strategies.

EP-0317

Comparison of Iodine-123 Metaiodobenzylguanidine scintigraphy with SPECT/CT and Fuorine-18-aluminum fluoride-1,4,7-triazacyclononane-1,4,7-triacetic acid-octreotide PET/CT in the Follow-Up of Neuroblastoma

Y. Liu[1], *S. Li*[2], *J. Liu*[2], *B. Sang*[1], *Y. Xu*[2], *J. Yang*[2], *X. Sun*[1];
[1]*Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA,* [2]*Beijing Friendship Hospital, Capital Medical University, Beijing, CHINA.*

Aim/Introduction: Detecting recurrence, metastatic, or residual lesions of neuroblastoma (NB) at follow-up was of great importance for evaluating therapeutic response, excluding subclinical relapse, and guiding therapy protocols. The aim of this study was to evaluate and compare the diagnostic performance of fuorine-18-aluminum fluoride-1,4,7-triazacyclononane-1,4,7-triacetic acid-octreotide PET/CT (^{18}F-AlF-NOTATATE PET/CT) and Iodine-123 Metaiodobenzylguanidine scintigraphy with SPECT/CT (^{123}I-MIBG SPECT/CT), thereby determining their role in follow-up of NB. ***Materials and Methods:*** A total of 59 patients were prospectively enrolled into the present study. All patients underwent ^{123}I-MIBG scintigraphy with SPECT/CT and ^{18}F-AlF-NOTATATE PET/CT within 1 weeks. Patient-based analysis, lesion-based analysis, and region-based analysis were performed. Patients with diffuse lesions were excluded from lesion-based analysis. ***Results:*** In patient-based analysis, ^{18}F-AlF-NOTATATE PET/CT evidenced positive in 31 of 59 patients, and ^{123}I-MIBG scintigraphy with SPECT/CT was positive in 30 of 59 cases. The area under the curve (AUC), sensitivity, positive predictive value (PPV), and negative predictive value (NPV) were 0.935 [95% confidence interval (CI): 0.840-0.983], 0.909 (95% CI: 0.757-0.981), 0.961 (95% CI: 0.804-0.999), 0.968 (95% CI: 0.814-0.995), 0.893 (95%CI: 0.739-0.961), respectively; and 0.955 (95% CI: 0.866-0.992), 0.909 (95% CI: 0.757-0.981), 1.000 (95% CI: 0.868-1.000), 1.000 (NA), 0.897 (95% CI: 0.747-0.962), respectively. Lesion-based analyses demonstrated that ^{18}F-AlF-NOTATATE PET/CT was superior to ^{123}I-MIBG scintigraphy with SPECT/CT in sensitivity [0.928 (95%CI: 0.862-0.968) vs. 0.625 (95%CI: 0.529-0.715), p=0.01]. In region-based analysis, the two imaging modalities has moderate to very good agreement in detecting involved patients (κ>0.40) and poor agreement in detecting focal lesions (κ<0.20). ***Conclusion:*** ^{18}F-AlF-NOTATATE PET/CT showed high sensitivity in detecting focal lesion of NB and demonstrated more lesions as compared with ^{123}I-MIBG scintigraphy with SPECT/CT. ^{18}F-AlF-NOTATATE PET/CT could be used as a complementary imaging modality of ^{123}I-MIBG scintigraphy with SPECT/CT in the follow-up of NB.

EP-0318

Prognostic Impact of Discordant Lesions on [^{18}F]FDG and [^{68}Ga]Ga-FAPI-04 PET/CT compared to Histological FAP expression in Neuroendocrine Neoplasms

T. Jedamzik[1], *A. Kosmala*[1], *S. Kircher*[2], *M. Heinrich*[1], *W. Schlötelburg*[1], *A. Buck*[1], *A. Meining*[3,4], *R. A. Werner*[3,5,6], *A. Weich*[3,4], *K. Michalski*[1];
[1]*Department of Nuclear Medicine, University Hospital Wuerzburg, Wuerzburg, GERMANY,* [2]*Institute of Pathology, University of Wuerzburg, Wuerzburg, GERMANY,* [3]*NET-Zentrum Würzburg, European Neuroendocrine Tumor Society Center of Excellence (ENETS CoE), University Hospital Wuerzburg, Wuerzburg, GERMANY* [4]*Internal Medicine II, University Hospital Wuerzburg, Wuerzburg, GERMANY,* [5]*Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY,* [6]*Johns Hopkins School of Medicine, The Russell H Morgan Department of Radiology and Radiological Sciences, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: The presence of discordant (FDG+/FAPI-) lesions on dual-tracer PET/CT using [18F]FDG and [68Ga]FAPI-04 in patients with aggressive neuroendocrine neoplasms (NENs) is associated with a reduction of progression-free survival (PFS). The aim was to investigate the prognostic value of discordant lesions compared to the histological expression of fibroblast activation protein (FAP) and its influence on PFS. ***Materials and Methods:*** A retrospective evaluation was performed on 23 patients with histologically confirmed NENs, who underwent both FAPI and FDG PET/CT, as well as biopsy. SUVmax, SUVmean, SUVpeak as well as tumor volume (TV) and total lesion uptake (TLU = TV * SUVmean) was measured for both radiotracers. Histologically, the immunoreactive score (IRS [0-12] = percentage of stained cells [0-4] * staining intensity [0-3]) of FAP expression was determined. Discordant lesions were identified visually and quantitatively. Spearman and point-biserial correlations were performed between PET parameters, IRS, and the presence of discordant lesions. Effects on PFS were analyzed using Cox regression. PFS was defined radiologically according to RECIST 1.1 and clinically as the presence of disease progression or death. ***Results:*** The primary site was mostly in the gastrointestinal tract (14/23) or unknown (= CUP, 7/23). IRS showed a statistical significant correlation for both radiotracers with TV ($p = 0.017$ for FDG, $p = 0.018$ for FAPI) as well as with TLU ($p = 0.017$ for FDG, $p = 0.025$ for FAPI). There was no statistically significant correlation between IRS and all SUV parameters. FDG+/FAPI- lesions were found in 9/23 patients. The median PFS was 6 months. The presence of FDG+/FAPI- lesions was significantly associated with shorter PFS (4 vs. 10 months, HR = 5.75, 95%CI: 1.74 - 18.97, $p = 0.01$). FDG-TV ($p = 0.012$) and FDG-TLU ($p = 0.008$) were significantly correlated with PFS in univariable analysis. No significant association was found between IRS and PFS (HR = 1.06, 95%CI: 0.92 - 1.21, $p = 0.39$). Similarly, no significant correlation was found between IRS and the presence of FDG+/FAPI- lesions ($p = 0.45$). ***Conclusion:*** FAP expression on immunohistochemistry is not correlated with the presence of FDG+/FAPI- lesions on FDG and FAPI PET/CT in patients with aggressive NENs, although the presence of discordant lesions is significantly associated with reduced PFS. Dual-tracer PET/CT as a whole-body diagnostic method may provide a better approach for risk stratification and treatment decision-making in NENs than immunohistochemical analysis of FAP expression in a single tumor manifestation.

EP-0319

Comparison of FDOPA PET/CT and MRI for the diagnosis and follow-up of pheochromocytomas and paragangliomas

L. Rodríguez Díaz*, C. Vigil Díaz, A. Álvarez Alonso, S. Menéndez Sánchez, M. Domínguez Grande, M. Fernández Llana, S. Naranjo Sancho, A. Álvarez Amigo, J. Guzmán de la Cerda, N. Martín Fernández, V. Pascual Pascual, F. Gonzalez García;*
Central University Hospital of Asturias (HUCA), Oviedo, SPAIN.

Aim/Introduction: Pheochromocytomas (PCC) and paragangliomas (PGL) are rare neuroendocrine tumors derived from adrenal or extra-adrenal neural crest chromaffin cells. Nuclear medicine imaging plays an important role in the diagnosis, staging, and follow-up of these patients. Precise imaging follow-up is essential, given the high risk of tumor recurrence in these patients. The aim of this study is to determine whether 6-l-[18f]-fluoro-3,4-dihydroxyphenylalanine PET/CT (FDOPA PET/CT) is an accurate technique for the diagnosis and follow-up of these patients. ***Materials and Methods:*** Retrospective study including 63 patients (19 male, 44 female; age range 18-87 years) (27 with known disease, 36 with no medical history of PCC/PGL), who underwent FDOPA PET/CT study between January/2021-June/2024. MRI and FDOPA PET/CT qualitative and semi- quantitative findings were studied. Our gold standard was defined by patient's follow-up and post-surgical anatomical pathology examination. ***Results:*** 73 FDOPA PET/CT studies were performed, in which pathological findings were seen in 37/73 studies: 5 PCC, 2 PCC/PGL and 41 PGG (21 carotid body, 8 jugulotympanic, 6 tympanic, 6 jugular, 1 bladder wall and 1 pericardial PGL). Mean SUVmax for PCC and PGL was 12.98 and 10.91, respectively. 30 follow-up FDOPA PET/CT studies were performed (2 patients with SDH gene mutations with no PCC/PGL history, and 28 with PCC/PGL history, out of which 16 had SDH gene mutations). The remaining studies were performed to evaluate extension and multicentricity (14 SDH gene mutation screening, 11 incidentalomas and 18 due to clinical symptoms or high metanephrines/catecholamines). 29 patients underwent MRI study at the time of FDOPA PET/CT evaluation. In our series, MRI and FDOPA PET/CT results were discordant in 7/29 patients, leading to a change in therapeutic management in 3. FDOPA PET/CT study ruled out PCC/PGL in 5 patients with positive MRI findings (2 laterocervical nodes, 1 lesion compatible with vagal PGL surgical remains and 2 neurinomas). 1 PGL (1 post-surgical disease) and 1 PCC were diagnosed in patients with normal MRI. 3 patients presented with progression during FDOPA PET/CT follow-up. ***Conclusion:*** Our results demonstrate that FDOPA PET/CT should be alongside with the MRI, an imaging technique of choice for both diagnosis and follow-up of these patients. FDOPA PET/CT provides an accurate diagnostic method for whole-body evaluation and metabolic response assessment with high accuracy and changes patient outcome.

EP-0320

Accelerating Lu-177 SPECT Imaging Post Radioligand Therapy Using Deep Learning-Enhanced Projection Interpolation

A. Sitek[1]*, S. Płotka*[2]*, J. Prządo*[3]*, H. Sabet*[1]*, P. Heidari*[1]*, J. B. Ćwikła*[3,4]*;*
[1]Massachusetts General Hospital and Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA [2]University of Warsaw, Warsaw, POLAND, [3]University of Warmia and Mazury in Olsztyn, Olsztyn, POLAND, [4]Diagnostic and Therapy Center Gammed, Warsaw, POLAND.

Aim/Introduction: SPECT imaging of lutetium-177 [^{177}Lu] targeted radioligand therapies (RLTs) plays a critical role in the therapeutic evaluation and monitoring of neuroendocrine tumors and prostate cancer RLT. While clinically valuable, SPECT imaging requires lengthy acquisition times, which can be burdensome for patients and hinder workflow efficiency. Therefore, strategies to shorten imaging times without compromising diagnostic accuracy are highly desirable. This study evaluates the feasibility and clinical applicability of substantially reducing ^{177}Lu-imaging acquisition time through deep learning (DL)-based interpolation of projection data. ***Materials and Methods:*** A total of 1,368 retrospective SPECT scans from 88 patients who underwent DOTATATE and DOTATOC RLT, somatostatin receptor scintigraphy (SRS), and prostate-specific membrane antigen (PSMA-T4) imaging, were used. The scans were acquired using multiple dual-head SPECT/CT scanners with either 60 or 120 projections obtained over 360-degree arcs. A DL interpolation model was developed and trained on 90% of these scans, validated on a 10% subset. The model was tested on a distinct set of 24 images derived from five patients different from those used for training and validation. To test, original 60-projection sinograms were reduced to simulate shorter acquisition protocols (30, 15, 10, and 6 projections), corresponding respectively to reductions of 50%, 75%, 83%, and 90% in acquisition time. These reduced datasets were subsequently interpolated back to the full complement of 60 projections using the trained DL model. Reconstruction was performed using 20 iterations of the maximum likelihood expectation maximization algorithm with Butterworth post-filtering. Image quality was quantitatively assessed by computing the mean and standard deviation of contrast recovery for 48 clearly identified focal lesions, with two lesions evaluated per test dataset; contrast recovery was defined as the ratio of the measured lesion contrast to the corresponding contrast in the original full-projection reconstruction. ***Results:*** Reconstructions using DL-interpolated sinograms demonstrated

image quality and noise characteristics comparable to the original full-projection acquisitions. Quantitative analysis indicated that lesion contrast recovery was substantially maintained, achieving up to 90% recovery at a 50% reduction in acquisition time. However, more aggressive reductions in acquisition time led to proportionally decreased contrast recovery, illustrating a trade-off between image quality and time savings. ***Conclusion:*** This study demonstrates the promising capability of DL-based interpolation methods to significantly reduce ^{177}Lu SPECT imaging acquisition time post-RLT, while largely preserving diagnostic quality. Although further algorithmic improvements and larger training datasets could enhance performance, the current findings already support the potential for integrating DL approaches into routine clinical imaging.

The Role of Ga-68 DOTA-TATE PET/CT in the Differential Diagnosis of Pheochromocytoma and Adrenal Adenoma

F. Demir[1], *H. Yıldız*[1], *S. Karaçavuş*[1], *C. Güneş*[1], *S. A. Salt*[2], *E. Gündoğan*[3];
[1]*Department of Nuclear Medicine, Kayseri City Training and Research Hospital, Kayseri, TÜRKIYE,* [2]*Department of Endocrinology, Kayseri City Training and Research Hospital, Kayseri, TÜRKIYE* [3]*Department of Gastroenterology Surgery , Kayseri City Training and Research Hospital, Kayseri, TÜRKIYE.*

Aim/Introduction: To assess the efficacy of Ga-68 DOTA-TATE PET/CT in distinguishing between pheochromocytoma and adrenal adenoma, and to evaluate the diagnostic utility of SUV ratios. ***Materials and Methods:*** A retrospective analysis was conducted on forty patients who underwent Ga-68 DOTA-TATE PET/CT for adrenal lesions between 2018 and 2025. The cohort comprised 16 males (40%) and 24 females (60%), with a mean age of 55.10 ± 9.69 years. Lesions were identified in the right adrenal gland in 15 patients (37.5%) and in the left adrenal gland in 25 patients (62.5%). The average lesion size was 28.6 ± 12.45 mm. Final diagnoses were established through histopathological examination (55%) or clinical and laboratory follow-up (45%). Data recorded included lesion location, size, Hounsfield Unit (HU), metabolic tumor volume (MTV), total lesion uptake (TLU), SUVmean, liver and spleen reference SUVmax, lesion SUVmax, and contralateral adrenal SUVmax. Ratios of lesion SUVmax to contralateral adrenal (LSUVmax/KASUVmax), spleen (LSUVmax/DSUVmax), and liver (LSUVmax/KSUVmax) SUVmax were calculated. Statistical evaluation was performed using the Mann-Whitney U test and ROC analysis. ***Results:*** Among the patients, 18 (45%) were diagnosed with pheochromocytoma, while 22 (55%) were diagnosed with adrenal adenoma. Significant differences were observed in the LSUVmax/KASUVmax, LSUVmax/DSUVmax ratios, and cortisol levels (p=0.007, 0.003, and 0.014, respectively). No significant differences were noted in other parameters (P >0.05). ROC analysis identified LSUVmax/KASUVmax (AUC=0.80, p=0.001) and LSUVmax/DSUVmax (AUC=0.76, p=0.006) as significant diagnostic indicators. A LSUVmax/KASUVmax cutoff of 1.2 demonstrated a sensitivity and specificity of 72% and 77%, respectively. A cutoff of 0.45 for LSUVmax/DSUVmax yielded a sensitivity and specificity of 72% and 73%, respectively. ***Conclusion:*** Ga-68 DOTA-TATE PET/CT is a reliable imaging modality for distinguishing between pheochromocytomas and adrenal adenomas. The LSUVmax/KASUVmax and LSUVmax/DSUVmax ratios offer valuable diagnostic insights that can aid clinicians in patient management.

EP-0322

Long-axial field-of-view dynamic ^{64}Cu-DOTATATE PET/CT in patients with neuroendocrine neoplasms

E. Carlsen[1,2,3], *C. B. Johnbeck*[1,2,3], *M. Loft*[1,2,3], *T. L. Andersen*[1,3,4], *A. Kjaer*[1,2,3];
[1]*Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital – Rigshospitalet, Copenhagen, DENMARK,* [2]*Cluster for Molecular Imaging, Copenhagen University Hospital – Rigshospitalet & Department of Biomedical Sciences, University of Copenhagen, Copenhagen, DENMARK,* [3]*ENETS Neuroendocrine Tumor Center of Excellence, Copenhagen University Hospital – Rigshospitalet, Copenhagen, DENMARK,* [4]*Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: Whole-body positron emission tomography (PET) with a radiolabeled somatostatin receptor (SSR) analogue (e.g. ^{64}Cu-DOTATATE) can visualize and quantify SSR expression non-invasively and plays a key role in managing patients with neuroendocrine neoplasms (NEN). Routinely, PET/CT is performed 1 hour post injection (p.i.) of ^{64}Cu-DOTATATE. We have previously shown that imaging is feasible up to 3 hours p.i. By applying long-axial field-of-view (LAFOV) PET/CT with dynamic acquisition from time of injection, we now aimed to investigate whether earlier imaging than 1 hour p.i. is possible without loss in tumor-to-background ratio (TBR). ***Materials and Methods:*** Between July 2022 and September 2023, we included 10 patients with biopsy-verified NEN referred for routine ^{64}Cu-DOTATATE PET/CT. All patients gave informed consent for participation, and the study was approved by the internal review board. Patients underwent dynamic LAFOV PET (vertex to mid-femur) from 0-45 minutes p.i., preceded by ultralow-dose CT for attenuation correction. Approximately 60 minutes p.i. patients underwent a 10-minute LAFOV PET with a diagnostic CT. PET was reconstructed using ordered subset expectation maximization, time-of-flight, and point spread function (4 iterations, 5 subsets, 440x440 matrices) with a gaussian post-filter of 2 mm. Regions of interest were manually drawn for the primary tumor, representative lesions in different organs, and background regions in blood and liver. Activity concentration (Bq/ml) over time from injection was plotted and TBR was calculated using liver as background. ***Results:*** Of the 10 patients (7 males, 3 females), 6 had small intestinal, 3 had pancreatic and 1 had lung primary NEN. All patients had metastatic disease with liver and/or bone metastasis as well as lymph node involvement. Histologically, patients had grade 1 (n=1), grade 2 (n=7) and grade 3 (n=2) NEN, with median Ki67-index 5.5% (min-max: 2-28%). NEN-specific treatment was somatostatin analog (n=8) or temozolomide/capecitabine (n=2). Following injection, ^{64}Cu-DOTATATE cleared from the blood pool, and liver uptake plateaued at 20 minutes. TBR reached plateau between 10-30 minutes p.i. and remained stable. Median TBR at 30 minutes and 1 hour was 3.55 (2.37-4.48) and 3.60 (2.65-5.00), respectively (p=0.47). ***Conclusion:*** Dynamic LAFOV ^{64}Cu-DOTATATE PET/CT enables optimized acquisition timing. In 10 patients with NEN, tumor/metastasis uptake plateaued within 30 minutes combined with plateau in liver uptake at 20 minutes. TBR was equivalent at 30 minutes with 1 hour p.i. acquisition. Together with our previous data, we suggest that ^{64}Cu-DOTATATE image acquisition can be performed any time between 30 minutes and 3 hours p.i.

EP-0323

Comparison of physiological uptake by semiquantitative analysis of [^{68}Ga]Ga-DOTA-TATE PET/CT performed on digital and analog cameras

K. Bienkowski, *K. Pełka, J. Kunikowska;*
Medical University of Warsaw, Warsaw, POLAND.

Aim/Introduction: [^{68}Ga]Ga-DOTA-TATE PET/CT is a leading diagnostic tool for staging and managing neuroendocrine tumors (NETs). With advances in technology, digital PET/CT cameras have been introduced. While physiological uptake patterns of [^{68}Ga]Ga-DOTA-TATE using analog cameras are well documented, data on digital camera uptake remain limited.The aim of the study was to compare semiquantitative parameter - SUVmax values of physiological [^{68}Ga]Ga-DOTA-TATE biodistribution between digital and analog PET/CT cameras to identify potential differences. ***Materials and Methods:*** We retrospectively analyzed 170 patients (73 men, 97 women, aged: 18-78) examined with a digital Biograph128 Vision 600 Edge PET/CT(Siemens) 60 ± 20 minutes after injection of 1.5-2 MBq/kg [^{68}Ga]Ga-DOTA-TATE (minimum

120 MBq), which were compared to a previously described group of 250 patients examined with an analog Biograph 64 TruePoint PET/CT (Siemens) [1]. Study assessment was performed on syngo. via Siemens workstation, documenting areas of increased uptake. SUVmax was measured using a VOI isocontour tool in organs excluding pathological lesions from NETs. ***Results:*** Both digital and analog cameras showed physiological uptake in the pituitary gland, salivary glands, thyroid, liver, spleen, adrenal glands, and kidneys, consistent with somatostatin receptor expression. Diffuse uptake in the pancreatic uncinate process was observed in 37% of digital scans versus 12% of analog. Additionally, medium-low uptake was seen in nerve plexuses, especially stellate and celiac ganglions, only on digital scans. SUVmax values between digital and analog cameras were compared, the higher values were observed with digital camera and were as follows (SUVmax, Mean (SD)): pituitary gland 11.8 (4.1) vs. 11.0 (4.5), spleen 27.5 (10.2) vs. 18.9 (6.6), adrenal glands 21.7 (6.9) vs. 14.0 (5.6), kidneys 18.5 (8.9) vs. 14.2 (3.6), pancreatic uncinate process 10.0 (3.7) vs. 9.2 (3.3). Moderate uptake was noted in salivary glands (4.2 vs. 3.4), thyroid (6.8 vs. 2.9), and liver (10.8 vs. 6.5). ***Conclusion:*** Understanding physiological [^{68}Ga]Ga-DOTA-TATE distribution is essential for accurate PET/CT interpretation in NET diagnosis. Digital PET/CT cameras demonstrate generally higher SUVmax values than analog systems, which should be considered in clinical evaluations to avoid misinterpretation of physiological uptake as pathological. ***References:*** 1. Kunikowska J, Królicki L, Pawlak D, Zerizer I, Mikołajczak R. Semiquantitative analysis and characterization of physiological biodistribution of (68)Ga-DOTA-TATE PET/CT. Clin Nucl Med. 2012 Nov;37(11):1052-7. doi: 10.1097/RLU.0b013e31825b2555. PMID: 22996234.

EP-0324

NETPET vs. Krenning score: Redifining Eligibility for PRRT through Dual PET Imaging in Neuroendocrine Tumors

A. Matamala-Bezmalinović[1], *M. Velasco-Nuño*[2], *M. Calls-Calahorro*[2], *P. Stefaneli*[2], *B. Serrallonga*[2], *Y. Delisau*[2], *S. Castejón*[2], *S. Asadurova*[2], *J. Duch*[2], *D. Paez*[3], *B. Martin*[3], *V. Camacho*[2], *A. Flotats*[2]; [1]*Nuclear Medicine Department, Hospital Clínico Universidad de Chile, Santiago, CHILE,* [2]*Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [3]*Oncology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

Aim/Introduction: To evaluate the impact of the NETPET score on determining eligibility for peptide receptor radionuclide therapy (PRRT) in patients with metastatic neuroendocrine tumors (NETs), in comparison to the traditional Krenning Score (KS). ***Materials and Methods:*** A single-center retrospective study was conducted involving 44 patients with NETs who underwent dual PET imaging with [^{68}Ga]DOTA-TOC and [^{18}F]FDG from June 2018 to March 2025. The interval between the two PET scans was less than three months, in accordance with ENETS recommendations. Tumor origin was classified as gastroenteropancreatic (GEP) in 32 patients, pulmonary carcinoid (PC) in 11 patients and paraganglioma (PG) in one patient. Both the KS (scale 0-4) and NETPET score (P1-P5) were calculated for each patient. Eligibility for PRRT (E-PRRT) was defined as having KS ≥2 or a NETPET classification between P1 and P4a. Tumor grade and Ki-67 proliferation index were also recorded. ***Results:*** According to the KS, 35 patients (79.5%) were classified as E-PRRT, while 9 (20.5%) were deemed ineligible. The KS distribution was: 3 patients with KS 0, 6 with KS 1, 4 with KS 2, 8 with KS 3, and 23 with KS 4. When applying the NETPET score, 29 patients (65.9%) were classified as E-PRRT, and 15 (34.1%) as ineligible. The NETPET distribution was: 10 patients in P1, 6 in P2a, 6 in P2b, 2 in P3a, 0 in P3b, 5 in P4a, 6 in P4b, and 5 in P5. Both systems were concordant in 36 patients (81.8%): 28 patients (63.6%) were considered eligible, and 8 (18.2%) ineligible. In 7 cases (15.9%), NETPET reclassified patients more restrictively, excluding individuals initially deemed eligible by KS. This subset included 6 GEP tumors (four G2, two G3) and one pulmonary atypical carcinoid, with a median Ki-67 of 26.4% (range: 15%-70%). Among these, 3 patients had KS 2, 3 had KS 3, and one had KS 4, suggesting that NETPET was particularly effective in refining PRRT candidacy in patients with intermediate KS scores. ***Conclusion:*** The NETPET score appears to be a more specific tool for characterizing the heterogeneous biological behavior of neuroendocrine tumors, particularly in cases with intermediate Krenning Scores. Its application resulted in more restrictive patient reclassification, identifying individuals less likely to benefit from PRRT. These findings underscore the clinical utility of dual PET imaging in optimizing treatment selection for patients with advanced NETs. ***References:*** J Neuroendocrinol. 2024;36:e13359.J Neuroendocrinol. 2022 March ; 34(3): e13040. doi:10.1111/jne.13040.

EP-0325

The utility of [^{18}F]FET PET in the clinical management of PitNET: a preliminary descriptive analysis

V. De Meulenaere[1], *B. Lapauw*[2], *F. Dewaele*[3], *T. Van Zele*[4], *E. Genbrugge*[1], *D. Van Weehaeghe*[1]; [1]*Department of Radiology and Nuclear Medicine, Ghent University Hospital, Ghent, BELGIUM,* [2]*Department of Endocrinology, Ghent University Hospital, Ghent, BELGIUM,* [3]*Department of Neurosurgery, Ghent University Hospital, Ghent, BELGIUM,* [4]*Department Otorhinolaryngology, University Hospital Ghent, Ghent, BELGIUM.*

Aim/Introduction: Pituitary neuroendocrine tumours (PitNETs) are the second most common intracranial neoplasms and can be functioning or non-functioning. Magnetic resonance imaging (MRI) is the primary diagnostic tool for PitNETs, but some lesions remain challenging to detect with MRI alone. Consequently, O-(2'[18F]fluoroethyl)-L-tyrosine ([18F]FET) positron emission tomography (PET) has emerged as a promising complementary imaging modality, improving tumour visualization through differential tracer uptake in healthy versus abnormal pituitary tissue. ***Materials and Methods:*** We performed a retrospective analysis of [^{18}F]FET PET data from 21 patients (14 F, 7 M, age 52±16 years) with PitNET (newly diagnosed, persistent after prior treatment or recurrent after remission), scheduled for surgical resection. Based on biochemical evaluation, PitNETs were categorized as growth hormone (n=7), ACTH (n=6), prolactin (n=2), TSH-secreting (n=1), or non-functioning tumours (n=5). All patients underwent [^{18}F]FET PET/CT imaging (185 MBq; GE Omni Legend: n=20, Siemens Biograph20: n=1) and dedicated pituitary MRI (1.5T: n=3, 3T: n=18). Dynamic and static PET data were reconstructed using OSEM i8s12. PET and MR images were co-registered, and regions of interest were manually delineated using MIM Software. Visual correlation between PET and MRI (0: none, 0.5: partial, 1: high), Metabolic Index (MI), and Time-Activity Curves (TACs) were evaluated. MI, a proxy for FET uptake, was calculated in analogy to glioma: SUVmax/SUVmean healthy appearing cortical tissue. ***Results:*** All PitNETs visualized by MRI were also detected with [^{18}F]FET PET imaging, corresponding to a sensitivity of 100%. Visual correlation between PET and MRI was high (score: 1) in 52% of PitNETs and moderate (score: 0.5) in 48% of PitNETs. A moderate correlation between [^{18}F]FET PET and MRI could be explained by lesion heterogeneity, cysts, or resolution limits. Notably, one patient showed an additional lesion in the pituitary gland on [^{18}F] FET PET that was not visible on MRI (score: 0), suggesting potential added diagnostic value for [^{18}F]FET PET. The mean MI for all PitNETs was 2.4±0.4 with functioning PitNETs showing a slightly higher MI (2.5±0.4) compared to non-functioning PitNET (2.3±0.4). TACs of the majority of PitNETs exhibited a descending profile (n=17), three cases showed stable TACs, and one was excluded due to motion artifacts. No differences in TACs were observed based on PitNET-functionality. ***Conclusion:*** [^{18}F]FET PET provides consistent metabolic visualization of newly diagnosed, recurrent, or persistent PitNETs. Its high sensitivity, strong correlation with MRI findings, and distinct TAC profiles suggest that [^{18}F]FET PET is a valuable tool in the diagnosis and management of PitNETs.

AI-based Quantitative Volumetric [^{68}Ga]Ga-DOTATOC PET/CT Image Analysis in Predicting Response to Peptide Receptor Radionuclide Therapy and Disease Outcome

S. Manoochehry[1], *F. Sharifian*[1], *S. Mirshahvalad*[1], *W. Hitzl*[2], *N. Capobianco*[3], *B. Spottiswoode*[4], *G. Schweighofer-Zwink*[1], *C. Pirich*[1], *M. Beheshti*[1];
[1]*Division of Molecular Imaging and Theranostics, Department of Nuclear Medicine, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA,* [2]*Biostatistics and Publication of Clinical Trial Studies, Research and Innovation Management (RIM), Paracelsus Medical University, Salzburg, AUSTRIA,* [3]*Siemens Healthineers AG, Erlangen, GERMANY,* [4]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: To evaluate the predictive value of [^{68}Ga]Ga-DOTATOC PET/CT for treatment response and disease outcomes, using a prototype convolutional neural network (pCNN) for automated detection and semi-quantitative analysis in patients with metastatic neuroendocrine tumours (NETs) receiving peptide receptor radionuclide therapy (PRRT). ***Materials and Methods:*** This retrospective study included patients with histologically proven well-differentiated metastatic NET treated with [^{177}Lu]Lu-DOTATATE who underwent baseline (bPET) and post-treatment (pPET) [^{68}Ga]Ga-DOTATOC PET/CT after the four cycles of [^{177}Lu]Lu-DOTATATE treatment. Lesion detection and semi-quantitative PET parameters were extracted using a pCNN. Standardized uptake values (SUVs), as well as whole-body somatostatin-expressed total tumour volume (SSTR-TV) and total lesion SSTR expression (SSTR-TLA) were analyzed. PERCIST criteria were used to assess the response to treatment. Progression-free survival (PFS) and overall survival (OS) were defined from the first cycle of PRRT. ***Results:*** From the 19 patients with metastatic NET (6 females and 13 males), 10 (52.6%) demonstrated partial response, 3 (15.8%) showed stable disease, 3 (15.8%) exhibited completed response, and 3 (15.8%) experienced disease progression. Among semi-quantitative bPET parameters, the SUVmax-to-liver background ratio of the most avid lesion was significantly higher in responders. Analysis of pCNN-based volumetric bPET parameters revealed significantly higher SSTR-TLA (p=0.003) and total SSTR-TV (p=0.005) in responders. The median PFS in patients was 24 months. From the bPET-derived parameters, SULpeak-to-spleen background ratio and total SUVmean of the most avid lesion were significant predictors of PFS (p=0.009 and p=0.021, respectively). Among the volumetric PET parameters, Δtotal SSTR-TV and Δtotal SSTR-TLA ratio were identified as significant predictors of PFS (p=0.035 and p=0.038, respectively). The median OS in patients was 39 months. Total SUVmean significantly predicted OS (p<0.001), as also did Δtotal SSTR-TV from the volumetric parameters (p=0.020). ***Conclusion:*** This study provides preliminary evidence supporting the use CNN-based automated volumetric whole-body assessment of [^{68}Ga]Ga-DOTA-peptide PET/CT images in metastatic NET patients undergoing PRRT. The findings highlight the feasibility and prognostic value of this approach, warranting validation in larger patient cohorts.

EP-0327

Head-to-head comparison between Al^{18}F-NOTA-LM3 and ^{68}Ga-DOTA-TATE PET/CT in patients with metastatic pheochromocytomas and paragangliomas

Y. Zhang, *M. Liu, Y. Cai, X. Yan, C. Ren, Z. Huang, M. Wang, A. Tong, L. Huo, H. Jing;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: ^{68}Ga-based somatostatin receptor (SSTR) PET/CT has become the cornerstone for staging and monitoring metastatic pheochromocytoma and paraganglioma (mPPGL), including its theranostic role in selecting patients for peptide receptor radionuclide therapy (PRRT). Compared to ^{68}Ga-DOTA-SSA analogs, ^{18}F-labeled SSTR antagonists offer advantages including higher yield, superior image resolution, and longer half-life, which may facilitate clinical workflow. This study aims to evaluate the diagnostic efficacy of the SSTR antagonist Al^{18}F-NOTA-LM3 versus ^{68}Ga-DOTATATE in mPPGL patients. ***Materials and Methods:*** Patients with histologically confirmed mPPGL (either at initial diagnosis or relapsed/progression), were prospectively recruited and underwent both Al^{18}F-NOTA-LM3 PET/CT and ^{68}Ga-DOTA-TATE PET/CT within one week, with a minimum 24-hour interval between scans. Focal uptake not attributed to physiological activity was deemed positive. Diagnostic efficacy was assessed at the patient-, region-, and lesion-level. Biodistribution in normal organs, lesion detection rates, SUVmax and tumor-to-liver ratios (TLRmax) was compared. Up to five lesions (≥1 cm diameter, highest SUVmax) per region were analyzed, with a maximum of 20 lesions per region if exceeded. Whole-body TLRmax was assessed to identify potential PRRT candidates. ***Results:*** Fourteen patients (median age 47.7 years; 3 males) were included, with both tracers detecting positive lesions in all patients. Al^{18}F-NOTA-LM3 exhibited lower physiological organ uptake and higher detection rates for liver metastases (20 vs. 6, P < 0.001) and lymph node metastases (57 vs. 54, P = 0.0625) compared to ^{68}Ga-DOTATATE. Additionally, Al^{18}F-NOTA-LM3 demonstrated significantly higher SUVmax in metastatic lymph nodes and greater TLRmax in lymph nodes, liver and bone lesions. Whole-body tumor TLRmax was superior with Al^{18}F-NOTA-LM3 (10.21±5.6 vs. 5.52±4.23, P<0.05), suggesting an enhanced suitability for 177Lu-labeled LM3 PRRT. ***Conclusion:*** Al^{18}F-NOTA-LM3 PET/CT demonstrates superior diagnostic performance compared to ^{68}Ga-DOTA-TATE in patients with mPPGL, with improved lesion detection, higher tumor-to-background contrast, and favorable biodistribution. These findings support its potential as a preferred imaging and theranostic agent for mPPGL management.

Diagnostic, Therapeutic, and Economic Impact of the Protocolized Use of ^{68}Ga-DOTATOC PET/CT in Patients with Neuroendocrine Tumors (IMDOTA-TNE Study).

M. Cruz Montijano[1], *J. A. Bonilla Plaza*[1], *L. Garcia Zoghby*[1], *J. Montalva Pastor*[1], *M. Meneses Navas*[1], *S. Guzman Ortiz*[1], *I. García Megías*[1], *J. Medina Martínez*[1], *A. Marco Martínez*[1], *M. Abradelo De Usera*[1], *J. Cano Cano*[2], *L. García Blasco*[3], *C. Alonso López*[3], *C. Ortiz Muñoz*[2], *C. Martínez Osorio*[2], *F. Pena Pardo*[2], *V. García Poblete*[2], *A. García Vicente*[1];
[1]*Complejo Hospitalario de Toledo, Toledo, SPAIN,* [2]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [3]*Complejo Hospitalario Universitario de Albacete, Albacete, SPAIN.*

Aim/Introduction: To evaluate the diagnostic, therapeutic, and economic impact of a protocolized imaging strategy using ^{68}Ga-DOTATOC PET/CT (PET/CT) following ^{99}mTc-HYNIC-TOC scintigraphy in patients with a diagnosis or suspicion of neuroendocrine tumors (NETs). ***Materials and Methods:*** Prospective multicenter study including consecutive patients from February to November 2024 referred for somatostatin receptor scintigraphy (SRS) with ^{99}mTc-HYNIC-TOC for various clinical indications. The study was approved by reference Ethical Committee (internal code 2024-051). PET/CT with ^{68}Ga-DOTATOC was subsequently performed only if its result could potentially lead to a change in patient management. A minimum clinical follow-up of 6 months was required. An economic analysis was also performed based on reimbursed costs using relative value units for each imaging modality. ***Results:*** A total of 142 patients were included (80 males), with a mean age of 63.96 years (range: 23-91). 51 patients underwent both SRS and PET/CT (Group 1), and 91 patients had only SRS (Group 2). Clinical indications included: 15 indeterminate lesions, 35 initial staging, 6 localization of unknown primary, 35 suspected recurrence or progression, 40 routine follow-up with clinical/biochemical stability, and 11 due to isolated elevation tumor markers without a previous diagnosis

of NETs.In Group 1, SRS and PET/CT were positive in 36 and 41 patients, respectively, identifying 160 and 286 lesions, respectively. PET/CT led to a change in disease staging in 24 patients and a therapeutic management change in 17, as well as detection of additional lesions in most cases.In Group 2, SRS was positive in 40/91 patients. During follow-up, 80 patients remained stable and 11 showed progression (3 due to other primaries with neuroendocrine features, and 8 due to metastatic NETs—4 with biochemical progression). Retrospectively, only 4 patients might have benefited from a PET/CT-based management change.This protocol resulted in a 17.35% cost saving (€42,147.74) compared to the direct use of PET/CT. ***Conclusion:*** Protocolized use of ^{68}Ga-DOTATOC PET/CT demonstrated a high diagnostic and therapeutic impact (47.05% and 33.33%, respectively), improving lesion detection and clinical decision-making. This selective approach minimized unnecessary radiation exposure and imaging redundancy, while achieving significant cost savings compared to a universal PET/CT strategy.

Aim/Introduction: We investigated the prognostic value of somatostatin receptor tumor burden on ^{68}Ga-DOTATOC PET/CT in patients with well-differentiated neuroendocrine tumors (NETs). ***Materials and Methods:*** We retrospectively analyzed 67 NETs patients who performed ^{68}Ga-DOTATOC PET/CT for staging/restaging purpose between November 2023 and December 2024. Data on age, sex, TNM stage, tumor grade (Ki-67 for grade 1, <3%; grade 2, 3-20%; grade 3, >20%), biomarkers (CgA, NSE) and previous treatments were collected. Information regarding time to progression (TTP), defined as the time from PET/CT imaging to the first event (progression or relapse), was achieved by clinical follow-up. The number of all ^{68}Ga-DOTATOC-avid lesions for specific organ (lymph nodes, liver, bone, others) was identified and SUVmax, SUVmean, Somatostatin receptor-expressing tumor volume (SRETV) and total lesion somatostatin receptor expression (TLSRE) were extracted for each lesion, using a semiautomatic segmentation. Then, whole-body SRETV (SRETVwb) and TLSRE (TLSREwb) were defined as the sum of SRETV and TLSRE. The prognostic value of both clinical and PET/CT semiquantitative parameters was evaluated using Chi-square Fisher's exact, and Mann-Whitney tests. Cox proportional-hazards regression model was employed to analyze the impact of the same variables on TTP. A p<0.05 was considered statistically significant. ***Results:*** 46 consecutive patients met the inclusion criteria (M:F=23:23, mean age 60y). Pancreas was the most frequent primary site (33%); 92% of the tumors were classified as grade 1-2. Fifty-two% had metastatic disease at the diagnosis. Liver was the most involved secondary site (50%) with a number of focal lesions ≤3 in 35% and >4 in 65% of patients. Median SRETVwb and TLSREwb was 53.30 cm^3 and 652.34 g/mLxcm^3, respectively. After a mean follow-up of 9mo (range 3-15mo), disease progression was confirmed in 12 patients (26%) and 2 patients died. Significant associations with disease progression were observed for higher values of SRETVwb (p=0.043) and TLSREwb (p=0.016); Ki67<3% (p=0.003), a negative PET result (p=0.032), the absence of secondary lesions (p=0.006) and the presence of liver lesions ≤3 (p=0.038) were favourable prognostic factors. In the univariate analysis, TLSREwb (p=0.042), Ki67 (p=0.023), PET/CT result (p=0.022), and the presence of secondary lesions (p=0.003) significantly correlated with a shorter TTP. In multivariate analysis with Cox Proportional-Hazards regression model, TLSREwb and Ki67 resulted independent predictors of TTP (p=0.010). ***Conclusion:*** Our preliminary results suggested that TLSREwb extracted from ^{68}Ga-DOTATOC PET/CT could represent a good predictor of TTP and, together with Ki67, might have important clinical utility in the management of NETs patients.

EP-0330

Utility of Ga-68 DOTA-RGD2 PET/CT in Grade 2 & 3 neuroendocrine tumours and comparison with Ga-68 DOTANOC PET/CT

K. Subramanian*;*
Post Graduate Institue of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Neuroendocrine tumors (NETs) are a heterogeneous group of tumors with variable somatostatin receptor (SSTR) expression. Their spectrum ranges from well-differentiated neuroendocrine tumors (NETs) to poorly differentiated neuroendocrine carcinomas (NECs), according to the WHO categorization system based on cell differentiation and mitotic index (Ki 67). Higher-grade NETs are poorly differentiated and more aggressive. Neoangiogenesis is a marker of aggressiveness and is necessary for tumor growth, invasion, and metastatic spread. In patients with high-grade NETs, we assessed angiogenesis in vivo using the novel imaging marker Ga-68 DOTA-RGD2 PET/CT and compared it with Ga-68 DOTANOC PET/CT for SSTR expression. ***Materials and Methods:*** 44 patients with histopathologically confirmed WHO grade 2 (n=34) and grade 3 (n=10) NETs (24 males, 20 females; mean age: 49.6 years, range: 32-69 years) participated in this prospective study. All patients underwent Ga-68 DOTA-RGD2 PET/CT and Ga-68 DOTANOC PET/CT within five days before starting any form of treatment. Both the PET/CT images were evaluated visually and semi quantitatively. Tracer uptake in the primary lesion was interpreted as positive if it exceeded the mediastinal blood pool activity. Semi-quantitative parameters such as maximum standardized uptake values (SUVmax) and tumour to background ratios (TBR) of the primary lesions were measured. Pearson correlation test was used to analyze the correlation between two normally distributed continuous quantitative data and Spearman's rho test for non-continuous and non-normally distributed data. The unpaired t-test was used to compare normally distributed continuous variables. ***Results:*** Using Ga-68 DOTA RGD2, the detectability of lesions was 73.4% for primary lesions and 47.8% for metastatic areas, such as the brain (100%), liver (18%), lymph nodes (68.4%), and bone (71.2%). Primary was found in the stomach (13.1%), retroperitoneum (14.1%), mesenteric NET (8.5%), breast (5.5%), liver (6.6%), small intestine (19.2%), and pancreas (32.8%). ^{68}Ga-DOTANOC showed 88.8% lesion detectability for primary lesions and 85.7% for metastatic locations, such as the brain (100%), liver (78.3%), bone (98%), and lymph nodes (100%). At every disease-involved site, the SUVmax and TBRmax values for Ga-68 DOTANOC PET/CT were substantially greater than those for ^{68}Ga-DOTA RGD2 PET/CT. The SUVmax and TBRmax on Ga-68 DOTA RGD2 PET did not show a statistically significant correlation (p=0.904; p=0.946 respectively) with the grade of the tumor. ***Conclusion:*** Patients with high-grade neuroendocrine tumors may benefit from angiogenesis imaging using Ga-68 DOTA RGD2 PET/CT. Except for liver-related metastatic lesions, lesion detectability is comparable to that of Ga-68 DOTANOC PET/CT.

Feasibility of an early-imaging ^{68}Ga-FAPI-PET/CT protocol in prone position for rectosigmoid and anal cancer

D. Ufton[1], *J. Heilinger*[1], *H. Weis*[1], *T. Fischer*[1], *K. Schomäcker*[1], *C. Bruns*[2], *G. Dieplinger*[2], *H. Dapper*[3], *E. Fokas*[3], *C. Kobe*[1], *A. Drzezga*[1], *S. Ferdinandus*[3], *K. S. Roth*[1];
[1]*University Hospital of Cologne, Department of Nuclear Medicine, Cologne, GERMANY,* [2]*University Hospital of Cologne, Department of Surgery, Cologne, GERMANY,* [3]*University Hospital of Cologne, Department of Radiation Oncology, Cologne, GERMANY.*

Aim/Introduction: Colorectal carcinoma (CRC) and squamous cell carcinoma (SCCA) present malignant entities with high expression of firoblast-activting-protein (FAP) suited for staging via ^{68} Ga-FAPI-PET/CT with improved staging accuracy compared to ^{18}-FDG-PET/CT. Previous studies focusing on other malignancies reported the viability of staging protocols 10 minutes after injection of ^{68}Ga-FAPI excluding intrapelvic tumors. Our aim was to assess the viability of an early imaging protocol for FAPI-PET/CT for CRC and SCCA in prone position. ***Materials and Methods:*** 15 patients underwent early-imaing ^{68}Ga-FAPI-46-PET/CT-scans in prone position for histologically confirmed CRC or SCCA 5.9 minutes after radiotracer injection. SUV_{max} and metric values for primary tumors and metastases and SUV_{mean} values for liver, spleen, muscle tissue and blood pool were measured. Tumor-to-background ratios (TBR) were calculated by dividing SUV_{max} of the primary tumor by the SUV_{mean} of the reference tissues. Statistical comparison was performed via two-sample t-test. ***Results:*** Uptake was high in all primary tumors with an average SUVmax and SUVpeak of 14.9 (± 4.79) and 9.5 ± 2.5. Uptake was significantly higher ($p = 0.004$, Figure 1) in SCCA (SUVmax =20.3 ± 5.8 and SUVpeak = 12.0 ± 2.8) than in CRC (SUV_{max} =11.2 ± 1.7 and SUV_{peak} = 7.8 ± 1.4). The average minimal distance between the urinary bladder and the primary malignancy was 2.56 cm ± 0.66 cm. Lesions suspect of regional lymph node metastases had an average SUVmax of 12.8 ± 1.8 and SUVpeak of 8.5 ± 1.9, with the low-dose CT-scans showing no malignant characteristics for the smallest metastases. Lesions suspect of distant metastases were found in four patients with an average SUVmax of 11.4 ± 6.7 and a SUVpeak of 8.3 ± 4.8. High TBR were achieved for all reference tissues with the TBR being significantly lower for the blood pool compared to the other reference tissues (5.8 ± 1. 5 vs. 8.0 ± 2.2 ($p = 0.02$), 9.2 ± 2.8 ($p = 0.005$) and 8.9 ± 3.0 ($p = 0.01$) compared to liver, spleen and muscle tissue respectively). ***Conclusion:*** Early-imaging protocol in prone position for 68Ga-FAPI-46-PET/CT presents a safe and viable option for non-invasive imaging for SCCA and CRC achieving high uptake values in primary tumors and even small metastases while showing only low background uptake leading to high TBR. Imaging in prone position leads to safe spatial seperation of the urinary bladder to the primary tumors, allowing for safe tumor delineation.

EP-0332

Clinical Application Value of FAPI Imaging in Colorectal Cancer: A Retrospective Study

T. Fang*;*
Department of Nuclear Medicine, Zhongnan Hospital of Wuhan University, Wuhan, CHINA.

Aim/Introduction: Colorectal cancer remains one of the most prevalent malignancies worldwide, characterized by high incidence and mortality rates. Although [^{68}Ga]Ga-FAPI-04 PET/CT has been widely validated as a powerful tool for CRC diagnosis and staging, its potential role in predicting molecular biomarkers and prognostic outcomes remains underexplored. This retrospective study aims to analyze and elucidate the relationship between semi-quantitative parameters of [^{68}Ga]Ga-FAPI-04 PET/CT in previously untreated colorectal cancer (CRC) patients and clinical data, including tumor PD-L1 expression status, tumor mutational burden (TMB), KRAS/NRAS/BRAF mutation profiles, and progression-free survival (PFS). ***Materials and Methods:*** We retrospectively enrolled 64 treatment-naïve CRC patients who underwent pretreatment [^{68}Ga]Ga-FAPI-04 PET/CT imaging, with follow-up exceeding one year. Semi-quantitative parameters—SUVmax, SUVmean, SUVpeak, tumor-to-background ratio (TBR), total metabolic tumor volume (MTV), and total total lesion fibroblast activation protein inhibitor (TLF)—were systematically measured in 30 patients. These parameters were analyzed for correlations with PD-L1 expression, TMB, KRAS/NRAS/BRAF mutations, and PFS. ***Results:*** Total MTV and TLF demonstrated statistically significant associations with PFS ($P < 0.05$, Cox regression analysis), whereas other parameters (SUVmax, SUVmean, SUVpeak, TBR) showed no prognostic relevance. Notably, none of the PET/CT-derived semi-quantitative metrics exhibited significant correlations with PD-L1 expression levels, TMB categories, or KRAS/NRAS/BRAF mutation status (all $P > 0.05$). ***Conclusion:*** Our findings suggest that pretreatment [^{68}Ga]Ga-FAPI-04 PET/CT lacking predictive value for non-invasive assessment of PD-L1 expression, TMB, or common oncogenic mutations (KRAS/NRAS/BRAF) in CRC. Specifically, elevated total MTV and TLF were associated with shorter PFS, providing clinicians with actionable insights for risk stratification and therapeutic planning. Further validation in larger cohorts is warranted to confirm these observations.

EP-0333

Variations in F-18-FMISO Physiological Uptake

M. Araz*, &. Mesci, E. D. Avci, C. Soydal, N. Ö. Kucuk;*
Ankara University, Ankara, TÜRKIYE.

Aim/Introduction: To evaluate differences in distribution of F-18-FMISO uptake according to age, gender and primary cancer type. ***Materials and Methods:*** A total of randomly chosen 30 F-18-FMISO PET/CT studies performed for evaluation of different malignancies in three prospective clinical trials were retrospectively reevaluated. SUVmax and SUVmean values of brain, bone marrow, liver, stomach, colon, aorta were recorded. No measurements were taken on primary or metastatic tumor sites. Use of oral antidiabetics was also noted. Spearman's correlation analysis was performed to assess the relationship between age and SUV. Significance of differences between mean values of age, SUVmax, SUVmean and TBR values were also assessed. ***Results:*** Included in the study were 30 patients(13F,17M, mean age:64,27±12.05). Primary cancers of the patients were prostate in 7 patients, gastric in 2, colon in 8, rectum in 7, HCC in 3, breast in 1 and ovarian cancer in 1 patient. There was no significant correlation between age and SUV values. Mean age values were not significantly different among primary cancer subtypes. The mean values of SUVmax and SUVmean values of brain and liver didn't differ according to primary cancer subtypes. SUVmax of colon, SUVmax and SUVmean of bone marrow were significantly higher in patients with gastrointestinal tumors compared to others($p=0.049$,$p=0.017$ and $p=0.005$). There was no significant difference between mean values of the studied variables according to gender or use of oral antidiabetics. ***Conclusion:*** Relatively higher bone marrow uptake in gastrointestinal cancer patents is a novel finding in need of further investigation. Although it was previously speculated that FMISO diffuses freely from the intestinal wall or luminal bacteria may cause hypoxia, pathophysiology of higher colonic uptake in gastrointestinal cancer is still scarce (1,2). Further investigations are necessary to determine the causal relationship between high colonic uptake of FMISO in patients with gastrointestinal system tumors and attention is needed in reporting or quantitative evaluation of FMISO PET studies. ***References:*** 1) Roels S, Slagmolen P, Nuyts J, Lee JA, Loeckx D, Maes F, Stroobants S, Penninckx F, Haustermans K. EP-0334

Cost-Effectiveness of [^{18}F]FDG PET/CT in Follow-Up after Thermal Ablation in Patients with Colorectal Liver Metastases in the Dutch Healthcare Setting

S. van Mossel[1,2], *O. Bijlstra*[1], *F. van Delft*[2], *B. Boekestijn*[1], *M. Burgmans*[1], *P. Hendriks*[1], *E. Kapiteijn*[1], *S. Mieog*[1], *E. Persijn van Meerten*[1], *D. Rietbergen*[1], *S. Shahbazi Feshtali*[1], *L. De Geus-Oei*[1,2,3], *H. Koffijberg*[2];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*Delft University of Technology, Delft, NETHERLANDS.*

Aim/Introduction: The European Society for Medical Oncology (ESMO) and the European Conference on Interventional Oncology and European Society of Oncological Imaging (ECIO-ESOI) consensus guidelines vary in their recommendations regarding the use of ^{18}F-Fluorodeoxyglucose ([^{18}F]FDG) PET/CT in the follow-up after thermal ablation in patients with colorectal liver metastases. This is partly because clinical trials commonly have a limited follow-up duration, which means that data on long-term health effects, survival benefits, and cost consequences of [^{18}F]FDG PET/CT are lacking. Therefore, a simulation model has been developed to study how follow-up with [^{18}F]FDG PET/CT impacts treatment planning, long-term health and cost outcomes. We aimed to explore whether [^{18}F]FDG PET/CT allows early re-treatment and results in (i) improved health outcomes as early re-treatment may prevent patients from reaching a palliative phase of disease and (ii) reduced treatment costs as early re-treatment may reduce the need for more expensive medication and for performing open abdominal surgeries. ***Materials and Methods:*** In an illustrative Dutch cohort (48 patients, >100 scans), lifetime health and cost outcomes were evaluated to assess the cost-effectiveness of adding a single [^{18}F]FDG PET/CT to follow-up 3-4 months after thermal ablation of colorectal liver metastases, compared to standard clinical practice. Patients followed a standard surveillance schedule consisting of three-monthly serum CEA, contrast-enhanced CT and additional upper abdominal contrast MRI upon request of the medical specialist, plus routine [^{18}F]FDG PET/CT 3-4 months after thermal ablation. Therapy could be repeated downstream the care pathway. Quality-of-life and survival estimates were based on disease stage and age using literature evidence. Costs were also determined from the literature incorporating the costs related to diagnostics and treatments. ***Results:*** Health benefits of the additional [^{18}F]FDG PET/CT were negligible, incremental QALYs<0.001, whereas costs increased by €1,277, mainly due to the additional imaging. This lack of health benefits can be explained by the small subset of simulated patients (<5%) in whom [^{18}F]FDG PET/CT affected treatment planning. ***Conclusion:*** An additional routine [^{18}F]FDG PET/CT 3-4 months after thermal ablation is unlikely to be cost-effective, given the current (but limited) evidence. More research is needed to determine if using [^{18}F]FDG PET/CT in subgroups of patients, or at alternative time points, is cost-effective. This requires collecting more (extensive) follow-up data, preferably across multiple hospitals, since clinical practice may vary widely between hospitals.

EP-0335

The Value of Staging FDG PET/CT Parameters in Predicting Liver Operability and Survival in Liver Metastatic Rectal Cancer

T. Bilgücü, *G. Uçmak, B. Demirel;*
Ankara Abdurrahman Yurtaslan Educational and Research Onkology Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Our study aims to examine the relationship between staging FDG PET/CT metabolic parameters with operability and survival in liver metastatic rectal cancer. ***Materials and Methods:*** Patients diagnosed with rectal cancer without extrahepatic visceral organ metastases on staging FDG PET/CT between September 2013 and July 2022 were included in our study. Metabolic parameters, pre-operative and post-operative findings were recorded. Logistic regression analysis was performed to identify factors predicting liver metastatic lesion operability. ROC analysis was used to determine the relationship between SUVmax value of liver metastatic lesions and disease progression. Progression-free survival (PFS) and overall survival (OS) were calculated. Survival analyses were conducted using the Kaplan-Meier method and also Cox Regression Analysis. ***Results:*** 38 patients [mean age: 60.8±9.1 (39-81)] were included, of whom 28 (%73.7) were male and 10 (%26.3) were female. Among patients tested for KRAS mutation, 12 results were positive, while 16 patients were negative (wild-type). A total of 29 patients received neoadjuvant therapy and 28 patients were performed liver metastasectomy. SUVmaks value of liver metastatic lesion below 7.5 had a significantly longer PFS value [30±8.3 months (%95 CI 13,7-46,2), compared to those with a value above 7.5 [11±4.2 months (%95 CI 2,5-19,4)] (p=0.02). In addition to this, a significant correlation was found between liver MTV and TLG burden with decreased likelihood of liver operability (p = 0.04, OR: 0.99, 95% CI: 0.98-1.00). Also, patients who underwent liver metastasectomy had clinically longer PFS and OS values. The characteristics of patients' liver metastatic lesions are shown in Table 1. Patients with positive KRAS mutation had significantly higher values for liver metastatic lesion SUVmax, liver MTV and TLG compared to those with negative KRAS mutations. Additionally, positive KRAS mutation was associated with clinically shorter PFS and OS values (p = 0.07). ***Conclusion:*** In staging FDG PET/CT, liver MTV-TLG burden were found to have a significant impact on liver operability. A significant inverse relationship was detected between increasing MTV and TLG values and the likelihood of operability. The liver metastatic lesion had SUVmax >7.5 showing a correlation with shorter PFS. Patients who underwent liver metastasectomy were clinically associated with longer PFS and OS compared to those who did not undergo surgery. Additionally, PET metabolic parameters predicted KRAS mutation positivity, which was also associated with clinically shorter PFS and OS values.

EP-0336

Prognostic Utility of Volumetric PET Parameters in Colorectal Liver Metastases: Identifying Optimal Segmentation Strategies for MTV and TLG

M. Badarna, *Z. Keidar;*
Rambam Health care campus, Haifa, ISRAEL.

Aim/Introduction: Colorectal liver metastases (CRLM) are a major cause of colorectal cancer mortality. FDG PET/CT plays a critical role in staging and treatment planning. While traditional metrics like maximal standardized uptake value (SUVmax) provide prognostic information, volumetric PET biomarkers- such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG)- offer a more comprehensive assessment of tumor burden. However, reproducibility is limited due to variability in segmentation methods especially in low tumor-to-background contrast like the liver. This study aims to identify the most robust segmentation method and threshold values for pre-treatment volumetric PET parameters in CRLM, and to evaluate their prognostic value by correlation with progression-free survival (PFS) and overall survival (OS). ***Materials and Methods:*** We retrospectively analyzed 42 patients with CRLM after primary tumor resection and before initiating systemic therapy. Three segmentation methods were compared: two threshold-based (absolute and relative) and one gradient-based. MTV and TLG were calculated using multiple

thresholds per method, and total MTV and TLG (tMTV and tTLG) were derived per patient. ROC analysis identified optimal thresholds for predicting PFS and OS. Kaplan-Meier survival and log-rank tests were used for outcome comparison. Additional analysis was conducted in a subgroup of patients with liver-only metastases (n=28). ***Results:*** None of the PET-derived parameters significantly predicted PFS (AUCs 0.52-0.60). Among segmentation methods, only the relative threshold method showed prognostic value for OS. The best-performing metric was tMTV30% (using 30% SUVmax threshold), with a cut-off of 45.49 mL (AUC=0.72); patients above this value had significantly shorter survival (mean OS 5.64 vs. 13.46 years, p=0.012). SUVmax also showed prognostic relevance (cut-off 7.97, AUC=0.74); unexpectedly, higher values were associated with better survival (10.4 vs. 6.3 years), though not statistically significant. In the liver-only subgroup, SUVmax and volumetric parameters using absolute threshold method with SUV = 4 (tMTV4.0, tTLG4.0) performed best. The prognostic trend was reversed: lower SUVmax (≤8.09), tMTV4.0 (≤10.68 mL), and tTLG4.0 (≤58.92) were associated with worse OS. Only SUVmax and tTLG4.0 were significant predictors (p=0.015 and p=0.002). The gradient-based method underperformed across all analyses. ***Conclusion:*** Volumetric PET parameters, particularly the relative threshold-based segmentation method (tMTV30%), show potential for OS prognostication in CRLM and may outperform SUVmax. However, reversed trends in the liver-only subgroup, where lower metabolic burden predicted poorer outcomes, suggest underlying biological heterogeneity or limitations of volumetric analysis in low-burden disease. These findings call for prospective validation prior to clinical implementation.

EP-0337

Comparison of qualitative and quantitative metabolic variables in FDG PET/CT inrectal cancer patients who achieved complete and incomplete response after neoadjuvantchemoradiotherapy

K. Amaral, *R. Moreira Siqueira, C. sa de Camargo, E. Etchebehere, M. CL Lima, A. O Santos, C. D. Ramos, B. Juarez Amorim; UNICAMP, Campinas, BRAZIL.*

Aim/Introduction: Patients diagnosed with advanced rectal cancer are often submitted to neoadjuvant chemoradiotherapy treatment. The aim of this study was to evaluate the metabolic parameters obtained by FDG PET/CT, before and after nCRT in advanced RC patients. ***Materials and Methods:*** Patients were divided in 2 groups: complete clinical response after treatment and the ones who did not achieved complete response. All patients underwent pre-treatment and post. Among the exclusion criteria were patients who began therapy before pre-treatment PET/CT and patients who did not have both studies. We included 34 patients in the good responder group and 40 patients in the poor responder group. FDG PET/CT was analyzed by two nuclear medicine physicians, and qualitative and quantitativeanalysis were performed. We used a visual response score in qualitative analysis to compare post-PET/CT with pre-PET/CT: grade 0 = no evidence of uptake reduction; grade 1= < 33% uptake reduction; grade 2 = > 33% to 66% uptake reduction; grade 3 = > 66% uptake reduction; grade 4 = no uptake evidence on post-PET/CT. The following quantitative parameters were analyzed: SUVmax, SUVmean, MTV and TLG. The VOIs were drawn onthe primary tumor by two methodologies: 1. applying a VOI with fixed threshold of 41%; 2. drawing a VOI with variable threshold which best delineated the metabolically active tumor (best visual fit - BVF). The variable thresholds were delineated according to each patient. ***Results:*** In visual analysis, grade 4 showed a very high specificity (95%) to discriminate good from poor responder group, with a positive predictive value of 90.9%, despite a low sensitivity (58.8%). There were only two false-positive patients, one with a carcinoma in situ and the other one with a mucinous tumor. The quantitative parameters which were able to discriminated between good and poor responders with significance were: post-treatment SUVmax41% ($p < 0.0001$), SUVmaxBVF ($p < 0.0001$), post-treatmentSUVmean41% ($p < 0.0001$) and SUVmeanBVF ($p < 0.0001$), TLGBVF post-treatment ($p = 0.0164$), ΔSUVmax ($p = 0.0306$), ΔSUVmean41% ($p = 0.0072$). ***Conclusion:*** FDG PET/CT can be an accurate tool to discriminate good responders from poor responders after nCRT in RC patients. Qualitative and quantitative PET parameters which are accessible in practical routine can differentiate both groups. Further multicentric studies are necessary to standardizethe methodology and cutoffs levels. ***References:*** Araghi et al. (2019) - CRC mortality; Patel et al. (2022) - CRC screening; Habr-Gama et al. (2023) - Non-op rectal CA.

EP-0338

Mechanistic Study on the Inhibition of Colorectal Cancer Tumor Progression in Nude Mice via CL316243 Activation of Brown Adipose Tissue Using ^{18}F-FDG MicroPET/CT

J. Li, *L. Zhang, X. Mu, W. Fu;*
Affiliated Hospital of Guilin Medical University, Guilin, CHINA.

Aim/Introduction: This study investigated the anti-tumor mechanisms of CL316243, a β3-adrenergic receptor agonist, through systemic activation of brown adipose tissue (BAT) in MC38 colon cancer-bearing nude mice. Utilizing ^{18}F-FDG PET/CT imaging, we dynamically monitored whole-body and tumor glucose metabolism to explore novel metabolic intervention strategies for colorectal cancer treatment. ***Materials and Methods:*** 1.Thirty male BALB/C nude mice with MC38 colon cancer subcutaneous xenografts were randomized into four groups (6-8 mice/group): Control, CL316243-treated, IBAT-surgically-removed control, and IBAT-removed + CL316243-treated.2.CL316243 groups received daily intraperitoneal injections of 1 mg/kg CL316243 for 5 days, while control groups received saline.3.^{18}F-FDG Micro PET/CT imaging was performed pre- and post-treatment. PMOD software quantified SUV_{max} and SUV_{mean} in tumors and IBAT, analyzed via paired t-tests. Tumor volume/weight and organ glucose metabolism were monitored. Post-imaging tumor tissues underwent immunohistochemistry (IHC) for UCP1 (IBAT), Ki67, and Glut1 (tumors). Statistical analyses included ANOVA and t-tests. ***Results:*** 1. Pre - and post - treatment glucose metabolism in brain, heart, lung, and muscle showed no significant change ($P>0.05$). Hepatic glucose metabolism decreased,but without statistical significance ($P>0.05$). Thus, ^{18}F-FDG Micro PET/CT can dynamically monitor glucose metabolism changes in normal organs of nude mice.2.Tumor volume and mass were significantly lower in the CL316243 and IBAT - removed + CL316243 groups than in their respective control groups ($P<0.01$). The inhibition rates were 51.05% and 63.67%, respectively, proving CL316243 inhibits tumor progression.3. In the control group and IBAT-removed control group, pre-and post-treatment tumor SUV_{mean} values showed no significant change ($P>0.05$). However, in the CL316243 and IBAT - removed + CL316243 groups, post - treatment tumor SUV_{mean} values were significantly lower than pre-treatment values ($P<0.01$), indicating CL316243 suppresses tumor glucose metabolism, possibly via IBAT activation or direct inhibition.4.IHC showed CL316243 treatment significantly reduced KI67 and Glut1 expression in nude mouse tumors compared to control groups ($P<0.05$), proving CL316243 inhibits tumor proliferation and glucose metabolism. ***Conclusion:*** In this study, using the MC38 colon cancer nude mouse model, it was found that CL316243 can effectively activate brown adipose tissue (BAT), significantly inhibiting tumor growth and progression. Also, ^{18}F-FDG PET/CT imaging proved to be an effective tool for monitoring these metabolic changes and their impact on tumors. This finding offers a novel metabolic intervention strategy for colorectal cancer treatment.

EP-0339

Assessment of the prognostic value of ^{18}F-FDG PET-CT metabolic parameters in patients with rectal cancer

G. Cuesta Domingo[1], *A. Ortega Candil*[1], *C. Rodríguez Rey*[1], *R. Cano Carrizal*[2], *P. Nespral Torres*[3], *P. Daudén Oñate*[1], *M. Vaillant López*[1], *M. Zapardiel Martínez-Falero*[1], *C. Wakfie Corieh*[1], *M. Cabrera Martín*[1];
[1]*Department of Nuclear Medicine, Hospital Clínico San Carlos, Madrid, SPAIN,* [2]*Department of Cardiology, Hospital Infanta Sofía, San Sebastián de los Reyes, SPAIN,* [3]*Department of Nuclear Medicine, Hospital Universitario Puerta de Hierro, Madrid, SPAIN.*

Aim/Introduction: Rectal cancer is one of the most common malignanciesof the digestive tract. Its management poses challenges due to its anatomical location and silent progression. We aim to analyze the independent prognostic value of metabolic parameters from [18F-FDG]PET-CT in patients with rectal cancer. ***Materials and Methods:*** We conducted a retrospective cohort study (2020-2023) including 59 patients with rectal cancer referred for staging with [18F-FDG]PET-CT. Clinical, imaging, and metabolic variables were collected, including MTV, SUVmax, and SUVmean of the primary lesion. Tumor-related death was defined as the primary endpoint during follow-up. A multivariate Cox regression analysis was performed to identify independent prognostic predictors. Model discrimination capacity was assessed using Harrell's C-index. ***Results:*** The mean age was 65.62 ± 12.06 years, with 49.15% of the cohort being male. Adenocarcinoma was the predominant histological subtype (98.31%). Nine patients (15.25%) presented with metastatic disease at diagnosis. The mean values for the metabolic parameters were: MTV 16.55 ± 20.44, SUVmax 21.36±8.07, and SUVmean 12.29 ± 4.62. The average follow-up time was 35.15 months. In the univariate analysis, MTV (HR 1.039; 95% CI 1.010-1.069; p=0.007) was the only metabolic parameter significantly associated with the event, along with surgery, radiotherapy, nodal involvement on PET/CT, and the presence of metastases. In the multivariate Cox regression analysis, surgery (HR 0.142; 95% CI 0.024-0.850 ; p=0.033), radiotherapy (HR 0.085; 95% CI 0.013-0.580; p=0.012), and MTV (HR 1.037; 95% CI 1.008-1.068; p=0.014) remained as independent prognostic factors. Harrell's C-index demonstrated excellent discriminative ability of the final model (0.931; 95% CI 0.873-0.989). ***Conclusion:*** In our cohort, MTV emerged as an independent prognostic factor for mortality in patients with rectal cancer, indicating that higher MTV values are associated with decreased survival.

EP-0340

Added predictive value of [18F-FDG]PET/CT over MRI in detecting nodal persistence after neoadjuvant therapy in rectal cancer

G. Cuesta Domingo[1], *C. Rodríguez Rey*[1], *A. Ortega Candil*[1], *R. Cano Carrizal*[2], *P. Nespral Torres*[3], *P. Daudén*[1], *M. Vaillant Lopez*[1], *M. Zapardiel Martínez-Falero*[1], *C. Wakfie Corieh*[1], *M. Cabrera Martín*[1];
[1]*Department of Nuclear Medicine, Hospital Clínico San Carlos, Madrid, SPAIN,* [2]*Department of Cardiology, Hospital Infanta Sofía, San Sebastián de los Reyes, SPAIN,* [3]*Department of Nuclear Medicine, Hospital Universitario Puerta de Hierro, Madrid, SPAIN.*

Aim/Introduction: The detection of nodal persistence after chemoradiotherapy (CRT) in rectal cancer is critical for surgical planning and prognostic stratification. Pelvic magnetic resonance imaging (MRI) is the reference technique for locoregional staging, although it has limitations in assessing nodal involvement. [18F-FDG]PET/CT provides crucial metabolic information for the evaluation of both locoregional and metastatic nodal disease. We aim to assess the concordance between MRI and PET/CT in detecting nodal disease and to determine whether PET/CT provides additional predictive value over MRI in identifying residual nodal involvement following CRT. ***Materials and Methods:*** A retrospective study (2020-2023) was conducted with 49 patients diagnosed with rectal cancer who underwent staging with both PET/CT and MRI prior to neoadjuvant treatment (CRT) and surgery. Concordance between the two techniques was assessed using the Kappa index. Two nested models for detecting nodal persistence were compared: one based solely on MRI and another combining MRI and PET/CT. The discriminative ability of both models was analyzed using ROC curves. ***Results:*** The mean age was 64.79 ± 11.45 years, with adenocarcinoma in all cases. 48.98% were women, and stage IIIB (32.65%) was the most frequent. MRI detected nodal disease in 37 patients (75.51%), compared to 25 patients (51.02%) with PET/CT. The concordance between both techniques was moderate (Kappa = 0.4226; p < 0.001). The combined model (MRI + PET/CT) provided a significantly added predictive value over the single MRI model (LR-chi2 9.11; p = 0.0025). ROC curve analysis also showed a higher discriminative ability for the combined model (AUC: 0.6354 vs. 0.7812; p = 0.0081). ***Conclusion:*** ^{18}F-FDG PET/CT provides added predictive value over MRI in detecting nodal persistence post-neoadjuvant therapy in rectal cancer. Its combined use enhances discriminative ability and aids in better surgical selection of patients.

EP-0341

Utility of ^{18}F-FDG PET/CT in the staging of rectal carcinoma

G. Cuesta Domingo[1], *A. Ortega Candil*[1], *C. Rodríguez Rey*[1], *R. Cano Carrizal*[2], *P. Nespral Torres*[3], *M. Vaillant López*[1], *P. Daudén Oñate*[1], *P. Bascuñana Almarcha*[4], *C. Wakfie Corieh*[1], *M. Cabrera Martín*[1];

Aim/Introduction: Rectal cancer is one of the most common neoplasms of the gastrointestinal tract. Its management presents significant challenges due to its anatomical location and often silent progression. In these patients, PET/CT has become a valuable tool for assessing both lymph node involvement and distant metastases. The aim of this study is to analyze how PET/CT influences modifications in neoadjuvant treatment strategies. ***Materials and Methods:*** We conducted a retrospective, observational, and descriptive study between 2020 and 2023, including 59 patients with rectal cancer (stages II-IV) referred to our center for staging. We collected various variables, including metabolic parameters from PET (SUVmax and MTV), and assessed how often PET/CT led to changes in initial staging and therapeutic management. ***Results:*** The mean age of patients was 65.44 ± 12.04 years. Stage IIIB was the most common (30.5%; n=18), and the most frequent histological subtype was adenocarcinoma (98.3%). Among the 59 patients, 9 (15.3%) were metastatic at diagnosis, and 1 (1.7%) had lymph node involvement not identified on MRI. PET/CT led to changes in staging and treatment in 10 patients (17%). The liver was the most common site of metastasis, found in 7 (78%) of the metastatic cases. Eleven patients (18.6%) died within 4 years of diagnosis. The mean SUVmax of the primary lesion was 21.3 ± 8.06, and the mean MTV was 16.5 ± 20.24. ***Conclusion:*** PET/CT proved to be a useful tool in the staging of rectal carcinoma, altering therapeutic management in 17% of patients by detecting metastatic or nodal involvement not identified on MRI.

EP-0342

Preliminary results of^{68}Ga-FAPI PET imaging in total neoadjuvant therapy of rectal cancer

S.-h. Chen*, K.-C. Ho, R.-E. Hsieh, E.-L. Shen, C.-K. Liao, H.-C. Hsu, A.-H. Chen, J.-F. You, P.-S. Hsieh, Y.-J. Hsu, Y.-J. Chern, C.-C. Cheng, Y.-C. Lin;
Chang Gung Memorial Hospital, Taoyuan County, TAIWAN.*

Aim/Introduction: Total neoadjuvant therapy (TNT) is increasingly utilised for locally advanced rectal cancer (LARC). Accurate

staging and response assessment are crucial for optimising treatment strategies. ^{68}Ga-labelled FAP inhibitors (FAPI) have shown promise as promising PET tracers which may offer higher specificity and reduced interference from physiologic uptake of fluorodeoxyglucose PET (FDG-PET). This study aimed to evaluate the potential role of 68Ga-FAPI PET/CT in the initial staging and assessment of treatment response in LARC patients undergoing TNT, comparing its performance with standard ^{18}F-FDG PET/CT. ***Materials and Methods:*** Eligible participatns included adult patients with biopsy-proven, newly diagnosed, clinical stage II-III rectal adenocarcinoma suitable for TNT. Key exclusion criteria included evidence of distant metastases, prior cancer therapy, prior pelvic radiotherapy and significant comorbidities. Participants underwent both ^{18}F-FDG and ^{68}Ga-FAPI PET/CT scans before and after treatment. PET parameters including maximum standardised uptake value (SUVmax), mean SUV (SUVmean), and metabolic tumour volume (MTV) were measured for primary tumours within the boundary of 42% SUVmax. Initial comparisons focused on tracer uptake in primary tumours and lymph node detection accuracy. Pathological findings from biopsy or surgical specimens served as the reference standard where available. Data on treatment outcomes, including disease-free survival (DFS), local regional recurrence (LRR), and overall survival (OS), are being collected. ***Results:*** To date, 24 patients have been enrolled, with 19 completing the first set of PET scans and 15 completing the second set. Pos-treatment pathology results were available for 8 patients. Initial visual assessment suggested 68Ga-FAPI PET/CT may offer better tumour visualization due to lower physiological background uptake in the colon compared to 18F-FDG. Quantitative analysis showed variable uptake for both tracers across patients. In comparing nodal staging (N-staging), preliminary analysis based on clinical consensus as the gold standard suggested ^{68}Ga-FAPI PET/CT might be less sensitive but potentially more specific than ^{18}F-FDG PET/CT for detecting lymph node metastases. Pre-treatment tumour volume and post-treatment tracer uptake may reflect therapeutic response. However, these associations require further validation. ***Conclusion:*** Initial results indicate that ^{68}Ga-FAPI PET imaging may offer clinical value in the staging and response evaluation of LARC patients undergoing TNT, particularly through improved specificity in nodal assessment and clearer primary tumour visualisation due to less interference from physiological uptake. Further patient recruitment and correlation with treatment response and long-term outcomes are necessary to establish the definitive role of 68Ga-FAPI PET/CT in this setting.

Association Between KRAS Mutation and Metabolic and Volumetric Parameters Measured from the Primary Tumor in Colorectal Cancer Using F-18 FDG PET/CT

E. Tunca[1], *R. H. Tokac*[1], *U. Yararbas*[1], *M. Sezak*[2];
[1]*Ege University Faculty of Medicine, Department of Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Ege University Faculty of Medicine, Department of Pathology, Izmir, TÜRKIYE.*

Aim/Introduction: In our study, we aimed to show the relationship between metabolic and volumetric parameters measured from the primary colorectal mass on Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (F18-FDG PET/CT), a non-invasive method in patients with colorectal cancer (CRC), and the presence of KRAS mutation in the primary mass and to investigate the potential to predict mutation. ***Materials and Methods:*** The archival and electronic patient file data of 216 patients who were pathologically diagnosed with CRC after biopsy or surgery and underwent F18-FDG PET/CT imaging for pre-treatment staging in our clinic between 2018 and 2024 were retrospectively analyzed. Among these patients, 72 patients who had KRAS mutation analysis from primary colorectal mass and met the other inclusion criteria were included in our study. Patients with KRAS mutation analysis from metastatic foci were not included in the study. The relationship between metabolic and volumetric parameters (SUVmax, SUVmean, SUVpeak, TLG and MTV) calculated from the primary mass on F18-FDG PET/CT imaging and KRAS mutation was analyzed. ***Results:*** Among 72 cases, KRAS mutation was detected in 30 patients (58.3%). SUVmax value measured from the primary mass was significantly higher in KRAS mutant patients compared to KRAS-wild type (WT) patients (p: 0.031). No significant difference was observed between KRAS mutant and WT patients with other parameters. As a result of ROC analysis, although the AUC (Area Under the Curve) of the parameters was greater than 0.5, their predictive values were low (SUVmax: 0.644, SUVmean: 0.632, SUVpeak: 0.584, TLG: 0.600, MTV: 0.591). With a cut-off value of 20.50 for SUVmax, sensitivity and specificity for KRAS mutation detection were calculated as 80% and 47.6%, respectively. ***Conclusion:*** Our study is valuable in terms of preventing misleading findings that may be caused by mutation heterogeneity between tumor and metastatic focus by excluding cases with KRAS mutation analysis from metastatic foci. Our study suggests that the SUVmax value measured from the primary mass may be a useful parameter in predicting KRAS mutation.

EP-0344

The Value of F18 FDG-PET/CT Parameters Measured at the Anastomosis Line for Predicting Local Recurrence in Operated Colorectal Cancer Patients

E. Tunca, *R. Tokac, U. Yararbas;*
Ege University Faculty of Medicine, Department of Nuclear Medicine, Izmir, TÜRKIYE.

Aim/Introduction: F-18 FDG PET/CT (PET/CT) is recommended for primary staging and restaging in suspected metastatic disease in colorectal cancer (CRC). Surgical resection is the main treatment modality. Although curative surgery is performed, local recurrence is observed in 10-30% of patients with CRC. In this study, we aimed to evaluate the effectiveness of metabolic and volumetric parameters measured from the anastomotic site on PET/CT in detecting local recurrence in operated CRC patients. ***Materials and Methods:*** We retrospectively reviewed 750 postoperative CRC patients who underwent PET/CT imaging between 2018 and 2024. Patients were included based on availability of colonoscopy within 3 months of imaging, or histopathology results from re-operation specimens. In addition, patients who did not have pathology/colonoscopy data but who were clinically accepted as local recurrence with other radiological imaging methods were also added and a total of 97 patients were included. PET/CT images were analyzed using Siemens syngo.via software to obtain metabolic and volumetric parameters (SUVmax, SUVmean, SUVpeak, MTV, TLG) from the anastomotic site. ***Results:*** Among 97 patients (35 female, 62 male; mean age: 60.44 ± 12.47 years), 78 had no recurrence based on colonoscopy or pathology results. According to the colonoscopy pathology of 7 patients and re-operation pathology of 6 patients, and radiological imaging follow-up of the other 6 patients, a total of 19 patients had local recurrence. Tumor locations included right colon (n=21), transverse colon (n=3), left colon (n=11), sigmoid colon (n=22), and rectum (n=40). Most tumors were adenocarcinomas (n=96). Mean PET/CT values at the anastomotic site were: SUVmax 7.71±5.32, SUVpeak 5.46±3.75, SUVmean 4.49±3.57, MTV 14.81±21.11, TLG 50.55±55.18. In the statistical analysis; SUVmax, SUVmean and SUVpeak values were more significant and all parameters were statistically related to local recurrence (SUVmax: p<0.001, SUVmean: p<0.001, SUVpeak: p<0.001, MTV-p:0.039, TLG-p:0. 031). According to the ROC analysis; SUVmax, SUVmean, and SUVpeak can predict local recurrence with high sensitivity and specificity at the identified cut-off values. In comparison, TLG showed lower diagnostic performance with reduced sensitivity and specificity, indicating limited utility in detecting recurrence. MTV didn't demonstrate sufficient discriminative power. ***Conclusion:*** In our study, metabolic parameters measured from the anastomotic site were significantly higher in cases with local recurrence. SUVmax, SUVmean, and SUVpeak were useful in predicting recurrence with good sensitivity and specificity. However, volumetric parameters such as MTV and TLG showed limited value.

EP-0345

Preliminary comparison of 68Ga-FAPI-46 against 18F-FDG, 68Ga-DOTATATE and 68Ga-Pentixafor PET/CT/MR imaging in the assessment of various cancer types

H. Dadgar[1], *M. Assadi*[2], *B. Al-balooshi*[3], *A. Cimini*[4], *M. Ricci*[5], *H. Arabi*[6];

[1]Nuclear Medicine and Molecular imaging research center, RAZAVI Hospital, Mashad, Iran, ISLAMIC REPUBLIC OF, [2]The Persian Gulf Nuclear Medicine Research Center, Department of Molecular Imaging and Radionuclide Therapy (MIRT), Bushehr Medical University Hospital, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF, [3]3Dubai Nuclear medicine & Molecular imaging Center- Dubai Academic Health corporation-DAHC, UAE, Dubai, UNITED ARAB EMIRATES, [4]Nuclear Medicine Unit, St. Salvatore Hospital, 67100 L'Aquila, ITALY, [5]Nuclear Medicine Unit, Cardarelli Hospital, Campobasso, ITALY, [6]Division of Nuclear Medicine and Molecular Imaging, Diagnostic Department, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: 68Ga-FAPI PET/CT imaging allows for effective lesion detectability in cancer microenvironment owing to the relatively high intra-tumoral uptake and low background. This work reports on preliminary comparison between 68Ga-Pentixafor and 68Ga-FAPI-46 PET radiotracers against commonly used ^{18}F-FDG and 68Ga-DOTATATE PET radiotracers in the assessment of various cancer types. ***Materials and Methods:*** Eleven patients with histopathologically confirmed breast cancer, gastric, cervical, glioblastoma multiform (GBM), well-differentiated adenocarcinoma, papillary thyroid carcinoma (PTC), Ewing's sarcoma, colon, and medullar thyroid cancer (MTC) were retrospectively studied. Nine patients were scanned with 18F-FDG, eleven patients with 68Ga-FAPI, three patients with 68Ga-DOTATATE, and one patient with 68Ga-Pentixafor on a Siemens Biograph 6 PET/CT scanner. PET/CT images were evaluated by two nuclear medicine physicians to identify malignant lesions and perform semi-quantitative analysis to calculate maximum standardized uptake value (SUVmax) and target-to-background ratio (TBR). ***Results:*** The evaluation of the eleven subjects demonstrated the effectiveness of 68Ga-FAPI-46 compared to ^{18}F-FDG for the detection of metastasis in the lymph nodes (55 vs. 49), liver (4 vs. 3), and bone (4 vs. 3). 68Ga-Pentixafor and 68Ga-DOTATATE PET/CT scans exhibited no significant differences with both being inferior to 68Ga-FAPI-46 PET radiotracer in terms of metastasis detection. Semi-quantitative analysis showed that the TBR and SUVmax were significantly higher in 68Ga-FAPI-46 PET than ^{18}F-FDG PET for bone metastases and lymph nodes. ^{18}F-FDG and 68Ga-FAPI-46 images exhibited similar SUVmax in liver metastases. However, the TBRs in 68Ga-FAPI-46 images were significantly higher than those in ^{18}F-FDG images. ***Conclusion:*** Improved malignancy detection rates for metastases in the liver, lymph nodes, and bone were observed for 68Ga-FAPI-46 PET compared to 68Ga-DOTATATE, 18F-FDG, and 68Ga-Pentixafor PET. ***References:*** 68Ga-FAPI-46, 68Ga-DOTATATE, 18F-FDG, 68Ga-Pentixafor PET, GBM, MTC.

EP-0346

Evaluating the Diagnostic Value of Dual-Time F-18 PSMA-1007 PET/CT in Prostate Cancer

S. Tsai[1,2], *Y. Pu*[3], *J. Hong*[3], *P. Chuang*[4], *H. Wen*[5], *P. Kuo*[6], *C. Lu*[4]; *[1]Department of Nuclear Medicine, National Yang Ming Chiao Tung University Hospital, Yilan County, TAIWAN, [2]School of Medicine, National Yang Ming Chiao Yung University, Taipei, TAIWAN, [3]Department of Urology, National Taiwan University Hospital, Taipei, TAIWAN, [4]Department of Nuclear Medicine, National Taiwan University Cancer Center, Taipei, TAIWAN, [5]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, TAIWAN, [6]Department of Radiology, National Taiwan University College of Medicine, Taipei, TAIWAN.*

Aim/Introduction: F-18 PSMA-1007 PET/CT has become an essential tool in the management of prostate cancer, particularly for staging and restaging. Owing to its favorable half-life and minimal urinary excretion, imaging is often performed at either 60 or 120 minutes post-injection. However, whether dual-time imaging provides additional diagnostic benefits remains under debate. This prospective single-center study aimed to evaluate the clinical relevance of 60-minute vs 120-minute F-18 PSMA-1007 PET/CT, and determine if a single time point is sufficient for accurate staging. ***Materials and Methods:*** Between March 11, 2022 and March 29, 2023, 130 patients with histologically confirmed prostate cancer underwent dual-time F-18 PSMA-1007 PET/CT at both 60&120 minutes post-injection. Imaging was performed from skull to mid-thigh. Indications included primary staging (n=31) and biochemical recurrence (BCR)/restaging (n=99). PET images were interpreted by two experienced nuclear medicine physicians using visual and semi-quantitative (SUVmax, SUVmean, SUVpeak) assessment. Staging comparisons and discordances between 1-hour and 2-hour scans were recorded and analyzed by indication group. ***Results:*** The mean age was 69.5±7.8 years. Mean PSA prior to PET was 22.67±75.30 ng/mL (range 0.02-664). Overall, TNM staging changed in 43.8% (57/130) of patients after PET, mostly due to newly detected metastases (38.5% upstaged). Only 5 patients (3.8%) demonstrated staging discrepancies between 60-minute and 120-minute scans. Of these, 2 patients were upstaged from M0 (no distant metastasis at 1 hr) to M1b (bone metastases at 2 hr), and 2 were upstaged from N0 to N1 due to clearer nodal visualization at 120 minutes. Conversely, 1 patient was downstaged from M1b to M0 due to resolution of equivocal bone uptake seen at 60 minutes but not at 120 minutes. All discrepant cases had equivocal or borderline findings at 1 hour. Notably, patients undergoing primary staging were more likely to have discrepant findings (3/31=9.7%) compared to those in the BCR/restaging group (2/99=2.0%; p=0.088). Semi-quantitative metrics were overall stable between time points with no significant impact on lesion classification. ***Conclusion:*** Our findings demonstrate that 60-minute and 120-minute F-18 PSMA-1007 PET/CT imaging have high concordance, with only 3.8% of patients experiencing clinically relevant staging differences. Discrepancies were limited to cases with borderline or equivocal lesions, mostly in the primary staging cohort. Routine dual-time imaging may therefore be unnecessary, and single-time-point acquisition at 60 minutes appears sufficient for most clinical scenarios. However, 120-minute delayed imaging may be considered in select cases, especially when early scans yield ambiguous findings in newly diagnosed patients.

EP-0347

Comparative Performance of PSMA PET PRIMARY Score and mpMRI PIRADS in Localizing Clinically Significant Prostate Cancer

S. Shekhar Singh[1], *P. Wadhwa*[2], *R. Parwar*[1], *S. Tandon*[1]; *[1]Globe Healthcare, Lucknow, INDIA, [2]United Imaging Healthcare, Delhi, INDIA.*

Aim/Introduction: Prostate-specific membrane antigen positron emission tomography (PSMA PET) and multiparametric magnetic resonance imaging (mpMRI) are pivotal in prostate cancer staging. This study investigates the concordance between the PRIMARY score (PSMA PET-based) and PIRADS (mpMRI-based) for lesion characterization and evaluates their correlations with histopathology (Gleason score) and serum PSA in 200 treatment-naïve patients. ***Materials and Methods:*** We retrospectively analysed 200 patients with elevated PSA who underwent 68Ga-PSMA-11 PET/CT and mpMRI prior to biopsy or treatment. Two

blinded specialists independently assigned PIRADS (v2) and PRIMARY scores based on lesion location (apex, mid-gland, base). Statistical correlations were assessed between imaging scores, Gleason grade, SUVmax, and PSA. ***Results:*** PRIMARY vs. Gleason Score: Strong correlation (*r* = 0.5, *p* < 0.001).PRIMARY vs. PIRADS: Moderate agreement (*r* = 0.4, *p* = 0.4), with regional variations:Base: Moderate correlation (*r* = 0.5).Apex/Mid-gland: Weak correlation (*r* = 0.2-0.3).PRIMARY vs. PSA: Weak association (*r* = 0.2, *p* = 0.04).SUVmax correlated moderately with Gleason score (*r* = 0.3, *p* = 0.002) but poorly with PIRADS/PSA. Higher PRIMARY scores predicted metastatic burden (*p* < 0.05). ***Conclusion:*** The PRIMARY score demonstrates robust alignment with histopathology and has a comparable agreement with PIRADS score. PET quantitative parameters like SUVmax can be used to predict the aggressiveness of the primary tumor in terms of Gleason score. Combined PSMA PET and mpMRI may enhance diagnostic precision for intraprostatic lesions. ***References:*** Hofman MS, et al. Lancet. 2020;395:1208-1216.Weinreb JC, et al. Eur Radiol. 2016;26:67-76.

EP-0348

Beyond the Standard: Enhancing prostate bed and regional lymph node detection in Prostate Cancer patients with Early and Delayed Imaging in 68Ga-PSMA PET/CT

A. Aghaee[1], *S. Soltani*[2], *Z. Bakhshi*[1], *K. Aryana*[1], *N. Norouzbeigi*[1], *H. Dadgar*[1];
[1]*Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Kidney Transplantation Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: The accuracy of Ga-PSMA scans can be enhanced by employing multiphasic imaging strategies. This study aims to evaluate the diagnostic value of early static and delayed imaging in conjunction with standard 68Ga-PSMA-11 PET/CT scans for the detection of prostate bed recurrence in prostate cancer patients. ***Materials and Methods:*** In this prospective study, 138 prostate cancer patients underwent routine 68Ga-PSMA-11 PET/CT imaging. Each patient received early imaging immediately following a 4-minute static acquisition after tracer injection, and delayed imaging was conducted 3 hours post-injection, focused on the pelvic region. The imaging results were analyzed for lesion count, type, localization, and maximum standardized uptake values. ***Results:*** Among the patients, 57.97% exhibited positive findings for pathologic prostatic lesions in the standard PET scans (median SUVmax: 10.24). In contrast, early PET imaging detected lesions in 58.01% of patients (median SUVmax of 5.86), while delayed scans revealed lesions suggestive of malignancy in 55.45% of patients (median SUVmax of 12.79). The analysis demonstrated a statistically significant difference in SUVmax values across the time points ($p < 0.001$). In patients, lymph nodes with pathological tracer uptake in the pelvic region on images 60 min p.i. were revealed by an SUV max 60 min p.i.: 15.78; lymph nodes considered for SUV measurements showed a pathologic tracer uptake within the first 4 min (SUV max 4 min: 7.36) and after 3 hours (SUV max 180 min p.i.: 19.19). Pathologic bone lesions regarded as metastases in the field of view on WB were found in 38 cases of patients, more than the ESI (f = 37) and DI (f = 24). In comparison, urinary bladder activity assessment was detectable with the WB imaging mean SUV max 60 min 11.07. Even though the mean SUV max for ESI and DI were 6.95 and 31.97, respectively. In the statistical analysis, pathologic radiotracer uptake in tumor lesions was statistically higher in ESI and WB than in urinary bladder activity. ***Conclusion:*** The findings indicate that neither early nor delayed imaging significantly enhanced the overall detection rate of malignant lesions in prostate cancer patients when using 68Ga-PSMA-11 PET/CT. However, the early acquisition of PET images, conducted as soon as 4 minutes after injection, proved beneficial for distinguishing local bladder invasion more effectively.

EP-0349

Reconstruction of ^{18}F-PSMA-1007 PET Scans Affects SUV-based Classification of Unspecific Bone Uptake

R. Poelarends*, A. G. Tegelaar - Kuiper, J. D. van Dijk, B. N. Vendel, J. A. van Dalen;*
Isala Hospital, Zwolle, NETHERLANDS.

Aim/Introduction: Interpreting 18F-PSMA-1007 PET scans can be challenging due to the occurrence of unspecific bone uptake (UBU), defined as focal PSMA uptake without a clear CT morphological correlate and uncertain clinical significance. While Standardized Uptake Value (SUV) in PET is widely used to differentiate between physiological uptake and metastases, it is known to be influenced by technical factors such as the applied image reconstruction. Our aim was to determine the impact of different iterative reconstruction settings on SUV measurements and lesion classification in 18F-PSMA-1007 PET. ***Materials and Methods:*** We retrospectively included 26 patients who underwent 18F-PSMA-1007 PET/CT (Vereos, Philips) and in whom UBUs were observed by expert nuclear medicine physicians. For each patient, three different Ordered Subset Expectation Maximization (OSEM) reconstructions that had diagnostic image quality were performed with increasing image noise: an EARL2-compliant reconstruction (3 iterations, 7 subsets, point spread function (PSF) modelling with 6 relaxation steps, 4 mm Gaussian post-filter), a high-resolution (HR) reconstruction (3 iterations, 13 subsets, without PSF or filtering) as used in our institute, and an ultra-high-resolution (UHR) reconstruction (4 iterations, 24 subsets, without PSF or filtering). A maximum of three UBUs per patient were identified using the HR-reconstruction. SUVmax and SUVmean were measured using a 50% iso-contour for the UBUs on each of the three reconstructions. Impact on SUV measurements was assessed using EARL2 reconstruction as a reference. Reclassification rates were evaluated between reconstructions using three groups: likely benign (SUVmax < 7), equivocal (SUVmax 7-11), and likely metastatic (SUVmax > 11). ***Results:*** A total of 43 UBUs were identified. Compared to the EARL2 reconstruction, the HR-reconstruction showed higher SUV: SUVmax increased by 20% (6.2 ± 3.7 vs. 7.2 ± 3.5, $p<0.001$) and SUVmean by 21% (3.9±2.2 vs. 4.6±2.3, $p<0.001$). The UHR-reconstruction also showed higher values compared to EARL2: SUVmax increased by 28% (6.2±3.7 vs. 7.6±3.7, $p<0.001$) and SUVmean by 29% (3.9±2.2 vs. 4.9±2.3, $p<0.001$). Compared to EARL2, 8 of 43 UBUs (19%) were reclassified from 'likely benign' to 'equivocal' in 7 patients when using HR-reconstruction. For the UHR-reconstruction, this reclassification occurred in 12 of 43 UBUs (28%) in a total of 9 patients. No other reclassifications occurred. ***Conclusion:*** SUV measurements for UBUs show high variability between 18F-PSMA-1007 PET reconstructions that can affect lesion classification when applying a SUV-based threshold. These findings underscore the need for standardization of PSMA-PET reconstructions when using SUV thresholds for making treatment decisions.

EP-0350

The Power Duo: PSMA PET/CT and Focal Ablation in Prostate Cancer (PCa) Care

J. Jandric[1], *V. Fasulo*[1,2], *P. Guglielmo*[2], *C. Vallone*[1], *M. Rodari*[1], *M. Lazzeri*[1], *N. Buffi*[1,3], *G. Lughezzani*[1,3], *L. Evangelista*[1,3];
[1]*IRCCS Humanitas Research Hospital, Rozzano, ITALY,* [2]*Humanitas University, Pieve Emanuale, ITALY,* [3]*Humanitas University, Pieve Emanuele, ITALY.*

Aim/Introduction: Accurate selection of PCa patients for focal therapies remains crucial. While mpMRI provides valuable information on tumor localization, it has limitations, such as detecting cancer in the transition zone, identifying small foci within the central gland and characterizing multifocal disease. This study aimed to evaluate the potential role of PSMA PET in a cohort of PCa patients candidate to focal therapies with curative intent at a tertiary referral center. ***Materials and Methods:*** From 02/2020 to 05/2024, we retrospectively reviewed the clinical records of PCa

patients who underwent PSMA PET at our center prior to receiving focal treatment. Prior to PETscans, all patients underwent mpMRI in accordance with international guidelines. Imaging scans were visually assessed, categorizing the PSMA uptake into focal, diffuse or mixed (focal+diffuse) patterns. Additionally, the PRIMARY score for the index lesion in the prostate gland was evaluated. Post-treatment PSA levels were recorded and correlated with PET patterns and PRIMARY scores. Data distribution and between-group comparisons were analyzed using non-parametric methods in MedCalc®. ***Results:*** Data from 48 patients were analysed. The median baseline PSA was 6.03 ng/mL (range 2.25-16.4), and Gleason scores ranged from 6 to 8, with a score of 7 in 31(64%). mpMRI was available for 45 patients(94%), revealing a unifocal lesion in 42(93%) and bifocal/multifocal lesions in 3 cases(7%). Using PI-RADS version 2.1, 8 patients(18%) were assigned a score of 3, 33(73%) a score of 4, and 4(9%) a score of 5. PSMA PET uptake patterns were focal in 25 patients(52%), diffuse in 20(42%), and mixed focal + diffuse in 2(4%); one scan (2%) showed no significant prostatic uptake. PRIMARY scores were distributed as follows: 1 in 1 patient(2%), 2A/B in 22(46%), 3 in 5(10%), 4 in 12(25%), and 5 in 8(17%). Focal therapies were delivered a median of 2.23 months after PET. Posttreatment PSA decreased in 32 patients(67%), increased in 10(21%), remained stable in 5(10%), and was unavailable for 1(2%). Although patients with PRIMARY scores ≤ 3 had a lower median posttreatment PSA than those with scores > 3 (3.9 vs 5.2 ng/mL), this difference was not statistically significant (Mann-Whitney p=0.267). Likewise, uptake pattern was not significantly associated with posttreatment PSA levels (Kruskal-Wallis p=0.45). ***Conclusion:*** PSMA PET demonstrated a high positivity rate (98%) in patients selected for focal treatments. Although uptake patterns and PRIMARY scores didn't significantly predict PSA response, lower PRIMARY scores trended toward greater posttreatment PSA reductions. ***References:*** DOI:10.1038/s41391-025-00944-1.

EP-0351

Triple-time point PSMA-PET imaging in primary staging of high-risk prostate cancer enabled by LAFOV PET/CT: potential clinical benefit?

E. Calderón Ochoa[1], *L. S. Kiefer*[1], *M. Maas*[2], *C. P. Reinert*[3], *H. Dittmann*[1], *I. Tsaur*[2], *J. Schwenck*[1,4,5], *C. la Fougère*[1,4];
[1]Department of Nuclear Medicine and Molecular Imaging, University Hospital of Tübingen, Tübingen, GERMANY, [2]Department of Urology, University Hospital of Tübingen, Tübingen, GERMANY, [3]Department of Diagnostic and Interventional Radiology, University Hospital of Tübingen, Tübingen, GERMANY, [4]Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", University of Tübingen, Tübingen, GERMANY, [5]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, University of Tübingen, Tübingen, GERMANY.

Aim/Introduction: PSMA PET/CT has transformed prostate cancer (PC) management, showing a specificity of 89% to 98% for the detection of lymph node metastases in primary staging. However, its sensitivity ranges from 53% to 64% compared to histology. Therefore, we hypothesize that the dynamic PSMA uptake in triple-time point LAFOV PET/CT scans may help overcome these limitations. ***Materials and Methods:*** In a prospective study, 15 patients with histologically diagnosed high-risk PC (PSA ≥ 20 ng/ml, Gleason ≥ 8, cT3/cT4) underwent PET imaging at 1.5h, 3h, and 5h p.i. (3.0 MBq/kg [^{18}F]PSMA-1007; 5 min, 10 min, 20 min scan time). The uptake of suspicious tumor lesions was evaluated using a 50% isocountour (SUV_{mean}; SUV_{max}). Lymph nodes (LN) were categorized according to their uptake (SUV_{mean}), analogous to the PROMISE criteria. To assess the tracer kinetics, the uptake of PT and LN was normalized to the corresponding SUV_{mean} of the spleen. The physiological uptake in the spleen, salivary glands, and blood pool (BP) was assessed (2-3 ml VOI; SUV_{mean}). Noise performance was assessed using the coefficient of variation (CV; standard deviation liver VOI/SUV_{mean} liver VOI). ***Results:*** Noise performance remained constant up to 5h p.i. without significant differences (CV 1.5h: 9.9±3.6%, 3h: 9.9±4.0%, 5h:10.6±3.9%, p = 0.33). The BP steadily decreased up to 5h p.i. (1.5h: 1,7±0.3, 3h:0,7±0.1, 5h: 0,4±0.1, p<0.001), while the uptake in the spleen and parotid gland increased. PTs showed an increasing tracer uptake from 1.5h to 5h p.i. (SUV_{max} 35.2±35.1 vs. 42.8±34.5; p = 0.01) while remaining relatively constant compared to 3h p.i. (SUV_{max} 3h p.i. 37.9±34.5). In suspicious LNs a steadily increasing tracer uptake was observed up to 5h p.i. (1.5h: SUV_{max} 15.2±11.2; 3h:19.9±13.6; 5h: 25.9±20.2; p = 0.004). The LNs, which were considered not suspicious for metastasis, displayed a similar dynamic (SUV_{max} 4.8±1.2; 3h:5.9±1.9; 5h: 7.2±3.0; p = 0.005), although the tracer uptake was significantly lower compared to suspicious LNs. Furthermore, the differences in normalized tracer uptake between 1.5h-5h p.i. in suspicious LNs were significantly higher than in unspecific LNs (0.4±0.26 vs 0.09±0.12; p = 0.01). ***Conclusion:*** LAFOV PET enables triple-time point imaging up to 5h p.i. with excellent noise performance. PT and suspicious LNs showed increased PSMA tracer uptake in late PET images. However, an increase in unsuspicious LNs was also observed. Further evaluation of tracer kinetics in correlation to histopathology and size of metastases is required to improve prostate cancer diagnostics and treatment precision.

EP-0352

P(yl)rimary: SUV Validation of PRIMARY score 5 in ^{18}F-DCFPyL PET/CT for staging of Prostate Cancer

E. O'Dwyer, *V. Marulanda Corzo, A. Ricaurte Fajardo, D. D'Angelo, T. McClure, S. Huicochea Castellanos, J. R. Osborne;
Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: ^{18}F-DCFPyL PSMA PET/CT is indicated in the staging of intermediate- and high-risk prostate cancer (PCa) as it has been shown to be superior to conventional imaging. In addition, ^{18}F-DCFPyL has been shown to be clinically equivalent in PCa staging to the other approved agents including ^{68}Ga PSMA-11. PSMA PET diagnostic scoring systems have been developed, including the PRIMARY scoring system which identified SUVmax≥12 in prostatic lesions as diagnostic of clinically significant prostate cancer (csPCa) (PRIMARY score 5)[1,2]. This scoring system, however, has only been validated on 68GaPSMA-11 radiotracer. This study aimed to determine what is the SUVmax cutoff for detection of csPCa in patients staged with ^{18}F-DCFPyL radiotracer and whether it is comparable to ^{68}GaPSMA-11 and thus PRIMARY score can be used in this patient cohort. ***Materials and Methods:*** Retrospective analysis of 91 treatment naïve men who underwent ^{18}F-DCFPyL PET/CT following biopsy-confirmed PCa. A total of 126 intraprostatic PSMA-avid lesions were identified and qualitatively scored using the PRIMARY scoring system (score 1-5), based on pattern (focal versus diffuse), zonal location, and uptake intensity. SUVmax values were recorded for each lesion. Youden's J index was used to determine the optimal SUVmax cutoff to predict a PRIMARY score of 5. A logistic regression model was fitted with PRIMARY score (5 versus ≤4) as the outcome and lesion SUVmax (continuous) as the predictor. An ROC curve was generated, and the SUVmax cutoff associated with the maximum Youden's J value was identified. Analysis was performed in all lesions (N=126), and in a subgroup with histologically confirmed clinically significant prostate cancer/grade group ≥2 (N=112). Statistical analysis was performed using SAS version 9.4 (SAS Institute Inc., Cary, NC). ***Results:*** Median age was 70 years (IQR 65-76), and median PSA was 6.4 ng/dL (IQR 4.9-9.9). Median interval from biopsy to PET was 16 days (IQR 7-27). ISUP Grade Group distribution included GG1 (n=10), GG2 (n=52), GG3 (n=29), GG4 (n=16), and GG5 (n=15). Among 126 lesions SUVmax≥ 12.4 was identified as optimal for detecting csPCa which is almost identical to PRIMARY score 5

SUVmax≥12. ***Conclusion:*** SUVmax≥ 12.4 accurately identifies prostatic lesions with csPCa (PRIMARY score 5) in ^{18}F-DCFPyL PET/CT for PCa staging. Thus, our study supports the robustness and transferability of the PRIMARY scoring system to ^{18}F-DCFPyL PET/CT in prostatic lesion assessment. ***References:*** 1. Emmett L et al. J Nucl Med. 2022 Nov;63(11):1644-1650. 2. Emmett L et al. J Nucl Med. 2024 Jan 2;65(1):94-99.

EP-0353

Prostate Cancer Detection with [99mTc]Tc-HYNIC-iPSMA SPECT: The Australian Experience.

P. Tually[1], *J. Meadows*[1], *L. Groombridge*[1], *N. Lenzo*[1], *G. Currie*[2]; *[1]Spartan First Imaging, Kalgoorlie, AUSTRALIA, [2]Charles Sturt University, Wagga Wagga, AUSTRALIA.*

Aim/Introduction: Rural Australians, particularly Indigenous communities, experience disproportionately higher morbidity and mortality rates from prostate cancer (PrCa), driven in part by delayed diagnosis and limited access to advanced diagnostic services. Geographic isolation, lower socioeconomic status, and workforce shortages contribute to a persistent rural health gap. Access to molecular imaging is a critical part of precision oncology, yet PET/CT remains cost-prohibitive or unavailable in many regional settings. This prospective study investigates the safety and clinical impact of 99mTc-HYNIC-iPSMA SPECT imaging—a more accessible alternative—among prostate cancer patients in remote Western Australia. By evaluating its role in improving diagnosis and informing treatment decisions, this study addresses a key area of rural health inequality and seeks to support more equitable access to theranostic options. ***Materials and Methods:*** Twenty-seven patients from rural Western Australia with histologically confirmed PrCa were enrolled in this observational study. Each underwent imaging 2-4 hours after intravenous injection of 650-800 MBq 99mTc-HYNIC-iPSMA. Imaging protocols included whole-body planar sweeps, static views of areas of interest, and SPECT/CT acquisitions of the chest, abdomen, and pelvis. Adverse events were recorded, and clinical follow-up data were extracted from medical records to assess the impact on patient management. ***Results:*** No adverse events were observed in any participant. Normal physiological biodistribution was seen in 96.3% (n = 26) of cases. The mean radiochemical purity was 92.5% (±1.7), ranging from 90% to 96%. At least one PSMA-positive lesion was identified in 81.5% (n = 22) of patients. Imaging findings directly influenced clinical management in 40.7% (n = 11) of cases, including changes to treatment pathways. ***Conclusion:*** 99mTc-HYNIC-iPSMA SPECT is a safe, feasible, and clinically impactful imaging modality that offers a cost-effective alternative for patients in remote and underserved areas. Its ability to guide treatment in over 40% of cases highlights its potential to reduce diagnostic delay and therapeutic inequity, particularly among Indigenous Australians and others affected by the rural health divide. Expanding access to this form of molecular imaging may be a key step toward improving prostate cancer outcomes across regional Australia.

EP-0354

Correlation Between PRIMARY Scores in Ga-68 PSMA PET and Histological ISUP Grades in Prostate Cancer

C. Soydal, *M. Cidemal, M. Araz, N. O. Kucuk; Ankara University Medical Faculty, Ankara, TÜRKIYE.*

Aim/Introduction: PRIMARY scoring system is recommended for the triage of patients with suspicious of csPCa. However, it is not common to use Ga-68 PSMA PET/CT before the prostate biopsy worldwide. For this reason, our knowledge to reflection of PRIMARY scoring to real-life experience is limited. Thus, in this study we aimed to analyze the correlation between PRIMARY scores in Ga-68 PSMA PET/CT and ISUP grades with biopsy in newly diagnosed prostate cancer patients. ***Materials and Methods:*** We retrospectively re-evaluated Ga-68 PSMA PET/CT images of patients who underwent PET/CT for staging of prostate cancer with histopathological proved diagnosis between Dec 2023 and Jan 2025. Prostatic region was evaluated based on the location, pattern and the SUVmax for PRIMARY scoring system from 1 to 5. Prostatic uptake with primary scores 1 and 2 accepted as an indicator of absence of csPC. Additionally, Gleason scores and ISUP grades of prostatic lesions from prostate biopsies was noted for correlative analysis. ***Results:*** Images of total 218 (mean age: 70.5 ±8.5) men were included to the analysis. Median of serum PSA level were calculated as 9.1 (min-max=0.27-1672) during Ga-68 PSMA PET/CT. PRIMARY scores were 1, 2, 3, 4 and 5 in 25, 8, 30, 78 and 77 patients, respectively. Distribution of ISUP grades were 1, 2, 3, 4 and 5 in 38, 59, 40, 29 and 48 patients. csPCa were detected in 176 patients. PRIMARY scoring predicted presence of csPCa in 153 patients and absence in 10 patients. As a result, the sensitivity, specificity, positive predictive value (PPV), negative value (NPV) and accuracy of PRIMARY scoring to predict csPCa were calculated as 87%, 26%, 84%, 30% and 76%, respectively. ***Conclusion:*** In this study as a noninvasive imaging method Ga-68 PSMA PET/CT has proved to have high sensitivity and PPV in the prediction of csPCa. However, the specificity and NPVs were found lower than the literature. This can be related with the study population that is included patients with already diagnosed. Further studies without patient selection bias is needed to clarify the real-life value of PRIMARY scoring system to triage of prostate cancer patients. ***References:*** Emmett L,et al. The PRIMARY Score: Using Intraprostatic 68Ga-PSMA PET/CT Patterns to Optimize Prostate Cancer Diagnosis. J Nucl Med. 2022 Nov;63(11):1644-1650. doi: 10.2967/jnumed.121.263448. Epub 2022 Mar 17. PMID: 35301240; PMCID: PMC9635676.

EP-0355

Awareness of the High Rate of False Positive Ga-68 PSMA-11 Uptake in the Prostate Gland: Can PET/MRI Solve This Problem?

L. Uslu-Besli[1], *B. Bakir*[2], *N. Urganci*[3], *I. Gurses*[3], *E. Karayel*[1], *H. Pehlivanoglu*[1], *S. Ozel-Yildiz*[4], *C. Demirdag*[5], *H. B. Sayman*[1]; *[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Istanbul University, Istanbul Medical Faculty, Department of Radiology, Istanbul, TÜRKIYE, [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Medical Pathology, Istanbul, TÜRKIYE, [4]Istanbul University, Istanbul Medical Faculty, Department of Biostatistics, Istanbul, TÜRKIYE, [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Urology, Istanbul, TÜRKIYE.*

Aim/Introduction: Our aim was to assess the false positive Ga-68 PSMA uptake rate in the prostate gland in patients with primary prostate cancer (PCa), and to determine whether multiparametric prostate MRI (mpMRI) within hybrid PET/MRI can reduce false positive results. ***Materials and Methods:*** Fifty-one biopsy-proven, treatment-naïve PCa patients undergoing radical prostatectomy were prospectively recruited. All patients underwent Ga-68 PSMA-11 PET/MRI together with mpMRI. PET and mpMRI images were assessed independently using the PRIMARY score and PIRADS v2.1, then jointly evaluated as fused PET/MRI. Imaging findings were compared with postoperative histological mapping. The prostate was divided into sextants for lesion localization, and false positive uptake was recorded. Diagnostic performance metrics were calculated. ***Results:*** Seven of 51 patients (13.7%) exhibited false positive PSMA uptake due to benign findings - asymmetrical central zone thickening, benign prostatic hyperplasia, or prostatitis. MpMRI was true negative in all. PET/MRI had higher sensitivity and accuracy (74.9% and 83.0%) then either PET (65.0% and 74.5%) and mpMRI (66.5% and 77.5%). In index lesion detection PET/MRI showed 92.2% sensitivity, outperforming PET (80.4%) and mpMRI (86.3%). PET/MRI was significantly more accurate than mpMRI ($p<0.001$) and PET ($p=0.014$), PET and mpMRI were statistically

similar (p=0.770). ***Conclusion:*** False positive Ga-68 PSMA uptake is common and can affect clinical decisions. MpMRI helps clarify benign mimics, improving diagnostic accuracy. PET/MRI offers a more reliable assessment of PCa, potentially aiding in focal therapy planning and post-treatment evaluation. ***References:*** 1. D.A. Ferraro, N.J. Rupp, O.F. Qi, et al., Benign Prostatic Hyperplasia-Related False-Positive of Prostate-Specific Membrane Antigen-Positron Emission Tomography in the Diagnosis of Prostate Cancer: The Achilles' Heel of Biopsy-Free Radical Prostatectomy?, Journal of Urology 210 (2023) 845-855.

EP-0356

The Diagnostic and Risk Stratification Significance of ^{68}Ga-PSMA PET/MR-Derived Parameters for Prostate Cancer

Z. Dai, *Y. Lv, W. Ruan, Y. Gai, X. Zhang, M. Li, X. Lan, C. Qin;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: To evaluate the diagnostic efficacy of ^{68}Ga-PSMA PET/MR-derived parameters for prostate cancer and their significance in risk stratification. ***Materials and Methods:*** A retrospective analysis was conducted on patients suspected of or diagnosed with prostate cancer who underwent ^{68}Ga-PSMA PET/MR at our hospital from November 2020 to April 2024, followed by pathological confirmation (biopsy or radical prostatectomy). Clinical data were collected, and SUV_{max} of the prostate region was measured. Using 40% SUV_{max} as the threshold, the PSMA expression volume (PTV40%) and the mean uptake value ($SUV_{40\%mean}$) of this volume were automatically segmented. The ratios of SUV_{max} in the prostate to the liver, blood pool, and parotid gland were calculated to obtain PLR, PBpR, and PPgR, respectively. MR parameters included mean apparent diffusion coefficient (ADC_{mean}), minimum ADC (ADC_{min}), and PI-RADS v2.1 assessment (score ≥ 4 indicating PCa). Receiver operating characteristic (ROC) curves assessed diagnostic efficacy. Mann-Whitney U, McNemar, and Delong tests compared groups and diagnostic performance. ***Results:*** A total of 74 patients were included, with a mean age of 65.9 ± 7.4 years; among them, 52 were in the PCa group and 22 in the non-PCa group. Significant differences were observed between PCa and non-PCa groups for PET parameters (SUVmax, PLR, PBpR, PPgR) and MR parameters (ADCmean, ADCmin) ($P < 0.05$). ROC analysis revealed excellent diagnostic performance: SUVmax (AUC 0.920, cutoff 7.665, sensitivity 76.9%, specificity 100%) and PLR (AUC 0.907, cutoff 1.551, sensitivity 92.3%, specificity 86.4%). PLR showed significantly higher sensitivity compared to SUV_{max} (P=0.002). In 31 patients with PSA < 20 ng/mL, the sensitivity of the optimal cut-off value for PLR was significantly higher than that of SUV_{max} (84.6% vs. 53.8%) ($P = 0.031$), with nine cases in the PCa group being SUV_{max}-negative but PLR-positive. $SUV_{40\%mean}$, SUV_{max}, PLR, PTU, ADC_{mean}, and ADC_{min} were significantly correlated with ISUP grading ($p < 0.05$), with ADC_{mean} showing a moderate negative correlation, $SUV_{40\%mean}$ and SUV_{max} showing moderate positive correlations, PLR and PTU showing weak positive correlations, and ADC_{min} showing a weak negative correlation. ROC analysis indicated that ADC_{mean}, ADC_{min}, $SUV_{40\%mean}$, and PLR had good diagnostic efficacy in distinguishing between ISUP grades 1-2 and 3-5. ***Conclusion:*** ^{68}Ga-PSMA PET/MR-derived parameters have excellent diagnostic performance for prostate cancer, with PLR showing the highest sensitivity, particularly in patients with low PSA levels. PSMA PET/MR and its derived parameters have significant implications for risk stratification in prostate cancer, providing diagnostic information for personalized treatment.

EP-0357

Diagnostic and Therapeutic Value of Dual-Tracer PET Imaging with ^{68}Ga-PSMA and ^{18}F-FDG In Prostate Cancer

Y. Zhang[1], *Y. Li*[1], *G. Fei*[1], *M. Su*[2], *Y. Ni*[1];
[1]Department of Radiology, Medical School, Southeast University, Nanjing, CHINA, [2]Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Assess the impact of dual-tracer PET imaging with ^{68}Ga-PSMA and ^{18}F-FDG on initial staging, restaging, and therapeutic decision-making in patients with PCa. ***Materials and Methods:*** Pca patients undergoing staging or restaging, with a baseline GS ≥8, were prospectively enrolled to undergo both ^{68}Ga-PSMA and ^{18}F-FDG PET imaging. The absolute number of lesions and lesion sites were recorded for each modality. Patients were evaluated for miTNM staging, prognostic staging, and therapeutic planning. Lesions were stratified into three categories based on tracer uptake: PSMA[+]/FDG[-], PSMA[+]/FDG[+], and PSMA[-]/FDG[+]. Comparative analyses were performed at the levels of lesion count, lesion site, and patient. Then compare the changes in staging, restaging and therapeutic planning outcomes. Modifications in therapeutic planning were categorized as no change, minor change, or major change. Associations between imaging phenotypes and clinicopathologic variables were analyzed. ***Results:*** A total of 65 Pca patients were enrolled, comprising 38 patients undergoing initial staging and 27 undergoing restaging. 941 lesions were found in the initial staging group, of which 422 (44.8%) PSMA[+]/FDG[-], 281 (29.9%) PSMA[+]/FDG[+], and 238 (25.3%) PSMA[-]/FDG[+], with 162 lesion sites, including 62 (38.3%) PSMA[+]/FDG[-], 89 (54.9%) PSMA[+]/FDG[+], and 11 (6.8%) PSMA[-]/FDG[+]. In the restaging cohort, 317 lesions were detected, of which 118 (37.2%) PSMA[+]/FDG[-], 133 (42.0%) PSMA[+]FDG[+], and 66 (20.8%) PSMA[-]FDG[+], with 99 lesion sites, including 35 (35.4%) PSMA[+]FDG[-], 47 (47.5%) PSMA[+]FDG[+], and 17 (17.2%) PSMA[-]FDG[+]. ^{68}Ga-PSMA PET was significantly less effective in identifying visceral metastases (initial staging: 3.9% vs. 28.5%, p<0.001; restaging: 13.9% vs. 22.4%, p<0.001). PSMA[-]FDG[+] lesions were identified in 5 of 38 (13.2%) patients in the initial staging group and in 7 of 27 (25.9%) restaging patients. In the initial staging group, 5 (13.2%), 2 (5.3%), and 5 (13.2%) experienced changes in miTNM staging, prognostic staging, and therapeutic strategy, respectively. Correspondingly, 3 (11.1%), 2 (7.4%), and 3 (11.1%) restaging patients had alterations in miTNM staging, prognostic staging, and therapeutic strategy. Importantly, in the initial staging group, PSMA[-] FDG[+] lesions were significantly more prevalent in patients with higher Ki-67 expression (≥12.5%) compared to those with lower Ki-67 levels (<12.5%) (p=0.046). ***Conclusion:*** Dual-tracer PET imaging enhanced diagnostic accuracy in both the initial staging and restaging of Pca, leading to staging refinement and treatment modifications in a subset of patients. ^{18}F-FDG PET demonstrated superior sensitivity for detecting visceral metastases. Notably, elevated Ki-67 expression in newly diagnosed patients may serve as a predictive biomarker for the presence of PSMA[-]FDG (+) lesions.

EP-0358

Is the D'Amico risk classification enough to define the indication of [18F]-DCFPyL PET/CT and promote therapeutic impact?

J. Bonilla Plaza[1], *M. Amo Salas*[2], *I. García Megías*[1], *J. Montalvá Pastor*[1], *L. Garcia Zoghby*[1], *M. Cruz Montijano*[1], *M. Meneses Navas*[1], *S. Guzman Ortiz*[1], *C. Lucas Lucas*[3], *M. de Cabo Ripoll*[4], *F. Leal Hernandez*[5], *A. Salinas Sanchez*[6], *V. Poblete García*[3], *A. García Vicente*[1];
[1]Hospital Universitario de Toledo, Toledo, SPAIN, [2]Universidad de Castilla la Mancha, Ciudad Real, SPAIN, [3]Hospital General Universitario Ciudad Real, Ciudad Real, SPAIN, [4]Hospital Virgen

de la Luz, Cuenca, SPAIN, [5]Hospital Universitario de Guadalajara, Guadalajara, SPAIN, [6]Complejo Hospitalario Universitario de Albacete, Albacete, SPAIN.

Aim/Introduction: This study evaluated the influence of clinical and biochemical disease characteristics on molecular-imaging TNM(miTNM) categories attending to PROMISE criteria and the therapeutic impact of PET/CT with [18F]-DCFPyL-PET/CT in initial staging of intermediate/high risk prostate cancer(PCa). ***Materials and Methods:*** A regional, retrospectively analyzed cohort comprising consecutive men staged with [18F]DCFPyL-PET/CT at seven hospitals in Castilla-La Mancha(Spain) from March 2021 to June 2024 was reviewed. The study was approved by a reference Ethical Committee (internal code 2022-053). Eligibility required no prior androgen-deprivation therapy, complete ISUP/PSA/clinical-T data, and ≥6 months follow-up. The impact of D'Amico high-risk(H-R) variables(ISUP 4/5, PSA>20 ng/mL and cT≥3), PSA and its kinetic on the diagnostic (N and/or M detection) and therapeutic impact was assessed. Univariate associations used Mann-Whitney U, Fisher's exact or Spearman trend; predictors with $p < 0.10$ were entered into step-down logistic regression. ***Results:*** 195 men(median age 71 years) met inclusion criteria. 41.4% had one, 29.2% two and 8.9% three H-R variables. 32.5%(cT-HR), 50.8 % (ISUP-HR) and 43.2% (PSA-HR). PET/CT detected miN+ and miM+ in 25.2% and 13.01%, respectively. A statistically significant relationship was found between the ISUP+cT high and miN(Chi^2=15.292; $p < 0.001$), as well as between T+PSA_high and miN(Chi^2=8.832; $p = 0.012$), and ISUP+T+PSA_high and miN(Chi^2=12.847; p=0.005). These findings suggest that these parameters may have predictive value for identifying nodal involvement. No clinical variable predicted distant metastases. PSA kinetics showed no correlation with miT, miN or miM categories. PET/CT prompted management change in 28 patients (14 %). Age, baseline PSA, PSA kinetics, cT, ISUP grade, T-HR, ISUP-HR or PSA-HR were unrelated to therapeutic change (p> 0.14). Distant metastasis detected on PET/CT(miM+) were strongly associated with therapeutic impact (64 % vs 6 %; $p = 0.004$) and remained the only independent predictor in the final model (adjusted OR 4.33, 95 % CI 1.66-11.32, $p = 0.003$; pseudo-$R^2 = 0.18$). ***Conclusion:*** In newly diagnosed PCa, the presence of D'Amico high-risk(H-R) variables suggest that these composite indices may serve as useful predictors for lymph node metastasis in the studied population. No correlation was found with miM, probable due the low rate of distant metastases. Only miM+ [18F]-DCFPyL-PET/CT independently predicts management change, multiplying the odds more than four-fold. These findings highlight the pivotal role of PSMA PET/CT in unmasking occult systemic disease and support its routine integration into initial staging when treatment selection depends on accurate metastatic assessment.

EP-0359

Evaluation of the Relationship of the Risk Status of Prostate Cancer Patient with PSA Density, PSA Metabolic Density and 68Ga-PSMA PET/CT Parameters

G. Inal[1], *N. Aydinbelge Dizdar*[1], *O. Duyar*[1], *O. Ozmen*[2];
[1]*Ankara Etlik City Hospital Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Department of Nuclear Medicine, Etlik City Hospital, University of Health Sciences, Etlik City Hospital Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a promising molecular target for the diagnosis and treatment management of prostate cancer. 68Ga-PSMA PET plays an important role in staging prostate cancer, assessing treatment response, and detecting recurrence. This study aimed to classify biopsy-proven patients with prostate cancer by risk status and evaluate the relationship between 68Ga-PSMA PET parameters and metastasis status. ***Materials and Methods:*** A total of 121 patients with biopsy-proven prostate cancer who underwent 68Ga-PSMA PET/CT for primary staging between 2023 and 2024 were classified as low, intermediate and high risk. The relationship between SUVmax, TL-PSMA, TV-PSMA, Tumour/Liver (T/L), Tumour/Parotid (T/P), PSA density (PSAD), PSA metabolic density (PSAMD) and metastasis status were evaluated ($p<0.05$ for statistical significant). ***Results:*** According to D'Amico classification, 7 patients were low risk, 36 intermediate, and 76 high risk (Table-1). In the high risk-group, approximately half of the patients had pathological uptake of regional lymph nodes and 15 had distant lymph node metastases (Table-2). PSAD is calculated by dividing the serum PSA value by the prostate volume. Accordingly, the mean PSAMD value was 5.79±0.81 by dividing the PSA value by the primary tumor volume. PSAMD was significantly associated with PSA value, prostate SUVmax, T/L, T/P, and PSAD (p=0.00, p=0.01, p=0.00, p=0.00, and p=0.00, respectively), but not with disease extent (local, locally advanced, advanced) ($p>0.05$). In patients with positive lymph nodes, PSA, prostate volume, prostate SUVmax, TL-PSMA, TV-PSMA, T/L, and T/P values were significantly higher compared to those without lymph node positivity (p=0.001, p=0.003, p=0.01, p=0.001, p=0.047, p=0.017, and p=0.001, respectively). ROC analysis based on data obtained from 68Ga-PSMA PET/CT showed that PSA, prostate TL-PSMA, TV-PSMA, and T/P increased the risk of pelvic lymph node and bone metastasis. According to miTNM, patients were classified as local, locally advanced, and advanced groups. PSA, prostate SUVmax, prostate TL-PSMA, T/L, and T/P values showed significant differences between local and locally advanced; PSA, prostate SUVmax, prostate TV-PSMA, prostate TL-PSMA, PSAD, T/L, and T/P between locally advanced and advanced; and prostate SUVmax and T/L between locally advanced and advanced groups (Table-3). SUVmax, TL-PSMA and TV-PSMA, T/L, T/P, PSAD and PSAMD showed significant differences between intermediate- and high-risk patients. ***Conclusion:*** Based on our findings, these parameters may be useful in distinguishing between high- and intermediate-risk patients. Compared with conventional imaging methods, 68Ga-PSMA PET/CT has been found to be more successful in staging intermediate to high-risk prostate cancer.

EP-0360

Head-to-head comparison of ^{99m}Tc-PSMA-T4 SPECT and ^{68}Ga-PSMA PET studies

P. Cichocki[1], *K. Stawski*[2], *R. Mikolajczak*[3], *W. Wojdowska*[3], *P. Garnuszek*[3], *Z. Adamczewski*[1];
[1]*Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND,* [2]*Department of Biostatistics and Translational Medicine, Medical University of Lodz, Lodz, POLAND,* [3]*National Centre for Nuclear Research, Radioisotope Centre POLATOM, Otwock, POLAND.*

Aim/Introduction: PSMA ligands play an increasingly important role in diagnosis and treatment of prostate cancer. ^{68}Ga-PSMA is among the most commonly used diagnostic radiopharmaceuticals. However, high cost and limited availability of gallium-68 limits its application in routine clinical practice. Therefore, introduction of alternative radiopharmaceuticals, especially labelled with commonly available technetium-99m, would greatly expand potential applications of PSMA studies, provided they have adequate clinical value. Our preliminary study aims to assess reliability of ^{99m}Tc-PSMA-T4 in staging of prostate cancer and qualification for therapy, in comparison with ^{68}Ga-PSMA PET studies used as reference. ***Materials and Methods:*** The study included selected patients enrolled in ongoing phase 2/3 PSMA-T4 clinical trial (ID: NCT05847166), who were also referred for a ^{68}Ga-PSMA study as part of routine prostate cancer staging evaluation before radiotherapy. SPECT and PET PSMA studies of each patient were assessed independently by experienced nuclear medicine physicians and consulted with radiologists. ***Results:*** ^{99m}Tc-PSMA properly detected primary tumors in prostate in all patients. Overall TNM staging was also the same in both SPECT

and PET studies, leading to the same clinical decisions regarding qualification of patients to radical surgery, radiotherapy or other forms of treatment. However, SPECT images had lower resolution compared to PET, and a few small lesions in lymph nodes visible in ^{68}Ga-PSMA studies were not detected in ^{99m}Tc-PSMA studies (they had no impact on staging due to presence of other lymph node metastases in all these cases). ***Conclusion:*** Our preliminary assessment showed that ^{99m}Tc-PSMA T4 study is adequate for initial qualification of all included patients for treatment. In all cases their results led to the same clinical decisions as ^{68}Ga-PSMA PET. However, it was characterized by lower sensitivity and did not detect some of the small lesions in lymph nodes found in PET studies. This was most likely caused by lower resolution of the SPECT gamma camera compared to a PET scanner. It cannot be ruled out that the use of new semiconductor SPECT gamma cameras with ring detector systems, which achieve similar resolutions as PET scanners, could improve diagnostic value of ^{99m}Tc-PSMA studies, but this requires further investigation.

EP-0361

Clinical Impact of Delayed Pelvic Imaging in PSMA PET/CT for Primary Prostate Cancer Staging and Management

G. Galnaitiene, *G. Grigaityte, K. Snarskis, I. Balciunaite, G. Aleksa, D. Vajauskas;*
Lithuanian University of Health Sciences, Kaunas, LITHUANIA.

Aim/Introduction: PSMA PET/CT is widely used for staging high-risk primary prostate cancer (PCa). Although a 60-minute uptake time is standard, urinary activity may limit assessment of tumour (T) and nodal (N) stages. Delayed pelvic imaging beyond 120 minutes may improve lesion visibility [1]. Previous studies mainly focused on biochemical recurrence or advanced disease. We evaluated the added value of delayed imaging in initial staging of primary PCa. ***Materials and Methods:*** We retrospectively analysed 59 patients with histologically confirmed primary PCa (mean age 65.2 ± 8.1 years) who underwent 68Ga-PSMA-11 PET/CT for initial staging. Whole-body imaging was performed at 60.9 ± 3.6 min post-injection, followed by delayed pelvic imaging at 132.1 ± 14.3 min. Data included T/N stage at both time points, SUVmax/SUVmean values of the lesions, PSA levels, and ISUP grade. PROMISE V2 was used for staging [2]. Treatment plans were reviewed. Non-parametric statistical tests, logistic regression, and ROC analysis were used. ***Results:*** Staging changed in 13 patients (22.0%), including 10 T stage (9 upstaged) and 4 N stage (3 upstaged) changes. No treatment plans were modified due to delayed imaging. SUVmax and SUVmean significantly increased at delayed imaging for both T lesions (+3.88 and +2.00; $p < 0.001$; n=58) and N lesions (+3.40 and +2.02; $p < 0.01$; n=15). Patients were grouped as ISUP 1-2 (28.8%) and ISUP 3-5 (71.2%). Patients with staging changes tended to have lower ISUP (1-2: 23.5% vs. 3-5: 21.4%; $p = 0.21$) and PSA (16.2 vs. 40.8; $p = 0.16$); differences were not significant. Logistic regression indicated a non-significant association between lower ISUP grade and T SUVmean at 60min and increased likelihood of staging change (OR = 0.66 and 0.83; $p = 0.18$ and 0.38, respectively). ROC analysis showed that a T SUVmax at 60min threshold of < 5.97 (AUC = 0.74) combined with ISUP 1-2 identified patients with a 50.0% staging change rate, compared to 16.3% in others ($p < 0.05$). ***Conclusion:*** Delayed pelvic imaging significantly increased lesion SUV values and altered staging in one-fifth of patients. Although it did not change management, it may add value in lower-grade cases with low uptake. Further studies in larger cohorts are needed. ***References:*** 1. EP-0362

Impact of [^{68}Ga]PSMA-PET/CT using PRIMARY and miPSMA Expression Scores on Clinical Decision-Making for ePLND in Staging of Intermediate-Risk Prostate Cancer patients

A. Safarian[1,2], *F. Szigeti*[3], *T. Kiener*[1], *H. Grießner*[4], *H. Nasrollahi*[1], *S. Hecht*[5], *L. Lusuardi*[4], *C. Pirich*[1], *M. Beheshti*[1];
[1]*Division of Molecular Imaging and Theranostics, Department of Nuclear Medicine, University Hospital, Paracelsus Medical University, Salzburg, AUSTRIA,* [2]*Rajaie Cardiovascular Medical and Research Center, Rajaie Cardiovascular Institute, Iran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Salzburg University of Applied Sciences, Radiation Technology degree program, Salzburg, AUSTRIA,* [4]*Department of Urology, Paracelsus Medical University, Salzburg, AUSTRIA,* [5]*Department of Radiology, Paracelsus Medical University, Salzburg, AUSTRIA.*

Aim/Introduction: Accurate lymph node (LN) staging is critical for treatment planning in prostate cancer (PCa) patients. Extended pelvic LN dissection (ePLND) provides definitive staging but is associated with higher morbidity. While ePLND is routinely performed in high-risk cases and generally avoided in low-risk patients, intermediate-risk patients fall into a grey zone, and the necessity of ePLND in this group remains controversial. The role of [^{68}Ga]PSMA-PET/CT for accurate N-staging in intermediate-risk patients has been discussed controversially. This study aimed to evaluate whether [^{68}Ga]PSMA-PET/CT using novel PRIMARY and miPSMA-expression scores may provide an accurate N-staging supporting clinical decision-making for ePLND in intermediate-risk PCa patients. ***Materials and Methods:*** This retrospective study included 94 strictly-defined intermediate-risk PCa patients, defined as clinical stage T2, Gleason score 7 (ISUP grade group 2 or 3), and PSA 10-20 ng/mL. All patients underwent [^{68}Ga]PSMA-PET/CT for initial staging, followed by radical prostatectomy with ePLND. The PRIMARY score, miPSMA-expression score (PROMISE V2), SUVmax, location, zone and number of prostate lesions as well as PIRADS scores were assessed for association with histopathological LN status. ***Results:*** Of the 94 patients, 8 (8.5%) had histologically confirmed LN metastases. [^{68}Ga]PSMA-PET/CT reported 87 patients as LN-negative, of whom 86 were truly LN-negative, resulting in a negative predictive value of 98.9%. The median number of dissected lymph nodes was 13. The observed imaging scores in these patients were: median PRIMARY score 4 (range 2-5), median miPSMA expression score 2 (range 1-3), and median PIRADS score 4 (range 2-5). [^{68}Ga]PSMA-PET nodal positivity remained the sole reliable predictor of LN metastasis in this cohort. Interestingly, no significant association was found between nodal status and intra-prostatic PSMA PET parameters using novel PRIMARY and miPSMA expression scores, as well as SUVmax, number and distribution of intraprostatic lesions, and PIRADS scores. In the single false-negative patient, only one out of 15 dissected lymph nodes was positive, representing a very small metastasis measuring 2.5 mm, without infiltration of the perinodal soft tissue. ***Conclusion:*** [^{68}Ga]PSMA-PET/CT demonstrated excellent concordance with pathological LN status in these strictly defined intermediate-risk PCa patients. The findings of this study are promising for enhancing clinical nomograms and supporting ePLND de-escalation strategies, while preserving oncological outcomes in this patient group.

EP-0363

PRIMARY Score: when radionuclide matters

P. Guglielmo[1,2], *L. Muraglia*[3], *R. Zanca*[1], *C. Vallone*[1,4], *J. Jandric*[3], *D. Aricò*[5], *N. Buffi*[1,6], *G. Lughezzani*[1,6], *L. Evangelista*[1,3];
[1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Milan, ITALY,* [2]*Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [4]*Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [5]*Nuclear Medicine Unit, Humanitas Istituto Clinico Catanese, Misterbianco, Catania, ITALY,* [6]*Urology Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY.*

Aim/Introduction: The PRIMARY score, which is based on SUVmax values, was originally validated using the radiotracer [^{Ga}68]Ga-PSMA-11. However, newer radiopharmaceuticals based on 18F are now being used in clinical practice, and their SUVmax values are not directly comparable to those of [^{Ga}68]Ga-PSMA-11. This study aimed to examine how semiquantitative values vary when using these two different tracers in patients with intermediate-risk prostate cancer. ***Materials and Methods:*** A retrospective, multicenter analysis of patients diagnosed with intermediate risk PCa between 2021 and 2024 was made. Patients were staged using pelvic multiparametric magnetic resonance imaging (mpMRI) and radiolabeled PSMA PET/CT, either [^{68}Ga]Ga-PSMA-11 or [^{18}F]F-PSMA1007, to evaluate the extent of disease before initiating appropriate treatment. PRIMARY score were used for quantitative analysis. ***Results:*** A total of 78 patients were included in the analysis. Of these, 49 patients (62.8%) underwent imaging with [^{18}F]F-PSMA-1007, and 29 patients (37.2%) underwent [^{68}Ga]Ga-PSMA-11 PET/CT. The distribution of PRIMARY scores was as follows: Score 1 in 6 and 3 patients, Score 2A/B in 8 and 2 patients, Score 3 in 3 and 5 patients, Score 4 in 17 and 13 patients, and Score 5 in 15 and 6 patients, respectively for ^{18}F and ^{68}Ga-based PSMA. SUVmax was useful primarily for distinguishing between PRIMARY scores 4 and 5. To further investigate this, SUVmax values for 51 patients were compared between [^{18}F]F-PSMA-1007 and [^{68}Ga]Ga-PSMA-11 groups using the Mann-Whitney U test. For PRIMARY score 4, the median SUVmax was significantly higher in the [^{18}F]F-PSMA-1007 group compared to the [^{68}Ga]Ga-PSMA-11 group (7.7 vs. 5.2; $p < 0.05$). In contrast, for PRIMARY score 5, median SUVmax values were similar between the two tracers (18.6 vs. 15.3; $p = 0.349$). ***Conclusion:*** Limited data are available on the use of the Primary score in patients who have undergone [68Ga]Ga-PSMA-11. The median SUVmax was significantly lower than those undergoing [18F]F-PSMA-1007 when the Primary score was 4. However, no significant difference was observed in patients with a Primary score of 5. Further analysis should be made in a larger population to test the reproducibility of the score by using diverse radiopharmaceutical agents.

EP-0364

Concordance and added diagnostic value of [^{18}F] PIFLUFOLASTAT PET/CT to pelvic MRI in the diagnosis of prostate cancer (Pca).

A. Peñaherrera Cepeda, *J. A. Badell Martínez, L. Díaz González, E. Casillas Sagrado, E. Campaña Díaz, P. García-Talavera San Miguel, J. G. Villanueva, S. Rama Alonso, B. Santos García, F. Caltagirone Gutierrez, P. Tamayo Alonso;*
Complejo asistencial universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To asses the rates of concordance between [18F]PIFLUFOLASTAT PET/CT to pelvic MRI in the diagnosis of Pca.To calculate the anatomical detection rate of Pca in prostate and seminal vesicles of [[18F]PIFLUFOLASTAT PET/CT and MRI, histologically confirmed. To determine the percentage of studies with extrapelvic uptake in [18F]PIFLUFOLASTAT PET/CT study. ***Materials and Methods:*** Thirty men (mean age: 69 +/- 8 years) diagnosed with intermediate an high risk Pca, who underwent [18F]PIFLUFOLASTAT PET/CT and pelvic MRI, performed with an interval of less than 3 months, during 2021- 2025, were included. Were interpreted using PI-RADS v2.1 (all ≥ 4) and PRIMARY scores (all ≥ 3), and reconciled using biopsy specimens. The concordance of both modalities was categorized as "positive concordance" when the same number of lesions and location, in prostate and seminal vesicles, coincided with the pathological anatomy findings in the biopsy. Another category of discordant findings were denominated as "higher in PET-CT"(more lesions were observed with respect to MRI, tested positive in the biopsy), and "higher in MRI" (when the same occurred with this other technique).The percentage of studies with extra pelvic uptake study (nodal, bone or visceral localization) in the 18F]PIFLUFOLASTAT PET/CT within the resonance field, was also calculated.Descriptive statistics were used, including median and standard deviation for continuous variables and frequency and percentage for categorical variables. ***Results:*** MRI and [18F]PIFLUFOLASTAT PET/CT had positive concordance in 17/30 (56.6%) patients, an discordant in 13/30 (43.3%) patients. Nine of these thirteen patients (69.2%) had a higher involvement in prostate and seminal vesicles in [18F] PIFLUFOLASTAT PET/CT than in the MRI. And 30.8% had a higher involvement in prostate and seminal vesicles [18F]PIFLUFOLASTAT PET/CT than in the MRI. The anatomical detection rate of disease in the prostatic lobules and seminal vesicles was 86.7% for [18F]PIFLUFOLASTAT-PET/CT and 70% by MRI. In addition, the pathological uptake in pelvic lymph nodes were detected in 10/30 (33.3%) patients in [18F]PIFLUFOLASTAT-PET/CT, not detected by MRI. And only 2/30 (6.7%) patients were positive in MRI, that was not visualized in [18F]PIFLUFOLASTAT PET/CT. These findings did not correlate with the biopsy. In 6.6% of [18F]PIFLUFOLASTAT PET/CT scans performed, distant disease was found outside the field of study of the MRI, which led to an increase in staging by MRI alone. ***Conclusion:*** [18F] PIFLUFOLASTAT PET-CT demonstrated an acceptable concordance with MRI pelvic findings and a great anatomical detection rate, as well as, the possibility of detection of distant disease.

EP-0365

The Influence of Pre-Imaging Prostate-Specific Therapy on PSMA Uptake and Outcomes

G. Galnaitiene, *G. Grigaitytė, K. Snarskis, I. Balčiūnaitė, G. Aleksa, D. Vajauskas;*
Lithuanian University of Health Sciences, Kaunas, LITHUANIA.

Aim/Introduction: PSMA PET/CT is widely used to stage primary prostate cancer (PCa), but the impact of pre-imaging prostate-specific therapies remains unclear. Short-term androgen deprivation therapy (ADT) may increase PSMA uptake, while long-term ADT may suppress it [1-2]. The effects of 5-alpha-reductase inhibitors (5-ARI) and alpha-blockers are less known. We assessed the effect of these therapies in newly diagnosed PCa patients undergoing initial staging. ***Materials and Methods:*** We retrospectively analysed 59 patients with histologically confirmed primary PCa (mean age 65.2 ± 8.1 years) who underwent 68Ga-PSMA-11 PET/CT for initial staging. Whole-body and delayed pelvic imaging were performed at 60.9 ± 3.6 and 132.1 ± 14.3 min post injection. Pre-imaging therapy, PSA, ISUP grade, SUVmax/SUVmean, T and N staging were recorded. Statistical tests included Mann-Whitney, Wilcoxon, Fisher's exact, and multivariate logistic regression. ***Results:*** From 59 patients, 32 received pre-imaging therapy: 15 alpha-blockers (median 297 days), 6 5-ARI (281.5 days), 7 anti-androgens (67 days), and 4 ADT (101 days). Median T SUVmax and SUVmean at both timepoints were lower in most treated groups and higher in 5-ARI patients, though not statistically significant. 5-ARI treatment led to a significantly greater increase in T SUVmax (median 5.96 vs 1.74, $p = 0.040$) and SUVmean (3.72 vs 1.10, $p = 0.019$) during delayed scan compared to untreated. Other treatments showed non-significant changes

in SUV and T staging. From 17 patients with nodal uptake, 7 had received: 6 alpha-blockers, 2 5-ARI, 1 anti-androgens, none ADT. Median N SUV values and changes were lower in treated groups but not statistically significant. N stage change during delayed scan occurred in 4 patients, significantly more frequent among alpha-blocker users ($p = 0.047$, $\varphi = 0.31$; OR = 10.75, 95% CI: 1.02-112.93), and remained significant in multivariate analysis ($p = 0.043$). No significant effects were seen for ADT, anti-androgens, 5-ARI, PSA, or ISUP grade. ***Conclusion:*** Pre-imaging use of 5-ARI was associated with increased T lesion uptake over time, while alpha-blocker may influence N staging on PSMA PET/CT. No other treatments demonstrated significant effects on SUV or staging, likely due to small subgroups. These findings suggest that pre-imaging prostate-specific therapies may influence PSMA PET/CT interpretation in primary PCa, and further investigation in larger cohorts is needed. ***References:*** 1. Gafita A, et al. Effect of androgen deprivation therapy on PSMA expression and PET/CT interpretation. EJNMMI Reports. 2023;7:18. 2. Emmett L et al. Changes in PSMA PET SUV after short-term androgen deprivation therapy. Eur J Nucl Med Mol Imaging. 2023;50:1234-1243.

EP-0366

Investigation of the Correlation Between the Briganti 2012 Nomogram and Ga-68 PSMA PET/CT Parameters in Localized and Locally Advanced Prostate Cancer

R. Tokac[1], *F. Avci*[1], *M. Dinckal*[2], *K. Ergun*[1], *A. Argon*[1], *U. Yararbas*[1]; [1]*Ege University, Izmir, TÜRKIYE,* [2]*Kars Harakani State Hospital, Kars, TÜRKIYE.*

Aim/Introduction: Extended pelvic lymph node dissection (ePLND) is a key staging tool for detecting nodal metastases in prostate cancer (PCa), with lymph node invasion rates ranging from 1.1% to 26%. Accurate patient selection is therefore critical. The Briganti Nomogram (BN), widely validated since its introduction, uses a 7% risk cut-off to guide ePLND decisions. Ga-68 PSMA PET/CT has also shown value in staging locally advanced PCa. This study investigates the correlation between the Briganti 2012 Nomogram and Ga-68 PSMA PET/CT parameters in localized and locally advanced PCa. ***Materials and Methods:*** This retrospective study included 47 patients who were diagnosed with localized or locally advanced PCa and underwent TRUS-guided biopsy, mpMRI, PSA testing, and Ga-68 PSMA PET/CT between November 2018 and December 2023 prior to prostatectomy. Ga-68 PSMA synthesis and PET/CT imaging were performed according to guidelines. Images were evaluated using Siemens syngo.via software, and the following values were calculated from the primary tumor: SUVmax, SUVmean, SUVpeak, PSMA-TV, TL-PSMA, and PSMA-TLQ. BN risk percentages were calculated, and a 7% cut-off was used to classify patients into low- and high-risk groups. Statistical analyses were conducted using IBM SPSS 25. ***Results:*** The mean age of the 47 patients meeting the inclusion criteria was 65.19 ± 5.26 years. Clinical T scores showed that 35 patients (74.5%) had T3 disease, 12 patients (25.5%) had T2. The mean PSA level was 14.86 ± 15.74 ng/mL. Gleason scores were distributed as follows: 3+3 in 4 patients (8.5%), 3+4 in 23 (48.9%), 4+3 in 10 (21.3%), 3+5 in 1 (2.1%), 4+4 in 4 (8.5%), 4+5 in 4 (8.5%), and 5+5 in 1 (2.1%). A moderate and statistically significant correlation was found between BN risk percentage and SUVpeak ($r=0.404$, $p=0.005$), PSMA-TV ($r=0.514$, $p<0.001$), and TL-PSMA ($r=0.553$, $p<0.001$). A weak but significant correlation was also observed with SUVmax ($r=0.366$, $p=0.11$), SUVmean ($r=0.315$, $p=0.031$), and PSMA-TLQ ($r=0.354$, $p=0.15$). There was a significant relationship between BN risk groups and PSMA-TV, TL-PSMA, and PSMA-TLQ values ($p=0.003$, $p=0.003$, and $p=0.022$, respectively; see Figure 1). No statistically significant relationship was found between BN risk groups and SUVmax, SUVmean, or SUVpeak ($p>0.05$). ***Conclusion:*** Our findings suggest that in localized and locally advanced PCa, there is a significant correlation between BN and Ga-68 PSMA PET/CT parameters, particularly volumetric measures. Predictive models like the BN are useful clinical tools for decision-making, and incorporating Ga-68 PSMA PET/CT may enhance their predictive power.

EP-0367

PSMA SPECT and PET Imaging in the Staging of High Intermediate Risk to High-Risk Prostate Cancer - an institutional experience in a resource limited setting

S. More*, M. Rivombo, K. Hlongwa;*
University of Cape Town, Cape Town, SOUTH AFRICA.

Aim/Introduction: Current standards of care highlight molecular imaging using PSMA PET to characterise disease in intermediate and high risk prostate cancer. Data specific to the local population was lacking, including evidence of any possible associations between image findings and the various qualitative or quantitative risk parameters. The additional diagnostic performance of PSMA imaging over bone scan alone was also not established in our population. The purpose was to objectively characterise diagnostic performance of a local hospital molecular imaging protocol for staging high-intermediate and high-risk prostate cancer (ISUP Grade >2) whereby iterative molecular imaging with [^{99m}Tc]Tc-MDP bone scan, [^{99m}Tc]Tc-PSMA SPECT/CT and [^{68}Ga]Ga-PSMA PET/CT was performed until metastases were convincingly detected. A supplementary aim was to determine if selective use of specific modalities is justified in certain groups. ***Materials and Methods:*** The prostate cancer staging protocol implemented at the time was adapted from the existing ASCO guidelines. More sensitive imaging with PSMA PET/CT was reserved for use in patients where metastatic disease remained undetected. Studies were interpreted independently by qualified nuclear physicians with experience exceeding 5 years and in line with accepted criteria. Patients considered for analysis were limited to those referred for primary staging of high-intermediate and high-risk prostate cancer or being considered for possible radical therapy. Overall detection rates for the presence of metastases at each iteration were calculated. Statistical analysis was performed for associations between diagnostic performance and risk stratification subcategories (clinical stage, PSA levels, histological grade; or age). ***Results:*** A total of 88 patients were enrolled with mean age of patients at baseline being 65.05 years with a mean PSA of 130.95µg/L. Detection rates for metastatic disease for those enrolled increased from 38% to 51% to 61% with each respective imaging iteration. There was a significant association of patient age, PSA level, histological grade, and clinical stage to bone scan positivity ($p = 0.005$), with a reduction in mean PSA for those demonstrating metastatic disease on subsequent [^{99m}Tc]Tc-PSMA SPECT/CT. No further significant associations were observed for the subgroup who proceeded to [^{68}Ga]Ga-PSMA PET/CT. ***Conclusion:*** Bone scan or [^{99m}Tc]Tc-PSMA SPECT/CT proved reasonable first line staging investigations to exclude evidence of metastases before [^{68}Ga]Ga-PSMA PET/CT, with enhanced efficiency in locally advanced disease, ISUP 5 or higher spectrum PSA/age. The findings favour [^{99m}Tc]Tc-PSMA SPECT/CT over bone scan where [^{68}Ga]Ga PSMA PET/CT is unavailable, due to lower mean PSA threshold for detecting metastatic disease.

EP-0368

Impact of Ga-68 PSMA PET/MRI on the Accuracy of MRI-derived Grading Systems for Predicting Extraprostatic Extension in Prostate Cancer

L. Uslu-Besli[1], *S. Durmaz*[2], *B. Bakir*[3], *I. Gurses*[4], *S. Ozel-Yildiz*[5], *C. Demirdag*[6], *H. B. Sayman*[1];

Department of Medical Pathology, Istanbul, TÜRKIYE, [5]Istanbul University, Istanbul Medical Faculty, Department of Biostatistics, Istanbul, TÜRKIYE, [6]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Urology, Istanbul, TÜRKIYE.

Aim/Introduction: Accurate preoperative staging and prediction of extra-prostatic extension (EPE) is crucial for optimal surgical planning in prostate cancer (PCa) patients. The aim of this study was to evaluate the diagnostic accuracy of Ga-68 PSMA PET for preoperative assessment of EPE and to compare it with the standardized multiparametric prostate MRI (mpMRI)-drived EPE grading system. We also aimed to assess whether incorporating semi-quantitative PSMA PET parameters enhances the diagnostic performance of the mpMRI-drived EPE grading system using hybrid PET/MRI. ***Materials and Methods:*** This single-center study, retrospective study included treatment-naïve, biopsy-proven PCa patients who underwent Ga-68 PSMA-11 PET/MRI along with mpMRI, followed by radical prostatectomy. Diagnostic accuracy was assessed for clinical parameters (serum prostate specific antigen [PSA] level and International Society of Urological Pathology [ISUP] score), mpMRI features (presence of capsular irregularity or bulge, presence of overt EPE, neurovascular bundle asymmetry, seminal vesicle invasion (SVI), curvilinear contact length (CLL) with the capsule and tumor size), the mpMRI-derived EPE grading system, visual PSMA PET findings, and semi-quantitative PET parameters (SUVmax, SUVmean and PSMA-tumor volume [PSMA-TV]. Optimal cut-off values for continuous variables were determined using the Youden Index. Multivariate logistic regression analysis and receiver operating characteristic (ROC) analysis were performed to compare the predictive value of clinical, mpMRI-derived and PET-derived variables for EPE. Postoperative histopathology was used as the reference standard. ***Results:*** Forty-five patients were included, with a mean interval of 44±29 days between PET/MRI and radical prostatectomy. Histopathology confirmed EPE in 19 patients. The following were identified as statistically significant predictors of EPE: Capsular irregularity or bulge, neurovascular bundle asymmetry, CLL ≥ 1.5 cm, SVI on MRI, tumor size ≥ 14.25 cm on MRI, EPE grade ≥ 2, ISUP grade ≥ 3, overt EPE on PET; SUVmax ≥ 13.84, SUVmean ≥ 7.195, PSMA-TV ≥ 1.395. On ROC analysis comparing the multivariate models, the combination of EPE grade ≥ 2 and ISUP grade ≥ 3 and PSMA-TV ≥1.395 yielded the highest AUC (0.916), although the difference was not statistically significant. The AUCs of PET-derived parameters were comparable to those of mpMRI and clinical variables. ***Conclusion:*** PSMA uptake in the primary prostate tumor is an independent predictor of EPE. Therefore Ga-68 PSMA-11 PET, in combination with mpMRI, may provide valuable information for the preoperative assessment of EPE. ***References:*** 1. Mehralivand S, et al. A Grading System for the Assessment of Risk of Extraprostatic Extension of Prostate Cancer at Multiparametric MRI. Radiology. 2019;290:709-192.

PSMA PET in Prostate Cancer Staging: Preliminary Radiomics Analysis and Machine Learning Model for Predicting PRIMARY and E-PSMA Scores

P. Alongi[1], *V. Benfante*[2], *P. Purpura*[2], *C. Messina*[3], *A. Comelli*[4]; *[1]University of Palermo, Department B.I.N.D., Palermo, ITALY, [2]Advanced Diagnostic Imaging-INNOVA Project, Department of Radiological Sciences, A.R.N.A.S. Civico Di Cristina e Benfratelli Hospitals, Palermo, ITALY, [3]Oncology Unit, ARNAS Civico, Palermo, ITALY, [4]Ri.MED Foundation, Palermo, ITALY.*

Aim/Introduction: Several scoring systems have been developed to improve the accuracy of prostate cancer (PCa) staging. Among them, the PRIMARY score and E-PSMA reporting guidelines have significantly influenced PSMA-PET clinical reporting. Recently, artificial intelligence (AI) approaches—including machine learning (ML), deep learning (DL), and convolutional neural networks (CNNs)—have shown promising results in automating the detection of PSMA-PET metastases, predicting response to PSMA-targeted therapies, and differentiating intraprostatic from extraprostatic high-grade PCa. This preliminary study aimed to explore the potential of ML models applied to radiomic features extracted from PSMA-PET in predicting PRIMARY and E-PSMA scores during PCa staging. ***Materials and Methods:*** Radiomic analysis was performed on 18F-PSMA-1007 PET images from 59 patients with histologically confirmed or 2-year follow-up-verified disease (31 prostate lesions, 15 lymph nodes, 13 bone lesions). Lesions were segmented using ITK-SNAP 4.2.2 and independently reviewed by two experts. A total of 112 radiomic features were extracted using Pyradiomics. We developed a hybrid ML model combining systematic feature selection and reduction with discriminant analysis to predict the PRIMARY score, E-PSMA 4-point Expression score, and 5-point Interpretation score. ***Results:*** For primary prostate lesions, two features (original_glcm_DifferenceEntropy and original_firstorder_Entropy) showed excellent performance in predicting E-PSMA Expression grades (sensitivity 100%, specificity 90.5%, AUROC 100%, p = 0.00). For predicting the E-PSMA Interpretation scale, original_gldm_LargeDependenceLowGrayLevelEmphasis was significant but with limited sensitivity (36.7%) despite good specificity (87.8%, AUROC 77.3%, p = 0.04). The feature original_glrlm_LongRunLowGrayLevelEmphasis showed suboptimal performance in predicting PRIMARY scores (sensitivity 52.6%, specificity 86.9%, AUROC 70.8%, p = 0.2). When including all lesion types (prostate, nodal, bone), E-PSMA Expression grades were accurately predicted by original_firstorder_Range (sensitivity 100%, specificity 67%, AUROC 98.3%, p = 0.00), while E-PSMA Interpretation was best predicted by original_shape_SurfaceVolumeRatio (sensitivity 94.5%, specificity 85.5%, AUROC 82.2%, p = 0.00). ***Conclusion:*** This exploratory study demonstrates for the first time the feasibility and potential clinical value of combining radiomics and AI for predicting validated international scoring systems on PSMA-PET in PCa staging. The ML model identified novel radiomic features that may help predict PRIMARY and E-PSMA scores in both primary and metastatic lesions. Larger prospective studies are needed to validate and extend these promising findings. ***References:*** PMC9635676; PMC8113168.

Aim/Introduction: Extended pelvic lymph node dissection (ePLND) is the standard approach for nodal staging in prostate cancer (PCa) patients undergoing radical prostatectomy (RP). However, its utility in intermediate-risk cases remains debated due to potential complications and uncertain oncologic benefits. This study aimed to assess whether incorporating Prostate-Specific

Membrane Antigen Positron Emission Tomography (PSMA-PET) nodal staging into traditional nomograms could enhance the selection of patients for ePLND. ***Materials and Methods:*** We retrospectively analyzed 110 intermediate-risk PCa patients who underwent preoperative PSMA-PET and subsequently received RP with ePLND at three referral centers in Italy between 2019 and 2023. For each patient, the risk of lymph node invasion (LNI) was calculated according to PSMA-PET reporting (positive/negative), and by using previously established cutoffs for current models (Memorial Sloan Kettering Cancer Center and the Briganti 2012, 2017, and 2019 nomograms). Receiver-operating-characteristic analysis was used to calculate area under the curve (AUC), sensitivity, specificity, positive and negative predictive values (PPV and NPV) of PSMA-PET and nomograms to predict LNI. Models' extent of over- or underestimation and net benefit were assessed using calibration plots and decision curve analysis (DCA). ***Results:*** PSMA-PET offered significantly higher specificity and PPV than all tested nomograms in identifying LNI ($p<0.01$ for all). While the adoption of nomograms would have spared 32%-65% of ePLND procedures missing 0%-1.1% of LNI cases, PSMA-PET would have resulted in 84% ePLND procedures spared ($p<0.01$ vs. all nomograms) and 0.9% of LNI cases missed (p=ns vs. all nomograms). Since the Briganti 2017 nomogram with a 7% cutoff was the most accurate in our cohort, we combined it with PSMA-PET to determine whether this combination could better discriminate between patients with and without histologically confirmed LNI. This combination would have further increased AUC, specificity and PPV for LNI ($p<0.05$ vs. PSMA-PET alone) and reduced unnecessary ePLND procedures without increasing the number of missed LNI cases. Specifically, if only patients with a Briganti 2017 score >7% and PSMA-PET N1 had been candidates for ePLND, 91% of procedures would have been spared ($p<0.01$ vs. all nomograms, p=ns vs. PSMA-PET alone), with only 0.9% of LNI cases missed (p=ns vs. all nomograms and p=ns vs. PSMA-PET alone). DCA demonstrated the net benefit of this combination for predicting LNI. ***Conclusion:*** Our findings suggest that integrating PSMA-PET with nomograms in intermediate-risk cases could optimise patient selection for ePLND, potentially reducing unnecessary surgeries without increasing the risk of missed LNI cases.

Smart risk-stratification: machine learning predicts LATITUDE high-risk prostate cancer at presentation using routine multimodal clinical data

B. Khangembam*, S. Sharma, R. Wakankar, M. Kavin, S. Kaushal, C. J. Das, R. K. Sahoo, A. Seth, A. R. Chanu, C. Patel, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To evaluate the feasibility of machine learning (ML) models utilizing routine clinical, conventional imaging, and laboratory data for predicting LATITUDE high-risk disease in treatment-naïve prostate cancer patients undergoing ^{68}Ga-PSMA-11 PET/CT. ***Materials and Methods:*** Between April 2024 to March 2025, 168 treatment-naïve prostate cancer patients (mean age: 67 ± 8 years) with pathologically confirmed diagnoses were prospectively enrolled. The primary outcome was the presence of LATITUDE high-risk disease, determined by ^{68}Ga-PSMA-11 PET/CT imaging and pathological findings. A training set (n = 168) was generated via stratified deterministic bootstrapping, with 65 patients reserved as an independent test cohort. After feature normalization, Information Gain Ratio scoring was used for feature selection. Four ML models (Random Forest, CatBoost, XGBoost, and Naïve Bayes) were trained using stratified 10-fold cross-validation. Model performance was assessed using AUC, accuracy, F1 score, precision, recall, and specificity. Permutation plots were used to assess overfitting, while SHAP plots and confusion matrices were used for model interpretation. A Naïve Bayes-based nomogram was constructed using the five most important features based on absolute feature importance. ***Results:*** High-volume disease was present in 26.8% (45) of patients. Information Gain Ratio scoring selected the best-ranked 9 features for cross-validation. In cross-validation, three models exhibited >0.850 in all performance metrics, with Random Forest achieving the highest AUC of 0.963 (CA 0.940, F1 score 0.894, precision 0.875, recall 0.913, specificity 0.951). On the test set, Random Forest maintained the highest AUC of 0.938 (CA 0.877, F1 score 0.789, precision 0.833, recall 0.750, specificity 0.933). No significant overfitting was observed, and SHAP plots revealed clear patterns of interpretability. The nomogram revealed that PSA ≥87.37 ng/mL, ALP ≥251.5 U/L, N1 status, primary tumor size 23.30 - 30.55 mm, and hemoglobin <11.5 gm/dL could predict high-risk disease with 94% probability. ***Conclusion:*** Machine learning models effectively predict LATITUDE high-risk disease in treatment-naïve prostate cancer patients using routine multimodal clinical data. These interpretable models and the derived nomogram could aid early decision-making and personalized patient management in clinical practice.

EP-0372

Optimizing metastatic work-up: machine learning predicts M1 disease in newly diagnosed prostate cancer using routine multimodal clinical data

B. Khangembam*, S. Sharma, R. Wakankar, M. Kavin, A. R. Chanu, C. J. Das, S. Kaushal, R. K. Sahoo, A. Seth, C. Patel, R. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To evaluate the feasibility of machine learning (ML) models utilizing routine clinical, conventional imaging, and laboratory data for predicting metastatic (M1) disease in treatment-naïve prostate cancer patients undergoing ^{68}Ga-PSMA-11 PET/CT. ***Materials and Methods:*** From April 2024 to March 2025, a total of 168 treatment-naïve patients with pathologically confirmed prostate cancer (mean age: 67 ± 8 years) were prospectively enrolled. The primary outcome assessed was the presence of M1 disease, as determined by ^{68}Ga-PSMA-11 PET/CT imaging. A training set (n = 168) was generated via stratified deterministic bootstrapping, with 65 patients reserved as an independent test cohort. After feature normalization, Chi-square scoring was used for feature selection. Six ML models (Random Forest, Neural Network, Naïve Bayes, Logistic Regression, CatBoost, and XGBoost) were trained using stratified 10-fold cross-validation. Model performance was assessed using AUC, accuracy, F1 score, precision, recall, and specificity. Permutation plots were used to assess overfitting, while SHAP plots and confusion matrices were used for model interpretation. A Naïve Bayes-based nomogram was constructed using the four most important features based on absolute feature importance. ***Results:*** M1 disease was present in 45.2% (76) of patients. The top 5 features selected by Chi-square scoring for cross-validation were ISUP grade, N1 status, PSA, ALP, and tumor size. In cross-validation, five models exhibited >0.800 in all performance metrics, with CatBoost achieving the highest AUC of 0.980 (CA 0.929, F1 score 0.919, precision 0.958, recall 0.883, specificity 0.967). On the test set, Neural Network achieved the highest AUC of 0.961 (CA 0.908, F1 score 0.914, precision 0.865, recall 0.970, specificity 0.844), correctly predicting 97% (32/33) of M1 cases. No significant overfitting was observed, and SHAP plots revealed clear patterns of interpretability. The nomogram revealed that PSA ≥87.37 ng/mL, N1 status, ALP 115.5 - 251.5 U/L, and ISUP grade ≥4 could predict M1 disease with 98% probability. ***Conclusion:*** Machine learning models demonstrated robust performance in predicting the presence of M1 disease in treatment-naïve prostate cancer patients using routinely available multimodal clinical data. The interpretable nature of these models, along with the developed nomogram, holds potential to support early clinical decision-making and facilitate individualized patient management in clinical practice.

EP-0373

Machine learning can predict CHAARTED high-volume disease in treatment-naïve prostate cancer patients undergoing^{68}Ga-PSMA-11 PET/CT

S. Sharma, *R. Wakankar, M. Kavin, S. Kaushal, C. J. Das, R. K. Sahoo, A. Seth, A. R. Chanu, B. Khangembam, C. Patel, R. Kumar; All Institutes of Medical Sciences, New Delhi, INDIA.*

Aim/Introduction: To assess the feasibility of using machine learning (ML) models based on routine clinical, conventional imaging, and laboratory data to predict CHAARTED high-volume disease in treatment-naïve prostate cancer patients undergoing Ga-PSMA-11 PET/CT. ***Materials and Methods:*** From April 2024 to March 2025, 168 pathologically confirmed treatment-naïve prostate cancer patients (mean age: 67 ± 8 years) were prospectively enrolled. The primary outcome was the presence of CHAARTED high-volume disease on Ga-PSMA-11 PET/CT. A training set (n = 168) was created using stratified deterministic bootstrapping, with 65 patients reserved as an independent test set. Feature selection was based on Chi-square scoring after feature normalization. Four ML models (Naïve Bayes, Random Forest, XGBoost, and CatBoost) were trained using stratified 10-fold cross-validation. Final model performance was evaluated on the test set using AUC, accuracy, F1 score, precision, recall, and specificity. Permutation plot was used to assess the degree of overfitting. SHAP plots and confusion matrices were used for model interpretation. A Naïve Bayes-based nomogram was developed using the top five features based on absolute feature importance. ***Results:*** High-volume disease was present in 28.0% (47) of patients. The top 7 features selected by Chi-square scoring for cross-validation were ALP, ISUP grade, PSA, N1 status, hemoglobin, albumin, and tumor size. In cross-validation, three models exhibited >0.800 in all performance metrics, with CatBoost achieving the highest AUC of 0.971 (CA 0.935, F1 score 0.876, precision 0.907, recall 0.848, specificity 0.967). On the test set, Naïve Bayes exhibited the highest AUC of 0.948 (CA 0.892, F1 score 0.844, precision 0.760, recall 0.950, specificity 0.867), correctly predicting 95% (19/20) of high-volume cases. No significant overfitting was observed, and SHAP plots revealed clear patterns of interpretability. The nomogram revealed that ALP ≥251.5 U/L, PSA ≥87.37 ng/mL, albumin 4.25 - 4.55 g/dL, N1 status, and ISUP grade ≥4 could predict high-volume disease with 94% probability. ***Conclusion:*** Machine learning models accurately predict CHAARTED high-volume disease in treatment-naïve prostate cancer patients using routine clinical, imaging, and laboratory data. The interpretable models and nomogram may support early decision-making and individualized patient management in clinical settings.

EP-0374

PET/CT for staging Intermediate-Risk Prostate Cancer in Routine Clinical Practice

D. Martínez Osorio[1], *C. Lucas Lucas*[1], *J. Rodríguez Gómez*[1], *E. Noriega Álvarez*[2], *F. Pena Pardo*[1], *A. Padilla Bermejo*[1], *C. Ortiz Muñoz*[1], *M. Contreras Ameduri*[1], *J. Gatón Ramírez*[1], *F. Lopéz-Bermejo García*[1], *N. Almeida Romera*[1], *M. Talavera Rubio*[1], *V. Poblete García*[1];
[1]*Hospital General Universitario Ciudad Real, Ciudad Real, SPAIN,* [2]*Hospital Universitario de Guadalajara, Ciudad de Guadalajara, SPAIN.*

Aim/Introduction: To evaluate the concordance between staging with conventional imaging, 18F-choline PET/CT, and [18F]F-DCFPyL PET/CT in the assessment intermediate-risk prostate cancer (Pca). ***Materials and Methods:*** We conducted a retrospective, observational study including consecutive patients diagnosed with intermediate-risk Pca through transrectal biopsy between 2021 and 2023. Nodal and metastatic staging was performed using standard imaging techniques such as MRI, CT, and bone scintigraphy, as well as 18F-choline PET/CT and [18F]F-DCFPyL PET/CT, with all scans completed within a 60-day interval. Imaging was independently interpreted by two experienced nuclear medicine physicians, with a third reviewer involved in case of discordance. The reference standard was the consensus established by a multidisciplinary tumor board, which included pathological findings from radical prostatectomy and lymphadenectomy whenever these were available. Concordance was evaluated using kappa statistic and chi-square tests. ***Results:*** Twenty-nine patients (mean age 71.1 years, range 44-87) were included; 41.4% had favorable and 58.6% unfavorable intermediate-risk disease. Seven patients underwent surgical staging. Conventional imaging exhibited moderate concordance with the reference standard (kappa 0.443, p <0.014), with discrepancies in 3 patients (11.11%), who were classified as N1M0 by the reference standard, but were identified as N1M1 or N0M1 by 18F-choline PET/CT.18F-Choline PET/CT also demonstrated moderate concordance (kappa 0.416, p <0.001), with a tendency toward upstaging: seven patients classified as N0M0 by the reference standard were upstaged by 18F-choline PET/CT. [18F]F-DCFPyL PET/CT achieved strong concordance (kappa 0.763, Kendall's tau-b 0.84, chi-square 87, all p <0.001) correctly identifying 86.36% N0M0 and 100% of M1 cases. Among the seven patients who underwent surgical staging, [18F]F-DCFPyL PET/CT findings were concordant with pathological results in six cases (85.7%), while both 18F-choline PET/CT and conventional imaging were concordant in only three cases (42.9%). ***Conclusion:*** In routine clinical practice, [18F]F-DCFPyL PET/CT demonstrates superior concordance with multidisciplinary staging consensus compared to conventional imaging and 18F-choline PET/CT. These findings reinforce the pivotal role of [18F]F-DCFPyL PET/CT in clinical staging and therapeutic decision-making for intermediate-risk Pca.

EP-0375

PSMA-PET vs wbMRI Performance in Detecting Local and Nodal Disease in Patients with Newly Diagnosed Prostate Cancer

E. Greco[1], *L. Bianchi*[2], *C. Gaudiano*[3], *B. Corcioni*[3], *C. M. P. Sgro*[1], *C. Mignogna*[4], *B. Renzetti*[5], *A. Cattabriga*[3], *R. Schiavina*[2,4], *E. Brunocilla*[2,4], *C. Mosconi*[3,5], *R. Mei*[6], *P. Castellucci*[6], *S. Fanti*[6,1], *A. Farolfi*[6];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Division of Urology, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [5]*Department of Radiology, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [6]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: High risk prostate cancer (PCa) patients require systemic staging to receive the most suitable treatment. PSMA-PET is an accurate technique for the detection of local and distant disease. Whole-body MRI (wbMRI) can be used to identify local disease and distant lymph node, bone and visceral metastases but there is no strong recommendation for its use in daily clinical practice. This study aims to compare PSMA-PET and wbMRI in detecting local disease and local lymph nodes metastases in patients with new PCa diagnosis. ***Materials and Methods:*** This is a single-center prospective study enrolling patients with newly diagnosed PCa, receiving both PSMA-PET and wbMRI within a 2-months' timeframe before any treatments. Exams were independently reviewed by two nuclear medicine physicians for PET scans and two radiologists for wbMRI. Regarding patients who underwent radical prostatectomy (RP), PSMA-PET and wbMRI performances, namely sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy, were evaluated for local disease (T) and local lymph node (N), using

histopathology as gold standard. ***Results:*** Overall, 80 patients with newly diagnosed PCa were enrolled (median age 70 years). PSMA-PET and wbMRI were performed within a median time of 13 days (IQR 7-22). Among these patients, 8 (10%) underwent radiation therapy, 19 (24%) received systemic treatment and 8 (10%) have not received any treatment yet at the time of data analysis. 45/80 (56%) patients in the staging cohort underwent subsequent RP. Regarding those patients, PSMA-PET and wbMRI sensitivity for local disease (T) was 96% vs 100% while PPV 100% vs 100%. Furthermore, for pelvic nodes involvement (N) sensitivity was 56% vs 33%, specificity 85% vs 89%, PPV 71% vs 67%, NPV 74% vs 67% and accuracy 73% vs 67%. ***Conclusion:*** Using histology as gold standard, wbMRI outperformed PSMA-PET for the detection of local disease (T), while PSMA-PET showed greater sensitivity, PPV, NPV and accuracy than wbMRI in evaluating pelvic lymph node metastases (N).

EP-0376

Role of PSMA PET/CT and mpMRI in Determining Focal Therapy Eligibility in Localized Prostate Cancer: Correlation with Histopathology

I. Sonni*, Z. Mohammadigoldar, G. Furey, K. Kimura, A. Holzgreve, A. Chung, J. Calais, J. Czernin, W. Brisbane, A. B. Weiner, S. S. Raman;*
University of California, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Focal therapies are increasingly employed in the treatment of prostate cancer, offering less invasive options for patients with localized disease. However, accurate patient selection remains a significant challenge. This retrospective study evaluates the ability of PSMA PET/CT, multiparametric MRI (mpMRI), and their combination to predict eligibility for focal therapy, using whole-mount histopathology (WMHP) as the reference standard. ***Materials and Methods:*** We screened all patients who underwent radical prostatectomy at UCLA between 1/2017 and 7/2024 with available pre-surgical PSMA PET/CT and mpMRI. Inclusion criteria included biopsy-confirmed Gleason score ≤7, absence of bilateral disease on biopsy. Exclusion criteria were: prostate cancer-related treatment between imaging studies, and an interval between PET and MRI >6 months. Three board-certified physicians independently assessed the PSMA PET/CT, mpMRI, and combined PET+MRI studies. All readers were blinded to each other's assessments and had access only to PSA levels and biopsy results, reflecting routine clinical practice. We calculated sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) to assess the ability of each imaging modality to correctly identify patients eligible for focal therapy, using WMHP as the gold standard. Eligibility was defined by the absence of extracapsular extension (EPE), seminal vesicle invasion (SVI), bilateral disease, and multifocal disease on histopathology. ***Results:*** Of 420 screened patients, 113 met all inclusion criteria. Based on imaging review, the number of patients deemed eligible/ineligible for focal therapy was: 21/92 for PSMA PET/CT, 30/83 for mpMRI and 28/85 for combined PET+MRI. WMHP confirmed 23 eligible and 90 ineligible patients. Sensitivity was 14% for PSMA PET/CT, 17% for mpMRI, and 30% for PET+MRI. Specificity values were 87%, 71%, and 77%, respectively. PPV were 20%, 13%, and 25%, while NPV were 81%, 77%, and 81%, respectively. ***Conclusion:*** PSMA PET/CT demonstrated high specificity and NPV in ruling out focal therapy eligibility, while sensitivity remained limited. mpMRI offered modestly improved sensitivity, but lower specificity. The combination of PSMA PET/CT and mpMRI showed the best overall performance, with improved sensitivity and NPV compared to either modality alone. These findings support a role for combined imaging in refining patient selection for focal therapy and guide non-invasive clinical decision-making. Further consensus review is ongoing to validate these results.

EP-0377

Predictive Value of Baseline PSMA-PET Parameters in Locally Advanced Prostate Cancer Patients Treated with Radical-Intent Radiotherapy and Androgen Deprivation Therapy: An Inverse Probability of Treatment Weighting Analysis

D. Dubois[1,2]*, F. Lanfranchi*[1,2]*, D. Vita*[1,2]*, S. Mastrogiovanni*[1,3]*, L. Sofia*[1,2]*, S. Raffa*[2]*, M. I. Donegani*[2]*, S. Chiola*[2]*, C. Marini*[2,4]*, G. Timon*[1,3]*, G. Sambuceti*[1,2]*, L. Belgioia*[1,3]*, M. Bauckneht*[1,2]*;*
[1]Department of Health Sciences (DISSAL), University of Genoa, Genova, ITALY, [2]Nuclear Medicine, IRCCS Ospedale Policlinico San Martino, Genova, ITALY, [3]Radiotherapy, IRCCS Ospedale Policlinico San Martino, Genova, ITALY, [4]Institute of Molecular Bioimaging and Physiology, National Research Council (CNR), Milan, ITALY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) PET/CT has become a key imaging modality for the primary staging of prostate cancer (PCa). However, the prognostic value of quantitative PSMA-PET parameters remains unclear, particularly in patients subsequently treated with radical-intent radiotherapy and androgen deprivation therapy (ADT). We thus aimed to assess the predictive value of baseline PSMA-PET parameters for clinical outcomes in patients with locally advanced PCa, using inverse probability of treatment weighting (IPTW) to adjust for clinical confounders. ***Materials and Methods:*** This single-centre retrospective study included PCa patients who underwent PSMA-PET/CT for primary staging. Patients with distant metastases were excluded. The following PET parameters were analysed: SUVmax and total lesion PSMA (PSMA-TL) of the dominant lesion, and total PSMA volume (PSMA-TV). Patients were dichotomised into high and low groups based on median values. IPTW was applied to adjust for baseline variables, including initial PSA, ISUP grade group at prostate biopsy, T stage, and N stage. Kaplan-Meier analyses with log-rank tests were conducted to assess associations with time to treatment failure (TTF), defined as a composite endpoint including any of the following events: biochemical recurrence according to Phoenix criteria; radiologic progression; clinical progression; initiation or change of systemic treatment for any reason; or mortality. ***Results:*** The study population included 145 patients, with a mean age of 75.94 ± 4.9 years. Most patients presented with an ISUP grade group of 3 (39.3%) or 2 (26.9%). The median baseline PSA level was 8.94 ng/mL [IQR: 6.60-15.00], and 28.3% of patients had pelvic nodal involvement (N1). Regarding PSMA-PET parameters, the median SUVmax of the dominant lesion was 12.19 [IQR: 8.80-20.32], and the median total PSMA-TV was 10.17 cc [IQR: 4.14-24.22]. After IPTW adjustment, total PSMA-TV was significantly associated with shorter TTF (p=0.042), with worse outcomes observed in patients with above-median values. On the contrary, SUVmax and PSMA-TL of the dominant lesion were not significantly associated with this endpoint following IPTW adjustment, underscoring the prognostic value of volumetric PSMA-PET assessment. ***Conclusion:*** Total PSMA-TV is an independent predictor of time to treatment failure in locally advanced PCa patients treated with radical-intent radiotherapy and ADT. These findings highlight the prognostic utility of PSMA-TV over other PET-derived metrics and support its potential role as a biomarker for treatment planning and risk stratification in clinical practice.

EP-0378

PET/CT with [18F]-Piflufolastat in the initial staging of patients with intermediate-high risk prostate cancer: relationship of SUVmax and SUVmean values of prostatic target lesion with gleason scale, ISUP prognostic grades and PSA values at diagnosis.

J. Badell*, A. C. Peñaherrera Cepeda, L. G. Díaz González, E. Casillas Sagrado, J. G. Villanueva Curto, E. Campaña Díaz, S. Rama Alonso, F. Caltagirone Gutierrez, P. García-Talavera San Miguel, F. Gomez-Caminero Lopez, P. Tamayo Alonso;*
Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To determine the relationship between SUVmax/SUVmean values of the prostatic target lesion obtained by [18F]-Piflufolastat PET/CT in the initial staging of patients with intermediate-high risk prostate cancer, with the gleason scale, ISUP prognostic grades and PSA values. ***Materials and Methods:*** We included 126 patients (71.1 years ± 8.1 years), diagnosed with intermediate-high risk prostate cancer, who were referred to our service for PET/CT study with [18F]-Piflufolastat between August/2023 and April/2025, for initial staging of their disease. A PET/CT study focused on cranio-pelvis was acquired 120 minutes after intravenous administration of 333 MBq of 18F-Piflufolastat, after administration of 20 mg of furosemide 60 minutes before image acquisition. In the positive studies, the SUVmax and SUVmean values of the prostatic target lesion were localized and quantified and their relationship was established in terms of gleason scale, ISUP prognostic grades and PSA values. ***Results:*** PET/CT was positive in 99.2% of patients (125/126). According to their prognostic grade at diagnosis, patients were classified into three groups (ISUP Grades), ISUP 1: 8/125, ISUP 2-3: 30/125 and ISUP 4-5: 87/125. According to PSA values (ng/ml) at diagnosis, they were classified into three groups, PSA<10: 48/125, PSA 10-20: 23/125 and PSA>20: 49/125 and finally, according to the gleason scale at diagnosis, they were classified into five groups (Gleason score), ≤6: 8/125, 7 (3+4): 14/125, 7 (4+3): 16/125, 8: 47/125 and 9-10: 29/125. The median SUVmax/SUVmean values of prostatic target lesion in the groups according to ISUP prognostic grade were: ISUP 1: 17.90/10.55 (SUVmax/SUVmean), ISUP 2-3: 17.94/10.56 and ISUP 4-5: 17.99/10.58. According to PSA values (ng/ml) at diagnosis, the mean values were: PSA<10: 17.81/10.49, PSA 10-20: 17.93/10.57 and PSA>20: 18.09/10.67. In the groups according to the gleason scale at diagnosis, the mean values were: ≤6: 17.82/10.52, 7 (3+4): 17.87/10.56, 7 (4+3): 17.90/10.55, 8: 17.93/10.47 and 9-10: 17.99/10.61. ***Conclusion:*** PET/CT with 18F-Piflufolastat is a useful technique for initial staging in patients with intermediate-high risk prostate cancer. A significant increase in mean SUVmax and SUVmean values was observed in all the groups studied, both when PSA levels were higher at diagnosis and when the ISUP prognostic grade and gleason scale were higher.

EP-0379

Utility of the PRIMARY Score on [^{99m}Tc]Tc-PSMA SPECT/CT - an exploratory study aimed to optimise prostate cancer diagnosis

S. More[1], *M. Rivombo*[1], *N. Jacobs*[1], *O. Kolade*[2], *K. Hlongwa*[1]; [1]*University of Cape Town, Cape Town, SOUTH AFRICA,* [2]*University College Hospital, Ibadan, NIGERIA.*

Aim/Introduction: The PRIMARY score has been validated in a real-world setting in patients imaged with [^{68}Ga]Ga-PSMA-11 and multiparametric MRI(mpMRI) before prostate biopsy to aid in the diagnosis of clinically significant prostate cancer(csPCa). With the advent of [^{99m}Tc]Tc-PSMA tracers in real-world application, the validation of the PRIMARY score with [^{99m}Tc]Tc-PSMA has not been explored. The aim of this exploratory study is to review utility of [^{99m}Tc]Tc-PSMA SPECT/CT in evaluating intra-prostatic uptake patterns and intensity scores, with a view to developing a surrogate score to improve diagnostic accuracy for csPCa based on the PRIMARY score for PET. ***Materials and Methods:*** Patients presented for staging with [^{99m}Tc]Tc-PSMA and were deemed fit for radical therapy according to local guidelines.mpMRI was performed in preparation for radical prostatectomy. The PRIMARY score and pattern were recorded based on previous PET work to delineate the peripheral zone(PZ), central zone(CZ) and transition zone(TZ).Regions of interest were drawn around the prostate primary, background skeletal muscle, liver and parotids to determine ratios relative to prostate counts and garner a cutoff for ratios concordant to the described PRIMARY score. PRIMARY 5 was defined as more than twice the score for PRIMARY4 on SPECT. PIRADS score and location on MRI were reviewed for each paired study. ISUP grading was recorded from histological samples of patients who presented for radical prostatectomy. csPCa was defined as ISUP grade≥2.PRIMARY score of 3-5 and PIRADS score 3-5 were deemed positive. ***Results:*** 44 men(median age 65 years) were analysed with median PSA 19.3ug/l at diagnosis. 32(73%) men had csPCa on biopsy with positive MRI. 4(9%) had diffuse TZ or symmetrical CZ activity, 14(32%) had focal TZ activity and 26 (59%) had focal activity in the PZ on PRIMARY. 40(91%) patients had a positive [^{99m}Tc]Tc-PSMA result, and 44(100%) a positive MRI result. Median PRIMARY score of 2, 3 and 4 correlated with a P/B ratio of 8.19, 10.63 and 19.38 respectively on [^{99m}Tc]Tc-PSMA. There was a significant association between the PRIMARY and PIRADS score($p = 0.026$), P/B ratio and PRIMARY score($p = 0.004$) and ISUP grade group and P/B ratio>8.19(PRIMARY2 cutoff for SPECT, $p<0.001$). No significant associations were seen between PIRADS and PRIMARY score against the ISUP grade. ***Conclusion:*** A modified 5-tier PRIMARY score based on [^{99m}Tc]Tc-PSMA incorporating intra-prostatic pattern and intensity on PSMA SPECT/CT shows potential for detection of csPCa. Further validation of this scoring system is recommended to characterise its fuller clinical applications and implementation.

EP-0380

Regional Experience on Tc99m-PSMA SPECT/CT in staging of Prostate Cancer in New Zealand: Correlation of pre-imaging PSA level with delayed 24-hour pelvic SPECT/ CT findings.

E. Ling[1], *N. Tag*[1], *S. Abubakar*[2], *P. Burns*[1], *R. M. Subramaniam*[1]; [1]*Wellington Regional Hospital, Wellington, NEW ZEALAND,* [2]*Auckland City Hospital, Auckland, NEW ZEALAND.*

Aim/Introduction: Technetium-99m labelled PSMA ligands (99mTc-PSMA) has the potential to increase access to PSMA imaging due to the wider availability of the gamma camera and Technetium-99m radionuclide. In our institution, 99mTc-PSMA imaging protocol includes 5-hour whole body SPECT/CT and 24-hour delay abdomen/pelvis SPECT/CT. The 24-hour images prolongs overall time of the study and necessitates more resource allocation. This study aims to identify the benefit of 24-hour SPECT/CT in lesion detection and correlation with pre-imaging PSA level. ***Materials and Methods:*** Retrospective cohort study including 63 patients between September 2023 and March 2025. Recurrent cases were divided into 3 groups based on PSA level: Group A (0.2-2 ng/mL), Group B (2.1-10 ng/ml) and Group C (>10 ng/mL). New patients were grouped into An (<20 ng/mL) and Bn (>20 ng/mL). Comparison of the 5-hour and 24-hour SPECT/CT was performed to identify differences in lesion detection and correlation to PSA level. The 24-hour SPECT/CT scans were read twice, initially blindly and then with knowledge of the 5-hour SPECT/CT findings. The SPECT/CT data were subsequently compared and were verified by clinical and radiological outcome. ***Results:*** Out of the 47 patients with recurrence, in group A (6 patients), 1 patient showed additional uptake in an abdominal node on the 24-hour SPECT/CT. In group B (17 patients), 15 patients had PSMA detected disease, with 1 patient showing an additional osseous uptake on the 24-hour SPECT/CT. In group C (24 patients), 23 patients had PSMA detected disease, with 1 patient showing pelvic node uptake only on the 24-hour SPECT/CT. For the 16 newly diagnosed cases, in both groups, no additional lesion demonstrated on 24-hour imaging. ***Conclusion:*** Results suggests that there may be no added value of a 24-hour delayed imaging for a 99mTc-PSMA protocol regardless of pre-imaging PSA levels, though study is limited by a small sample size. ***References:*** 1. ^{99m}Tc-PSMA SPECT/CT in the primary staging of prostate cancer - a retrospective analysis

O. Jonmarker[1,2], *C. Samuelsson*[1,2], *L. Steffens*[2], *M. Sunderland*[2], *D. O'Keeffe*[2,3], *S. Gabrielson*[1,4,2];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Christchurch Hospital, Christchurch, NEW ZEALAND,* [3]*University of Canterbury, Christchurch, NEW ZEALAND,* [4]*University of Otago, Christchurch, NEW ZEALAND.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) imaging with PET/CT has become a cornerstone in the staging of prostate cancer, yet access to PET technology is limited. ^{99m}Tc-PSMA SPECT/CT represents a more accessible and cost-effective modality, but its role in primary prostate cancer staging remains underexplored. The aim of this study was to assess the diagnostic utility of ^{99m}Tc-PSMA SPECT/CT in comparison to MRI and biopsy findings in patients undergoing primary staging of prostate cancer. ***Materials and Methods:*** We conducted a retrospective study of 85 patients with newly diagnosed prostate cancer who underwent MRI and ^{99m}Tc-PSMA SPECT/CT within a 90-day interval in Christchurch, New Zealand. Imaging was reviewed independently by four radiologists using a segmental scoring system for prostatic, extraprostatic and metastatic disease. Diagnostic concordance with MRI was assessed segment-by-segment and across anatomical regions. Both MRI and SPECT were compared with systematic biopsies and related to calculated standardised uptake value (SUV). Intraclass correlation and Cohen's kappa were used to evaluate agreement. ***Results:*** ^{99m}Tc-PSMA SPECT/CT demonstrated high sensitivity in detecting intraprostatic disease, with at least partial anatomical concordance with MRI in over 75% of cases. Inter-reader PSMA SPECT/CT agreement was overall poor, but highest for bone metastases and lesion laterality, and lowest for seminal vesicle invasion (SVI) and extraprostatic extension (EPE). The number of pathological prostate sectors identified on SPECT was comparable to MRI, though SPECT showed broader coverage when equivocal lesions were considered. MRI and SPECT were in similar agreement with biopsies. Higher SUVs, above the median, showed better agreement between SPECTs and biopsies compared to lower SUVs. Agreement between MRIs and biopsies was not clearly affected by SUV. ***Conclusion:*** 99mTc-PSMA SPECT/CT is a viable alternative to PSMA PET/CT for detecting malignancy in the primary staging of prostate cancer, particularly in settings with limited access to PET imaging. While limitations remain in the assessment of SVI and EPE, SPECT/CT demonstrates promising diagnostic performance, especially for intraprostatic and osseous disease. High SUVs appear to increase agreement between biopsies and SPECT. Further prospective studies with complete histopathological validation would be of value.

EP-0382

Impact of PET/MR-guided biopsy with ^{18}F-PSMA in patients with suspected prostate cancer: a prospective single-center pilot study.

Aim/Introduction: To determine the feasibility of ^{18}F-PSMA PET/MRI fusion-guided transperineal prostate biopsy with real-time transrectal ultrasound(TRUS)study in patients with suspected prostate cancer(PC). ***Materials and Methods:*** Prospective study with the first 20 patients with suspected PC(persistently increased PSA;mean 11.2 ng/ml;range 4.5-20.8,)referred for disease characterization by ^{18}F-PSMA PET/MRI.Prostate selective PET/MRI study with sequences MRAC,T1,T2fat, DWI, DCE.MRI was assessed using PIRADSv.2 criteria, and PET using Primary. Subsequently,a whole-body MRI study was performed with sequences MRAC,T1,T2fat, DWI.The PET/MRI images were loaded into the bkFusion software(MIM®),performing segmentation of the prostatic anatomical structure on T2 images,including the lesions evident on MRI and PET,thus planning the optimal target of the biopsy needle.Transperineal biopsy was performed with patient deep-sedated,using US-MRI fusion software(BiopSee®). Co-registration of PET/MRI and TRUS images was performed using a 1-plane,1-point method,including an additional point whenever needed.A minimum of five cores were obtained for each target lesion,along with systematic biopsy tailored to the prostate volume. ***Results:*** Transperineal prostate biopsy was successfully achieved in all 20 patients, with adequate PET/MRI segmentation and real-time co-registration with TRUS. Twenty-three lesions were detected in 17 patients:a single lesion was evident in 11 patients(4 in the anterior transitional zone and 7 in peripheral zone),and 2 lesions in 6 patients(in the peripheral zone).The detection rate of PC was 82.6% (19 patients):clinically significant(csPC) in 13/19(68.2%) and non-significant (cnsPC) in 6/19(31.6%).In 14 lesions PSMA and MRI images were concordant, with biopsy identifying csPC in 9/14,cnsPC in 4/14 and negative in 1/14.In 9 lesions PSMA and MRI images were discordant(Primary4-5 vs. PIRADS2-3),with biopsy identifying csPC in 4/9,cnsPC in 2/9 and negative in 3/9. In the 3 patients in whom no significant lesions were detected on PET/MRI,systematic biopsy was either negative.In two patients there was evidence of pelvic lymphadenopathy on selective imaging,with no more lesions detected on the whole-body study. ***Conclusion:*** Our study demonstrated the feasibility and usefulness of ^{18}F-PSMA PET/MR to target biopsy in patients with suspected PC.Our detection rate for PC was 82.6%, with csPC in 68.2% of patients.In the 9 patients in whom ^{18}F-PSMA proved superior to MRI,PC detection rate was 67%, with csPC in 44.4% of patients. ***References:*** 1. EP-0383

Automated Extraction of TNM Staging from PSMA PET/CT Reports Using AI

A. Ghujeh[1,2], *A. Alrahim*[1], *M. Altinyay*[1], *M. Kharita*[1,3], *F. Alves*[4], *H. Fayad*[1,3];
[1]*Hamad Medical Corporation, Doha, QATAR,* [2]*University of Coimbra, Coimbra, PORTUGAL,* [3]*Weill Cornell Medicine- Qatar, Doha, QATAR,* [4]*CIBIT/ICNAS, Institute for Nuclear Sciences Applied to Health, University of Coimbra, Coimbra, PORTUGAL.*

Aim/Introduction: Accurate staging of prostate cancer according to the Tumor, Node, Metastasis (TNM) classification is crucial for determining eligibility for clinical treatment plan. However, manual extraction of TNM stages from PET/CT reports is labor-intensive, susceptible to human error, and its inclusion is clinician dependent. The objective of this study is to develop and validate

an Artificial Intelligence (AI)-based Natural Language Processing (NLP) pipeline, adhering to the prostate cancer molecular imaging standardized evaluation (PROMISE) V2 criteria, to automatically extract the T, N, and M stages from PET/CT reports. ***Materials and Methods:*** A total of 400 prostate cancer PSMA PET/CT reports were collected. 95 of them were initial staging studies. Each report was reviewed by an experienced physician and assigned a TNM classification (gold standard). The proposed NLP pipeline is built on the DeBERTa (Decoding-Enhanced BERT with Disentangled Attention) transformer model. The model was further adapted with a keyword-sensitive attention mechanism that targets key staging terms, along with a custom rule-based module, adapted from NegEx, to accurately handle negation. Final AI-generated TNM predictions were compared against the reference dataset using leave one out strategy. In addition, compared the performance of the AI pipeline against a textual search method, which relied on keywords derived from terms used by physicians. ***Results:*** On the independent test set of 95 reports, the baseline keyword search achieved accuracy of 51.0% for T stage, 62.7% for N stage, and 45.7% for M stage. In contrast, the AI-module outperformed this baseline, achieving 90.5% accuracy for T stage, 80.9% for N stage, and 73.7% for M stage. Statistical comparison using McNemar's test confirmed that the improvements in staging accuracy were statistically significant for all three components ($p < 0.05$), 0.00001 for T stage, 0.0058 N stage, and 0.0013 M stage. ***Conclusion:*** The NLP pipeline automates TNM staging from PET/CT reports, reducing manual effort and inconsistencies. It enhances report accuracy, efficiency, and supports informed clinical decisions. Initial results are promising, with future research needed to expand training data and test generalizability across institutions. ***References:*** Brierley JD, Gospodarowicz MK, Wittekind C. EP-0384

Impact of ^{18}F-PSMA PET/MRI Imaging on Prostate Cancer Patients Staging: Prognostic Imaging Biomarkers Associated with Tumor Aggressiveness.

L. Pinilla[1], *A. Compte*[1], *N. Garrido*[1], *J. Vela*[2], *L. Mont-Castro*[1], *S. Ruiz*[1], *J. Garcia*[1], *J. Romero*[1], *J. Santabárbara*[1], *M. Soria*[1], *P. Bassa*[1], *E. Riera*[1], *A. Sertsios*[3], *M. Figols*[3], *M. Galdeano*[3], *N. De La Torre*[3], *D. Coll*[3];
[1]*ASCIRES Cetir, Barcelona, SPAIN,* [2]*Hospital Universitario de Canarias, Tenerife, SPAIN,* [3]*Fundació Althaia, Manresa, SPAIN.*

Aim/Introduction: To assess the impact of initial staging of prostate cancer patients by 18F-PSMA PET/MRI, and to evaluate the prognostic value of pre-treatment PET/MRI imaging biomarkers. ***Materials and Methods:*** Prospective study with 55 consecutive patients diagnosed with prostate cancer: Gleason score: 7-9, PSA levels: 1.6 -213 ng/ml.Simultaneous PET/MRI (SIGNA GE) acquisition 1 hour after IV administration of 296±10% MBq of 18F-PSMA 1007 as follows: Prostate study: (20 min): PET+MRI (DIXON,T1, T2, DWI, DCE sequences).Whole body study (30 min): PET+MRI (DIXON, T1, T2, DWI, STIR sequences).TNM staging was reached by consensus with nuclear physician and radiologist. Visual imaging interpretation. Patient treatment decision by Oncology Committee.SUV and ADC values were obtained. Correlation with Pearson's coefficient. Radiomic analysis extracting 93 characteristics: first-order and textural. Evaluation of significant differentiation by ANOVA test in two prognostic groups: 1) TxN0M0/ TxN1M0; 2) TxN1M1a/ M1b. ***Results:*** All patients completed PET/MRI protocol, with no artifacts due to simultaneous acquisition.Prostate PET/MRI staged the primary tumour ≥T3b in a total of 33/55 patients: 15/33 N0M0; 11/33 N1M0; 4/33 M1a; 6/33 Mb (1 N0M1b, 3 N1M1B, 2 N1M1a/M1b). A significant inverse correlation was observed between SUV & ADC ($p<0.05$).Patient staging on whole-body PET/MRI was: 30/55 N0M0; 15/55 N1M0; 6/55 N1M1a; 6/55 M1b (1 N0M1b, 3N1M1b, 2 N1M1aM1b).The therapy decision after PET/MRI was: radical treatment in 45/55 patients, with prostatectomy in 29 and PET/MRI-guided radiotherapy (≥T3b) in 16; systemic treatment in 10/55 patients.SUVmax, ADC and first-order characteristics did not show significant differences between the two selected prognostic groups. Only textual characteristics showed statistical significance ($p<0.05$) between the two groups. ***Conclusion:*** 18F-PSMA PET/MRI may be a "one-stop diagnostic procedure" useful for staging of patients with intermediate/high-risk prostate cancer, with an impact on therapy strategy (18% systemic treatment).Radiomic analysis of textual features seems the only prognostic biomarker of 18F-PSMA PET/MRI.

EP-0385

A retrospective clinical study evaluated the diagnostic performance of ^{18}F-PSMA-137 PET/CT in men newly diagnosed with prostate cancer and those experiencing biochemical recurrence

X. Liao[1], *J. Zhang*[1], *Y. Fan*[1], *N. Zhang*[2];
[1]*Department of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA,* [2]*Peking University – Yunnan Baiyao International Medical Research Center, Beijing, CHINA.*

Aim/Introduction: Prostate cancer (PCa) is one of the most common malignancies among men and its incidence continues to rise globally. Traditional imaging methods such as CT and MRI have been widely used in detecting and staging PCa; however, these techniques have limitations, especially in detecting small lesions or diagnosing recurrent cancer early. Thus, developing imaging technologies with higher sensitivity and specificity is vital for improving early diagnosis and therapeutic outcomes of PCa. ***Materials and Methods:*** A retrospective analysis was conducted on patients who underwent ^{18}F-PSMA-137 PET/CT scans, and were diagnosed with PCa from December 2020 to November 1, 2023. Among them, 66 patients were selected who received the ^{18}F-PSMA-137 PET/CT scan before undergoing radical prostatectomy and pelvic lymph node dissection, with pathological diagnosis results serving as the gold standard to evaluate the diagnostic efficacy of ^{18}F-PSMA-137 PET/CT for preoperative pelvic lymph node metastasis(LNM). Additionally, 40 patients with elevated PSA suspected of recurrence revealed after radical treatment and underwent ^{18}F-PSMA-137 PET/CT scans were selected, and a composite reference standard was used to assess the diagnostic effectiveness of ^{18}F-PSMA-137 PET/CT in recurrent /metastatic lesions. ***Results:*** An analysis of the diagnostic efficacy of ^{18}F-PSMA-137 PET/CT for preoperative pelvic LNM showed that CT/MRI examination had a sensitivity of 42.9% and specificity of 100%, while ^{18}F-PSMA-137 PET/CT examination had a sensitivity of 71.4% and specificity of 98.3%. Univariate analysis did not identify any significant influencing factors for SUV_{max}. An analysis of the diagnostic effectiveness of ^{18}F-PSMA-137 PET/CT in patients with elevated PSA suspected of recurrence revealed that the sensitivity was 87.88% (95% CI: 0.72-0.97), positive predictive value was 85.29% (95% CI: 0.69-0.95), and accuracy was 72.50% (95% CI: 0.56-0.85). The researchers used the CMH method to evaluate whether the positive detection rate of ^{18}F-PSMA-137 PET/CT correlated with baseline PSA levels and Gleason scores, finding no correlation with Gleason scores but a correlation with baseline PSA levels. Univariate logistic regression analysis indicated that scan time, PSA doubling time, and the absolute increase in PSA over three months were not significant factors affecting the positive predictive value. ***Conclusion:*** Compared to conventional CT/MRI scans, ^{18}F-PSMA-137 PET/CT demonstrates higher sensitivity and specificity for preoperative diagnosis of pelvic LNM in PCa. It

also demonstrates high sensitivity and positive predictive value in diagnosing patients with suspected recurrence, warranting further large-scale studies for validation.

Aim/Introduction: Prostate cancer is a leading cause of cancer-related mortality in elderly men. This study evaluates the clinical utility of hybrid PET/MR imaging, combining prostate-specific membrane antigen-targeted positron emission tomography (PSMA-PET) and diffusion-relaxation correlation spectroscopy imaging (DR-CSI), to enhance the diagnostic accuracy and risk stratification of prostate cancer. ***Materials and Methods:*** 31 patients with pathologically confirmed prostate cancer underwent ^{18}F-PSMA PET/MR examination (uPMR890, United Imaging Healthcare; 3.7 MBq/kg injection). DR-CSI constructed the T2-D spectrum from voxel-wise MRI signals, defining six compartments using T2 = 50 ms, D = $1\times10^{-3}/2\times10^{-3}$ mm^2/s as thresholds, with signal proportion ratio (f_a-f_f) of each compartment calculated via the integration. Group differences in the maximum standardized uptake value (SUV_{max}), the mean standardized uptake value (SUV_{mean}), and f_a-f_f were compared between the lesion and normal prostate tissue. Spearman correlation analyses were applied to explore the relationship between different imaging parameters and clinical information, including PSA concentration and Gleason score. The receiver operating characteristic (ROC) curve evaluated the diagnostic performance of PSMA PET and DR-CSI, and their combination in predicting high-risk (Gleason > 7) and medium/low-risk (Gleason <= 7) groups of prostate cancer. ***Results:*** Comparative analysis between lesion and normal prostate tissue revealed statistically significant differences in SUV_{max} ($p < 0.0001$), SUV_{mean} ($p < 0.0001$), and f_d ($p = 0.0206$). Correlation analysis demonstrated significantly positive association between SUV_{max} ($r = 0.5134$, $p = 0.0031$) and SUV_{mean} ($r = 0.4446$, $p = 0.0122$) of the lesion were with the PSA concentration, while f_d ($r = -0.3712$, $p = 0.0398$) exhibited significant negative correlation with PSA. Notably, f_a ($r = 0.3755$, $p = 0.0374$) and f_e ($r = 0.3763$, $p = 0.0369$) showed significant positive correlation with the Gleason score. ROC curve analysis showed that the areas under the curve (AUC) of SUV_{max}, f_a+f_e, and SUV_{max}+f_a+f_e in predicting high-risk and medium-low risk groups of prostate cancer were 0.543 (95% CI: 0.331-0.754), 0.709 (95% CI: 0.517-0.902), and 0.718 (95% CI: 0.527-0.909), respectively. ***Conclusion:*** The integration of ^{18}F-PSMA PET and DR-CSI provides complementary information, significantly enhancing diagnosis and risk stratification in prostate cancer. The multimodal ^{18}F-PSMA PET/MR approach shows considerable promise for optimizing clinical decision-making and personalized therapy. Future large-scale prospective studies are warranted to validate the clinical utility of this imaging paradigm in prostate cancer management.

EP-0387

Value of Prostatic Tumor Volume and Prostatic tumor Uptake on 18F-DCFPyL PSMA-PET/CT as Predictors of Lymph Node and Metastatic Involvement in the Initial Staging of Intermediate-High Risk Prostate Cancer.

X. Guarnizo Poma, *A. Gómez Grande, P. Zaragoza-Ballester, S. Angiolillo Grau, E. López Llobet, B. Manzarbeitia Arroba, M. Áviles Jurado, R. García Delgado, P. Sarandeses Fernández, R. Sopeña Sutil, M. Tabuenca Mateo;*
Hospital Universitario 12 Octubre, Madrid, SPAIN.

Aim/Introduction: To evaluate the prostatic tumor volume (PSMA-TV) and prostatic tumor uptake (PSMA-LTU) using 18F-DCFPyL PSMA-PET/CT in prostate cancer staging as predictive factors for regional lymph node and distant metastatic involvement, as well as their association with clinical parameters and risk stratification scales. ***Materials and Methods:*** Patients diagnosed with intermediate and high-risk prostate cancer who underwent initial staging with 18F-DCFPyL PSMA-PET/CT between August-2024 and April-2025 were included. We collected baseline clinical and histopathological data. Risk classification scores were calculated according to NCCN and EAU guidelines and miTNM was based on PROMISE V2 criteria. PSMA-TV and PSMA-LTU values were calculated using LIFEx software v7.7.0. Statistical analysis was performed using R software, v4.3.3. ***Results:*** 71 patients were analyzed (mean age of 69.1±7.82 years). The median of basal PSA was 14ng/ml (range: 3.4-98.4). Regarding Gleason score, 40.8%(n=29) presented Gleason 9, 38% (n=27) Gleason 8, 18.3%(n=13) Gleason 7, and 2.8% (n=2) Gleason 10. According to NCCN classification, 54.9% (n=39) were categorized as high risk, 33.8%(n=24) as very high risk, and 11.3%(n=8) as intermediate risk. PSMA-PET/CT staging identified lymph nodal involvement (N+) in 32.4% (n=23) and metastatic disease (M+) in 21.1% (n=15). A significant correlation was observed between PSMA-TV and PSMA-LTU with PSA levels (rho=0.34, p<0.001 and rho=0.48, p<0.001, respectively). No significant correlations were found between PSMA-TV or PSMA-LTU and Gleason score, ISUP grade, or risk classifications (p>0.05). Patients with N+ showed higher levels of PSMA-TV and PSMA-LTU compared to N- (9.26±11.12cm^3 vs 2.91±4.24cm^3, p<0.001 and 86.83±112.01 SUV·cm^3 vs 20.42±30.73 SUV·cm^3, p<0.001, respectively). Similarly, M+ patients also presented higher PSMA-TV and PSMA-LTU values compared to M– (10.72±13.03cm^3 vs 3.67±4.57cm^3, p<0.001 and 146.90±107.95 SUV·cm^3 vs 22.01±35.30 SUV·cm^3, p<0.001, respectively). No significant differences were found in PSMA-TV or PSMA-LTU values according to local extension. ROC curves analysis demonstrated acceptable discriminative power for both parameters. For PSMA-TV, the AUC was 0.78 (95%CI: 0.66-0.91) for N+ and 0.74 (95%CI: 0.56-0.92) for M+, with cutoff values of 5.87cm^3 (sensitivity: 82.6%; specificity: 79.2%) and 6.11cm^3 (sensitivity: 84.6%; specificity: 74.1%), respectively. For PSMA-LTU, the AUC was 0.81 (95%CI: 0.69-0.93) for N+ and 0.80 (95%CI: 0.62-0.98) for M+, with cutoffs values of 55.92 SUV·cm^3 (sensitivity: 69.6%; specificity: 87.5%) and 64.92 SUV·cm^3 (sensitivity: 76.9%; specificity: 82.8%), respectively. ***Conclusion:*** PSMA-TV and PSMA-LTU demonstrated good predictive capability for nodal and distant metastatic involvement in the initial staging of intermediate to high-risk prostate cancer. Their incorporation may enhance initial risk stratification and guide therapeutic decision-making.

EP-0388

Role of Androgen Receptor Targeted Agents in high risk prostate cancer staging by PSMA PET/CT

M. Simo Perdigo, *I. Navales Mateu, J. Echeverri Diaz, S. Asadurova, C. Franco Monterroso, A. Hernandez Fructuoso;*
Hospital Universitari vall Dhebron, Barcelona, SPAIN.

Aim/Introduction: The aim of the study was to quantify the stage-shift with prostate-specific membrane antigen (PSMA) PET/CT imaging in the staging of high risk prostate cancer patients and

explore treatment implications. ***Materials and Methods:*** We analyzed a total of 106 high risk prostate cancer patients with a median age was 71 years (range 53-86). Median prostate-specific antigen was 11.7 ng/ml (PSA > 20ng/ml in 25.4%) and 51.9% had ISUP 5 or 4. The majority of patients had high-risk (89.6%) whereas very high risk disease was observed in 10.4%. All patients were studied with PSMA PET/CT and results were compare to conventional imaging including RMI (Bone scan was performed in 90 patients (84.9%), abdominal CT scan in 44%(n=41.5%) and RMI in104 (98.1%). Treatment decisions was assessed in weekly tumor board. ***Results:*** Primary tumor was visualized in all except two patients by PSMA PET/CT (Primary score 5 or 4 in 97.5%). In nodal pelvic staging, discordance between conventional imaging and PSMA-PET was achieved in 27.2% of them (Positive by PET and negative/equivocal by RMI in 20 patients and positive by RMI and negative by PET in 5). Bone scan was negative in 81 of patients (90%), positive in 6 (6.6%) and equivocal in 3 patients. No add value to PSMA PET/CT scan was observed since more extended disease was detected in 5 patients and no false negative was documented. In total, PSMA PET/CT detected metastases in 21.7% (n=23) of patients: Retroperitoneal/common iliac node chain infiltration in 12 (52%), bone metastases in 8 and extended disease in 2. Impact of PMSA PET-CT in the staging was 36,3%. Androgen deprivation therapy ± radiotherapy was the most selected treatment in this cohort of patients (78%). Only 17 patients (17.9%) were treated by radical prostatectomy plus lymphadenectomy. Androgen Receptor Targeted Agents were added in more than one third of all patients (35.7%). ***Conclusion:*** PSMA PET/CT showed superior performance in nodal and metastatic staging of prostate cancer than conventional imaging. No add value was found for bone scan versus PSMA PET/CT. PSMA findings had impact on treatment planning since 35.7% of all patients received androgen receptor targeted agents.

EP-0389

Stage Migration in Prostate Cancer: The Role of PSMA-PET in Identifying Oligometastatic Disease

F. Mattana[1], *V. Dragonetti*[1], *F. Ceci*[1], *S. Luzzago*[2], *V. Kasivisvanathan*[3], *S. Conlon*[4], *P. Castellucci*[5], *A. Farolfi*[5];
[1]IEO European Institute of Oncology, Nuclear Medicine, Milan, ITALY, [2]Department of Urology, IEO European Institute of Oncology IRCCS, Milan, ITALY, [3]British Urology Researchers in Surgical Training (BURST) Research Collaborative, London, UNITED KINGDOM, [4]Centre for Urology Imaging, Prostate, AI and Surgical Studies (COMPASS) Research Group, Division of Surgery and Interventional Sciences, University College London, London, UNITED KINGDOM, [5]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Oligometastatic disease (OMD) represents an intermediate disease state between localized and metastatic prostate cancer (PCa), where patients may still benefit from curative treatments. The prevalence of "de novo" metastatic disease detected by positron emission tomography (PET) with prostate specific membrane antigen (PSMA) in a real-world setting is still to be clarified. The primary aim was to compare the detection rates of OMD between PSMA-PET and conventional imaging (CI) in patients with intermediate- to high-risk PCa. ***Materials and Methods:*** This multicenter retrospective study included patients with intermediate- to high-risk PCa who underwent both PSMA-PET and CI (contrast-enhanced CT and bone scintigraphy) within four months. The primary endpoint was to compare the detection rates of OMD (defined as ≤3 metastatic) between PSMA-PET and CI. The secondary endpoint was to assess treatment changes prompted by PSMA-PET findings. ***Results:*** Data of 497 patients were collected, and 255 patients met inclusion/exclusion criteria for the primary endpoint analysis, and all were considered for the secondary endpoint. OMD was identified using PSMA-PET in 11.4% of patients (29/255), significantly higher than the 6.7% rate (17/255) with CI (p =0.040). Clinical management was changed in 36.5% (93/255) of cases, with 18.5% experiencing major changes (e.g., switching from curative therapy to systemic treatment) and 18.0% experiencing minor changes. ***Conclusion:*** This study highlights how conventional imaging may underestimates de novo metastatic prostate cancer. PSMA-PET improves staging accuracy in intermediate- to high-risk patients, influencing treatment decisions and supporting its inclusion in routine diagnostic pathways.

The Potential Utility of PSMA PET/CT in Prostate Cancer Biochemical Failure - A Global Retrospective Cohort Study

B. Miles[1], *Q. Oza*[2], *J. Mackey*[3], *U. Oza*[1];
[1]Baylor University Medical Center, Dallas, TX, UNITED STATES OF AMERICA, [2]Greenhill High School, Dallas, TX, UNITED STATES OF AMERICA, [3]West Virginia University, Dallas, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Biochemical failure, marked by rising PSA levels after radical prostatectomy without evidence of metastatic disease, affects some early-stage prostate cancer patients. According to NCCN guidelines, salvage external beam radiation therapy (EBRT) is recommended for patients with a life expectancy greater than five years. PSMA PET-CT has shown promise in detecting recurrences at lower PSA levels, helping identify candidates for salvage therapy. This study evaluates how PSMA PET-CT influences the decision to administer pelvic salvage radiation therapy for prostate cancer patients with biochemical recurrence. ***Materials and Methods:*** Following the STROBE guideline, we used the TriNetX Research Network, comprising over 134 million deidentified medical records. We included prostate cancer patients (ICD-10: C61) who had undergone radical prostatectomy (CPT: 55866) and reached a PSA nadir <0.1 ng/mL. Patients were excluded if they had prior IMRT (CPT: 77338) or known skeletal metastases (ICD-10: C79.51). Eligible patients had a PSA >0.2 ng/mL at least six months post-prostatectomy. The cohort was divided into two groups based on exposure to PSMA PET-CT (CPT: 78815). Propensity score matching was applied, balancing age, race, and ethnicity, yielding 715 patients per group. The primary outcome was receiving IMRT within three months of biochemical failure. ***Results:*** Out of 1,430 patients, 178 (24.9%) in the PSMA PET-CT group received salvage radiation therapy, compared to 90 (12.6%) in the non-PSMA group. PSMA PET-CT was associated with a significantly higher likelihood of receiving salvage radiation therapy (RR 1.99, 95% CI: 1.57-2.49, P < 0.0001). ***Conclusion:*** Our study demonstrates that PSMA PET-CT nearly doubles the likelihood of receiving salvage radiation therapy after radical prostatectomy. However, limitations exist. The study relies on retrospective data, which can introduce biases. Despite matching, unmeasured factors like PSA kinetics and comorbidities may confound results. The predominantly North American dataset may also limit the generalizability to regions with less access to PSMA PET-CT. Additionally, the short-term follow-up prevents assessment of long-term outcomes like overall survival. Lack of stratification by key factors such as Gleason score and PSA doubling time may also impact findings. PSMA PET-CT appears effective in identifying candidates for salvage radiation therapy, but access remains limited, potentially affecting equitable

care. Further studies with diverse, international cohorts and longer follow-up are needed to validate the long-term impact of PSMA PET-CT on patient outcomes.

EP-0391

Evaluation of ^{18}F-JK-PSMA-7 PET/CT as new imaging tool for the detection of biochemically recurrent prostate cancer

M. Vanneste[1], *W. Deckers*[1], *K. Serdons*[1], *K. Van Laere*[1,2], *K. Goffin*[1,2]; *[1]Department of Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, [2]Nuclear Medicine & Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Prostate specific membrane antigen positron emission tomography with computed tomography (PSMA PET/CT) has replaced conventional imaging for localizing biochemically recurrent prostate cancer due to its superior accuracy (1). Several PSMA-based diagnostic tracers have been developed, some having pitfalls causing false negative or false positive results. The goal of this study was to evaluate the diagnostic value of the recently developed PSMA-tracer ^{18}F-JK-PSMA-7 (2) in patients with biochemically recurrent prostate cancer. ***Materials and Methods:*** In this retrospective study, the detection ratio of ^{18}F-JK-PSMA-7 PET/CT (according to PROMISE v2 (3)) and its correlation to the PSA value at the moment of the scan was evaluated in 116 patients with biochemically recurrent prostate cancer. In addition, tracer uptake was quantified in PSMA-positive lesions and normal organs (salivary glands, spleen, liver, bone, bloodpool, muscle) and related tumor-to-background ratios were evaluated. ***Results:*** ^{18}F-JK-PSMA-7 PET/CT was positive in 60 of 116 patients (52%; PSA mean 2.4 ng/mL, range 0.1-53.7). In these patients, a total of 211 PSMA-positive lesions were detected with a median of 2 lesions per patient. Patients with a positive PSMA PET/CT scan had a significant higher PSA value than patients with a negative scan (3.5 vs 1.1; p = 0.03). The detection ratio increased with increasing PSA values (39% at PSA<0.2 ng/mL - 83% at PSA>10 ng/mL). Lymph node metastases were detected in 55% of patients (37.9% of lesions, 80/211), followed by bone metastases in 33% of patients (48.3% of lesions, 102/211), local recurrences in 22% of patients (6.2% of lesions, 13/211) and visceral metastases in 15% of patients (7.6% of lesions, 16/211). Salivary glands presented with the highest physiological uptake (SUV_{mean} 15.1±4.3 (mean±SD)), followed by liver (SUV_{mean} 9.6±2.0 and spleen (SUV_{mean} 6.6±2.3). In the current cohort, bone metastases showed the highest TBR. ***Conclusion:*** ^{18}F-JK-PSMA-7 PET/CT showed a good detection ratio in biochemically recurrent prostate cancer, with increasing values at higher PSA value at the moment of the scan. ***References:*** (1) Hofman MS et al. Hospital Universitario de Bellvitge, L'Hospitalet de Llobregat, SPAIN, [5]Servicio de Radiología. Hospital Germans Trias i Pujol, Badalona, SPAIN, [6]Servicio de Anatomía Patológica. Hospital Germans Trias i Pujol, Badalona, SPAIN.*

Aim/Introduction: The aim of this bicenter prospective study is to evaluate the impact of a combined ^{18}F-PSMA protocol with pelvic PET/MRI and whole-body PET/CT in the selection of patients for focal therapy (FT) in radiorecurrent prostate cancer. ***Materials and Methods:*** Twenty-nine patients with prostate cancer recurrence after radiotherapy ± electroporation (median PSA: 2.2 ng/ml, range 0,64-3,56; median time to recurrence: 5.5 years; range 1,3-21) were studied. All patients underwent selective pelvic PET/MRI acquisition 90 minutes post-injection of ^{18}F-PSMA-1007 and subsequent skull-to-midthigh PET/CT acquisition 120 minutes post-injection. Patients with exclusively local disease eligible for focal treatment were summited to systematic and targeted biopsies. Agreement between PET, MRI and PET/MRI were calculated (Kappa) and related to pathological anatomy (PA). Impact on therapeutic management attributable to this new PET protocol was also calculated. ***Results:*** Per-patient analysis: Positive test in 27/29 patients (93%, 22 exclusively local recurrence eligible for focal treatment; 7% non-eligible due to locoregional (1 patient) or distant (4 patients) dissemination. Of the 27 patients with positive test, 6 are awaiting biopsy, 1 died of unrelated causes, 1 refused biopsy. Therapeutic management changed in 5 of the remaining 19 patients (26%) due to findings exclusive to PET (4 due to lymphatic spread, 1 due to PSMA-RADS 4 prostate lesion not identified by MRI). Per-lesion analysis: Agreement between PET and MRI was found in 21 patients (Kappa 0,28) and 23 in-site lesions (Kappa 0,19). At this moment, biopsy results are available for 15/22 patients with local recurrence (16 biopsied lesions: 15 detected by MRI; 16 by PET). MRI-PA agreement: 11/15 (73%). PET-PA agreement: 12/16 (75%). PET/MRI-PA: 12/16 (75%). ***Conclusion:*** This new PET protocol combining pelvic PET/MRI and whole-body PET/CT helped to select recurrent prostate cancer patients for focal therapy, changing therapeutic management in 26% of the patients. High agreement between PET/MRI to histopathology was demonstrated.

EP-0393

PSMA PET/CT for the detection of prostate cancer (PCa) biochemical recurrence (BCR) after primary radiation therapy (RT): is it time to review the Phoenix criteria?

C. Vallone[1,2], *P. Guglielmo*[2,3], *C. Franzese*[2,4], *R. Lucchini*[4], *R. Mazzola*[2,5], *J. Jandric*[6], *M. Rodari*[6], *G. Di Grigoli*[6], *M. Marenco*[6], *S. Del Vecchio*[1], *L. Evangelista*[2,6]; *[1]Department of Advanced Biomedical Sciences, University of Napoli, Napoli, ITALY, [2]Department of Bioscience, Humanitas University, Pieve Emanuele, Pieve Emanuele (MI), ITALY, [3]Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY, [4]Radiation Oncology Unit, IRCCS Humanitas Cancer Center, Rozzano (MI), ITALY, [5]Radiation Oncology Unit, Humanitas Gavazzeni, Bergamo, ITALY, [6]Nuclear Medicine Unit, IRCCS Humanitas Cancer Center, Rozzano (MI), ITALY.*

Aim/Introduction: RT is a cornerstone of curative treatment for PCa. BCR after RT is defined by the Phoenix criteria as a PSA rise of ≥ 2.0 ng/mL above the nadir. However, PSMA PET/CT can detect recurrences at lower PSA levels. Our primary aim was to assess the detection rate of PSMA PET/CT in patients who received primary RT and subsequently experienced a PSA elevation below the Phoenix threshold. Secondary aims were to: 1) describe the anatomical patterns of recurrence, 2) perform a riskstratified analysis of positive findings and 3) determine how PSMA PET/CT might influence clinical decisionmaking. ***Materials and Methods:*** We conducted a retrospective, observational, multicenter analysis of PCa patients treated with curativeintent RT who underwent PSMA PET/CT for rising PSA—below the Phoenix threshold—

between September 2020 and August 2023. We included only those patients who had not received any prior treatment for recurrent disease. Positive PSMA PET/CT scans were classified according to the PROMISE score, and risk stratification was performed using D'Amico criteria. Clinical decisionmaking data were extracted from patient charts. A nonparametric statistical analysis was employed to compare distributions across the various subsets (MedCalc® software). ***Results:*** Fiftyfour patients were included (median age 78 years, range 57-89). The overall PSMA PET/CT detection rate was 68.5% (n=37/54). Of those with positive scans, 81% (n=30/37) were oligometastatic and 19% (n=7/37) were multimetastatic. According to the PROMISE score, 24% (n=9/37) had local recurrence, 27% (n=10/37) nodal disease, 8% (n=3/37) boneonly metastases, and the remainder had multiple sites of involvement. By D'Amico risk classification, 83.9% (26/31) of unfavourable intermediate/highrisk patients had a positive PET, compared with 45.8% (11/24) of low/favourable intermediaterisk patients (chi squared, p<0.05). Followup data were available for 48 patients (89%). In 92% (n=44/48), PET findings guided therapy choice: 97% (n=32/33) of PETpositive patients received additional treatment (hormonal therapy, RT, or chemotherapy), whereas 80% (n=12/15) of PETnegative patients were managed with watchful waiting (chi-square, p<0.001). ***Conclusion:*** This study shows that PSMA PET/CT detects PCa recurrence in about 70% of patients with PSA rises below the Phoenix threshold. By identifying the disease at an earlier stage, patients may be eligible for curative local treatment and receive a personalized therapeutic approach. ***References:*** DOI: 10.1016/j.euo.2024.09.015.

EP-0394

PROMISE V.2. Staging with a Novel 18F-Piflufolastat PET/CT Protocol for the Detection of Prostate Cancer Recurrence

M. Romero, *M. Cornide Carvallo, M. Zapardiel Martinez-Falero, M. Vaillant Lopez, A. Berardinelli Isea, P. Daudén Onate, G. Cuesta Domingo, R. Couto Caro, M. Nieves Cabrera;*
HCSC, Madrid, SPAIN.

Aim/Introduction: To assess the value of a novel 18F-Piflufolastat PET/CT protocol aimed at minimizing urinary excretion artifacts and evaluating potential modifications in TNM staging according to PROMISE V2 criteria. ***Materials and Methods:*** A retrospective study was conducted on patients with biochemical recurrence of prostate cancer who underwent 18F-Piflufolastat PET/CT between February 2024 and January 2025. The protocol included radiotracer injection under camera with dynamic pelvic imaging from 0 to 5 minutes post-injection. This was followed by a resting period of 90 minutes, during which oral contrast and 50 ml of non-ionic intravenous contrast were administered 10-15 minutes prior to delayed imaging acquisition. An additional 50 ml of i.v. contrast was administered during the delayed scan, which included inspiratory chest CT and standard whole-body imaging. ***Results:*** A total of 100 patients were included, with a mean age of 71.26 years (range 45-86; SD 8.4). Of these, 76 had previously undergone radical prostatectomy, while 24 had received radical-intent radiotherapy and/or hormone therapy. The median PSA at recurrence was 0.8 ng/mL (range 0.2-8.8; SD 1.1). PET/CT was positive in 61% of patients, leading to TNM PROMISE V2 modification in all positive cases. The positivity rate was 48% for PSA 0.2-0.5 ng/mL, 83.3% for PSA 0.5-1.0 ng/mL, 81.25% for PSA 1.0-1.5 ng/mL, 50% for PSA 1.5-2.0 ng/mL, and 100% for PSA >2 ng/mL.Local recurrence was identified in 30% of patients (18% with isolated local recurrence), pelvic nodal involvement in 27% (21 N1 and 6 N2), extrapelvic nodal metastases (miM1a) in 11%, osseous metastases (miM1b) in 5 patients, and pulmonary metastases (miM1c) in 3 cases. One patient with a negative PET/CT scan was diagnosed with invasive breast adenocarcinoma. The positivity rate was higher in patients treated with radical radiotherapy compared to those with prostatectomy (72.7% vs. 56.6%).This protocol enhanced detection of local recurrence (e.g., ruled out bed recurrence in 4 cases; identified recurrence in seminal vesicle [3], vesicourethral anastomosis [1], and adjacent to surgical clips [1]) and pelvic nodal metastases (N1-N2 in 4 cases; M1a in 4 cases). ***Conclusion:*** Early imaging with 18F-Piflufolastat PET/CT improves detection of local recurrence even at low PSA levels, minimizing urinary excretion artifacts. It led to PROMISE V2 TNM stage modifications in all positive cases.

EP-0395

Prognostic Value of Total Tumor Volume Derived from ^{18}F-FSU-880 PSMA-PET Imaging in Prostate Cancer Patients

R. Nakamoto, *Y. Shimizu, Y. Nakamoto;*
Kyoto University Hospital, Kyoto, JAPAN.

Aim/Introduction: There has been growing interest in the prognostic value of quantitative parameters derived from prostate-specific membrane antigen (PSMA)-targeted PET imaging in patients with prostate cancer. This study aimed to evaluate the prognostic capability of quantitative values derived from PSMA-PET images acquired using ^{18}F-FSU-880, Japan's first F-18 labeled PSMA targeting agent developed by our group. ***Materials and Methods:*** We retrospectively analyzed 69 prostate cancer patients who underwent ^{18}F-FSU-880 PET/CT between February 2018 and April 2021 following biochemical recurrence (BCR). Of the initial 76 patients, 7 were excluded due to loss to follow-up at other institutions. Seven clinical parameters including PSA doubling time (PSADT), and nine PSMA-PET parameters including Total Tumor Volume (TTV) and DmaxVox (distance between the two lesions furthest apart using the two outermost voxels) were assessed for their association with prognosis as of March 2025. Quantitative PET metrics were calculated using the open-source software LIFEx v7.80. Lasso regression and Firth's penalized Cox proportional hazards model were applied using R software (version 4.3.2). Model performance was evaluated using the concordance index (c-index), with 95% confidence intervals calculated via 1000 bootstrap resamples. ***Results:*** The median follow-up period was 49 months (range: 7-84 months), during which 12 patients died. Lasso regression was applied to select prognostic variables, and Primary treatment (surgery, radiotherapy, or hormone therapy), Disease status at PET/CT (BCR, conventional non-metastatic CRPC [nmCRPC], metastatic CRPC [mCRPC], or metastatic hormone-sensitive prostate cancer [mHSPC]), PSADT, TTV, and DmaxVox were retained for further analysis. In the Firth Cox model, TTV emerged as a significant prognostic factor (hazard ratio 1.0199; 95% CI: 1.0019-1.0383; p = 0.0324), while PSADT and DmaxVox were not statistically significant (p = 0.1899 and 0.1905, respectively). The model showed strong overall fit, with a likelihood ratio test p-value of 0.00086 and Wald test p-value of 0.00081. The c-index was 0.8144 (95% CI: 0.7045-0.9091), indicating good predictive accuracy. ***Conclusion:*** Total Tumor Volume (TTV) derived from PSMA-PET images using ^{18}F-FSU-880 was identified as a significant independent prognostic factor in prostate cancer. TTV, obtained from our institution's proprietary PSMA-PET imaging, may serve as a clinically useful predictor for guiding future therapeutic strategies. ***References:*** 1:Saga T, et al. EP-0396

VAULT: Value of Long-Axial Field-of-View Tomography in [68Ga]Ga-PSMA-11 PET/CT for the Management of Biochemical Recurrent Prostate Cancer

A. Di Giorgio[1], *M. Di Franco*[1], *M. Rapa*[1], *F. Monastero*[1], *M. Assenza*[2], *L. Bianconi*[3], *C. Nanni*[3], *P. Castellucci*[3], *A. Farolfi*[3], *S. Fanti*[1,3];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Professional Development and Implementation of Research in Health Professions Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Biochemical recurrence(BCR) affects a significant proportion(20-50%) of localized prostate cancer(PC)

patients post-radical prostatectomy(RP), often with conventional imaging failing to detect early recurrences at low PSA levels. [68Ga]Ga-PSMA-11-PET/CT(PSMA-PET/CT) has demonstrated high sensitivity and specificity in this setting. This study aims to compare the diagnostic capability of long-axial field-of-view(LAFOV) PET/CT (uEXPLORER) against conventional digital short-axial field-of-view(SAFOV) PET/CT systems using [68Ga]Ga-PSMA-11 in early BCR PC patients. A secondary objective is to evaluate its potential impact on therapeutic decision-making and clinical management in this specific cohort. ***Materials and Methods:*** Single-center prospective study consecutively enrolling male patients referred to our institution between October 2024 and March 2025 for PSMA-PET/CT due to BCR of PC (defined as PSA>0.2ng/mL post-RP, according to EANM/EAU guidelines) who consented to undergo dual PET/CT scanning with both SAFOV and LAFOV systems(CE AVEC: 598/2024/Oss/AOUBo). Paired SAFOV and LAFOV scans were interpreted according to PROMISE criteria v2. The total number and sites of lesions identified on each scan were recorded. Per-patient and per-lesion analyses were conducted. Follow-up data were collected. ***Results:*** A total of 62 patients(median age 75 years;IQR 65-75) with BCR were enrolled and underwent paired SAFOV and LAFOV PSMA-PET/CT, resulting in 124 acquisitions. The median PSA level at the time of PSMA-PET/CT was 0.45ng/mL(IQR 0.27-1.15). Forty-one out of 62(66%) SAFOV scans were reported as negative and 21/62 (34%) as positive. Twenty-six out of 62(42%) LAFOV scans were negative and 31/62(50%) were positive. In 5/62(8%) cases, SAFOV was negative while LAFOV was equivocal: in 2/5(40%) due to doubtful disease localization in the prostatic bed near physiological high urinary activity, in 3/5(60%) due to focal rib uptakes without clear anatomical correlates on CT images, suspicious for unspecific bone uptake(UBU). Overall positivity/negativity concordance between the two scan types was observed in 35/62(56.5%) cases(Cohen's kappa=0.387; agreement=69%). The total number of positive lesions detected was 40/83(40%) on SAFOV acquisitions and 83/83(100%) on LAFOV acquisitions(weighted Cohen's kappa=0.67;agreement 61%), with all lesions identified on SAFOV also being detected on LAFOV. In 18/62(29%) patients, findings identified on LAFOV but not on SAFOV PET/CT impacted patient management, leading to a therapeutic change in all 18 cases. ***Conclusion:*** In patients with BCR of PC undergoing PSMA-PET/CT, LAFOV PET acquisitions demonstrated a higher positivity-rate compared to conventional SAFOV acquisitions. The enhanced diagnostic performance of LAFOV PET led to changes in clinical decision-making in a significant proportion of cases, suggesting a potential impact on patient management strategies in this setting.

EP-0397

[18F] DCFPYL PET/CT in Prostate Cancer Patients Candidates for Salvage Radiotherapy for Very Low Biochemical Recurrence ≤0.25 ng/mL after Radical Prostatectomy: Impact on Restaging and Therapeutic Strategy.

N. Alvarez Mena, *J. Gómez Hidalgo, F. Sebastián Palacid, B. Pérez López, C. Riola Parada, R. Ruano Pérez;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Recent multicenter studies have shown that in patients with prostate cancer with biochemical recurrence after radical prostatectomy, delaying salvage radiotherapy until a PSA level above 0.25 ng/mL is reached significantly increases the risk of mortality, especially if they have a high-risk factor (pT3/4 or Gleason score 8-10). Therefore, our objective is to assess the clinical impact of [18F]DCFPYL PET/CT on very low biochemical recurrence (≤0.25 ng/mL) in prostatectomy patients who are candidates for salvage radiotherapy. ***Materials and Methods:*** Prospective study of 33 patients (mean age 66.06 ± 6.29 years) with very low biochemical recurrence (≤0.25 ng/mL) after radical prostatectomy who underwent [18F]DCFPYL PET/CT prior to salvage radiotherapy. Variables such as PSA level (ng/mL), D'Amico risk classification and ISUP grade, [18F]DCFPYL PET/CT detection capacity, and recurrence uptake degree (SUVmax and PSMA-RADS) were analyzed. In addition, disease restaging and final therapeutic approach were evaluated according to the [18F] DCFPYL PET/CT result. ***Results:*** Mean level of PSA was 0.22±0.02 ng/mL (range 0.17-0.25). Up to 61% (14/23) of patients in the high-risk group (ISUP grades 4-5) had a positive PET scan for recurrence (SUVmax up to 25.41 and PSMA-RADS 5), leading to a change in therapeutic management in 12 of them: 7 with EBRT of the prostate bed + regional lymph nodes for N1 and 5 with ADT + ARPI + docetaxel for M1a/b. In the intermediate-risk group (7 patients with ISUP grades 2-3), PET detected recurrence in 43% (3/7), with SUVmax up to 22.25 and PSMA-RADS 4-5. Two of these patients had recurrence outside the prostate bed (1 N1 and 1 M1a due to pararectal lymph node recurrence). Therefore, these lymph node regions were included in the EBRT planning. The three patients in the low-risk group (ISUP grade 1) had a negative PET result and were candidates for salvage EBRT of the prostate bed only. Finally, Spearman's correlation showed a significant correlation between the D'Amico risk classification and the degree of recurrence uptake (PSMA-RADS), with r=0.9; p<0.001. ***Conclusion:*** [18F] DCFPYL PET/CT has adequate detection capacity in patients with intermediate and high-risk prostate cancer who are candidates for salvage radiotherapy due to biochemical recurrence after radical prostatectomy, even with very low PSA levels (≤0.25 ng/mL). The more widespread incorporation of this diagnostic tool into clinical practice suggests it could be useful in reducing morbidity and mortality in these patients by leading to a change in therapeutic strategy in up to 50% of them.

EP-0398

A Comparative Analysis of PSMA-PET/CT and Whole-Body MRI for Staging and Restaging in Patients with Prostate Cancer

E. Greco[1], *L. Bianchi*[2], *C. Gaudiano*[3], *B. Corcioni*[3], *C. M. P. Sgro*[1], *C. Mignogna*[4], *B. Renzetti*[5], *A. Cattabriga*[3], *R. Schiavina*[2,4], *E. Brunocilla*[2,4], *C. Mosconi*[3,5], *R. Mei*[6], *P. Castellucci*[6], *S. Fanti*[6,1], *A. Farolfi*[6];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Division of Urology, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [5]*Department of Radiology, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [6]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Systemic staging of high-risk prostate cancer (PCa) patients and restaging of patients with biochemical recurrence (BCR) after radical treatment and low PSA values can be done using PSMA-PET. Whole-body MRI (wbMRI) is an accurate technique for the identification of PCa local and distant disease but there is no strong recommendation for its use in daily clinical practice. This study's aim is to compare PSMA-PET and wbMRI in detecting metastasis in PCa patients before radical or systemic treatment (staging) and after radical therapy in patients with BCR (restaging). ***Materials and Methods:*** We conducted a single-center prospective study, enrolling PCa patients who underwent both PSMA-PET and wbMRI in a 2-months' timeframe for staging or restaging purposes. No treatments for PCa were allowed between the two imaging techniques. The images were independently reviewed by two nuclear medicine physicians for PET scans and two radiologists for wbMRI. The concordance of both techniques in the detection of local or residual disease (T/Tr), local (N) and distant (M1a) lymph node, bone (M1b) and visceral (M1c) metastasis was assessed with Cohen's kappa. ***Results:***

Overall, 114 patients were enrolled (median age 69 years), 81/114 (71%) with newly diagnosed PCa and 33/114 (29%) with BCR. PSMA-PET and wbMRI were performed within a median time of 16 days (IQR 8-28). Overall, PSMA-PET was positive for PCa in 90/114 (79%) patients and wbMRI in 87/114 (76%). PSMA-PET compared to wbMRI led to up-staging in 6% (7/114) and resulted in down-staging in 3% (4/114) patients. Using Cohen's k for T/Tr, N, M1a and M1b, the concordance between the two techniques (n=114) was 0.84, 0.72, 0.82 and 0.59, respectively. No patients showed visceral metastasis (M1c). ***Conclusion:*** Both PSMA-PET and wbMRI demonstrated almost perfect agreement in detecting local disease (T) and distant lymph nodes metastasis (M1a), substantial agreement for the detection of local lymph nodes involvement (N), while moderate agreement was observed for bone disease (M1b).

EP-0399

Prediction of Occult Lymph Node Metastasis Using PSMA PET/CT-Based Radiomic Model in Clinical N0 Prostate Cancer

T. Li*;*
The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Occult lymph node metastasis (OLNM) significantly impacts treatment planning and prognosis in prostate cancer (PCa). This study aimed to develop and validate a PET radiomics-based model derived from primary prostate lesions on [18F]-PSMA-1007 PET/CT to predict OLNM in clinical N0 prostate cancer patients undergoing radical prostatectomy and extended pelvic lymph node dissection (ePLND). ***Materials and Methods:*** A total of 227 patients with histologically confirmed prostate cancer who underwent preoperative [18F]-PSMA-1007 PET/CT followed by radical prostatectomy and ePLND were retrospectively included. Patients with visually negative lymph nodes on PET imaging but pathologically confirmed lymph node metastasis were classified as having OLNM. Radiomics features were extracted from the primary prostate tumors using LIFEx software. A predictive radiomics signature was developed using the least absolute shrinkage and selection operator (LASSO) regression. Model performance was evaluated by the area under the receiver operating characteristic curve (AUC), and clinical utility was assessed through decision curve analysis (DCA). ***Results:*** Out of 227 clinically N0 patients, 34 were found to have occult nodal metastases on final pathology.The developed radiomics signature consisted of several robust PET radiomics features that effectively distinguished patients with OLNM. The radiomics-based model demonstrated good predictive performance with an AUC of 0.81 in the training cohort and 0.77 in the validation cohort. Decision curve analysis confirmed significant clinical benefit of the radiomics model over conventional clinical factors alone. ***Conclusion:*** Our study successfully developed a [18F]-PSMA-1007 PET-based radiomics model to non-invasively predict occult lymph node metastasis in prostate cancer patients. This radiomics approach provides a valuable tool for better preoperative risk stratification, potentially reducing unnecessary lymph node dissections and guiding personalized therapeutic strategies.

Development and validation of a Nomogram forpredictingpositive [^{99m}Tc]Tc-HYNIC-PSMASPECT/CT in patients withbiochemically recurrent prostate cancer after radical prostatectomy

B. Li*, X. Wu, Y. Yu, Y. Gao;*
Department of Nuclear Medicine, Henan Key Laboratory of Novel Molecular Probes and Clinical Translation in Nuclear Medicine, Henan Provincial People's Hospital; Zhengzhou University People's Hospital, Henan University People's Hospital, Zhengzhou, CHINA.

Aim/Introduction: Prostate cancer (PCa) recurrence following radical prostatectomy (RP) poses significant clinical challenges, with biochemical recurrence (BCR) serving as a crucial indicator for subsequent metastasis. This study aims to develop and validate a nomogram predicting the accuracy of [^{99m}Tc]Tc-HYNIC-PSMA SPECT/CT imaging positivity in PCa patients experiencing BCR post-RP. ***Materials and Methods:*** A retrospective cohort study included 192 patients meeting inclusion criteria from Henan Provincial People's Hospital & Zhengzhou University People's Hospital, with an external validation cohort of 40 patients from Henan Cancer Hospital. Multivariate logistic regression and LASSO analysis identified three independent predictors (ISUP grade group, PSA prior to PSMA SPECT/CT, and PSA doubling time). These predictors were integrated into a nomogram, whose performance was assessed using ROC analysis, calibration curves, and decision curve analysis (DCA). ***Results:*** The overall detection rate of [^{99m}Tc] Tc-HYNIC-PSMA SPECT/CT imaging was 43.5% (n = 101), with varying sites of recurrence observed. ISUP grade group (OR: 20.35; 95% CI: 4.64-89.25), PSA prior to PSMA SPECT/CT (OR: 2.86; 95% CI: 1.84-4.44), and PSA doubling time (OR: 0.03; 95% CI: 0.01-0.16) were independently associated with positivity on PSMA SPECT/CT imaging. The nomogram exhibited robust predictive accuracy with AUCs of 0.960, 0.891, and 0.872 in the training, internal validation, and external validation cohorts, respectively. The best nomogram's cutoff was 40%. DCA demonstrated significant clinical net benefit, especially at higher threshold probabilities. ***Conclusion:*** This study introduces a novel nomogram predicting the likelihood of [^{99m}Tc] Tc-HYNIC-PSMA SPECT/CT imaging positivity in PCa patients with BCR post-RP. The nomogram enhances patient stratification and may optimize the selection of candidates for PSMA SPECT/CT imaging, thereby improving clinical decision-making and patient outcomes.

EP-0401

Can Tumour Burden On PET/CT With [18F]DCFPyL Predict Progression In Patients With Prostate Cancer Recurrence After Radical Treatment?

L. García Zoghby*[1], J. Bonilla Plaza[1], M. Cruz Montijano[1], M. Meneses Navas[1], S. Guzmán Ortiz[1], J. Moltalvá Pastor[1], I. García Megías[1], M. Amo Salas[2], A. García Vicente[1];*
[1]Hospital General Universitario de Toledo, Toledo, SPAIN, [2]Facultad de Medicina de la Universidad de Castilla-La Mancha, Ciudad Real, SPAIN.

Aim/Introduction: The objective was to analyse the associations between clinical and molecular imaging variables and progression-free survival (PFS) in patients with first biochemical recurrence (FBR) of prostate cancer (PCa) after radical treatment. ***Materials and Methods:*** We analysed patients with FBRPCa visualized in [18F]DCFPyL-PET/CT. Minimum follow-up: 36 months. ISUP grade group, recurrence risk classification, PSA kinetics, initial treatment and treatment after FBRPCa were the clinical variables collected. [18F]DCFPyL-PET/CT were visually assessed by two experienced nuclear medicine physicians independently and lesions segmentation was performed using aPROMISE platform. Molecular tumour burden variables: TNM, total molecular tumour volume (total_MTV), total tumour lesion activity (total_TLA) and total PSMA index (total_PSMAi). During follow-up, two consecutive PSA values ≥ 0.2 ng/ml after [18F]DCFPyL-PET/CT was considered as progression. We compared mean values by Mann-Whitney test. Kaplan-Meier method (qualitative variables) and Cox regression (quantitative variables) were used in survival analysis. ***Results:*** One hundred and seventeen patients were analysed (mean age: 69.5 years), 66.7% high risk. Initial treatment: 50 radical prostatectomy, 46 radiotherapy, 21 both. Progression was observed in 31/117 patients. Median follow-up after [18F]DCFPyL-PET/CT of 41 months. [18F]DCFPyL-PET/CT observed metastatic disease in 34.2%. Total_MTV, total_TLA and total_PSMAi mean values (± SD)

were 8.10 ± 17.32 ml, 42.15 ± 100.39, 15.03 ± 33.38, respectively. After [18F]DCFPyL-PET/CT, 60.68% (71/117) underwent androgenic deprivation therapy (ADT) ± androgen receptor targeted therapy (ARTT), median time: 28 months. Six patients underwent only surgery, 25 radiotherapy and in 15 patients follow-up was elected. Initial treatment (p=0.031), grade ISUP group (p=0.073) and treatment after FBRPCa (p=0.060) showed association with PFS. We observed significant differences in mean time under ADT ± ARTT between patients who progressed (16.82 ± 10.42 months) and did not progress (31.42 ± 12.42 months). No significant association was found between molecular tumour burden variables and PFS. ***Conclusion:*** No significant association was found between molecular tumour burden on [18F]DCFPyL-PET/CT and progression, probably due to high election of ADT ± ARTT and the sensitivity to the hormonal treatment of the patients in our analysis. Therefore, maybe an effort should be made to promote radical treatments in order to a more effectively assessment of the real diagnostic reach of molecular imaging in this context.

EP-0402

Possibility of 18F-PSMA-1007 PET/CT in patients with biochemical recurrence of prostate cancer after radical prostatectomy

M. Komarova*, A. Pronin, E. Davydova, O. Ryzhova, I. Amosova;*
N.N Blokhin National Medical Research Center of Oncology of the Russian Ministry of Health, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: to detect efficacy of 18F-PSMA-1007 PET-CT in patients with biochemical recurrence of prostate cancer after radical prostatectomy. ***Materials and Methods:*** 89 patients (mean age 68,23±7,97) were included in the study. All patients had the biochemical recurrence of prostate cancer - prostate-specific antigen (PSA) levels of greater than or equal to 0.2 ng/mL. The mean PSA level was 0,96 [0,42-2,19] ng/mL. We evaluated all lesions suggestive of recurrent prostate cancer including local recurrence, lymph node metastases, bone metastases, and other metastases. Quantitative analysis was based on the measurement of the SUVmax. ROC-analysis was used to determine the threshold PSA level at which the maximum sensitivity and specificity of 18F-PSMA-1007 PET/CT in detecting signs of tumor recurrence was achieved. Mann-Whitney test was used to compare median PSA level between patients with tumor lesions and negative results. ***Results:*** 70 patients (78,6 %) had 1 or more localized areas suggestive of recurrent prostate cancer. In 19 patients (21.4%) we couldn't determine the reason of the increase PSA level in the blood serum. In the group of patients with positive 18F-PSMA-1007 PET-CT the mean PSA level was 1,24 [0,59-2,97] ng/ml. The frequency of detection disease increased with increasing PSA level - in 19 patients with negative PET-CT results, PSA values were 0,30 [0,20-0,47] ng/mL versus 1,24 [0,59-2,97] ng/mL in patients with tumor lesions on PET/CT, p<0,0001. Based on ROC curve analysis, the appropriate PSA cut-off value to diagnose cancer lesions was 0,49 ng/mL (sensitivity of 80,00 % and specificity 84,2 %) with an area under the curve (AUC) of 0.894 (P<0.001). ***Conclusion:*** 18F-PSMA-1007 PET-CT demonstrated a high detection rate of tumor lesions for patients with biochemical recurrence after radical prostatectomy. A PSA cut-off value of 0,49 ng/mL was identified, providing a sensitivity of 80,00 % and a specificity of 84,2 % of 18F-PSMA-1007 PET-CT in detecting signs of tumor recurrence. ***References:*** 1. The impact of 18F-PSMA-PET/CT on clinical decision making in biochemically recurrent prostate cancer

C. A. Poulsen*[1], K. M. Buch-Olsen[1,2], M. H. Vilstrup[3], K. T. Pedersen[1], S. Hansen[4,2], M. H. A. Poulsen[5,6], P. C. Holdgaard[7], O. Gerke[1,2], M. G. Hildebrandt[1,2], J. Holm[1,2];*
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Clinical Research, Faculty of Health Science, University of Southern Denmark, Odense, DENMARK, [3]Department of Radiology and Nuclear Medicine, Esbjerg and Grindsted Hospital, University Hospital of Southern Denmark, Esbjerg, DENMARK, [4]Department of Oncology, Odense University Hospital, Odense, DENMARK, [5]Department of Urology, Esbjerg and Grindsted Hospital, University Hospital of Southern Denmark, Esbjerg, DENMARK, [6]Department of Regional Health Research, University of Southern Denmark, Odense, DENMARK, [7]Department of Nuclear Medicine, Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: Prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA-PET/CT) is currently the most accurate imaging modality for detecting recurrent prostate cancer (PCa). However, prospective data on its clinical impact on individualized treatment strategies remain limited. This cohort study prospectively evaluated how 18F-PSMA-PET/CT influences clinical decision-making in patients with biochemically recurrent PCa. ***Materials and Methods:*** Patients were prospectively included from the Region of Southern Denmark between January 2020 and January 2025, and discussed in a structured two-step multidisciplinary team (MDT) conference. An initial treatment decision was made based on conventional diagnostic workup - primarily Gleason score at initial diagnosis, current clinical performance, and prostate-specific antigen (PSA) level - while blinded to PSMA-PET/CT results. Subsequently, the [^{18}F]-PSMA-1007-PET/CT scan was unblinded, and a second MDT discussion was held. The final treatment plan, offered to the patients, was based on the second MDT evaluation. Changes in treatment strategy between the two MDT sessions were defined as the primary outcome. ***Results:*** A total of 249 men with suspected recurrent PCa, all previously treated with radical prostatectomy and presenting with rising PSA levels (mean PSA 1.13 µg/L), were included. PSMA-PET/CT imaging led to a change in treatment strategy in 67 patients (27%) compared to the initial decision. Of these, 50 patients (20.1%) were initially planned for curative-intent treatment. However, 35 (14.1%) were reclassified to non-curative treatment based on PSMA findings, five (2%) were shifted to an alternative curative modality, six (2.4%) required additional diagnostic workup, and four (1.6%) had findings suspicious for synchronous cancer. Among the 17 patients (6.8%) originally planned for watchful waiting or androgen deprivation therapy (ADT), five (2%) were reclassified for curative-intent treatment based on PSMA-PET/CT results, while 12 (4.8%) had their management altered to another treatment modality. ***Conclusion:*** This prospective, blinded cohort study demonstrates that 18F-PSMA-PET/CT decisively influences clinical management in patients with biochemically recurrent PCa. Treatment plans were altered in more than one in four patients, including both redirection from curative to non-curative strategies and vice versa. These findings highlight the pivotal role of PSMA-PET/CT in optimizing personalized treatment strategies and supporting informed clinical decision-making in recurrent PCa.

Short-term androgen deprivation therapy, ^{68}Ga-PSMA-11 binding potential and MR apparent diffusion restriction coefficient in hormone- sensitive, prostate cancer patients

O. Jonmarker[1], *A. Sanchez-Crespo*[1,2], *F. Jäderling*[1,3], *S. Carlsson*[1,2], *M. Olsson*[2], *C. Li*[1,4], *R. Axelsson*[1,2];
[1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Karolinska University Hospital, Stockholm, SWEDEN,* [3]*Capio S:t Görans Hospital, Stockholm, SWEDEN,* [4]*Södersjukhuset, Stockholm, SWEDEN.*

Aim/Introduction: In vitro and animal studies have shown that short-term androgen deprivation therapy (ADT) upregulates prostate specific membrane antigen (PSMA) expression in prostate cancer cell lines. Published prospective human clinical studies on the long- and short-term effect of ADT on diagnostic performance of ^{68}Ga-PSMA-PET are scarce and show contradictory results. PSMA upregulation appears heterogeneous but generally predominant in bone metastases of castration-resistant cancers compared to hormone-sensitive cancers.The aims of this study was to investigate the effect of short-term ADT on cellular changes in PSMA, lesion apparent diffusion restriction coefficient (ADC) and plasma prostate specific antigen (PSA) values in a cohort of hormone- sensitive, prostate cancer patients without bone metastases. ***Materials and Methods:*** Nine patients were included in the study. Participants underwent dynamic ^{68}Ga-PSMA- PET/MRI at baseline, after one, three and four weeks under ADT. PSA, calculated lesion binding potential of non-displaceable radioligand (BP_{ND}), standard uptake values (SUV) at 60 minutes post tracer administration, and the lesion ADC were determined at every imaging session. Linear mixed effect models were generated to investigate interactions of these variables during ADT. Agreement analysis between SUV metrics and dynamic PET derived BP_{ND} during ADT was also investigated. ***Results:*** Eight patients with a total of ten lesions showed a positive ^{68}Ga-PSMA uptake at baseline. Disease staging was not modified for any patient during ADT. All lesions showed a curvilinear trajectory in BP_{ND} changes from baseline with peak values within 7-21 days. 60% of these dynamic changes in PSMA receptor expression could be explained by the interactions between changes in ADC and plasma PSA from baseline and across time under ADT but with a complex nonlinear relationship. SUV metrics showed a poor agreement with BP_{ND}. ***Conclusion:*** Results suggest that short term PSMA upregulation across time in ADT could potentially be predicted which may be useful for individualising the timing for treatment with PSMA-binding radioligands and provides a rationale for further prospective studies in selected patients.

EP-0405

Long axial field-of-view 68Ga-PSMA PET-CT detects physiological uptake in nerve roots

L. Badawy[1], *S. Datta*[1], *T. Wagner*[1,2];
[1]*Royal Free London NHS Foundation Trust, London, UNITED KINGDOM,* [2]*Centre for Medical Imaging, Department of Imaging, University College London, London, UNITED KINGDOM.*

Aim/Introduction: Long-axial field-of-view (LAFOV) positron emission tomography-computed tomography (PET-CT) is a technological development with better sensitivity and signal-to-noise ratio than short-axial field-of-view (SAFOV).[1] Since installing the Siemens Vision Quadra PET-CT (Siemens Healthineers, Erlangen, Germany) at our centre in March 2024, we have observed ^{68}Ga-PSMA uptake in nerve roots exiting the neural foramina. We are the first to describe a formal comparison of uptake in the nerve roots of consecutive prostate cancer patients on the Siemens Quadra LAFOV PET-CT and the Siemens Biograph PET-CT. ***Materials and Methods:*** We conducted a retrospective study of 63 adult patients with confirmed prostate cancer who underwent ^{68}Ga-PSMA PET-CT at our institution on Siemens LAFOV Quadra PET-CT in 2024, and Siemens Biograph PET-CT in 2022. Baseline characteristic data were extracted from the electronic patient records and Radiology information system. PET-CT images were reviewed by two of the authors who assessed for evidence of nerve root radiotracer uptake. Intensity at each spinal level was visually measured on a scale of 0 to 4, representing no to intense uptake. Inter-rater agreement for nerve root intensity was assessed using Cohen's kappa. We summed the authors' nerve root radiotracer intensity ratings to form a new numerical variable called "total rater score" and calculated average maximum standardised uptake values (SUVmax). ***Results:*** We analysed data from 63 patients, 32 (51%) of which were scanned on the Siemens Quadra PET-CT. Baseline characteristics were similar between the two cohorts. Cohen's Kappa was 1.0 ($p<0.001$) for a positive finding of nerve root uptake. The total rater score was significantly higher at three spinal levels (cervical; lumbar; sacral) in the Quadra group than in the Biograph group (5.0 vs 4.0, $p=0.012$; 3.0 vs 1.0, $p=0.003$; 4.0 vs 0.0, $p<0.001$). Average SUVmax values were greater with the Quadra in the lumbosacral regions (2.3 vs 1.1; $p=0.008$) and were similar in the cervical spine ($p=0.700$). Two patients with large volume metastatic disease had reduced nerve root avidity. ***Conclusion:*** This is the first study to describe nerve root uptake at the neural exit foramina in prostate cancer patients scanned with ^{68}Ga-PSMA PET-CT, which was more prevalent and better visualised on the LAFOV Quadra PET-CT than on SAFOV. ***References:*** 1. Alberts I et al. Clinical performance of long axial field of view PET/CT: a head-to-head intra-individual comparison of the Biograph Vision Quadra with the Biograph Vision PET/CT. EP-0406

Explorative analysis on the role of the PRIMARY Score in PSMA PET-guided re-irradiation for recurrent prostate cancer

P. Guglielmo[1,2], *L. Di Cristina*[3,4], *C. Franzese*[1,3], *R. Mazzola*[4,5], *J. Jandric*[6], *L. Setti*[2], *L. Evangelista*[1,6];
[1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Milan, ITALY,* [2]*Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY,* [3]*Department of Radiotherapy and Radiosurgery, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [4]*Department of Biomedical Sciences, Humanitas University, Via Rita Levi Montalcini 4, Pieve Emanuele, Milan, ITALY,* [5]*Department of Radiotherapy, Humanitas Gavazzeni, Bergamo, ITALY,* [6]*Nuclear Medicine Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY.*

Aim/Introduction: Despite progress in locoregional treatments, local recurrence after curative radiotherapy (RT) for prostate cancer (PCa) remains frequent, with biochemical relapse occurring in nearly one-third of cases. The optimal management of RT failure is still under investigation. In recent years, re-irradiation (re-RT), either via brachytherapy or stereotactic body radiotherapy (SBRT), has gained traction. Advances in imaging, particularly PSMA PET, now integrated into guidelines for biochemical recurrence (BR), have improved localization of relapse and guidance of targeted treatments. The PRIMARY SCORE (PS), a 5-point scale for intraprostatic disease assessment via PSMA PET, is established for initial diagnosis, but its utility in other clinical contexts is uncertain. This study aims to assess the potential role of PS in guiding re-RT in patients with recurrent PCa. ***Materials and Methods:*** We retrospectively evaluated patients with BR after definitive RT who were referred to two Nuclear Medicine departments for a

PSMA PET/CT scan for restaging purposes. The PS was assessed, considered positive for values 3-5, and then correlated with the re-RT treatment plan. ***Results:*** Between October 2021 and May 2024, 14 patients with a median age of 76 years (range: 65-83) underwent re-RT for PCa recurrence. According to the ISUP grade, 4 patients had ISUP 1, 5 had ISUP 2, 1 had ISUP 4, and 3 had ISUP 5. Additionally, one patient had a Gleason Score of 3+2. The median PSA value was 8.15 ng/mL (range: 1.58-332 ng/mL). Re-RT was performed at a mean interval of 7.7 ± 4.1 years from initial radical RT, with a median dose of 30 Gy in 5 fractions. The PSs were distributed as follows: 4 and 5 occurred three times each, 2A was recorded three times, and 1 and 3 were recorded once each. PSMA PET images was unavailable for two patients. The RT plan was guided by PSMA PET findings in all cases except for three patients: in one case, uptake was extremely low, making proper lesion irradiation potentially inadequate; in the other two cases, uptake was diffusely increased. Conversely, for all patients with a PS of 2A, PSMA PET was used to guide re-RT. ***Conclusion:*** Our results indicate that the PS offers limited value in guiding re-irradiation planning for recurrent PCa. Low or diffuse PSMA uptake patterns hinder accurate target delineation, reducing the applicability of PS in this context. Larger studies are needed to identify alternative PSMA-based criteria to improve re-RT planning in this setting.

EP-0407

Diagnostic Evaluation of Blood Biomarkers and Multiparametric ^{18}F-PSMA-1007 PET/MR Imaging in Prostate Cancer

L. Wang[1], *X. Su*[2], *Y. Yang*[2], *W. Wu*[1];
[1]Jilin Cancer Hospital, Changchun, CHINA, [2]Beijing United Imaging Healthcare Co., Ltd., Beijing, CHINA.

Aim/Introduction: Accurate differentiation between malignant and benign lesions in patients with suspected prostate cancer (PCa) remains an essential goal in nuclear medicine. Conventional diagnostic markers, such as total prostate-specific antigen (TPSA) and imaging criteria like the Prostate Imaging-Reporting and Data System (PI-RADS) score, often lack sufficient accuracy, leading to unnecessary biopsies. Recent advances in hybrid imaging and blood-based biomarkers offer promising strategies for improving diagnostic performance. This study aimed to evaluate the diagnostic performance of both conventional and advanced blood biomarkers and PET/MR parameters for histologically confirmed PCa. ***Materials and Methods:*** This retrospective study included 20 patients with suspected PCa who underwent ^{18}F-PSMA-1007 PET/MR imaging followed by MRI-targeted biopsy. Fourteen patients were histopathologically confirmed with PCa, and six had benign results. The multiparametric MRI protocol included T2-weighted imaging and multi-b-value diffusion-weighted imaging (DWI). Evaluated parameters included blood biomarkers, such as TPSA and prostate health index (PHI), MRI-derived PI-RADS score from MRI, DWI-derived apparent diffusion coefficient (ADC), and PET-derived mean standardized uptake value (SUVmean). Receiver operating characteristic (ROC) curve analysis was performed to evaluate the diagnostic performance of individual and combined parameters with area under the curve (AUC). ***Results:*** Among single parameters, ADC showed the highest diagnostic value (AUC = 0.7619), followed by SUVmean (AUC = 0.7024) and TPSA (AUC = 0.6905). PHI and PI-RADS showed lower performance, with AUCs of 0.6429 and 0.6786, respectively. Combining parameters improved diagnostic performance. The combination of TSPA+ADC+SUVmean achieved an AUC of 0.8214. A more complex model, including TPSA + PHI + ADC + SUVmean, achieved the highest AUC of 0.8333, but showed limited additional benefit. Other combinations, such as PHI + ADC + SUVmean, also showed well performance (AUC = 0.8059), suggesting potential flexibility in biomarker selection. ***Conclusion:*** This study demonstrates the synergistic diagnostic value of combining blood-based and PET/MR-derived imaging biomarkers for PCa assessment. The combination of ADC from DWI and SUVmean from PSMA PET imaging with the PHI or TPSA enables a more biologically comprehensive evaluation of prostatic lesions. Multimodal combinations significantly outperformed individual parameters. These findings support the clinical utility of compact diagnostic models in reducing unnecessary biopsies and enhancing diagnostic accuracy in PCa detection.

EP-0408

Enhancing Patient Selection for PSMA Radioligand Therapy: The Role of Dual-Tracer Imaging Biomarkers in Optimizing Outcomes for mCRPC

S. Xue*, H. Einspieler, S. Wen, M. Hacker, S. Rasul, X. Li;*
Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: PSMA radioligand therapy (PSMA-RLT) is a promising treatment for metastatic castration-resistant prostate cancer (mCRPC). However, variability in patient responses may stem from limitations in current patient selection criteria, which rely on a binary yes/no analysis of PSMA/FDG concordance. This study evaluates the potential of quantitative imaging biomarkers derived from dual-tracer PSMA/FDG PET/CT imaging to improve patient stratification and predict therapeutic response to PSMA-RLT. ***Materials and Methods:*** A retrospective analysis of 24 mCRPC patients who underwent PSMA and FDG PET/CT imaging prior to PSMA-RLT was conducted. Automated lesion and organ segmentation, combined with advanced imaging fusion techniques, were used to extract quantitative features from concordant and non-concordant lesions, including SUVmean, SUVmax, molecular tumor volume (MTV), total lesion glycolysis (TLG), and total lesion PSMA (TLP). Organ-based imaging features were derived from key organs such as the bone and liver. Decision tree analysis stratified patients into three response categories: non-responders, suboptimal responders, and optimal responders. ***Results:*** SUVmean from PSMA PET imaging was identified as the most significant predictor of therapeutic response, with a threshold of 11.3 g/mL distinguishing responders from non-responders. Concordant PSMA/FDG lesion features, such as volume and lesional FDG uptake, showed significant correlations with post-therapy PSA level changes. Organ-based metrics, including SUVmax, SUVmean, and Overlap SUVmean, demonstrated high predictive accuracy for distinguishing responders from non-responders, achieving accuracies of 95.83%, 95.45%, and 87.50%, respectively. ***Conclusion:*** Dual-tracer imaging biomarkers, particularly SUVmean of PSMA and FDG concordant metrics, provide actionable insights for refining patient selection and stratifying response to PSMA-RLT. These findings support the transition from binary concordance criteria to a comprehensive, multi-metric approach for personalized treatment strategies. Further prospective studies with larger cohorts are needed to validate these biomarkers and facilitate their integration into clinical practice.

EP-0409

Is Dual-Time-Point PSMA-PET/CT a Predictive Tool for Response to PSMA Radioligand Therapy?

A. Weissensee*, A. D. Sidandy, N. Gözlügöl, R. Saiyed Alsheikh, F. Caobelli, R. Seifert, A. Rominger, A. Afshar-Oromieh;*
Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Prostate cancer (PC) lesions often demonstrate an increase in PSMA-ligand uptake over time. However, the extent of this uptake varies between individuals. It remains unclear whether different metastasis types exhibit distinct temporal uptake patterns, or whether all metastases within a single patient

behave uniformly. This study aimed to investigate this question and to determine whether the intensity change of PSMA-ligand uptake on dual-time-point PET/CT serves as a predictive marker for response to [^{177}Lu]Lu-PSMA radioligand therapy ([^{177}Lu]Lu-PSMA-RLT). ***Materials and Methods:*** Twenty patients who underwent dual-time-point PSMA-PET/CT imaging prior to clinically indicated [^{177}Lu]Lu-PSMA-RLT were included in this retrospective analysis. SUVmax was measured separately for local PC lesions, lymph-node metastases, bone metastases, and organ metastases. These groups were compared regarding differences in SUVmax between standard and late scans (Kruskal-Wallis test with post-hoc Dunn's test). For each lesion type, a maximum of 10 lesions per patient were randomly selected. In an additional logistic regression analysis, changes in SUVmax (ΔSUVmax) between standard and late scans were assessed for correlations with long-term biochemical response to [^{177}Lu]Lu-PSMA-RLT, based on Prostate Cancer Working Group 3 (PCWG3) criteria. ***Results:*** Overall, we analyzed 383 PC lesions in 20 patients (15 local tumors, 188 bone metastases, 135 lymph node metastases and 45 organ metastases). Across all lesions the median SUVmax in late images was 16.1 % higher than in standard images (p<0.001). A Kruskal-Wallis test showed significant differences in relative ΔSUVmax depending on metastasis type (p=0.021). However, a post-hoc Dunn's test was unable to identify statistically significant, specific inter-group differences (p=0.078-0.424). Logistic regression showed a positive, but non-significant effect of relative ΔSUVmax on therapy response (p=0.752). In contrast, the SUVmax of the hottest measured lesion significantly predicted therapy response (OR = 1.14 per unit increase, 95% CI [1.04-1.34], p=0.029). ***Conclusion:*** Consistent with previous findings, PC lesions exhibited significantly higher PSMA-ligand uptake in late scans. However, the magnitude of this uptake increase between time-points (ΔSUVmax) neither differed significantly across PC lesion types nor correlated with response to [177Lu]Lu-PSMA-RLT. Notably, higher SUVmax values at standard time-point imaging were associated with an increased likelihood of biochemical response to [^{177}Lu]Lu-PSMA-RLT. In summary, SUVmax measurements from late scans appear to provide limited additional prognostic value compared to those obtained at standard time-point scans.

EP-0410

The added value of MRI to AI^{18}F-PSMA-BCH PET/CT in detection of clinically significant prostate cancer

J. Ma[1], *C. Wang*[1], *M. Wang*[2], *C. Ren*[1], *Z. Huang*[1], *M. Liu*[2], *L. Huo*[1];
[1]*Peking union medical college hospital, Beijing, CHINA,* [2]*Beijing hospital, Beijing, CHINA.*

Aim/Introduction: PSMA PET/CT has shown great potential in diagnosis and biopsy guidance in clinically significant prostate cancer (csPCa). However, false positive and false negative lesions occur in a small group of patients. MRI has high accuracy in diagnosis of csPCa and may improve the performance of PSMA PET/CT. This study aims to investigate the added value of MRI to AI^{18}F-PSMA-BCH PET/CT in diagnosis and targeted biopsy of csPCa. ***Materials and Methods:*** This is a retrospective analysis of a prospectively collected dataset. AI^{18}F-PSMA-BCH PET/CT and MRI were performed within 3 months in patients with suspected csPCa and the results were provided to surgeons for targeted biopsy. Then patients received systematic biopsy (if PSMA PET/CT and MRI were both negative), targeted biopsy (only if intraoperative frozen section pathology was positive) or targeted biopsy plus systematic biopsy. Pathology of PSMA PET/CT targeted biopsy, MRI targeted biopsy and systematic biopsy were recorded. The primary outcome was whether the addition of MRI improved the accuracy of diagnosis. The secondary outcome is whether an MRI-targeted biopsy changed the result of biopsy based on PSMA PET/CT. ***Results:*** 142 patients were included in this analysis. The incidence of csPCa in PRIMARY score 1-5 is 0 (0/12), 8.3% (3/36), 18.2% (2/11), 64.3% (18/28), 92.7% (51/55). Patients with a PRIMARY score equal or more than 3 were classified as positive. The sensitivity, specificity, positive predict value (PPV) and negative predict value (NPV) of PSMA PET/CT are 95.9%, 51.5%, 75.5% and 93.8%. Because of the low incidence of csPCa in PRIMARY score 3-4 and a large number of false positive patients, we assigned patients without suspected malignancy in MRI as negative. 11 patients were changed to the negative group. Only 1 of 11 patients had csPCa. The sensitivity, specificity, PPV, and NPV of the new model were 94.6%, 80.9%, 84.3%, and 93.2%. The specificity increased significantly (p=0.002) while the sensitivity remained the same (p=1.000). When adding MRI targeted biopsy during the surgery, the pathology was changed only in 1 patient, from ISUP 2 to ISUP 3. ***Conclusion:*** Addition of MRI will improve the diagnosis accuracy of PSMA PET/CT and should be performed in patients with PRIMARY score 3 and 4. An MRI targeted biopsy cannot change the result of biopsy based on PSMA PET/CT.

Aim/Introduction: Physiologic PSMA uptake in benign prostate tissue may affect PET interpretation in suspected prostate cancer (PCa). This interim analysis of the BIOPSTAGE trial assessed uptake patterns across benign histologies and examined the influence of 5-alpha reductase inhibitor (5ARI) therapy. ***Materials and Methods:*** Ninety-six men with suspected PCa underwent [^{68}Ga] Ga-PSMA-11 PET/CT and mpMRI before biopsy. SUVmean values were measured in histologically benign tissue, including atrophy, inflammation, and benign prostatic hypertrophy (BPH). Uptake distributions were compared across tissue types and between 5ARI users and non-users using the Mann-Whitney U test. ***Results:*** Median SUVmean values were 2.20 (IQR: 2.10-2.40) for atrophy, 2.20 (IQR: 1.90-2.70) for inflammation, and 2.30 (IQR: 2.10-2.50) for BPH. Inflammation showed the greatest variability in uptake values. Among patients receiving 5ARI therapy (n=14), SUVmean was significantly higher than in non-users (2.40 vs. 2.20; p = 0.032). While no csPCa lesions were missed in this subgroup during interim analysis, increased background uptake—especially in inflamed or hormonally modulated tissue—may reduce lesion-to-background contrast and affect interpretation confidence. ***Conclusion:*** PSMA uptake in benign prostate tissue is generally low, but inflammation introduces notable variability. 5ARI therapy is associated with a modest but statistically significant increase in background uptake. These factors should be considered when interpreting PSMA PET and applying uptake-based thresholds in biopsy planning.

EP-0412

MRI characterization of 18F-PSMA 1007 bone uptake on integrated/hybrid PET/MRI exam in prostate cancer patients.

J. Vela León[1], *J. García*[2], *A. Compte*[2], *L. Pinilla*[2], *L. Mont-Castro*[2], *S. Ruiz*[2], *M. Soria*[2], *P. Bassa*[2], *E. Riera*[2];
[1]*Hospital Universitario de Canarias, Tenerife, SPAIN,* [2]*ASCIRES CETIR BCN, Barcelona, SPAIN.*

Aim/Introduction: To evaluate the MRI characteristics of ^{18}F-PSMA 1007 bone uptake sites of PET/MRI studies performed in prostate cancer patients. ***Materials and Methods:*** Prospective study

including the first 100 consecutive patients diagnosed with prostate cancer: 41 for patient staging and 59 for recurrence detection purposes. Simultaneous acquisition on PET/MRI (SIGNA-GE) equipment, 1h. after IV administration of 296±10%MBq of 18F-PSMA 1007: - Prostate study (20min): PET+MR with DIXON, T1, T2, DWI, DCE sequences. - Whole-body study (30 min): PET+MR with DIXON, T1, T2, DWI, STIR sequences. Independent assessment of the PET study by a Nuclear Physician, and MRI by a Radiologist, reaching consensus for the integrated PET/MRI findings. ***Results:*** For the per-patient analysis: 52/100 (52%) of patients presented with bone uptake of ^{18}F-PSMA 1007, 16 (31%) in staging and 36 (69%) in recurrence detection studies. Of these, MRI confirmed the presence of lesions in 15 (28%) of patients, corresponding to bone malignancy in 10 (67%) and benign origin in 5 (33%). Of these patients with bone metastases, 4 (40%) were detected in staging study and 6 (60%) in recurrence study; one lesion only was shown in 20% of patients, two lesions in 20%, and three lesions in 60%. For the per-^{18}F-PSMA 1007 uptake analysis: We found 56 bone uptake sites of ^{18}F-PSMA 1007: 18 in pelvis, 5 in lumbar spine, 8 in thoracic spine, 3 in femur, 5 in sternum, 1 in clavicle, 1 in scapula, 15 in ribs. Of these, 33 sites of 18F-PSMA 1007 bone uptake did not correspond with MRI findings: 13 in pelvis, 3 in lumbar spine, 3 in thoracic spine, 1 in femur, 1 in sternum, 12 in ribs. In 18 cases of ^{18}F-PSMA 1007 uptake, MRI corresponded with bone metastases: 5 in pelvis, 2 in lumbar spine, 4 in thoracic spine, 1 in femur, 4 in sternum, 1 in clavicle, 1 in scapula. In 5 cases of ^{18}F-PSMA 1007 uptake, MRI corresponded with characteristic benign lesions: 1 femoral enchondroma, 1 thoracic haemangioma, 1 rib fibrous dysplasia, 2 rib fractures. ***Conclusion:*** The evaluation of the MRI component of the integrated/hybrid PET/MRI scan allowed a better characterization of the frequent bone uptake sites of ^{18}F-PSMA 1007 in our series (52% of patients), with lesion confirmation in 28% of patients, and 67% of them corresponded with bone metastases.

EP-0413

Feasibility of Single-Time-Point Dosimetry from Voxel-Wise TAC Estimation Following 177Lu-PSMA Therapy

M. Alhashim[1], *E. Alwuhaib*[1], *N. Ibrahim*[1], *M. Alabedi*[1], *H. Dadgar*[2], *X. Hong*[3], *M. Azimi*[4], *S. Rezaei*[5], *H. Arabi*[6];
[1]*King Fahad Specialist Hospital Dammam, Dammam, SAUDI ARABIA,* [2]*Cancer Research Center, RAZAVI Hospital, Imam Reza International University, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [3]*School of Biomedical Engineering, Southern Medical University, Guangzhou, CHINA,* [4]*Department of Medical Radiation Engineering, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [5]*Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, ISLAMIC REPUBLIC OF,* [6]*Division of Nuclear Medicine and Molecular Imaging, Diagnostic Department, Geneva University Hospital, Geneva, SWITZERLAND.*

Aim/Introduction: Due to the challenges of performing multi-time-point imaging in routine personalized dosimetry for radioligand therapy, interest in single-time-point (STP) dosimetry has increased—especially approaches that estimate time-activity curves (TACs) and absorbed doses from a single SPECT/CT scan [1-2]. However, the reliability of STP methods remains under investigation, with limited validation studies available. We assessed retrospectively, whether voxel-wise TACs derived from a single imaging time point could accurately approximate the full TAC for dosimetry following ^{177}Lu-PSMA therapy. ***Materials and Methods:*** We analyzed data from 15 patients treated with ^{177}Lu-PSMA. SPECT/CT scans were acquired at 24, 48, and 72 hours post-injection (p.i.). For each patient, voxel-wise TACs were generated using data from all three time points. We then evaluated the feasibility of reconstructing full 3-time-point TACs based on each individual time point and assessed the accuracy of the resulting dose estimations. The predictive performance of each time point (24 h, 48 h, and 72 h p.i.) was systematically analyzed, IRB: RAD0343. ***Results:*** The TACs generally followed a mono-exponential decay pattern, though with notable inter-patient variability. Among the three time points, the 48 h p.i. scan yielded the most reliable approximation of the full TAC, enabling accurate dose estimation for the majority of voxels (typically with errors <30%). The 72 h p.i. scan also produced acceptable estimates, albeit with slightly reduced performance in some regions. In contrast, the 24 h p.i. scans were less predictive of the full TAC. ***Conclusion:*** We demonstrated the feasibility of STP dosimetry using a single SPECT/CT scan at 48 h p.i. in patients undergoing ^{177}Lu-PSMA therapy. Offering a practical balance between clinical convenience and dosimetric accuracy. The 72 h scan remains a valid alternative when 48 h imaging is not feasible. Our findings provide valuable insights for the clinical implementation of simplified STP dosimetry protocols; however, further validation with larger patient cohorts and additional radiopharmaceuticals is needed. ***References:*** 1. EP-0414

[68Ga]Ga-PSMA PET/CT response evaluation after metastasis- directed therapy (MDT) in Low Burden Metastatic Prostate Cancer

M. Usmani, *K. al Riyami, A. Jain, A. Al Busaidi, N. Pervaiz, B. Mir Khan, Z. Al-Mandhari;*
Sultan Qaboos Comprehensive Cancer Care and Research Center (SQCCCRC), University Medical City, Muscat, OMAN.

Aim/Introduction: De novo metastatic prostate cancer accounts for 5-10% of all prostate cancer (PC) diagnoses but it is responsible for nearly 50% of PC-related deaths. There is no current agreement on the response assessment after metastatic directed therapy (MDT) in metastatic prostate cancer. The aim of this study is to assess the feasibility of [^{68}Ga]Ga-PSMA PET/CT in response assessment in low burden metastatic prostate cancer after MDT. ***Materials and Methods:*** A total 19 patients (mean age, 70.6±8.9 years) de Novo low burden metastatic prostate cancer treated with radical doses of radiotherapy to primary and metastatic sites along with Luteinizing Hormone Releasing Hormone (LHRH) ± Abiraterone (with Prednisolone) or Enzalutamide. Baseline and follow-up [^{68}Ga]Ga-PSMA PET/CT after 6-9months were performed. Visual and quantitative PET image analyses were performed, according to Response Evaluation Criteria in PSMA imaging (RECIP1.0). The PSMA-PET results categorize patients into complete response (CR), partial response (PR), stable disease (SD), and progressive disease (PD). Biochemical response was assessed by PSA level. ***Results:*** Baseline [^{68}Ga]Ga-PSMA PET/CT show prostate lesion with SUV max 27.67±20.31, regional nodes are positive in 16/19 (84%), extra pelvic lymph nodes involvement noted in 6 (31%), seminal vesicle involvement seen in 7 (37%) patients. Four patients had bone metastasis in; left iliac, left pubis, ribs, right humerus with right iliac crest. Median initial PSA was 31.7 ng/ml (range = 13-182). Median follow up was 21.6 months (range = 7-37). Follow-up [^{68}Ga]Ga-PSMA show complete response in 16 (84%) patients and partial response in 3 (16%) patients. Out of 19 patients, 8 (42%) patients had undetectable PSA (< 0.006 ng/ml), 10 (53%) had PSA range from 0.006 to 0.2 ng/ml and 1 (5%) had PSA of > 0.2 ng/ml. ***Conclusion:*** Our initial experience suggests that [^{68}Ga]Ga-PSMA

PET imaging may offer metastatic directed therapy and PSMA PET- based response assessment is a simple and easy method and can be used as a response biomarker. It refines assessment of therapeutic efficacy, detects recurrence or new lesions early, and guides further treatment strategies, more timely intervention and offering a pathway to more individualized care.

EP-0415

Defining Patient Selection for Lutetium-177[177Lu]Lu-PSMA Radioligand Therapy: Evaluating the Probability of FDG PET/CT to Identify Discordant Disease according to PSMA PET/CT SUVmean?

J. Weindler, *J. P. Buteau, N. Papa, M. S. Hofman;*
Prostate Cancer Theranostics and Imaging Centre of Excellence; Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.

Aim/Introduction: The TheraP study utilized both PSMA- and FDG-PET/CT to determine eligibility for Lutetium-177 [177Lu]Lu-PSMA (LuPSMA) therapy for patients with metastatic castration-resistant prostate cancer (mCRPC). 31% of patients were excluded in total including 18% owing FDG-discordant (FDG-positive PSMA-negative) disease. Biomarker analysis identified PSMA-PET SUVmean ≥10 as a predictive and prognostic biomarker for PSA response and overall survival respectively. High PSMA-PET SUVmean may be a marker of a homogeneous phenotype where the likelihood of FDG-discordant lesions is low. We hypothesized that utility of FDG-PET/CT in identifying FDG-discordant disease is limited in patients with high PSMA-PET SUVmean. ***Materials and Methods:*** In this retrospective single-center study, we included consecutive patients with mCRPC referred for LuPSMA therapy from 01 April 2021 to 31 October 2024 and underwent dual-tracer PET-imaging with PSMA and FDG within 15 days. Included patients had PSMA-positive disease on PSMA-PET/CT, defined by at least one lesion with PSMA uptake above liver level. PSMA-PET SUVmean was measured using MIM Software (SUV≥3 threshold). FDG-discordant lesions were patient-based and defined as ≥1 lesion with uptake greater than liver on FDG-PET/CT and lower than liver on PSMA-PET/CT. Logistic regression was used to predict the probability of FDG-discordance according to PSMA-PET SUVmean with a chi-square test to evaluate a difference in discordance proportion below and above an SUVmean of 10. ***Results:*** 490 patients were referred and underwent dual-tracer PET-imaging of which 480 patients had PSMA-avid-disease (98 %). FDG-discordance was present in 89/480 (19%) of patients with PSMA-positive disease. Median PSMA-PET SUVmean was 7.9 (IQR: 6.3 - 10.5). In patients with PSMA-PET SUVmean ≥10, FDG-discordance was observed in 8/139 patients (5.8%) versus 81/341 (24%) in those with PSMA-PET SUVmean <10 (p<0.001). The probability of FDG-discordance for a patient with PSMA-PET SUVmean of 5 was 44% (95%CI: 35%-53%) versus 8.8% (95%CI: 5.1%-15%) if the PSMA-PET SUVmean was 10. FDG-discordant lesions were present in bone (74%), nodes (30%), liver (14%), and other organs (2.2 %). ***Conclusion:*** FDG-discordance is inversely associated with PSMA-PET SUVmean. Patients with high PSMA-PET SUVmean (≥ 10) have a substantially lower rate of FDG discordance.

EP-0416

Intra-Individual Head-to-head Comparison of ^{18}F-PSMA-1007 vs ^{68}Ga-PSMA-11 PET-CT in Assessment of Prostate Carcinoma. A PRostate Imaging with ^{18}F-PSMA-1007 Study in Malaysia (PRISM-My).

M. Abdul Onny[1,2], *M. Mohd Rohani*[3], *T. Selvarajoo*[4,5], *M. Ahmad Fadzil*[1], *Z. Md Safee*[1], *N. Razali*[1], *M. Mahamood*[1], *M. Said*[1], *N. Yaacob*[1], *R. Abdul Rahman*[1], *N. Mat Ail*[1], *S. Sukar*[1], *M. Wakiran*[1], *M. Mat Jusoh*[6], *S. Jamaludin*[4], *N. Ali*[1], *S. Amir Hassan*[3], *C. Ng*[5];
[1]National Cancer Institute Malaysia, Putrajaya, MALAYSIA, [2]University Medical Center Groningen, Groningen, NETHERLANDS, [3]Hospital Kuala Lumpur, Kuala Lumpur, MALAYSIA, [4]Advance Medical & Dental Institute, Universiti Sains Malaysia, Kepala Batas, MALAYSIA, [5]Hospital Sultanah Aminah, Johor Bahru, MALAYSIA, [6]Hospital Sultan Idris Shah, Serdang, MALAYSIA.

Aim/Introduction: Prostate cancer (PCa) is ranked as the second most frequent cancer in male globally and the third most common in Malaysia. Imaging modalities play a big role in the evaluation of disease extent and Nuclear Medicine armamentarium such as bone scintigraphy and recently, Prostate Specific Membrane Antigen PET-CT (PSMA-PET) are pivotal in the management of PCa. Traditionally, in Malaysia, PSMA has always been tagged with ^{68}Ga. However, short half-life and low yield of radioisotope has impeded the widespread usage of PSMA-PET in Malaysia. Recently, usage of ^{18}F-based PSMA has been explored as an alternative and a first in Malaysia clinical trial was conducted to intra-individually compare normal organ biodistribution and lesional uptake between ^{68}Ga-PSMA-11 and ^{18}F-PSMA-1007 PET-CTs. ***Materials and Methods:*** A prospective interventional study was conducted in the National Cancer Institue Malaysia between March 2022 to December 2024. A total of 37 patients with histopathologically proven PCa were recruited and undergo ^{68}Ga-PSMA-11 and ^{18}F-PSMA-1007 PET-CTs within 30-days of the first PET-CT. Both radiopharmaceuticals were produced in-house, in compliance with local regulatory bodies and GMP standards. Image acquisition was performed using GE Discovery 690 MIDR. Image interpretation was done by 3 Nuclear Medicine physicians. Descriptive analysis was used to assess lesion identification whereas difference and concordance between SUVmax of ^{68}Ga-PSMA-11 and ^{18}F-PSMA-1007 was determined using repeated measure ANOVA and Wilcoxon Sign-Ranked Test. ***Results:*** Majority of patients (89.2%) were of Gleason score ≥7 and of intermediate or higher risk stratification. Median PSA level was 6.58ng/ml (IQR 23.63). The highest mean SUVmax and absorbed dose were recorded in the kidney; 27.37mg/ml and 0.09mGy/MBq respectively followed by the salivary glands, spleen and liver. Normal organ SUVmax was predominantly higher on ^{18}F-PSMA-1007 PET-CT except notably the kidney. There were 90 discordant lesions identified, with ^{18}F-PSMA-1007 PET-CT outperforming ^{68}Ga-PSMA-11 PET-CT, most evident at the prostatic bed and regional nodes. ^{18}F-PSMA-1007 PET-CT showed significantly higher uptake and was able to localize smaller lesions (2-3mm). Significantly more bone uptake on ^{18}F-PSMA-1007 PET-CT, likely attributed to unspecific bone uptake (UBU). More importantly, all likely pathological lesions detected using ^{68}Ga-PSMA-11 were also detected with ^{18}F-PSMA-1007 PET-CT. ***Conclusion:*** This study showed that ^{18}F-PSMA-1007 is comparable to the ^{68}Ga-PSMA-11 PET-CT in its organ biodistribution and lesion detection with the added value of higher uptake and less urinary excretion thus improving lesion detection at the prostatic bed and regional nodes. However, the inadvertent findings of UBU may complicate image interpretation.

EP-0417

Low sensitivity of mpMRI and 18F-PSMA-1007 PET/CT in localization of Primary Prostate cancer

A. Loimaala[1], *O. Kerro*[2], *T. Mirtti*[3], *M. Paloranta*[4], *T. Koivula*[5], *A. Rannikko*[6];
[1]Helsinki University Hospital, Diagnostic Center, Helsinki, FINLAND, [2]Helsinki University Hospital, Urology, Stomac center, Helsinki, FINLAND, [3]Helsinki University Hospital, Diagnostic Center, Pathology, Helsinki, FINLAND, [4]Helsinki University, Helsinki, FINLAND, [5]Helsinki University Hospital, Diagnostic Center, Nuclear medicine, Helsinki, FINLAND, [6]Helsinki University Hospital, Stomac center, Urology, Helsinki, FINLAND.

Aim/Introduction: Accurate local staging is critical for treatment planning and prognosis in prostate cancer (PCa). Multiparametric magnetic resonance imaging (mpMRI) and ^{18}F-PSMA-1007 PET/CT have high specificity for detection of extraprostatic disease and seminal vesicle invasion (SVI), their sensitivity and agreement is not

well established in localization of PCa in the prostate bed. Thus, our aim was to assess the diagnostic performance of mpMRI and ^{18}F-PSMA-1007 PET/CT in comparison to histopathology (ground truth) and detection of seminal vesicle invasion (SVI) in men with high risk primary PCa (GG 3-5, cT2-cT3, rT2-3) undergoing robot-assisted radical prostatectomy (RARP). ***Materials and Methods:*** Between March 2022 and January 2024, 40 treatment-naïve men with biopsy-proven high-risk PCa undergoing mpMRI and ^{18}F-PSMA-1007 PET/CT before RARP were prospectively enrolled. The study was approved by the institutional ethics committee, all patients gave written informed consent. Men with clinically significant (csPCa) undergoing RARP and extended pelvic lymph node dissection (ePLND) were eligible for the study. The mpMRI was performed at 3 T (Siemens Skyra 3T) for the men in accordance with established guidelines and included high-resolution T2- weighted, diffusion-weighted, and apparent diffusion coefficient sequences. ^{18}F-PSMA-1007 PET/CT was performed on a Siemens Biograph 64 or a GE MI 128 scanner using standard low-dose-protocol. RARP ± ePLND was performed by an experienced urologist using the da Vinci Xi platform. One experienced urogenital pathologist who was blinded to the imaging results evaluated RP specimens according to ISUP protocols. ***Results:*** RARP ± ePLND was performed to 30 men, 10 men received antiandrogen therapy. Five men had PCa only either the right or the left prostate bed, and seminal vesicle invasion was found in eight men. The per-segment sensitivity for mpMRI and PSMA PET was 58% (50-66%) and 68% (60-74%) (p= 0.014) and specificity 93% (87-96%) and 80% (73-86%) (p=0.0015), respectively. Positive predictive values (PPV) for MRI and PSMA PET were 90% vs. 79%, and negative predictive values (NPV) 67% vs. 69%, respectively (p>0.05 for both). Per-segment agreement (kappa) for localizing PCa in the prostate bed for mpMRI was 0.50 and 0.47 for ^{18}F-PSMA-1007 PET/CT, respectively. ***Conclusion:*** Both imaging methods have quite low sensitivity in primary diagnosis of PCa to show the precise location of the PCa focus but ^{18}F-PSMA-1007 PET/CT performs slightly better. MpMRI has significantly higher specificity compared to PSMA PET. Agreement between the imaging methods and the histopathology was fair.

EP-0418

Effect of different scan duration on image quality and quantification in long axial field-of-view PSMA-PET/CT

L. Airo' Farulla*, A. F. Scarale, G. Cabrini, S. Capitanio, A. Franchini, E. Gay, A. Spataro, K. Shyli, C. Rossetti;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Long axial field of view (LAFOV) positron emission tomography/computed tomography (PET/CT) offers improvements in sensitivity and image quality, but minimum acquisition duration required to preserve these benefits with prostate-specific membrane antigen (PSMA)-ligands remain unclear. We evaluated whether rapid acquisitions (30 sec-6 min) on a LAFOV PET/CT yield lesion detectability and image quality that are non-inferior to the standard 10-min protocol in prostate cancer (PCa) patients. ***Materials and Methods:*** In this single-center retrospective study, 39 PCa patients underwent LAFOV PSMA-PET/CT (31/39 with [^{68}Ga]PSMA-11, 8/39 with [^{18}F]DCFPyl). Inclusion criteria: histologically-proven PCa; age ≥ 18 years; clinical indication for PSMA-PET/CT; available 10-minute list-mode acquisition; and at least one measurable PSMA-avid primary lesion. The 10-min acquisitions were reconstructed into 30 sec, 1, 2, 3, 4, 5, and 10 min frames. For each reconstruction we collected semiquantitative parameters [e.g. tumour-to-background ratio (TBR), or signal-to-noise ratio (SNR)], and three blinded nuclear medicine physicians rated overall image quality on a 5-point Likert scale. Non-inferiority versus the 10-min reference was tested by two-one-sided t-tests (TOST) with margins ΔTBR = -0.3, ΔSNR = -10, ΔLikert = -0.5; analyses were repeated by clinical setting. ***Results:*** In the overall cohort (n = 39), rapid acquisitions preserved quantitative and qualitative metrics. TBR remained non-inferior at every time point (e.g. 30 s: 4.84 ± 5.80 vs 10 min: 4.67 ± 5.72; Δ -0.17; p < 0.05). Mean image-quality Likert scores were non-inferior at 5 minutes (4.75 ± 0.38 vs 5.00 ± 0.00; Δ -0.25; p < 0.001). When stratified by clinical setting, staging group (n = 13) showed non-inferior TBR at every reconstruction, while SNR and Likert non-inferiority were reached only at 5 minutes (Likert: 4.59 ± 0.45 vs 5.00 ± 0.00; p < 0.001). In the PSA-persistence group (n = 7), TBR and SNR were non-inferior from 2 minutes (TBR: 4.69 ± 6.15 vs 4.67 ± 5.72; p = 0.023), and Likert non-inferiority was attained at 3 minutes (4.29 ± 0.49 vs 5.00 ± 0.00; p < 0.001). Among biochemical recurrence patients (n = 19), quantitative metrics were non-inferior from 2 minutes (SNR: 39.2 ± 95.4 vs 61.7 ± 74.4; p = 0.080) and Likert score at 5 minutes (4.88 ± 0.25 vs 5.00 ± 0.00; p < 0.001). ***Conclusion:*** LAFOV PSMA-PET/CT acquisition lasting 3-5 minutes maintain lesion conspicuity, semiquantitative accuracy and reader-perceived image quality comparable to the 10-minute reconstruction.

EP-0419

PI-RADS scoring in long-axial-field-of-view PSMA-PET/CT: effects of scan duration on diagnostic confidence

L. Airo' Farulla*, A. F. Scarale, A. Spataro, E. Gay, A. Franchini, S. Capitanio, G. Cabrini, K. Shyli, C. Rossetti;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Longaxialfieldofview (LAFOV) PSMAPET/CT markedly enhances lesion detectability in prostate cancer (PCa) patients, but requires prolonged acquisition duration. The Prostate Imaging Reporting and Data System (PIRADS) is a validated 5point scale to grade the likelihood of clinically significant prostate cancer on imaging. A noninferiority study was performed to identify the shortest LAFOV PSMAPET/CT acquisition duration that yields PIRADS assessments equivalent to the standard 10minute protocol. ***Materials and Methods:*** We retrospectively reviewed 39 prostate cancer patients (mean age 68 ± 8 years; ISUP grade 2-5) who underwent LAFOV PSMAPET/CT between January and April 2025, using [^{68}Ga]PSMA11 (n = 31) and [^{18}F]DCFPyL (n = 8) radiotracers. Inclusion criteria were: histologically-proven PCa, age ≥ 18, clinical indication for PSMAPET/CT, available 10min listmode acquisition, and at least one measurable primary lesion. Acquisitions were reconstructed offline into 30 s, 1, 2, 3, 4, 5, and 10 min frames using vendorstandard OSEM with timeofflight and pointspreadfunction modelling. Regions of interest were drawn on the dominant intraprostatic/prostatic bed lesion and normal liver parenchyma to derive SUVmax and background SUVmean, lesion-to-background contrast was expressed as TBR. Three nuclear medicine physicians, blinded to frame duration, independently scored image quality and diagnostic confidence for the primary PCa lesion using PIRADS (1-5). We computed perpatient mean PIRADS and lesion TBR at each timepoint. Interreader agreement was assessed by weighted Cohen's κ. Noninferiority versus the 10min reference (Δ = -0.5 PIRADS units) was tested with twoonesided Wilcoxon signedrank tests. Subgroup analyses were performed by clinical setting: staging (n = 13), PSA persistence (n = 7), and biochemical recurrence (n = 19). ***Results:*** Average TBR at 10 min was 4.67 ± 5.72; at 3 min it was 4.53 ± 5.65 (Δ = -0.14; p < 0.05), confirming noninferiority of lesion conspicuity. PIRADS mean rose from 3.45 ± 0.82 at 3 min to 5.00 ± 0.00 at 10 min; twoonesided Wilcoxon tests demonstrated noninferiority at ≥ 3 min (p_lower < 0.0001). Interreader κ for PIRADS increased from 0.65 at 30 s to 0.66 at 3 min and 0.81 at 5 min. In staging patients, TBR noninferiority held at all times, but PIRADS required ≥ 5 min (4.59 ± 0.45 vs 5.00; p_lower < 0.001). In PSA persistence, TBR and PIRADS were noninferior from 1 min (PIRADS_mean 4.14 ± 0.52; p_lower < 0.001). In recurrence, noninferiority was reached at 1-2 min for PIRADS (3.95 ± 0.60 vs 5.00; p_lower < 0.01) but overscoring emerged at ≥ 3 min. ***Conclusion:*** LAFOV

PSMAPET/CT acquisitions lasting 3 minutes preserve PIRADS scoring equivalent to the 10minute standard. Tailoring scan duration by clinical scenario (1-2 min for PSA persistence; ≥ 5 min for staging) can optimize workflow and patient comfort without compromising diagnostic confidence.

EP-0420

Clinical Impact of Repeated 18F-PSMA-1007 PET/CT in the Longitudinal Follow-Up of Prostate Cancer Patients in Sub-Saharan Africa

W. Olwit, *K. Makhdomi, M. Mwania, P. K. Loyal, J. Nyamari, S. Nguku;*
Aga Khan University Hospital Nairobi, Nairobi, KENYA.

Aim/Introduction: Prostate cancer is the most common malignancy among men in Kenya, with a significant proportion presenting at advanced stages. Accurate post-treatment surveillance is critical for detecting recurrence, guiding therapy, and improving outcomes. 18F-PSMA-1007 PET/CT has demonstrated high diagnostic accuracy in prostate cancer imaging, but its longitudinal utility in follow-up remains underexplored in sub-Saharan Africa.We aimed to evaluate the clinical utility of repeated 18F-PSMA-1007 PET/CT imaging in the follow-up of prostate cancer patients at Aga Khan University Hospital, Nairobi, focusing on treatment impact, prognostic relevance, and disease monitoring. ***Materials and Methods:*** This retrospective study included 150 prostate cancer patients who underwent at least two 18F-PSMA-1007 PET/CT scans between June 2020 and February 2025. Clinical data, PSA levels, Gleason scores, and imaging findings were analyzed. Treatment changes following imaging, disease recurrence patterns, and survival outcomes were assessed. Multivariable Cox regression was used to identify prognostic factors. ***Results:*** The mean patient age was 71.0 years (42-93). Most patients presented with advanced disease (40% metastatic, 35% locally advanced). The initial mean PSA was 113.8 ng/mL, and 18% of patients had ISUP grade 5 tumors. Hormonal therapy was the most common initial treatment (48%). Repeat 18F-PSMA-1007 PET/CT scans led to treatment changes in 35.1% of cases, including initiation of systemic therapy or radiotherapy. At first follow-up, radiologic improvement or stability was observed in over 67% of patients. Disease progression remained detectable in later scans, with 33.3% of third or subsequent scans prompting further management changes. Progression-free survival was significantly associated with ISUP grade, SUVmax, PSA levels, and imaging response. ***Conclusion:*** Repeated 18F-PSMA-1007 PET/CT imaging plays a valuable role in the longitudinal management of prostate cancer, influencing clinical decisions, monitoring therapeutic response, and offering prognostic insights. These findings support its integration into routine follow-up protocols, particularly in patients with biochemical recurrence or ambiguous disease trajectories. Prospective studies are warranted to define optimal imaging intervals and refine its prognostic applications.

EP-0421

Prognostic Utility of Dynamic PSMA PET/CT and Kinetic Modeling with LAFOV in Advanced Prostate Cancer

A. Di Giorgio[1], *I. Brusa*[2], *D. Dall'Olio*[3], *V. Mollica*[4], *F. Massari*[3,4], *M. Rapa*[1], *M. Assenza*[5], *P. Castellucci*[2], *S. Fanti*[1,2], *A. Farolfi*[2];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY,* [4]*Medical Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Professional Development and Implementation of Research in Health Professions Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: While PSMA PET/CT with short axial field-of-view (SAFOV) is accurate for staging advanced prostate cancer (PCa), its role in evaluating response to systemic therapies in hormone-sensitive (HSPC) and castration-resistant (CRPC) PCa remains less defined. Large Axial Field-of-View (LAFOV) scanners and dynamic acquisitions may enhance response evaluation through kinetic parameter analysis. The aim of this study is to evaluate the prognostic role of PSMA PET/CT, utilizing LAFOV and dynamic acquisition, by investigating kinetic parameters and tumor volume changes for assessing treatment response. ***Materials and Methods:*** Prospective, observational, Italian multicenter (CE AVEC: 737/2024/Oss/AOUBo) study consecutively enrolling ≥18-year-old males with histologically confirmed advanced PCa, scheduled for systemic therapies. All participants undergo a 60-minute dynamic PSMA PET/CT using LAFOV(FOV=194cm). The protocol involves intravenous radiopharmaceutical administration with continuous data acquisition. Baseline scans precede therapy, with follow-up scans during/after treatment. For comparison, dynamic 68-PSMA PET/CT scans from two patients with no history of prostate cancer (for other indications) were used. Kinetic analyses were performed on healthy organs (e.g., prostate, femur) as reference. Compartment models will quantify PSMA uptake and kinetics (K_1, k_2, k_3, K_i and distribution volume), correlated with treatment response and clinical outcomes alongside static PET metrics(SUVmax, total lesion volume). ***Results:*** From September 2024 to February 2025, we enrolled 10 patients with metastatic prostate cancer (median age 76 years, IQR 68-80) who were candidates for systemic therapy. The median baseline PSA level was 26 ng/mL(IQR 11-53). Subsequently, 2 of these patients underwent a second dynamic 68Ga-PSMA PET/CT scan at the end of therapy (median time 6 months). In the baseline PET scans, a total of 43 lesions were analyzed, including 11/43(26%) prostatic lesions, 18/43(42%) lymph node lesions, and 14/43(33%) bone lesions. At the end-of-treatment PET scans, 10 lesions were identified and analyzed, comprising 2/10(20%) prostatic lesions, 5/10(50%) lymph node lesions, and 3/10(30%) bone lesions. Kinetic parameter analysis revealed a significant difference in K_1 between bone lesions(p=0.03) and prostatic lesions(p=0.01). No significant difference was observed in SUVmax between these lesion types(p=0.08). k_2 and K_i showed significant differences between lesions and healthy tissue(p=0.003 and p=0.001, respectively). ***Conclusion:*** Preliminary data from this study indicate the potential of dynamic Ga-PSMA PET/CT with LAFOV to offer new insights into prostate cancer lesion biology through kinetic analysis. Further investigation in a larger cohort is needed to determine the role of these dynamic parameters in predicting treatment response and improving risk stratification.

EP-0422

The Value of VolumeIntensity-Sum and Other Volumetric PET Parameters in Predicting Progression in Patients with Metastatic Prostate Cancer Receiving Lu-177 PSMA Therapy

N. Unsal[1], *S. Karabulut*[1], *A. Aksu*[2], *G. Capa Kaya*[1];
[1]*Dokuz Eylul University Medical Faculty Hospital, Izmir, TÜRKIYE,* [2]*Izmir Katip Celebi University Medical Faculty Hospital, Departmant of Nuclear Medicine, Izmir, TÜRKIYE.*

Aim/Introduction: The aim of this study is to evaluate the role of quantitative parameters obtained from pre-treatment Ga-68 PSMA PET/CT in predicting disease progression after four cycles of Lu-177 PSMA therapy in patients diagnosed with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Patients who received four cycles of Lu-177 PSMA therapy between 2016 and 2024 and underwent both pre and post-treatment Ga-68 PSMA PET/CT were included. The presence of bone, pelvic lymph node, and distant soft tissue metastases on baseline PET/CT and treatment response per RECIP criteria were recorded. Pre-treatment images were analysed using LIFEx software. Tumour lesions were segmented using liver SUVmean as threshold. Extracted parameters included PSMA-BulkVolume, highest tumour SUVmax (tSUVmax), total PSMA tumour volume

(tPSMA-TV), total lesion PSMA (tTL-PSMA), sum of mean SUVs across lesions (Intensity_sum), and the VolumeIntensity_sum calculated as the sum of the product of voxel intensity and volume across all VOIs were computed. The association between these parameters and progression status (progressive vs. non-progressive disease) was statistically analysed. ***Results:*** Fifty-nine patients (mean age: 70±9 years) were evaluated. Twelve patients (20.3%) showed progression on post-treatment PET/CT. Bone metastases were present in 88.1%, pelvic lymph node metastases in 42.4%, and distant soft tissue metastases in 62.7%. No significant association was found between progression and location of metastases ($p > 0.05$). However, PSMA-BulkVolume ($p = 0.032$), tPSMA-TV ($p = 0.014$), tTL-PSMA ($p = 0.029$), VolumeIntensity_sum ($p = 0.004$), and Intensity_sum ($p = 0.006$) were significantly lower in the progressive group. Among these, VolumeIntensity_sum had the highest predictive value (AUC: 0.771; sensitivity: 70.2%; specificity: 83.3%). For tPSMA-TV, sensitivity and specificity were 51.1% and 100%, while for tTL-PSMA, they were 57.4% and 91.7%, respectively. ***Conclusion:*** In patients with mCRPC receiving Lu-177 PSMA therapy, quantitative parameters derived from baseline Ga-68 PSMA PET/CT demonstrated significant value in predicting disease progression. Among these, VolumeIntensity_sum showed the highest prognostic value. As this parameter directly accounts for PSMA activity intensity in each voxel, it may more accurately reflect tumour biological aggressiveness and thus has potential as an imaging biomarker. Moreover, to our knowledge, no previous study has evaluated the VolumeIntensity_sum parameter in PSMA PET, suggesting that our findings could provide a valuable contribution to the literature.

EP-0423

The role of Choline PET/CT in patients with recurrent prostate cancer and a negative PSMA-PET/CT

N. Gözlügöl[1], *H. Sari*[1], *A. Rominger*[1], *K. Strobel*[2], *A. Afshar-Oromieh*[1];
[1]*Inselspital Bern University Hospital, Bern, SWITZERLAND,*
[2]*Cantonal Hospital Lucerne, Lucerne, SWITZERLAND.*

Aim/Introduction: The sensitivity of PSMA-PET/CT for the detection of recurrent prostate cancer (rPC) is good at low PSA values and rapidly rises to >90% in patients with PSA >1.5 ng/ml. However, some PC (approx. 5-10%) do not sufficiently express PSMA. Currently, there exists no general rules on how to handle PSMA-PET-negative patients despite PSA >1.5 ng/ml. Some of these patients are referred to MRI, some are treated without a clear target and some remain untreated until a subsequent PSMA-PET/CT at higher PSA values is conducted. The aim of this evaluation was to assess the value of a choline PET/CT following a negative or equivocal PSMA-PET/CT in patients with rPC. ***Materials and Methods:*** We conducted a retrospective analysis incorporating data from 01/2017-04/2025 from two institutions. Eligible patients included those with rPC and a negative or equivocal [^{68}Ga]-Ga-PSMA-11 or [^{18}F]-F-PSMA-1007 PET/CT despite a PSA level of ≥ 1.5 ng/ml, who were subsequently referred for choline-PET/CT within a time window of 2 months. Two experienced nuclear medicine physicians reviewed both scans (choline and PSMA-PET/CTs) in a blinded consensus read. ***Results:*** Twelve patients met all inclusion criteria. The median PSA level at the time of PSMA-PET/CT was 4.2 ng/ml (range: 1.7 - 56.0). Among these, 9 patients had negative PSMA-PET/CT, while 3 were classified as equivocal. Following [^{18}F]F-Fluorocholine PET/CT scan, 7 out of 12 patients (58.3 %) demonstrated pathologic choline positive findings indicative of PC. In total, these 7 patients exhibited 12 pathological lesions, predominantly located in the prostatic bed and locoregional lymph nodes. ***Conclusion:*** Nearly 60% of patients with a negative or equivocal PSMA-PET/CT showed lesions of rPC following choline PET/CT. The data, although generated with a low number of patients, suggests that despite the high sensitivity and specificity of PSMA imaging, some PC lesions may remain undetected due to low PSMA expression. In such scenarios, choline PET/CT serves as a valuable complementary imaging modality.

EP-0424

Comparison of Early Response Assessment Using Post-Therapy Imaging After Lu-177 PSMA Therapy with Interim Ga-68 PSMA PET/CT

O. Sahin*, T. Bodur, K. Saglam, R. L. Uslu, S. Asa, S. Sager, L. Kabasakal, K. Sönmezoğlu, H. B. Sayman;*
Department of Nuclear Medicine, Istanbul University-Cerrahpasa, Faculty of Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Radioligand therapy (RLT) with Lu-177 PSMA is an increasingly utilized treatment modality with proven efficacy in metastatic prostate cancer (mPCa). Although consensus has yet to be reached regarding the ideal timing for progression evaluation, interim Ga-68 PSMA PET/CT after the second RLT cycle is frequently used in clinical practice. This study aimed to evaluate the effectiveness of post-therapy Lu-177 PSMA imaging (RLT PSMA) in identifying early disease progression, comparing it with interim PSMA PET and/or PSA-based evaluation. ***Materials and Methods:*** This retrospective study included 40 mPCa patients treated between 2017 and 2024, who received at least two RLT cycles and underwent interim PSMA PET imaging. Lu-177 PSMA was administered at a standard dose of 7.4 GBq per cycle. Post-therapy imaging (RLT PSMA) included whole-body planar scintigraphy and SPECT/CT of the thoracic and abdominopelvic regions. Baseline and follow-up PSMA PET scans, as well as first- and second-cycle RLT PSMA images, were compared. Progression was assessed using the PSMA PET Progression (PPP) criteria. The performance of each method in detecting progression was compared using McNemar's test. A secondary analysis combined RLT PSMA and PSA findings, with progression defined as positivity in either. PSA progression was defined as a ≥25% increase. ***Results:*** The mean patient age was 68±9 years, and baseline PSA level was 53±77 ng/mL. The mean interval between RLT cycles was 65±22 days, and interim PSMA PET was performed at an average of 50±22 days after the second cycle. PSMA PET detected progression in 25 of 40 patients (63%). There was no significant difference in baseline PSA between patients with and without progression (p=0.22). RLT PSMA identified 80% (20/25) of patients with progression, while missing 5 (20%). No statistically significant difference was observed between PSMA PET and RLT PSMA in detecting progression (p=0.063) (Figure 1-2). The combined use of RLT PSMA and PSA findings yielded a detection rate of 92%, improving progression detection performance. ***Conclusion:*** Interim PSMA PET detected progression in 63% of patients, underlining its value in early identification of disease progression. Post-therapy RLT PSMA imaging yielded comparable results. Combining PSA data further increased the detection rate to 92%, improving overall progression detection. These findings emphasize the importance of interim evaluation and suggest that the combination of RLT PSMA imaging with PSA may offer a reliable alternative to PSMA PET in identifying early progression.

Aim/Introduction: PSMA-PET/CT is currently used for the staging and restaging of prostate cancer (PCa) patients and to identify metastatic castration-resistant prostate cancer (mCRPC) patients suitable for ^{177}Lu-PSMA-therapy. Higher PSMA expression seems to be correlated with better responsiveness to the radioligand treatment (RLT). However, recommended cut-offs and universally recognized criteria for the suitability of ^{177}Lu-PSMA are urgently needed. ***Materials and Methods:*** Our retrospective analysis includes 78 PSMA-PET/CT studies in either hormone-sensitive (HS) or castration-resistant (CR) settings. These come from 70 patients with de novo metastatic PCa treated with androgen deprivation therapy (ADT), ADT+docetaxel, ADT+Androgen receptor pathway inhibitor (ARPI), or ADT+ARPI+Docetaxel in the HS setting between 2021 and 2023. Clinical and demographic variables and PSMA-PET/CT semi-quantitative parameters (SUVmax, SUVmean, Total Lesion Activity-TLA) were collected. Associations between categorical and continuous variables were examined using Pearson's chi-square and Kruskal-Wallis tests, respectively. Cox analyses were performed for overall survival (OS). ***Results:*** In the CR phase, we found higher PSMA-PET/CT semiquantitative parameters in ARPI-exposed patients compared to non-ARPI-exposed patients, with a median reference lesion SUVmax (SUVmaxRL) 33.9 (95%CI: 25.1-55.5) vs. 14. 6 (95%CI: 12.3-24.2) [p=0.02], a median SUVmean 12.5 (95%CI: 9.7-15.9) vs. 5.8 (95%CI: 4.4-11.3) [p=0.02] and a median TLA 1544.4 (95%CI: 311.8-2957.2) vs. 600.2 (95%CI: 73.5-870) [p=0.08]. In contrast, patients previously exposed to docetaxel tended to have lower PSMA-PET/CT uptake values, with a median SUVmaxRL of 27.8 (95%CI: 18.3-28.3) vs. 40 (95%CI: 30.4-71.4). These results are consistent with the percentage of mCRPC patients eligible for RLT, 70% vs 40% between ARPI-exposed and non-ARPI-exposed patients respectively (p=0.04). Furthermore, clinical (age, Chaarted criteria) and pathological (Gleason score) characteristics were similar in the two groups. In 38 PSMA-PET/CT studies performed in the CR phase, a higher SUVmaxRL (above 50) was significantly correlated with a lower OS (HR 3.55, 95% CI: 1.39-9.11, p=0.008). ***Conclusion:*** Our preliminary data show that systemic treatments administered in the HS metastatic setting appear to influence PSMA expression, detected by PET/CT, in CR metastatic stages, with ARPIs increasing SUVmean, SUVmax, and TLA and thus the indication for RLT. In addition, evaluation of SUVmaxRL might play a role in predicting survival outcomes in mCPRC, but further analyses are needed.

EP-0426

Clinical and Imaging Parameters to Predict the Efficacy of Androgen Receptor Pathway Inhibitors in Patients with Metastatic Castration-Resistant Prostate Cancer

O. Kodaz*, Y. Eryilmaz, M. Caglar, M. Tuncel;*
Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Androgen-receptor pathway inhibitors (ARPIs) have become the new standard of care for both metastatic hormone-sensitive and castration-resistant prostate cancer (mCRPC). However, the benefits of this treatment vary among patients, and it is unknown whether molecular imaging parameters provide predictive value. The aim of this study is to assess the clinical outcomes for mCRPC patients treated with ARPIs focusing on the predictive role of 68Ga-PSMA PET/CT-derived parameters. ***Materials and Methods:*** We retrospectively analyzed 40 mCRPC patients who had undergone 68Ga-PSMA-11 PET/CT imaging prior to the initiation of treatment with ARPIs. In addition to clinical history, several imaging parameters were investigated to predict PSA progression-free survival (PSA-PFS). PET-derived parameters included SUVmax, SUVmean, total-tumor-volume (TTV), soft-tissue-volume (STV, lymph nodes and prostate), TL-PSMA and HIT score. Pre-therapy laboratory tests included serum-PSA, LDH, albumin, and ALP levels, PSA doubling-time (PSAdt), PSA-velocity, as well as histopathological and clinical parameters such as ISUP-grade, time from diagnosis to ARPI initiation, previous therapies, site of metastases, and the distinction between de novo and recurrent metastatic disease. ***Results:*** Among the 40 patients, 24 (60%) had de novo metastatic disease, and 24 (60%) had previously received chemotherapy. Median pre-ARPI serum-PSA value and PSAdt 8.96 (range 0.15-863) and 2.3 months (range 0.4-22) respectively. On the pre-treatment PSMA PET scan median SUVmax, median TTV, median STV, median TL-PSMA and median SUVmean was 16.32 (range 4.64-76.03), 23.86 ml (range 0.1-643.55), 1.08 ml (range 0-349.26), 158.66 (range 0.45-5929.19) and 6.41 (range 3.51-14.58). During a follow-up period of 30.7 months (SD: 15.7 months), PSA progression occurred in 31 patients (77.5%). Median PSA-PFS was 12 months (range 3-71 months). In Cox regression analysis, patients with a higher TL-PSMA (cut-off: 99.3 g/ml x cm^3; p=0.022; 35 months vs. 14 months) and STV (cut-off: 0.89 ml; p=0.037) experienced a shorter PSA-PFS. In addition patients with less than 3 years since initial diagnosis (p=0.034), higher PSA-velocity (cut-off: 4 ng/ml/yr; p=0.008), and prior chemotherapy (p=0.002) were associated with significantly worse PSA-PFS. Other clinical, laboratory and molecular imaging parameters were not significantly associated with patients outcomes. ***Conclusion:*** This data suggest that certain clinical and PSMA PET/CT-based molecular imaging parameters may be useful to predict patient response to ARPI therapy. TL-PSMA and STV were the only prognostic molecular-imaging-biomarkers identified for predicting ARPI failure. This may necessitate considering alternative treatment options or combination therapies for patients with a high potential of therapy failure. This hypothesis requires further validation in larger prospective-studies.

EP-0427

The impact of scan duration on detection of unspecific findings on large axial field-of-view PSMA PET/CT studies in Prostate cancer patients

A. Scarale*, L. S. Airò Farulla, A. Spataro, A. Franchini, S. Capitanio, G. Cabrini, E. Gay, K. Shyli, A. M. Lazar, C. Rossetti;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Long axial field-of-view (LAFOV) PET/CT allows imaging with increased sensitivity and shorter scan duration. The effect of reduced-duration protocols on the detection of non-pathological findings remains unclear. This study aimed to investigate the impact of different scan duration on the detectability of non-pathological findings in a cohort of prostate cancer patients undergoing LAFOV PSMA PET/CT. ***Materials and Methods:*** This retrospective study included 39 patients with histologically confirmed prostate cancer who underwent LAFOV PSMA-PET/CT using [68Ga]Ga-PSMA-11 or [18F]F-DCFPyL. List-mode acquisitions were reconstructed into images of 30 seconds, 1, 2, 3, 4, 5 and 10 minutes. Unspecific bone uptake (UBU) and sympathetic ganglia uptake were assessed by three nuclear medicine physicians. Binary presence (0 = absent, 1 = present) and maximum standardised uptake value (SUVmax) were recorded. Impact of scan duration on frequency detection of UBU and ganglia was assessed using Cochran's Q and McNemar's tests. Repeated measures ANOVA, Friedman tests were used to compare SUVmax across scan duration. Subgroup analyses were performed by radiotracer, clinical setting, and primary tumour burden. ***Results:*** In this cohort, UBU was observed in 46% of patients at 10 minutes, increasing gradually from 36% at 30 seconds. Median SUVmax of UBUs rose from 2.2 at 30 seconds to 2.8 at 10 minutes ($p = 0.001$). Linear mixed model analysis confirmed a significant positive trend in SUVmax over time ($\beta = +0.12$/min, $p < 0.001$). ROC analysis for distinguishing UBU presence yielded an AUC of 0.81 at 5 minutes and 0.86 at 10 minutes. Ganglia were identified in 51% of patients at 10 minutes, with detection rates rising from 33% at 30 seconds. Median SUVmax of ganglia increased from 1.9

to 2.6 across the acquisition span ($p < 0.001$), with a similar positive time-dependent slope ($\beta = +0.14$/min, $p < 0.001$). ROC AUC for ganglia presence reached 0.83 at 10 minutes. Notably, over 85% of ganglia and 80% of UBU visualised at 10 minutes were already detectable at 3 minutes, with negligible improvement beyond 5 minutes. No significant differences in UBU or ganglia metrics were observed between radiotracers. Subgroup analysis across clinical settings (staging, PSA persistence, biochemical recurrence) showed consistent patterns. ***Conclusion:*** In LAFOV PSMA-PET/CT, the detectability and SUVmax of UBU and sympathetic ganglia increase slightly with longer acquisition times, although most of the diagnostic yield is already achieved at 3-5 minutes. These findings support the feasibility of reduced-duration protocols without compromising lesion characterisation.

EP-0428

The Relationship Between Clinical Scoring and Ga-68 PSMA PET/CT Parameters in Predicting Biochemical Failure After Radical Prostatectomy

F. Avci[1], *R. H. Tokac*[1], *M. Dinckal*[2], *K. E. Ergün*[3], *A. M. Argon*[1], *U. Yararbas*[1];
[1]*Ege University, Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Harakani Training Researh Hospital, Urology, Kars, TÜRKIYE,* [3]*Ege University, Urology, Izmir, TÜRKIYE.*

Aim/Introduction: Predicting persistent PSA (BCP) or biochemical recurrence (BCR) after radical prostatectomy (RP) is crucial, as it alters treatment and follow-up strategies. This study aims to evaluate the association between Ga-68 PSMA PET/CT parameters and scoring systems in predicting BCR/BCP. ***Materials and Methods:*** We retrospectively evaluated 55 patients with locoregional prostate cancer who underwent Ga-68 PSMA PET/CT between 2018 and 2024 prior to RP, without receiving neoadjuvant therapy. Demographic data, pathology findings, and biochemical profiles were collected. Quantitative PET parameters including SUVmax, SUVmean, SUVpeak, PSMA-TV, TL-PSMA, and PSMA-TLQ were measured. miTNM and PROMISE v2 classifications were assessed, along with clinical staging systems such as D'Amico (preoperative) and CAPRA-S (postoperative). Statistical analyses were performed using SPSS v25. ***Results:*** The mean age was 65.38 years (52-72), with a median follow-up of 28.19 months. BCR/BCP occurred in 14 cases (4 BCR, 9 persistent PSA, 1 both). PSMA-TV ($p=0.002$), TL-PSMA ($p=0.006$), and PSMA-TLQ ($p=0.03$) were significantly higher in BCR/BCP cases. ROC analysis showed moderate predictive performance for PSMA-TV and TL-PSMA (AUC: 0.783 and 0.749). SUVmax, SUVmean, and SUVpeak showed no correlation. miTNM T ($p=0.015$) and N ($p=0.004$) stages were significant; T2/N0 correlated with no BCR/BCP ($p=0.01$), while N1b correlated with BCR/BCP ($p=0.01$). No difference was observed for T3-T4. PROMISE v2 showed no predictive value. CAPRA-S, stratified into three groups (0-3, 4-7, 8-12), significantly predicted BCR/BCP ($p<0.001$). Groups 1-2 correlated with no BCR/BCP ($p<0.01$), while Group 3 correlated with BCR/BCP ($p<0.001$). However, individual CAPRA-S scores were not significant. TL-PSMA ($p<0.001$) and other parameters (except PSMA-TLQ) correlated with CAPRA-S. Preoperative PSA, PSA density, D'Amico risk, and Gleason score significantly predicted BCR/BCP ($p<0.001$). D'Amico risk also correlated with TL-PSMA ($p=0.002$) and PSMA-TV ($p=0.006$). ***Conclusion:*** This study highlights the strong diagnostic performance of PSMA-TV derived from Ga-68 PSMA PET/CT in localized prostate cancer, demonstrating its correlation with clinical risk classifications and PSA levels. The findings support its potential as a non-invasive biomarker. PSMA PET/CT may play a critical role not only in diagnosis but also in risk stratification and treatment planning. Integrating quantitative PET parameters into existing risk models could enhance patient categorization and contribute to personalized therapeutic strategies, reinforcing the value of multidisciplinary approaches.

EP-0429

Prediction of 2-year overall survival in mCRPC patients by total tumor volume (TTV) under PROMISE risk stratification scheme in a single Asian center

T. Tsoi*, S. Chen, K. Yip, Y. Yip, K. Wu, Y. Wong, S. Cheung, C. Ho;*
Hong Kong Sanatorium & Hospital, Hong Kong, CHINA.

Aim/Introduction: "PROMISE" is a reporting scheme proposed to include molecular information obtained from PSMA-ligand PET/CT to predict prognosis in mCRPC patients. It aims to combine molecular TNM (miTNM) staging with molecular PSMA parameters (miPSMA) stratified as nomogram-based risk factors such as tumor volume, SUV, locoregional and distant metastases, so that the reporting can be standardized across different imaging centers and for longitudinal assessment of treatment response. The scheme is an improved modification to the Gafita normograms by including more detailed miPSMA parameters, but no prediction of overall survival (OS) is yet proposed. This pilot study attempts to identify the significant predictor(s) in PSMA-ligand PET/CT for OS assessment in a cohort of mCRPC patients in a single Asian center. ***Materials and Methods:*** We consecutively analyzed 42 clinically-identified mCRPC patients (age:72±10 years, range:50-87 years) who were assessed by PSMA-ligand PET/CT for mCRPC and then followed for >2 years (25-64 months). The primary endpoint was the OS. The prognostic predictors included categorical parameters: (1) locoregional, (2) extrapelvic lymph node, (3) bone (disseminated/diffuse marrow involvement), (4) other distant metastases, and continuous parameter: (5) total tumor volume (TTV) on PSMA-ligand PET/CT. The diagnosis of bone metastases on PSMA PET/CT was combined with CT findings in bone window. ROC curve analysis was performed on TTV for OS assessment. Survival analysis utilized Kaplan-Meier estimates and Cox regression to identify independent predictors. ***Results:*** 31/42 patients died during the follow-up period. ROC curve analysis for TTV on PSMA PET/CT identified a 2-year OS with the best AUC accuracy (AUC=0.975), consistent with the risk stratification results (HIGH/LOW) by PSMA-PET PROMISE. "TTV≥183ml" was calculated as the best cut-off value. The 2-year OS rate was 48% (20/42) in our study. Among all the selected prognostic predictors, "extrapelvic lymph node metastases" and "TTV≥183ml" were found to be significant predictors for 2-year overall survival using univariate analysis. Further multivariate analysis found that "TTV≥183ml" was the only independent predictor (sensitivity: 86.4% [19/22], specificity: 95.0% [19/20], accuracy: 90.5%). mCRPC patients with TTV≥183ml (N=20) had a significantly shorter median OS than those (N=22) with TTV<183 ml (estimated median survival: 9 vs 39 months; log-rank test, $p<0.001$). ***Conclusion:*** The tumor burden quantified as TTV by combining all the metastatic sites on PSMA PET/CT is found to be the most significant predictor of 2-year OS in this study. A threshold TTV of 183 ml is a strong differentiator of prognosis in this cohort of mCRPC patients.

EP-0430

Which Patients with Negative PSMA-PET Imaging Can Safely Avoid Biopsy for Prostate Cancer? A Novel Step Towards PSMA-based Biopsy-Free Strategy

Y. Li*, Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: The initial diagnosis of prostate cancer (PCa) traditionally relies on prostate biopsy driven by serum prostate-specific antigen (PSA), which is an organ-specific biomarker and lacks sufficient specificity. mpMRI has the potential to reduce the number of unnecessary biopsies. However, owing to its suboptimal and highly variable negative predictive value (NPV), the reliability of negative mpMRI as a triage test to safely rule out the need for biopsy remains less established and controversial. Moreover, its moderate specificity limits the reduction in the net number of unnecessary biopsies. We aimed to identify if a

subset of men can safely avoid or delay prostate biopsy based on negative prostate-specific membrane antigen positron emission tomography (PSMA-PET), using data from a prospective biopsy cohort. ***Materials and Methods:*** Among 341 consecutive cases in the prospective biopsy cohort NCT05073653, 111 treatment-naïve men with negative PSMA-PET (PRIMARY-score 1/2) were included. All participants underwent PSMA-PET and histopathological examinations. Clinically significant PCa (csPCa) was defined as Grade Group ≥ 2. Multivariate logistic regression was employed to identify predictors of non-csPCa. Receiver operating characteristic (ROC) analysis was performed to detect non-csPCa on prostate pathology. PSMA-postive patients were additionally reviewed to assess the pathological outcomes. ***Results:*** Younger age was identified as an independent predictor (P = 0.006) for the absence of csPCa. ROC analysis of csPCa revealed the largest areas under the curve of 0.77 (0.67-0.87) and 0.78 (0.68-0.88) for individual age in the entire PSMA-negative cohort and the MRI subset, respectively (both P < 0.001). The NPV of PSMA-PET for csPCa detection improved with a decreasing age, from 88% in all, to 98% in men aged under 65 years (98% vs. 88%, P = 0.021), and to 100% in men aged under 60 years (100% vs. 88%, P = 0.040). The NPV of PSMA-PET improved from 88% to 94% when combined with negative MRI, and to 100% in men with negative MRI and aged under 65 years. The prevalence was 57% for csPCa and 65% for PCa of any grade. ***Conclusion:*** We preliminarily propose that omission or postponement of prostate biopsy should be considered for men under the age of 65 years with negative PSMA-PET scored as PRIMARY 1/2. Conversely, prostate biopsy might be considered for biopsy-naïve men aged 65 years or older with strong clinical suspicion of PCa, despite negative PSMA-PET. Further prospective and external evaluations are needed to prove the robustness of this novel strategy.

EP-0431

18F-PSMA 1007 PET/CT metrics as a biomarker for progression-free survival in Patients with Metastatic Prostate Cancer

S. Moustafa*;*
Assiut university hospital, Assiut, EGYPT.

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeting PET imaging is becoming the reference standard for prostate cancer staging, especially in advanced disease. Metastases are often responsible for prostate cancer-related morbidity and mortality. Thus, the quantification of the whole-body tumor volume is clinically relevant, and it could predict the progression-free survival (PFS) and overall survival of patients. yet, there is no clear evidence that PSMA PET-derived biomarkers can predict the progression-free survival of patients with prostate cancer. Our aim is to evaluate whole-body PSMA PET metrics as imaging biomarkers for determination of PFS. ***Materials and Methods:*** We enrolled 49 patients with prostate cancer who had PSMA-avid metastatic lesions. From all pathological lesions, the mean and maximum SUV (SUV mean, SUVmax) and the tumor volume of each lesion were determined in VOIs with isocontours set at 41% of the maximum uptake; that is called PSMA-TR (tumor volume) and finally, PSMA-TL (total lesions) calculated by multiplying the respective TV and mean SUV. We calculated the total metrics then; we correlated it with PFS. Then we divided total metrics into osseous and non-osseous. We classified patients in low & high-volume disease based on PSMA PET/CT on parrel of CHAARTED trial. We used the Cox regression model to determine the most prognostic factor for PFS. ***Results:*** Total metrics SUVmax, SUVmean, PSMA-TR and PSMA-TL were significantly correlated with PFS, r= - 0.4& p=0.01, r= - 0.31& p=0.03, r=-0.4& p=0.008, r=-0.35& p=0.014 respectively. Osseous total SUV max, SUV mean, PSMA-TR and PSMA-TL were significantly correlated with PFS; r= -0.5& p<0.001, r= -0.5& p<0.001, r= -0.6& p=0.001, r= -0.44& p=0.002 respectively. As regards non-osseous metrics; only PSMA-TR was significantly correlated with PFS, r=- 0.3&p=0.031 whilst no significant correlation between SUVmax, SUVmean and PSMA-TL and PFS, p=0.3, p=0.7, p=0.3 respectively We found that PSMA-based volume disease significantly correlated with PFS with a P value of 0.04. The total osseous SUV mean was considered the most independent variable of PFS in the current population study, meaning that increasing the total osseous SUV mean by 0.3% increased the hazard of progression or death by 10%, HR (Hazard Ratio) = 1.9, 95% CI of (1.026 - 3.443) and p value 0.041. ***Conclusion:*** PSMA PET metrics are significant predictors of PFS in patients with advanced prostate cancer. PSMA-based volume disease significantly correlated with PFS. The mean SUV for total osseous PSMA is the most important prognostic indicator for PFS in these patients.

EP-0432

Comparative evaluation of SUV variability in reference tissues and tumor lesions for defining the PSMA-positivity threshold in PSMA-targeted radioligand therapy

A. Khalimon[1]*, A. Nikiforuk*[1]*, A. Shakirova*[1]*, A. Lokhova*[1]*, V. Bagaturya*[1]*, I. Baltabaev*[1]*, M. Khodzhibekova*[1]*, G. Khamadeeva*[1]*, D. Khodakova*[1]*, T. Lazutina*[1]*, I. Pylova*[1]*, A. Leontev*[1]*, A. Pronin*[2]*, E. Bezumova*[2]*;*
[1]P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION, [2]N.N. Blokhin National Medical Research Center of Oncology of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: The aim of this study was to compare the SUV variability in reference tissues and tumor lesions for defining the PSMA-positivity threshold in PSMA-targeted radioligand therapy. ***Materials and Methods:*** This research included single-center patient study and multicenter phantom study with following single-center validation study for evaluation the SUV variability in reference tissues and tumor lesions, respectively. Single-center patient study included 100 patients with prostate cancer who underwent [^{18}F]PSMA-1007 PET/CT using the BGO PET/CT-system. BSREM algorithm with β-value 400 was used for PET image reconstruction. [^{18}F]PSMA-1007 uptake was analyzed by measurement of SUVmax, SUVmean and SUVpeak in the parotid glands (dVOI=0.5cm); blood pool (dVOI=1cm); liver (dVOI=2cm); spleen and gluteus muscles (dVOI=1.5cm). The coefficients of variation (CoVs) for SUVmax, SUVmean and SUVpeak were calculated for each reference tissue. The phantom study was performed on three PET/CT-systems (with BGO-, LSO- and LYSO-based detectors) using the NEMA IEC Body Phantom NU2-2018. The phantom filling and acquisition procedure were performed in accordance with the EARL ^{18}F-standards manual. A total of 20 EARL2-compliant reconstructions were included into the analysis. SUVmax and SUVpeak Recovery Coefficients (RCmax and RCpeak) for each phantom's sphere across all reconstructions were calculated. The validation study was performed on 36 patients who underwent both [^{18}F]FDG and [^{18}F]PSMA-1007 PET/CT using the BGO PET/CT-system. Raw PET data were used to obtain 10 EARL2-compliant reconstructions (3D-OSEM+PSF). 96 lesions approximately spherical in shape were selected with diameters almost evenly distributed from 10 to 37mm, grouped according to intervals of phantom's spheres diameters. SUVmax and SUVpeak of each lesion across all reconstructions were measured. The CoVs for RCmax, RCpeak and SUVmax, SUVpeak were calculated for each phantom's sphere and patient's lesion within each group of reconstructions respectively. ***Results:*** The CoVs of SUVs (max, mean and peak) in the reference tissues were as follows: 24.9%,24.8%,24.2% - in the liver, 44.2%,44.3%,43.3% - in the spleen, 26.6%,29.5%,26.7% - in the parotid glands, 27.5%,27.2%,28.7% - in the

blood pool, 19.8%,19.4%,18.9% - in the gluteus muscles. The CoVs of RCmax and RCpeak for each phantom's sphere (from smallest to largest) were as follows: 12.3%,5.6%,5.3%,5.5%,3.2%,3.2%, and 8%,4.8%,2.9%,2.4%,3.3%,1.6%. The CoVs of SUVmax and SUVpeak for each interval of lesions' diameters (from smallest to largest) were as follows: 8.4[7.2;10.5],8[5.9;9.1],5[4;5.8],4.3[3.2;5.4],3.7[2.7;6.3], and 5[3.9;6.5],4[3.4;6.9],2.7[2.3;5.1],2.3[1.6;3.2],1.6[1.5;2.2] in percents. ***Conclusion:*** The application of tumor lesions' EARL-harmonized SUV may be preferable to SUV in reference tissue for defining the PSMA-positivity threshold in PSMA-targeted radioligand therapy due to its lower variability.

EP-0433

The impact of patient hydration and forced diuresis on [^{18}F]PSMA-1007 urinary bladder uptake in PET/CT imaging

A. Khalimon[1], *A. Nikiforuk*[1], *M. Khodzhibekova*[1], *G. Khamadeeva*[1], *D. Khodakova*[1], *T. Lazutina*[1], *I. Pylova*[1], *A. Leontev*[1], *V. Bobrov*[1], *O. Mukhortova*[2], *I. Aslanidi*[2];
[1]*P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION,* [2]*A.N. Bakulev National Medical Research Center for Cardiovascular Surgery of the Russian Ministry of Health, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: [^{18}F]PSMA-1007 has minimal renal excretion, allowing for better assessment of the pelvic area in patients with prostate cancer (PCa). Nevertheless, there have been instances of notably high [^{18}F]PSMA-1007 uptake in the urinary bladder. The purpose of this study was to assess the impact of preliminary patient hydration and forced diuresis on [^{18}F]PSMA-1007 urinary bladder uptake. ***Materials and Methods:*** A prospective single-center study included 185 patients with PCa, who underwent [^{18}F] PSMA-1007 PET/CT. Patients were divided into 11 groups: a control group with no hydration or furosemide administration (n=35) and ten experimental groups (n=15 in each) with different preparation protocols: (#1) 500ml IV; (#2) 1000ml IV; (#3) 500ml IV + furosemide 90 minutes before PET (at the same time as [^{18}F]PSMA-1007 administration); (#4) 500ml IV + furosemide 30 minutes before PET; (#5) 1000ml IV + furosemide 30 minutes before PET; (#6) 500ml orally; (#7) 1000ml orally; (#8) 500ml orally + furosemide 30 minutes before PET; (#9) 1000ml orally + furosemide 30 minutes before PET; (#10) furosemide 30 minutes before PET with no hydration. LBM SUVmean was used to quantify [^{18}F]PSMA-1007 bladder uptake. The differences in bladder SUVmean among the different preparation groups, as well as compared to the control group, were evaluated. A $p<0.001$ was considered statistically significant. Additionally, the variability of bladder SUVmean was assessed by evaluating the interquartile ranges (IQRs). ***Results:*** Urinary bladder SUVmean were 4.2 [2.4;12.0] with IQR 9.6 in the control group. In the experimental groups bladder SUVmean were as follows: (#1) - 6.2 [2.9;9.3] IQR 6.4; (#2) - 6.4 [3.2;9.8] IQR 6.6; (#3) - 1.8 [1.2;2.1] IQR 0.9; (#4) - 0.7 [0.5;0.9] IQR 0.4; (#5) - 1.0 [0.7;1.2] IQR 0.5; (#6) - 2.2 [1.6;4.5] IQR 2.9; (#7) - 3.4 [2.7;5.2] IQR 2.5; (#8) - 0.6 [0.5;0.8] IQR 0.3; (#9) - 0.6 [0.5;0.8] IQR 0.3; (#10) - 0.9 [0.7;1.4] IQR 0.7. The results indicate that the application of furosemide significantly reduced the median and variability of bladder SUVmean ($p<0.001$), 30 minutes time interval of furosemide application prior to PET scan is preferable compared to 90 minutes ($p<0.001$). Hydration alone, without furosemide, was insufficient for effectively reducing the median and variability of bladder SUVmean ($p=0.5$). There was no significant difference between the groups with different routes and volumes of hydration ($p=0.03$ and 0.45). ***Conclusion:*** Forced diuresis is an effective tool for reducing the [^{18}F]PSMA-1007 urinary bladder uptake and its variability when it is routinely increased.

EP-0434

Identifying Genetics Biomarkers in Correlation to Pathological and PSMA-PET Characteristics in Prostate Cancer

L. Xin;
Qilu Hospital, Shandong University, Jinan, CHINA.

Aim/Introduction: Prostate cancer is a prevalent disease with varied tumor characteristics complicating treatment. The integration of spatial patterns from PSMA PET and pathology with expanding genomic data is pioneering advances in histo-imaging-genomics. This study aim to elucidate inter-network mapping between genetic biomarkers and PSMA-PET imaging in prostate cancer. ***Materials and Methods:*** mRNA sequencing and clinical data from 433 prostate cancer cases were sourced from the TCGA database. Differential gene expression between GS-high risk and GS-low risk groups was analyzed. Univariate and multivariate logistic regressions facilitated feature selection, and a GS predictive model was developed via multivariate logistic regression. Additionally, local samples and images from 27 patients were gathered. PSMA-PETCT imaging preceded before radical prostatectomy, and mRNA sequencing of prostate cancer lesions was conducted via next-generation sequencing. Genes differentially expressed, as identified from the TCGA dataset, were then analysized for correlating with PET-related metrics in the local dataset by utilizing the Pearson correlation. ***Results:*** Out of the TCGA dataset, 174 genes showed differential expression. Post feature selection, 53 genes persisted. In the local dataset, ten genes (EFNA2, CACNA1I, CA1, MYBPC3, CYP1A1, TLCD3B, LRTM2, GBX2, SPSB4, and GDF3) demonstrated significant association with PET-related metrics. When the differential expression of genes between high-risk and low-risk groups was compared, six genes (STMN2, CYP1A1, THRSP, LIPC, GBX2, and SPSB4) in the high-risk group and eight genes (FBXL16, KLK14, DIRAS2, TERB2, PRAME, UTS2B, UGT2B15, and LINC02798) in the low-risk group were found to be significantly correlated with PET-related parameters. ***Conclusion:*** The study identified genetic markers that have a significant correlation with PSMA-PET imaging features in prostate cancer. These findings might provide a valuable foundation for optimizing prostate cancer diagnostic procedures and tailoring therapeutic approaches based on genetic and imaging biomarkers. ***References:*** 1.Sung H, Ferlay J, Siegel RL, Laversanne M, Soerjomataram I, Jemal A, et al. Aim/Introduction: Prostate cancer (PCa) is a leading cause of morbidity and mortality in men worldwide, with late-stage diagnoses due to limitations in conventional imaging techniques,

such as CT and MRI. The novel ^{18}F-labeled PSMA-targeted radiotracer demonstrates high targeting affinity, favorable biodistribution, and clear lesion imaging, offering the potential to improve the accuracy of initial PCa diagnosis. ***Materials and Methods:*** This study is a multicenter, prospective, open-label phase I/IIa clinical trial systematically evaluating the safety, biodistribution, pharmacokinetics, and diagnostic performance of ^{18}F-PSMA-137 PET/CT in healthy individuals and suspected PCa patients. Phase I included 8 healthy male volunteers to evaluate the radiotracer 's safety, biodistribution, radiation dosimetry, and pharmacokinetics. Phase IIa enrolled 24 suspected PCa patients with elevated PSA levels (≥3 ng/mL) who had no previous PCa diagnosis or treatment history, and who were scheduled for prostate biopsy before/after imaging. Phase IIa assessed the diagnostic performance of ^{18}F-PSMA-137 PET/CT at different doses and different scan times. Diagnostic performance, including sensitivity, specificity, and accuracy, was compared with multiparametric MRI (mpMRI), with prostate biopsy pathology as the reference standard. Adverse events (AEs), laboratory tests, and ECG were monitored throughout to assess safety. ***Results:*** In phase I, ^{18}F-PSMA-137 demonstrated rapid in vivo distribution, primarily excreted through the renal and hepatobiliary pathways, with the liver, kidneys, and salivary glands as the main uptake organs. The mean effective radiation dose was 7.59 ± 1.17 mSv, with rapid clearance of the drug, clear biodistribution, and excretion pathways, and no serious adverse events reported. In phase IIa, ^{18}F-PSMA-137 showed good uptake in prostate lesions. In the low-dose group, the sensitivity at 80 and 120 minutes post-injection was 100.0%, specificity was 85.7%, accuracy was 90.9%, positive predictive value (PPV) was 80.0%, negative predictive value (NPV) was 100.0%, Youden index was 0.86, and the Kappa value was 0.81, indicating high concordance with pathology. In the high-dose group, the sensitivity was 87.5%, specificity was 75.0%, accuracy was 83.3%, Youden index was 0.63, and the Kappa value was 0.63. PET/CT demonstrated higher specificity and accuracy compared with multiparametric MRI (mpMRI), supporting its clinical value in the preliminary diagnosis of suspected PCa patients. ***Conclusion:*** ^{18}F-PSMA-137 PET/CT demonstrates a favorable safety profile, robust pharmacokinetics, and high diagnostic performance in suspected PCa. Its superior sensitivity and specificity position ^{18}F-PSMA-137 PET/CT as a potential global benchmark in the initial diagnosis of PCa, warranting further large-scale studies for validation.

Defining Semiquantitative PSMA PET Thresholds for Clinically Significant Prostate Cancer: Interim Analysis of the BIOPSTAGE Study

M. Celli[1], *R. Gunelli*[2], *F. Ferroni*[1], *M. Costantini*[2], *A. Rossi*[1], *L. Fantini*[1], *E. Fragalà*[2], *I. Marini*[1], *D. Bezzi*[3], *V. Rossetti*[1], *I. Grassi*[1], *M. Sansovini*[1], *E. Giunta*[1], *S. Bellia*[1], *V. Di Iorio*[1], *F. Foca*[1], *F. Matteucci*[1], *P. Caroli*[1];
[1]*IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola (FC), ITALY,* [2]*Morgagni Pierantoni Hospital, Romagna Local Health Service, Forlì (FC), ITALY,* [3]*Bufalini Hospital, Romagna Local Health Service, Cesena (FC), ITALY.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) PET is gaining interest as a non-invasive diagnostic tool in the primary staging of prostate cancer (PCa). While its utility in advanced disease is well established, its role in detecting clinically significant PCa (csPCa) remains under investigation. In particular, standardized uptake thresholds for defining PET positivity are lacking, which limits clinical applicability. This interim analysis from the prospective BIOPSTAGE trial aimed to define optimal semiquantitative criteria (SUVmax and SUVratio) for PSMA PET and explore their association with histopathological outcomes and clinical parameters. ***Materials and Methods:*** Ninety-six men with clinical suspicion of PCa were prospectively enrolled. All patients underwent [^{68}Ga]Ga-PSMA-11 PET/CT and multiparametric MRI (mpMRI) prior to prostate biopsy. csPCa was defined as ISUP grade group ≥2. ROC curve analysis was used to determine optimal SUVmax and SUVratio cutoffs for PSMA PET positivity. Logistic regression assessed clinical and imaging predictors of PSMA uptake. ***Results:*** ROC analysis identified SUVmax ≥9.1 and SUVratio ≥3.6 as optimal thresholds, yielding AUCs of 0.87 and 0.88, respectively. Using these thresholds, PSMA PET showed a sensitivity of 85.7% and specificity of 86.3%, with a positive predictive value (PPV) of 48.0% and a negative predictive value (NPV) of 97.6%. Of 25 PET-positive lesions, 14 were also mpMRI-positive, while 11 had no mpMRI correlate. One PET-only lesion was confirmed as csPCa (ISUP 3), and two small csPCa lesions (5 mm and 8 mm, both ISUP 2) were not detected by PET but were identified on mpMRI. PSA density emerged as the only independent predictor of PSMA PET positivity (OR: 6.35; p = 0.006), supporting its value in clinical risk stratification. ***Conclusion:*** The use of standardized SUV thresholds improves the diagnostic performance of PSMA PET for csPCa and may facilitate its incorporation into biopsy decision-making. While PET offers high specificity and NPV, mpMRI remains essential, particularly for identifying small, low-uptake lesions. These interim findings support a combined PET-MRI approach for optimizing patient selection and reducing unnecessary biopsies.

EP-0437

Role of PET/MRI in Prostate Cancer: Indications and Potential Uses. Our Preliminary Experience

J. Díaz Moreno[1], *J. Robles-Barba*[1], *J. Martín-Marcuartu*[1], *D. Durany-Lara*[2], *A. Bagán-Trejo*[1], *A. Caresia-Aroztegui*[3], *N. Picola-Brau*[4], *J. Súarez-Novo*[4], *B. Hervás-Sanz*[1], *P. Servian-Vives*[5], *A. Abella-Serra*[5], *M. Cortés-Romera*[1];

Aim/Introduction: This descriptive study aims to present our current experience with PET/MRI in prostate cancer, focusing on its clinical indications, potential uses, the various radiotracers available, and their therapeutic implications. ***Materials and Methods:*** Between 2023 and 2024, a total of 70 PET/MRI studies were performed in patients with prostate cancer using three different radiotracers: 18F-PSMA-piflufolastat (40/70) for biochemical recurrence (BCR) and characterizing PI-RADS 3 lesions; 18F-PSMA-1007 (19/70) for patients eligible to focal therapies (FT) and BCR with very low PSA levels, and 18F-choline (11/70) for screening, staging and BCR. Radiotracer selection was based on clinical criteria, availability and regulatory constraints at that moment in our country. Detection rates (DR), agreement between PET and MRI and change in therapeutic managment (CTM) were assessed. ***Results:*** Forty PET/MRI studies using 18F-PSMA-piflufolastat were performed (median PSA 1.4 ng/ml, range: 0.2-32.4), 17/40 for BCR with DR of 70% and CTM in 58% of cases. 23/40 studies were part of a research protocol assessing the role of PSMA PET/MRI in characterizing PI-RADS 3 lesions, with histopathology (AP) as the gold standard. 20/23 showed a PRIMARY score 1A/2A on PET with no findings suspicious for clinically significant prostate carcinoma, showing agreement with MRI findings (kappa 0,25). Nineteen studies with 18F-PSMA-1007: 17/19 in patients with BCR after radiotherapy eligible for FT such as IRE or HIFU, as part of a prospective study. PET imaging changed management in up to a quarter of patients by detecting lymphatic dissemination that would not have been identified using MRI alone. The remanining 2/19 studies were performed in patients with low PSA (0.2-0.5 ng/ml) and suspected local recurrence (DR 50%). Eleven studies were performed using 18F-Choline: 2/11 for screening (both negative),

2/11 for staging (both positive), and 7/11 for BCR. DR was 100% in these BCR patients, likely due to the high PSA levels they presented (median PSA 7,2 ng/ml, range 2,2 - 50,9), with CTM in 63% of them. ***Conclusion:*** Our preliminary experience highlights the clinical value of PET/MRI in prostate cancer on indications such as staging or biochemical recurrence, where it shows a high impact in changing therapeutic management. The greater resolution provided by the MRI component also allows the use of PET imaging on potential indications such as the characterization of PI-RADS 3 lesions or selecting patients eligible for focal therapies.

Clinicopathologic Features and Prognostic Stratification of Thyroid Carcinoma with Antecedent Distant Metastasis: A Retrospective Analysis of 44 Consecutive Cases

Y. Wu, *L. Zhang, J. Gui, H. Chen, J. Wang, X. Long, W. Cao;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan City, CHINA.

Aim/Introduction: Thyroid carcinoma typically has a favorable prognosis, but some patients present with distant metastasis before the primary tumor is detected—termed antecedent distant metastasis. This rare and underrecognized form is linked to worse outcomes. Identifying prognostic factors is essential to guide treatment in this high-risk group. This study aimed to define their clinicopathologic features and evaluate prognostic indicators. ***Materials and Methods:*** A retrospective study analyzed 44 consecutive patients with antecedent metastatic thyroid carcinoma, selected from 7,374 cases managed between Jan 1, 2019, and Mar 31, 2025. Clinical data included demographics, histopathology, TNM stage, metastatic sites, surgery type, and gene mutations. Treatment response was evaluated using RECIST 1.1 (PR, SD, PD) and the 2015 ATA response-to-therapy system (ER, BIR, SIR). ***Results:*** Among 44 patients (65.9% female, mean age 59.6 ± 11.5), follicular carcinoma was the most common subtype (34.1%) and had the highest partial response (PR) rate (66.7%), followed by papillary carcinoma (15.4%). Most were T1 (45.0%), N0 (58.3%), and M1 (94.4%). PR was achieved in 31.8%, stable disease in 43.2%, and progression in 25.0%. ATA stratification showed 2 excellent responses, 1 biochemical incomplete, and 41 structural incomplete. Gene testing (n = 5) revealed various mutations, including BRAF, RET, TERT, and ALK. Bone metastasis (χ^2 = 7.560, P = 0.023), surgical method (χ^2 = 9.976, P = 0.041), and histology (χ^2 = 20.879, P = 0.022) significantly impacted outcomes. Patients with bone metastases had higher PR (42.4%), likely due to other metastatic sites. Total thyroidectomy showed better PR (38.2%) than partial or conservative treatments. ***Conclusion:*** Patients with antecedent distant metastasis of thyroid carcinoma exhibit heterogeneous clinical outcomes, with prognosis significantly affected by histologic subtype, metastatic site, and surgical approach. Follicular thyroid carcinoma demonstrated the highest partial response rate , suggesting better responsiveness compared to papillary and other subtypes. Bone metastasis was associated with a more favorable treatment response than other metastatic sites such as lungs and lymph nodes. Total thyroidectomy resulted in significantly better outcomes compared to partial thyroidectomy or conservative treatment . Although genetic testing was limited, actionable mutations were identified in several cases, highlighting the potential role of molecular profiling in guiding targeted therapies. These findings underscore the importance of aggressive surgical management and tailored therapeutic strategies based on clinicopathologic and molecular features to improve prognosis in this rare but high-risk subset of thyroid carcinoma.

EP-0439

Exploring Factors of Achieving Excellent Response in Intermediate- and High-Risk Patients with Differentiated Thyroid Cancer after therapy with 100mCi Iodine-131

J. Xin, *F. Kang, W. Ma, J. Wang;*
Department of Nuclear Medicine, Xijing Hospital, FourthMilitary Medical University, Xi'an, CHINA.

Aim/Introduction: To explore the factors for achieving an excellent response (ER) in patients with intermediate- and high-risk differentiated thyroid cancer (DTC) after treatment with 100 mCi of iodine-131. ***Materials and Methods:*** A retrospective analysis was conducted on 725 DTC patients who were treated in the Department of Nuclear Medicine of Xijing Hospital from June, 2021 to April, 2024. All patients were pathologically diagnosed with DTC and received 100 mCi iodine treatment. Univariate analysis and binary Logistic regression analysis were used to identify the influencing factors, and ROC curve analysis was performed to determine the optimal critical values for predicting ER. ***Results:*** Among 725 patients, 477 patients (65.79%) achieved ER, and 248 patients (34.21%) did not achieve ER. Univariate analysis indicated that multiple factors were correlated with achieving ER, and binary Logistic regression analysis revealed that the number of metastatic lymph nodes, pre-treatment stimulated thyroglobulin(psTg), Tg/TSH, and Tg*TgAb were independent risk factors influencing the attainment of ER in intermediate- and high-risk patients with DTC after 100 mCi iodine-131 treatment, ROC curve analysis determined the optimal critical values for these factors in predicting ER. ***Conclusion:*** The number of metastatic lymph nodes, psTg, Tg/TSH, and Tg*TgAb are independent predictive factors for achieving ER in intermediate- and high-risk DTC patients after treatment with 100 mCi of iodine.

EP-0440

Evaluation of the clinical utility of [^{18}F]FDG PET/CT in the detection of non-metastatic disease in differentiated thyroid cancer

M. Opalinska[1], *K. Undas*[2], *M. Olesiński*[2], *M. Osiowski*[2], *K. Kaczmarek*[2], *E. Chudyba*[2], *T. Gorczański*[2], *A. Sowa-Staszczak*[1], *M. Buziak-Bereza*[1], *M. Trofimuk-Muldner*[1], *A. Hubalewska-Dydejczyk*[1];
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, POLAND, [2]The Student Scientific Group of Nuclear Medicine, Jagiellonian University Medical College, Krakow, POLAND.

Aim/Introduction: Approximately 30% of patients with disseminated differentiated thyroid cancer (DTC) experience loss of iodine sensitivity during the course of therapy. This clinical feature is associated with increased tumor aggressiveness and reduced survival at 10 years. The localization of non-radioiodine avid DTC metastases in the setting of elevated concentrations of thyroglobulin (Tg) often remains a diagnostic challenge. In this clinical setting, positron emission tomography with 2-[18F]fluoro-2-deoxy-D-glucose (PET/CT with [18F]FDG) is increasingly used, usually after stimulation with exogenous thyrotropic hormone (rhTSH).The primary objective of the study was to determine the cut-off point of baseline and stimulated Tg levels in patients with differentiated thyroid cancer (DTC) who have elevated baseline Tg levels, negative aTg under the TSH suppression and a negative whole body scintigraphy (WBS) with 131I. A secondary aim of the study was to analyze the clinical and histopathological factors associated with FDG avidity of metastatic lesions on PET/CT. ***Materials and Methods:*** Eighty-one patients with DTC, negative 131I-WBS and

neck ultrasound but elevated baseline Tg levels who underwent FDG-PET/CT for suspected recurrent/metastatic disease were included in the analysis. All patients had undergone a total or near-total thyroidectomy followed by radioiodine therapy. The [^{18}F]FDG PET/CT results were correlated with baseline and stimulated Tg levels as well as clinical and histopathological findings. ***Results:*** The mean age of the patients was 53.94 (42-69) years. Papillary carcinoma was diagnosed in 62 patients, follicular carcinoma in 14 and oncocytic carcinoma in five. Women accounted for 63.9% and men for 36.1% of patients. In the evaluated population, recurrence was detected in the thyroidectomy bed by PET/CT with [18F]FDG in 15 patients (16.7%), metastatic lesions in the neck lymph nodes in three patients (4.3%) and in the bones in four patients (4.9%). Of all histopathological parameters analyzed, only the presence of angioinvasion discriminated patients with FDG-avid metastatic lesions (p=0.019). A significant correlation was observed between positive PET results and elevated Tg levels (p = 0.03). ROC curve analysis showed a cut-off point 6,775 ng/ml for baseline Tg ((AUC): 0,737 (95% CI: 0,611-0,862), Youden index 0,489, sensitivity 60%, specificity 89,9%). For baseline and stimulated Tg, the minimum baseline value at which PET detected a relapse was 0.04 and 1.93 ng/ml, respectively. ***Conclusion:*** PET/CT with [18F]FDG is a very sensitive tool for the detection of recurrent and/or metastatic DTC. Baseline Tg and stimulated Tg concentrations are strongly correlated with positive PET/CT with [18F]FDG.

EP-0441

Quantitative Tc-99m MIBI SPECT/CT parameters can predict malignancy in indeterminate thyroid nodules-preliminary results

M. Araz*, &. Mesci, E. D. Avci, C. Soydal, O. B. Aksu, E. Eraslan, C. Konca, M. F. Erdogan, N. Ö. Kucuk;*
Ankara University, Ankara, TÜRKIYE.

Aim/Introduction: Tc-99m MIBI planar scan is useful in predicting thyroid malignancy, despite high false positivity rates.The aim of this study was to evaluate if quantitative Tc-99m MIBI SPECT/CT parameters can predict malignancy in patients with indeterminate thyroid nodules and to compare its performance with planar only imaging. ***Materials and Methods:*** In this prospective study, following ethics committe approval, 50 patients were planned to be recruited. The preliminary results including data of 17 patients (14F,3M mean age:56.05±11.5) with thyroid nodules enrolled between March 2024-April 2025 are presented here. All patients had at least one FNAB result in Bethesda Category III-IV. Tc-99m MIBI thyroid SPECT/CT imaging was performed. Planar images were evaluated visually to define target nodules as Tc-99m MIBI positive or negative. SUVmax, SUVmean, volume and total Tc-99m MIBI uptake (SUVmeanXvolume) were calculated on SPECT/CT images. All patients underwent surgery (lobectomy or total thyroidectomy) and final histopathological results are used for confirmation. Mean values of quantitative parameters are compared in groups with benign and malignant pathology. Sensitivity, specificity, PPV,NPV and accuracy are calculated both for planar imaging and SPECT/CT quantitative imaging. ***Results:*** A total of 21 nodules in 17 patients were evaluated, 8 of which were malignant and 13 benign on final pathology. On planar images, 9 nodules were Tc-99m MIBI negative, and 12 nodules were Tc-99m MIBI positive. Chi-square test revealed signficant difference in malignancy frequency according to Tc-99m MIBI positivity (p=0.016). None of the benign nodules were Tc-99m MIBI positive. Sensitivity, specificity, PPV, NPV and accuracy of planar imaging were calculated as: 100%, 50%, 46%, 100%, %65. Mean value of SUVmean was significantly higher in malignant nodules compared to benign nodules (p=0.045, 8.33±3.78 vs 4.39±2.34). Although not reached statistical significance, mean SUVmax values were also higher (p>0.05, 18.55±11.53 vs 8.46±5.31). ROC curves generated for SUVmax revealed that a cutoff of 6.8 was able to determine malignancy with a sensitivity of 100% and specificity of 72% (AUC: 0.857, p=0.042). PPV, NPV and accuracy were 66%,100%, 81%. Volume calculated within the ROI and total Tc-99mMIBI uptake didn't differ among groups. ***Conclusion:*** The results imply that Tc-99m MIBI planar imaging can be used as a rule out test for malignancy in thyroid nodules with indeterminate cytology. SUVmax of thyroid nodules calculated on SPECT/CT imaging increases specificity, PPV and accuracy of Tc-99m MIBI planar scintigraphy.

EP-0442

Quantification of I-131 Thyroid Remnant Uptake in Patients with Thyroid Cancer

E. Amini*[1], C. Kim[2], A. Al-Busaidi[3], R. Klein[4], W. Zeng[4];*
[1]Ottawa Hospital Research Institute, Ottawa, ON, CANADA, [2]University of Ottawa, Ottawa, ON, CANADA, [3]Sultan Qaboos Comprehensive Cancer Care and Research Centre, Muscat, OMAN, [4]The Ottawa Hospital, Ottawa, ON, CANADA.

Aim/Introduction: Radioiodine ablation is commonly performed after thyroidectomy for well-differentiated thyroid cancer (DTC). While thyroid remnant assessment is primarily visual, advancements in imaging software now allow for quantitative evaluation using standardized uptake values (SUV). Due to conflicting findings on the association between thyroid remnant uptake and thyroglobulin (Tg) levels, we sought to quantify thyroid remnant uptake in SUV and evaluate its correlation with post-therapy Tg across different risk groups. ***Materials and Methods:*** This retrospective study included patients with DTC referred for radioiodine ablation between 2015 and 2017 at an academic-affiliated hospital. All patients received Thyrogen pretreatment, and those with distal metastases or positive anti-Tg antibody were excluded. Post-therapy single-photon emission computed tomography/computed tomography (SPECT/CT) was used to quantify thyroid remnant uptake in SUV, with attenuation, scatter, and resolution recovery corrections. The remnant was segmented using an SUV_{max} threshold of 0.5, and total remnant uptake (SUV_{total}) was obtained; a threshold of 0.1 was also tested for robustness. Patients were stratified into low-intermediate, high-intermediate, and high-risk groups based on clinical risk with the corresponding therapeutic doses (mCi) of 31 ± 5, 100 ± 3, and 138 ± 14. The primary outcome was the correlation between SUV_{total} and post-therapy Tg levels. ***Results:*** The cohort included 174 adults (age: 50.7±16.0 yr, F:M=110:64). For the low-intermediate, high-intermediate, and high-risk groups (n=58, 52, and 64), stimulated Tg (pmol/L) values (median [interquartile range (IQR)]) were 3.8 [1.2, 8.7], 7.1 [1.7, 25.3], and 13.4 [3.6, 74.0], respectively. Corresponding thyroid remnant SUV_{total} values (median [IQR]) were 271.5 [82.9, 665.5], 51.4 [9.8, 138.8], and 33.1 [10.7, 108.5], respectively. Moderate correlations were found between SUV_{total} and Tg in low- and high-intermediate groups (Spearman's ρ = 0.65, $p<0.001$; ρ = 0.61, $p<0.001$, respectively). No significant correlation was found in the high-risk group (ρ = 0.12, p=0.33). Repeat analysis with a lower SUV_{max} threshold showed mildly higher SUV_{total} values, without significant correlation changes (ρ = 0.64, 0.60, and 0.12 for the low-intermediate, high-intermediate, and high-risk groups, respectively). ***Conclusion:*** Thyroid remnant quantification with current software tools is both feasible and robust. A good correlation between remnant uptake and Tg levels was observed in low- and high-intermediate risk groups, but no significant correlation was found in the high-risk group, possibly due to micro-metastases, inflammation, or aggressive histological subtypes. These findings support the potential of quantitative thyroid uptake as a reliable alternative to Tg in post-ablation follow-up and a promising predictor of disease recurrence.

EP-0443

Focal FDG Uptake in the Thyroid Gland: A Clinical Dilemma in Primary Malignancy

M. Dasar, *G. Koca, A. Özden, K. Demirel, A. Akbulut, M. Korkmaz; University of Health Sciences, Ankara Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: Incidentally detected focal thyroid lesions are common clinical situation in PET-CT scans performed for other primary origin. However, uncertainty in differentiating the benign from malignant lesions may influence treatment strategies. This study retrospectively analyzed the clinical significance of incidental focal thyroid involvement and the diagnostic role of SUVmax values in patients evaluated for primary malignancies, with reference to literature data. The aim was to determine the optimal SUVmax cutoff value for predicting thyroid malignancy and to contribute to clinical decision-making. ***Materials and Methods:*** A retrospective analysis of 3720 patients with primary malignancies who underwent FDG PET/CT scans (February 2022-April 2025) was performed. Patients with primary thyroid cancer were excluded. Cases with focal thyroid FDG uptake were included. SUVmax values of all lesions were recorded, and serum thyroid function tests (TSH, free T4) were evaluated. Histopathological confirmation (biopsy) and clinical-radiological follow-up served as the reference standard for benign-malignant differentiation. ***Results:*** Focal thyroid FDG uptake was detected in 82 of 3720 patients (2.2%). The mean age was 65±9.74 years (female: 51.5%, male: 48.5%), with no significant differences in age, sex, or thyroid function tests (TSH, free T4) between benign and malignant groups (p>0.05). Fine-needle aspiration biopsy was avaliable in 33 patients, confirming malignancy in 10 cases (1 renal cell carcinoma metastasis, 9 papillary carcinomas). The mean SUVmax of malignant lesions (14.89±11.04) was significantly higher than that of benign lesions (7.46±3.94) (p<0.001). ROC analysis revealed an AUC (Area Under Curve) of 0.801 (95% CI: 0.65-0.95) for SUVmax in discriminating malignancy. The optimal cut-off SUVmax ≥8.01 yielded 78% sensitivity and 83% specificity. ***Conclusion:*** In our study, the incidence of focal thyroid FDG uptake in patients with primary malignancies undergoing FDG PET/CT was 2.2%. Malignancy was confirmed in 30.3% of biopsied cases and diagnostic performance with SUVmax of ≥8.01 aligns with the existing literature. However, our small malignant cohort (n=9) and high SUVmax variance limit generalizability of the findings. Further large-scale studies are needed to emphasize the clinical significance of FDG PET/CT in incidentally detected focal thyroid lesions.

EP-0444

Early FDG-PET Post-RAI in Differentiated Thyroid Cancer: Detecting Disease with Sub-Standard Thyroglobulin Levels

E. Greco[1], *E. Fortunati*[2], *L. Zanoni*[3], *C. M. P. Sgro*[1], *G. A. Fuso*[1], *G. Bianciardi*[1], *G. Cuzzani*[1], *L. Carrara*[1], *C. Malizia*[2], *A. Golemi*[2], *E. Lodi Rizzini*[4], *L. Calderoni*[2], *E. Tabacchi*[2], *S. Fanti*[1,2];
[1]*Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [3]*Nuclear Medicine, AST Pesaro-Urbino, Pesaro-Urbino, ITALY,* [4]*Radiation Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: FDG-PET is not routinely performed early postoperatively or post-radioiodine treatment for differentiated thyroid cancer (DTC). However, American Thyroid Association (ATA) guidelines suggest its consideration in selected patients with suspected recurrent or metastatic disease, particularly those exhibiting elevated or rising serum thyroglobulin (Tg) levels despite a negative 131-Iodine (131-I) whole body scan (WBS), or with aggressive histologic variants, especially in intermediate and high-risk ATA categories. ***Materials and Methods:*** Retrospective single-centre study enrolling patients (n = 41) who underwent FDG-PET from 2022 to 2024 and 131-I WBS within a 1-year timeframe. Patients were stratified by ATA risk (low, intermediate, high) and PET status (positive/negative), with basal and stimulated Tg recorded, alongside assessment of thyroglobulin antibodies (TgAb) and mutation status. A qualitative analysis per patient was conducted in order to search for a correlation between PET positivity and patient's basal and stimulated Tg, TgAb and mutation. ***Results:*** Overall, 41 patients with DTC were enrolled (median age 55 years). In the low-risk group (n=2), 1 PET-positive patient had basal Tg 8.2 ng/mL and stimulated Tg 227.2 ng/mL, with negative TgAb and mutations present. In the intermediate-risk group (n=32), 12/32 (38%) were PET-positive with mean basal Tg 2.3 ng/mL (median 0.85 ng/mL, IQR 0.48-1.05) and mean stimulated Tg 21,13 ng/mL (median 5,9ng/mL, IQR 1,7-15,85). Among these, 3 had positive TgAb (two with basal Tg < 2 ng/mL), 5 had mutations. In the high-risk group (n=7), 5/7 (71%) were PET-positive with mean basal Tg 1099.34 ng/mL (median 15.7 ng/mL, IQR 11.8-468.7) and mean stimulated Tg 1282.04 ng/mL (median 118.2 ng/mL, IQR 21.8-1257.6). One high-risk patient with positive TgAb had basal Tg 0.5 ng/mL and stimulated Tg 12.6 ng/mL. ***Conclusion:*** While basal Tg 2-5 ng/mL and stimulated Tg > 10 ng/mL are often considered thresholds for further investigation including FDG-PET, our data reveal PET positivity in patients, particularly in the intermediate-risk group, with values below these cut-offs. The presence of mutations in PET-positive patients and PET positivity in some TgAb-positive individuals with low Tg suggests these factors may influence FDG avidity independently of absolute Tg levels. Integrating molecular profiling and TgAb assessment into risk stratification might improve early FDG-PET selection beyond traditional Tg measurements, potentially identifying more patients with persistent/recurrent disease. Larger studies are needed to refine these criteria in line with ATA guidelines.

EP-0445

Value of ^{18}F-FCH PET/CT for Diagnosing and Differentiating Hyperplasia From Adenoma

M. Li, *H. Pang;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: Objective: Due to the different surgical approaches for hyperplasia and adenoma in primary hyperparathyroidism, accurate preoperative diagnosis and identification are key factors affecting the surgery. 18F-FCH PET/CT is an effective tool for imaging the parathyroid glands and allows quantitative analysis. The purpose of this study is to analyze the diagnostic and differential value of 18F-FCH PET/CT for hyperplasia and adenoma. ***Materials and Methods:*** This was a retrospective analysis of data related to 63 patients undergoing 18F-FCH PET/CT at the First Hospital of Chongqing Medical University between December 2023 and December 2024. All procedures were completed, and postoperative pathological data were available for all patients. Based on the patient level, laboratory parameters such as PTH and serum calcium were compared between groups, and the analysis of PET/CT diagnosis and differences in metabolic parameters was performed based on individual parathyroid lesions. The Mann-Whitney U test and binary logistic stepwise regression analysis were also used for univariate and multivariate analyses of information related to hyperplasia and adenomas, and the indicators found to be significant on multivariate analysis were used to determine cutoff values by receiver operating characteristic analysis. ***Results:*** A total of 75 parathyroid lesions were ultimately removed postoperatively in 63 patients, including 41 hyperplasia and 34 adenoma, and multiple lesions were present simultaneously in 9 patients. Based on patient-level analysis, there were no significant differences in laboratory parameters between the hyperplasia, adenoma, and hyperplasia combined with adenoma groups (P > 0.05). Based on individual lesion analysis, the

sensitivity of PET/CT for the diagnosis of hyperplasia was 68.29% and that of adenoma was 97.06%. The sensitivity of PET/CT for adenoma was significantly higher than that for hyperplasia, and lesion size had a significant effect on the imaging results; in terms of differences in metabolic parameters, dual-phase SUVmax, MTV and TLG were significant in univariate analysis, and multivariate analysis showed the delayed TLG (cut-off value of 6.421) was a more reliable index for differentiating hyperplasia from adenoma (P=0.002). ***Conclusion:*** The diagnostic value of 18F-FCH PET/CT for adenoma is higher than that of hyperplasia, and delayed-phase TLG (cut-off value of 6.421) can differentiate between hyperplasia and adenoma.18F-FCH PET/CT is a more reliable means of imaging the parathyroid and can provide effective information for the diagnosis and etiology of hyperparathyroidism, and delayed TLG can differentiate hyperplasia from adenoma at the imaging level and help in the selection of clinical treatment options.

EP-0446

Prognostic risk factors in patients with papillary thyroid microcarcinoma (PTMC) with excellent response (ER) one year after initial treatment.

A. Marongiu, *S. Nuvoli, A. Falchi, S. Vargiu, A. Spanu, G. Madeddu; Unit of Nuclear Medicine, University of Sassari, Sassari, ITALY.*

Aim/Introduction: PTMC, generally with a favorable prognosis, may exhibit a high risk of disease progression, in some cases, during follow-up after primary therapy. We further investigated whether the evaluation of the response to thyroidectomy and radioiodine therapy one year after initial treatment may serve as a useful tool for predicting recurrence or disease persistence in PTMC patients during follow-up. ***Materials and Methods:*** We retrospectively enrolled 342 PTMC patients from a large cohort, all of them with ER defined to the 2015 ATA guidelines as negative imaging and stimulated thyroglobulin (Ps-Tg) level <1.0 ng/ml. All patients underwent total thyroidectomy and radioiodine therapy; 277/342 patients were females, and 195/342 were younger than 55 years. Tumor size was >5 mm in 198/342 patients. Risk factors identified at surgery included capsular infiltration (CI, 23 cases), minimal extrathyroid extension (mETE, 29 cases), multifocality/multicentricity (MM, 105 cases), and vascular invasion (VI, 15 cases). One year after treatment, Ps-Tg was <0.2 ng/ml in 258 patients (Group 1) and between 0.2 and 1.0 ng/ml in 84 patients (Group 2). ***Results:*** During follow-up, 27/342 patients (7.9%) developed metastases in the neck in 25 cases, and in lung and mediastinum in two cases; 16/27 (6.2%) belonged to Group 1, and 11 (13%) to Group 2, with significant difference (p=0.04). Twenty-five/27 patients were females, 15 were younger than 55 years. Tumor size was >5 mm in 20 cases. Risk factors, such as CI, mETE, MM, and VI, either individually or in combination, were present in 11/16 Group 1 patients and 5/11 Group 2 patients. Univariate analysis evidenced that metastasis development was significantly influenced by Ps-Tg levels between 0.2 and 1.0 ng/ml (OR 2.279 [95% CI 1.013-5.129]; p=0.047) and by mETE (OR 3.627 [95% CI 1.332-9.877]; p=0.012). Age, sex, tumor size, CI, MM, or VI were not metastasis predictors. Multivariate analysis confirmed the significance of Ps-Tg >0.2 but <1.0 ng/ml (OR 2.335 [95% CI 1.026-5.317]; p=0.043) and mETE (OR 3.733 [95% CI 1.353-10.303]; p=0.011) as independent metastasis predictors. ***Conclusion:*** Our study suggests that in PTMC patients with ER at the first year after initial therapy, Ps-Tg levels between 0.2 and 1.0 ng/ml and the presence of mETE at surgery are important prognostic factors for predicting metastasis appearance, particularly in the neck. The evaluation of these factors one year after primary therapy may provide valuable insights for better identifying patients at risk for disease progression.

EP-0447

^{18}F-FDG PET/CT Illuminating The Roadmap For Tracking Differentiated Thyroid Cancer

T. Dardouri[1], *H. Boudriga*[1], *A. Ezzine*[1], *S. Mensi*[1], *J. Houas*[2], *M. Grassa*[2], *R. Sfar*[1], *K. Chatti*[1];
[1]*Department of nuclear medecine of Sahloul hospital, Sousse, TUNISIA,* [2]*Department of Otorhinolaryngology of Farhat Hached hospital, Sousse, TUNISIA.*

Aim/Introduction: Fifteen per cent of patients with differentiated follicular thyroid carcinoma (DTC) develop metastatic disease progression during follow-up. Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography (^{18}F-FDG PET) is an accurate imaging tool for the evaluation of agressive disease extension. The aim was to assess the value of ^{18}F-FDG PET/CT in the follow-up of DTC and its therapeutic impact. ***Materials and Methods:*** We included 30 patients followed for DTC who underwent ^{18}F-FDG PET with at least 18-month follow-up after iodine treatment. ***Results:*** The mean age was 58 years, with a predominance of females. All our patients had undergone total thyroidectomy with or without lymph node dissection and postoperative iodine treatment. According to ATA 2015, 73% of our patients were classified as high-risk group. During follow-up, 23 patients (77%) had an incomplete structural response and thyroglobulin (Tg) level was greater than 100 ng/ml in almost cases. For the seven remaining patients classified as having an incomplete biochemical response, ^{18}F-FDG PET scans were negative in four patients with Tg average under stimulation of 32.2 ng/ml. Besides, they identified cervical lymph node metastases in two patients and thus upgraded as incomplete structural response. The results of ^{18}F-FDG PET/CT led to a change in treatment plan in 30% of cases, due to upgrading or identification of new metastatic sites. ***Conclusion:*** Following iodine treatment , ^{18}F-FDG PET/CT has proven to be effective in dynamic response classification of persistent and recurrent DTC in addition to biochemical tumour markers and conventional imaging procedures. It helps with individualized treatment approaches and provides clinicians with insightful information on tumor biology.

EP-0448

Loco-regional relapse and metastatic recurrence in BRAFV600E-mutated papillary thyroid carcinoma patients during more than five years of follow-up

T. Makazlieva[1], *N. Manevska*[1,2], *S. Stojanoski*[1], *N. Bozinovska*[1], *A. Jankulovska*[1], *B. Stoilovska Rizova*[1], *A. Eftimov*[3], *S. Kostadinova-Kunovska*[3], *R. Jovanovic*[3];
[1]*Institut of pathophysiology and nuclear medicine, Medical faculty, University Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [2]*University Institute of positron emission tomography, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [3]*Institut of pathology, Medical faculty, University Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF.*

Aim/Introduction: The BRAFV600E mutation is the most frequent genetic alteration in patients with papillary thyroid carcinoma (PTC). Our study aimed to evaluate the frequency of loco-regional relapse and metastatic recurrence in BRAFV600E-mutated PTC patients followed for more than five years. ***Materials and Methods:*** Thirty-five PTC patients with detected BRAFV600E mutation from the primary tumor tissue were followed after initial diagnosis and treatment for more than 5 years (range: 5 - 20 years). We used the Cobas® 4800 BRAFV600 Mutation Test on the Cobas Z480 Real-Time PCR IVD Machine (Roche) for detecting the V600E mutation. All 35 patients underwent total thyroidectomy, and 31 patients additionally received radioiodine ablation followed by a post-ablative whole-body scan. Follow-up included laboratory assessments - free thyroxine (FT4), TSH, serum thyroglobulin (sTg), and antithyroglobulin antibodies (TgAb)-measured 3 to 6 months during the first year, then at regular intervals thereafter.

Neck ultrasonography (US) was performed using a linear probe for small parts in all patients. According to laboratory and imaging data, their therapy response was classified into three categories: complete response, biochemical incomplete response, and structural incomplete response (persisting structural disease). ***Results:*** Among the 35 patients, the female-to-male ratio was 30/5, and the mean age at diagnosis was 48.6±12.8 years. Thirteen patients (37.1%) were aged ≥ 55 years, and 22 (62.9%) were < 55 years. According to TNM staging, 18 patients (51.4%) were in Stage I, 6 (17.1%) in Stage II, 8 (22.9%) in Stage III, and 3 (8.6%) in Stage IV. During follow-up 6 (17.1%) of the patients demonstrated elevated sTg level (with 2 patients classified as biochemical incomplete responders). Meanwhile, 29 patients (82,9 %) maintained low or undetectable sTg and TgAb levels, representing complete responders. Structural disease persistence was confirmed in 3 patients (8.6 %) through neck ultrasonography and histopathology after lymphadenectomy. Distant metastases were detected in 2 patients (5%): one with pulmonary metastases and one with tracheal infiltration and lymph node involvement. ***Conclusion:*** In our study, 29 out of 35 patients (82.9 %) responded completely to treatment. Our analysis did not reveal a significant association between the BRAFV600E mutation and the risk of loco-regional relapse or distant metastases during a more than 5-year follow-up.

EP-0449

Efficacy of Ca-125 exchange rate and ^{18}F-FDG Pet/Ct in predicting progression in ovarian cancer

Z. Mammadkhanli, *F. Ustun;*
Trakya University, Edirne, TÜRKIYE.

Aim/Introduction: Ovarian cancer is one of the leading causes of cancer-related deaths among gynecologic malignancies. Many studies have shown that ^{18}F-FDG PET/CT provides high accuracy in recognizing ovarian cancer recurrence. The aim of this study was to investigate the relationship between progression in CA-125 marker and ^{18}F-FDG PET/CT and to compare the diagnostic accuracy of these two methods and to evaluate their contribution in progression follow-up. ***Materials and Methods:*** In this retrospective study, a total of 330 patients with serous ovarian cancer who were admitted to the Nuclear Medicine Clinic between January 2013 and January 2018 were analyzed. The study included 23 patients who underwent 18F-FDGPET/CT imaging for suspected recurrence and for whom CA-125 marker data were available. Each patients CA-125 value at the time of imaging and CA-125 values approximately one month ago were recorded. In addition, ^{18}F-FDG PET/CT images were re-evaluated for progression. In the study, CA-125 change rate was calculated and its relationship with progression was evaluated and the predictive power of CA-125 change rate was determined by statistical analysis. ***Results:*** All patients included in the study were diagnosed with serous ovarian carcinoma. All patients underwent ^{18}F-FDG PET/CT imaging with suspicion of recurrence due to elevatedCA-125 marker. The mean age of the patients was 55±12 years (32-80). In the study, CA-125change rate was calculated and its relationship with progression was evaluated. Then, Receiver Operating Characteristic (ROC) analysis was performed to evaluate the predictive power ofCA-125 change rate. As a result of the ROC analysis, the area under the curve (AUC) of CA-125 change rate was calculated as 0.826 with a standard error of 0.077 and p=0.070. The confidence interval was 0.676-0.976. The optimal cut-off value was determined as 41.5, indicating that patients with a percentage increase of CA-125 change rate above 41.5 constituted an important cut-off value for detecting progression with 18F FDG PET/CT. Sensitivity and specificity calculations showed that the sensitivity and specificity of CA-125 change rate were 87.5% and 66.7%,respectively. ***Conclusion:*** This study shows that ^{18}F-FDG PET/CT imaging can detect progression inpatients with a CA125 rate of change rate cut-off value above 41.5. Further studies with a larger number of patients are needed.

EP-0450

PET/CT-Guided Patient Selection for Secondary Cytoreduction in Recurrent Ovarian Cancer

C. Csikos[1], *A. Varga*[1], *Z. Hascsi*[2], *S. Molnár*[3], *Z. T. Krasznai*[3], *I. Garai*[1,2];
[1]*Division of Nuclear Medicine and Translational Imaging, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY,* [2]*Scanomed Ltd., Debrecen, HUNGARY,* [3]*Department of Obstetrics and Gynaecology, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.*

Aim/Introduction: Secondary cytoreductive surgery (SCS) may improve survival in recurrent ovarian cancer, but patient selection remains challenging. Conventional imaging modalities (CT, MRI) are limited in predicting complete surgical success. Our prior meta-analysis suggested that a favorable PET/CT result could predict complete cytoreduction in almost 90% of the cases [1]. This study aimed to evaluate the added value of PET/CT in preoperative assessment for SCS. ***Materials and Methods:*** We retrospectively reviewed 196 patients with ovarian cancer who underwent [^{18}F]FDG PET/CT between 2018-2023 in our clinic. Of these, 22 patients with recurrent ovarian cancer were eligible for SCS based on conventional imaging, and also underwent [^{18}F] FDG PET/CT as part of the preoperative assessment. Diagnostic performance metrics were calculated, and decision curve analysis (DCA) was performed to assess the clinical utility of PET/CT in guiding surgical decision-making. ***Results:*** Among the 22 patients selected for SCS based on conventional imaging, PET/CT prevented surgery in 9/22 patients by identifying findings suggestive of inoperability. Of the 13 patients who were considered operable by PET/CT and underwent surgery, 11/13 had complete cytoreduction (PPV: 84.6%). PET/CT demonstrated superior clinical utility in decision curve analysis compared to both a "treat all" and a "treat none" strategy, offering greater net benefit across a wide range of surgical thresholds. As an operable state on conventional imaging was the initial inclusion criterion for surgery, it functioned as the "treat all" approach in this analysis. ***Conclusion:*** Our findings confirm that preoperative PET/CT can provide clinically meaningful value in selecting candidates for secondary cytoreduction. PET/CT results improved decision-making and offered a higher net benefit compared to conventional imaging. These results support the finding of our prior meta-analysis in which a high positive predictive value of PET/CT was found in this setting. Our results suggest that PET/CT may be a useful tool to evaluate patient eligibility for secondary cytoreduction of recurrent ovarian cancer and avoid non-beneficial interventions. ***References:*** 1. Csikos C, Czina P, Molnár S, Kovács AR, Garai I, Krasznai ZT. Predicting Complete Cytoreduction with Preoperative [^{18}F]FDG PET/CT in Patients with Ovarian Cancer: A Systematic Review and Meta-Analysis. Diagnostics. 2024;14(16):1740. https://doi.org/10.3390/diagnostics14161740.

EP-0451

Prognostic Value of Metabolic Biomarkers in Locally Advanced Cervical Cancer: Is Survival Predictable?

Y. Eryilmaz, *O. Kodaz, G. Kaya, P. Özgen Kıratlı;*
Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Cervical cancer is one of the most common malignancies among women. Guidelines recommend chemoradiotherapy (CRT) followed by brachytherapy for patients with locally advanced cervical cancer (LACC). However, recurrence occurs in approximately one-third of patients within two years following CRT, and the 5-year overall survival rate is around 70%. This study aims to examine the relationship between pre-treatment FDG PET/CT-derived volumetric parameters and progression-free survival (PFS) and overall survival (OS) in LACC. ***Materials and Methods:*** LACC patients staged with FDG PET/CT were retrospectively analyzed. For the primary tumor and metastatic lymph nodes, SUVmax, SUVmean, SUVpeak, metabolic tumor volume (MTV), total lesion glycolysis (TLG), and total lesion quotient (TLQ, product of MTV and SUVmean) were calculated. Follow-up data of the patients were obtained. Survival analyses were performed to assess the relationship between the volumetric parameters and both PFS and OS. ***Results:*** 35 patients with LACC followed for at least 6 months were included. The mean age was 55.1 ± 14.3 years. During the follow-up (mean 36.1 ± 2.4 months), disease progression was observed in 17 patients (49%, 8 local recurrences, 9 distant metastases) and sixteen patients died (46%). Median PFS and median OS were not reached (mean PFS: 43.5 ± 3.2 months). Among patients with a lower primary tumor TLQ value, median OS was 37 months (95% CI: 32.4-41.5), while in those with a higher TLQ, it was 55 months (95% CI: 51.2-58.7). OS was significantly shorter in the group with lower TLQ values ($p = 0.017$). When patients were grouped according to SUVmax, SUVmean, SUVpeak, MTV, and TLG values of the primary tumor and lymph node metastases, no statistically significant differences were found in predicting survival or the development of lymph node metastases. In binary regression analysis, among the 27 patients (77%) with lymph node metastases, only a lower TLQ value of the primary tumor was identified as a statistically significant poor prognostic factor for OS (Odds ratio: 5.62, $p = 0.032$). ***Conclusion:*** Previous studies have demonstrated an association between metabolic parameters and both PFS and OS in LACC. In contrast, our study found no significant association, possibly due to the limited sample size. Nonetheless, TLQ, introduced as a novel biomarker, was identified for the first time in the literature as a statistically significant prognostic marker for survival in LACC. TLQ may serve as a new metabolic parameter for predicting prognosis in terms of PFS and OS in LACC. Further validation in larger prospective cohorts is warranted.

EP-0452

Correlation of metabolic parameters and dissemination of preoperative 18F-FDG-PET/CT in endometrial cancer and its prognostic value

C. Ortiz Muñoz[1], *J. Rodríguez Gómez*[1], *E. Noriega Álvarez*[2], *F. Lopez-Bermejo García*[1], *D. Martínez Osorio*[1], *F. Pena Pardo*[1], *M. Talavera Rubio*[1], *V. Poblete García*[1];
[1]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Hospital Universitario de Guadalajara, Guadalajara, SPAIN.*

Aim/Introduction: To assess the concordance of metabolic and dissemination parameters from preoperative staging 18F-FDG-PET/CT and their relationship with the prognosis of patients with endometrial cancer (EC). ***Materials and Methods:*** A retrospective observational analytical study of consecutive patients with a diagnosis of endometrial cancer (EC) confirmed by histopathology, who underwent preoperative 18F-FDG-PET/CT between January 2018 and December 2022, with a minimum follow-up of 2 years. We collected demographic variables and tumour characteristics (histology, grade, type, stage, affected nodal stations, and immunohistochemistry); as well as metabolic parameters from 18F-FDG-PET/CT such as metabolic tumour volume, total lesion glycolysis and maximum standardized uptake value (MTV, TLG, and SUVmax), and dissemination parameters (Dmax). Its relationship with progression-free survival (PFS) and overall survival (OS) was studied using Pearson's bivariate correlation and Kendall's Tau. ***Results:*** A total of 39 patients were evaluated, with a mean age of 65.7 years (range 39-91). Of these, 24 patients (61.5%) presented with endometrioid-type cancer, 13 patients (33.3%) with non-endometrioid-type, and 2 patients (5.1%) with mixed-type. Tumour grading were revealed, 17 patients (43.6%) grade G1, 12 patients (30.8%) grade G2, and 10 patients (25.6%) grade G3. During follow-up, 18 patients (46.2%) experienced recurrence, while 23 patients (59%) passed away. A positive correlation was found between MTV and tumour grade (Pearson 0.340; $p<0.05$). Besides, a negative correlation was observed between tumour type and both progression-free survival (PFS) and overall survival (OS) (Pearson -0.355 and -0.396, respectively; $p<0.05$), indicating that patients with non-endometrioid and mixed-type endometrial cancer exhibited lower PFS. Additionally, significant negative correlations were found between MTV and both progression-free survival (PFS) and overall survival (OS) (Kendall's Tau -0.243 and -0.309; $p<0.05$ and $p<0.01$, respectively), as well as between TLG and OS (Kendall's Tau -0.252; $p<0.05$), indicating that higher MTV and/or TLG values are associated with an increased risk of progression and death. The remaining variables studied, including dissemination parameters (Dmax), did not show statistically significant correlations. ***Conclusion:*** Our findings suggest that the metabolic parameters MTV and TLG obtained from preoperative staging 18F-FDG-PET/CT have potential prognostic value in determining the aggressiveness and progression of endometrial cancer (EC).

[18F]F-FDG PET-CT Imaging in Ovarian Carcinoma Patients: IAEA Coordinated POCA Project Study from Azerbaijan

F. Novruzov[1], *K. Huseynzade*[1], *E. Mehdi*[1], *N. Orujova*[2], *N. Aliyeva*[1], *G. Alibayli*[2], *D. Paez*[3], *F. Giammarile*[4,5], *E. Estrada Lobato*[6], *E. Mansurov*[7], *M. Isayeva*[8], *J. Aliyev*[9];
[1]*Department of Nuclear Medicine, The National Centre of Oncology, Baku, AZERBAIJAN,* [2]*Department of Nuclear Medicine, The National Centre of Oncology, Baku, AZERBAIJAN,* [3]*Head of the Nuclear Medicine and Diagnostic Imaging Section, Division of Human Health, Vienna, AUSTRIA,* [4]*International Atomic Energy Agency, Vienna, AUSTRIA,* [5]*Deaparment of Nuclear Medicine, Université de Lyon, Lyon, FRANCE,* [6]*International Atomic Energy Agency, Division of Human Health, Vienna, AUSTRIA,* [7]*Department of Medical Oncology, The National Centre of Oncology, Baku, AZERBAIJAN,* [8]*Columbia University, New York, NY, UNITED STATES OF AMERICA,* [9]*Department of General Surgery, The National Centre of Oncology, Baku, AZERBAIJAN.*

Aim/Introduction: Ovarian carcinoma is among the most challenging gynecologic malignancies, often diagnosed at an advanced stage due to its vague symptoms and silent progression. In this context, [^{18}F]FDG PET/CT has proven to be a powerful imaging modality—not only for staging and restaging but also for assessing recurrence and guiding therapeutic decisions with high sensitivity. Its ability to detect unexpected metastatic spread further enhances its clinical utility. ***Materials and Methods:*** This study included 95 ovarian carcinoma patients (mean age 53.7 years, range 23-79) enrolled in the IAEA POCA Project from Azerbaijan. Patients were grouped into ARM1 (pre-laparoscopy, n=8; post-laparoscopy, n=75) and ARM2 (elevated CA125, n=15). All underwent [^{18}F]FDG PET/CT imaging. Standard imaging protocols were followed: patients fasted for 6 hours, blood glucose was <150 mg/dL, and images were acquired 60 minutes post-tracer injection from skull base to mid-thigh. Low-dose CT was used for attenuation correction and anatomical localization; contrast-enhanced CT was performed when clinically indicated. ***Results:*** In ARM2, two patients showed critical findings: one had tracer uptake in paracolic fat and distant nodes, and the other had intense peritoneal involvement—both leading to treatment changes. Among the remaining 13 ARM2 patients: peritoneal implants were seen in 4; abdominal lymph nodes in 7; extra-abdominal nodes in 3; hepatic lesions in 1; ascites in 3;

and umbilical metastasis (Sister Mary Joseph nodule) in 1.In ARM1, abdominal lymph node metastases were seen in 32 patients; extra-abdominal nodes in 16; liver lesions in 11; ascites in 9; pleural effusion in 8; peritoneal carcinomatosis in 2; and other distant hypermetabolic lesions (lungs, adrenals, surgical sites) were noted. Bone metastasis (L1 vertebra) was detected in 1 patient. Overall, [^{18}F]FDG PET/CT prompted management changes in 25 patients: 16 major (e.g., shift in chemotherapy due to progression or poor response) and 9 minor (e.g., initiation of therapy based on newly identified distant disease). ***Conclusion:*** [^{18}F]FDG PET/CT demonstrated significant clinical utility in our ovarian carcinoma patients by providing comprehensive disease assessment in a single examination. The modality effectively guided treatment decisions through precise localization of disease sites and accurate evaluation of disease extent. For patients with elevated CA125 levels, [^{18}F]FDG PET/CT offered clear visualization of recurrence patterns, enabling tailored therapeutic approaches. This imaging approach streamlined the diagnostic pathway and enhanced clinical management efficiency.

EP-0454

Development and validation of pretreatment ^{18}F-FDG PET/CT and MRI radiomics deep learning signatures to predict progressionfree survival in locally advanced cervical cancer

J. Song, *H. Yi;*
Zhejiang Cancer Hospital, Hangzhou, CHINA.

Aim/Introduction: Data regarding whether patients can achieve long-term progression-free survival (PFS) through treatment is essential to improve risk-adapted treatment strategies of locally advanced cervical cancer (LACC). However, the routinely used preoperative determination method is not accurate enough. The present study investigated and validate a combination model based on ^{18}F-FDG PET/CT and contrast-enhanced MRI to predict the diseases progression in LACC patients treated with chemoradiotherapy (CRT). ***Materials and Methods:*** Retrospective data were gathered for 346 patients (276 for training and 70 for testing) with LACC who underwent ^{18}F-FDG PET/CT and MRI [T2, T1C, diffusion-weighted imaging (DWI) and apparent diffusion coefficient (ADC)] before CRT between June 2016 and October 2021. Radiomics deep learning signature (RDPs) were developed based on ten machine-learning techniques. These signatures were integrated with the clinicopathological factors into a nomogram for clinical applications. The evaluation of the model's performance was conducted through the metrics of the area under the curve (AUC). ***Results:*** The median follow-up was 35.82 (range: 1.17-67.92) months. During the observation period, 96 (27.75%) patients exhibited disease progression. The RDPs showed excellent performance with a high AUC for predicting disease progression and PFS in training cohort (AUC, 0.93; 95% CI: 0.89-0.96; PFS, $p < 0.05$) and testing cohort (AUC, 0.82; 95% CI: 0.72-0.92; PFS, $p < 0.05$). The clinical factors of International Federation of Gynecology and Obstetrics (FIGO) stage and squamous cell carcinoma antigen (SCC-Ag) level were associated with PFS ($p < 0.05$). The combination nomogram showed better prediction capability for disease progression (AUC, 0.97; 95% CI:0.95-0.99) in training cohort and testing cohort (AUC, 0.87; 95% CI:0.79-0.96), with high sensitivity (0.84 and 0.79), specificity (0.93 and 0.84) and accuracy (0.91 and 0.83). ***Conclusion:*** ^{18}F-FDG PET/CT and MRI radiomics deep learning signatures had significantly good predictive value for diseases progression in patients with LACC treated with CRT, which may justify more aggressive treatment in patients identified with high probability of progression.

EP-0455

Enhanced tumor PET imaging with self-assembled peptide probe [^{68}Ga]HGFYp-NOTA

H. Wu[1,2], *Y. Liu*[1], *H. Wang*[1], *J. Wu*[1], *X. Li*[2], *P. Zou*[1];
[1]*NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA,* [2]*College of Pharmaceutical Science, Zhejiang University of Technology, Hangzhou, CHINA.*

Aim/Introduction: Positron emission tomography (PET) plays a crucial role in the early detection and monitoring of tumors. However, the rapid clearance of most small molecule PET probes from the tumor site limits their clinical utility. This study aims to investigate the potential of a novel ^{68}Ga-labeled self-assembled peptide probe, [^{68}Ga]HGFYp-NOTA, to enhance PET signal retention in tumors and provide a basis for designing long-lasting PET probes. ***Materials and Methods:*** The probe precursor HGFYp-NOTA and its control probe precursor HGFY-NOTA were synthesized using solid-phase peptide synthesis. The self-assembly properties of HGFYp-NOTA were evaluated using alkaline phosphatase (ALP) and characterized by transmission electron microscopy (TEM) and rheological analysis. The in vivo experiments were conducted on BALB/c nude mice bearing HeLa tumor xenografts. The mice were divided into three groups: the control group ([^{68}Ga]HGFY-NOTA), the low-concentration probe group ([^{68}Ga]HGFYp-NOTA), and the high-concentration probe group ([^{68}Ga]HGFYp-NOTA). Each group received intravenous injections of the respective probes followed by micro-PET imaging. ***Results:*** After 3 h of incubation with ALP, over 98% of HGFYp-NOTA was converted to HGFY-NOTA, resulting in a transparent elastic semi-solid. Rheological data showed that the storage modulus was significantly higher than the loss modulus, confirming the formation of a gel. TEM images revealed interconnected nanofibers with an average width of 26.85 ± 3.11 nm. Micro-PET imaging indicated that the tumor-specific uptake in the low-concentration probe group was 3.85 ± 0.35 %ID/g, which was significantly higher than that in the control group (1.39 ± 0.25 %ID/g). The high-concentration probe group exhibited a continuous increase in tumor signal from 4.05 ± 0.28 %ID/g at 0.5 h to 5.62 ± 0.40 %ID/g at 3 h, demonstrating that higher self-assembly concentration significantly enhanced probe retention in the tumor. ***Conclusion:*** The [^{68}Ga]HGFYp-NOTA peptide probe demonstrated excellent self-assembly properties, forming a stable gel with interconnected nanofibers. Increasing the self-assembly concentration significantly improved PET signal retention in tumors, thereby enhancing imaging quality. This study provides a promising strategy for developing long-lasting tumor-specific PET probes and has the potential to improve clinical PET imaging applications.

EP-0456

Enzyme-activated nanocarriers for efficient ^{68}Ga delivery and tumor targeting

P. Zou, *H. Wu, Y. Liu, H. Wang, J. Wu;*
NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: The utilization of positron emission tomography (PET) nanoprobes holds significant promise for the diagnosis and treatment of tumors. However, traditional nanocarriers often face limitations such as poor targeting, insufficient tumor penetration, and suboptimal biocompatibility. To address these challenges, we propose a novel enzyme-activated nanocarrier system designed to enhance the delivery and retention of ^{68}Ga in tumors. This system leverages the specific catalytic activity of enzymes to trigger the self-assembly of nanocarriers, thereby improving the targeting and efficacy of PET imaging. ***Materials and Methods:*** The probe precursor, NPX-DOTA, was synthesized using SPPS. The purity and structure of the synthesized precursor were confirmed through

mass spectrometry and nuclear magnetic resonance spectroscopy. For micro-PET imaging, HeLa tumor-bearing nude mice were divided into two groups: the experimental group received an intravenous injection of [^{68}Ga]NPX-DOTA, while the control group was pre-treated with an L-phenylalanine inhibitor to block alkaline phosphatase (ALP) activity before injection. The cytotoxicity of the nanocarriers was assessed using CCK-8 assays on HeLa cells. Additionally, the potential tissue toxicity was evaluated through hematoxylin-eosin staining of major organs and tumor tissues after exposure to the nanocarriers. ***Results:*** Under the catalysis of ALP, the probe precursor NPX-DOTA rapidly self-assembled into nanofibers with an average diameter of 22.52 ± 2.19 nm. TEM images revealed uniform and well-defined nanofibers, indicating successful self-assembly. Micro-PET imaging showed that the experimental group exhibited significantly higher tumor uptake of ^{68}Ga compared to the control group. The tumor signal intensity in the experimental group increased from 3.21 ± 0.35 %ID/g at 0.5 h to 4.65 ± 0.32 %ID/g at 3 h, while the control group maintained a low signal intensity below 0.75 %ID/g throughout the imaging period. The tumor-to-background ratio reached 6.2 ± 0.4 at 3 h in the experimental group, demonstrating effective tumor targeting. CCK-8 assays indicated that HeLa cell viability remained above 97% after 24 h of incubation. Hematoxylin-eosin staining showed no significant histological changes in major organs or tumor tissues, suggesting low toxicity and good biocompatibility of the nanocarriers. ***Conclusion:*** We have successfully developed an enzyme-activated nanocarrier system for the delivery of ^{68}Ga to tumors. The self-assembly mechanism triggered by ALP significantly enhanced the targeting and retention of ^{68}Ga in tumors, as demonstrated by the sustained increase in tumor signal intensity. Furthermore, the nanocarriers exhibited minimal toxicity and good biocompatibility, making them a promising candidate for clinical translation in PET imaging applications.

EP-0457

^{18}F-FDG-PET/CT in cervical cancer - challenging clinical acknowledgment for more accurate staging and therapy tailoring: single-centre experience

L. Chavdarova[1], *N. Piperkova-Slavova*[2], *E. Piperkova*[1];
[1]*University Specialized Hospital for Active Treatment in Oncology "Prof. I. Chernozemsky", Sofia, BULGARIA,* [2]*Neoclinic, Sofia, BULGARIA.*

Aim/Introduction: Despite screening and HPV-prophylaxis, cervical cancer (CC) is often detected in locally advanced stages (LACC). ^{18}F-FDG-PET/CT is established for whole-body staging but its standardized use is still lacking clinicians' acknowledgement. Our aim is to assess PET/CT-impact on staging and follow-up in CC patients. ***Materials and Methods:*** In the period 03.2024-03.2025, ^{18}F-FDG-PET/CT was performed in 116 CC pts (34-85y), 71,4% LACC. 102 pts had squamous-cell CC, 14 adenocarcinoma. Previous scans and treatment were analyzed retrospectively. Staging (b) PET/CT was done in 10pts (10,85%). Restaging PET/CTs were done after surgery, radio-/brachytherapy, chemo-/immunotherapy. Visual and semiquantitative interpretation using SUVmax was performed. Post-primary treatment (pPET) and follow-up scans (fuPET1-8) were assessed as complete (CR), partial (PR) response, stable (SD) or progressive disease (PD)."CR unconfirmed" (Cru) was interpreted in case of minor residual activity of primary, 3-4 months after deffinitive radio/chemotherapy or surgery. ***Results:*** In (b)PET/CT SUVmax of primary tumor ranged 5,04-27,48 (mean 12,03±5,7). 4pts had metastatic lymph nodes (MLN), 1 distant peritoneal lesion - not otherwise detected. pPET was done in 99pts, SUVmax ranged 3,09-34,8 (mean 9,76±9,16). pPET in pts with former bPET showed CR in 3, PR in 2, Cru in 3, PD in 1pt (MLN, oss). pPET in "no (b)PET" pts was pathologic in 26%: 4 local relapses (LR), 13 - MLN, 6 -distant M (oss,pul,hep). A during pregnancy diagnosed patient had early PD in pPET (pul, lym). All pts with Cru in pPET (16) had rest-SUVmax of 2,57-4,36 (mean 3,28), one showed LR, the rest resolved. fuPET1 had 90pts (4 LR, 10 MLN, 5 pulmonary, 4 peritoneal M), fuPET2 - 52 (6 PD), fuPET3 - 36 (8 PD), fuPET4 - 22 (2 PD), fuPET5 - 11 (1PD), fuPET6 - 7 (1PD), fuPET7 - 3 (1 PD), fuPET8 - 1pt. All pts with pathologic pPET and fuPET were tailored to either radiotherapy (27), surgery (6), chemo-(25) or immune-(8) therapy. In 2 pts fuPET detected breast cancer as unknown second oncologic primary. ***Conclusion:*** ^{18}F-FDG-PET/CT has significant impact on treatment tailoring in LACC. In our study most Cru findings resolved to CR, indicating sometimes prominent post-treatment reparation changes. The small number of (b)PET which hampers pPET interpretation, the relatively high number of pathologic pPET which indicates a probable incorrect staging and the LR/PD rate of fuPET imply the need of more standardized clinical algorithm for patient referral to PET/CT, to individualize treatment and improve prognosis. Further analysis is needed for statistical significance.

EP-0458

Value of ^{18}F-FDG PET/CT in Uterine Metastases From Invasive Lobular Breast Carcinoma

C. Mas*, M. Feriche, E. Espinosa, T. Rudolphi, S. Sanz;*
Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN.

Aim/Introduction: Uterine metastases from breast cancer remain exceptionally rare (<1% of metastatic cases), with invasive lobular carcinoma (ILC) accounting for >80% due to its distinctive peritoneal dissemination pattern. Although ILC constitutes 10-15% of breast malignancies, its propensity for late recurrence and atypical metastatic spread poses unique diagnostic challenges. This case demonstrates the critical utility of ^{18}F-FDG PET/CT in detecting occult uterine metastases, directly informing therapeutic strategies and emphasizing the necessity for enhanced surveillance in high-risk cohorts. ***Materials and Methods:*** A 58-year-old woman with ER/PR-positive (95%), HER2-negative ILC (pT3pN2a, Ki67 35%) underwent right mastectomy in 2020 followed by adjuvant chemotherapy and hormonal therapy (tamoxifen → exemestane). At her 48-month surveillance, PET/CT revealed three key findings: a focal endometrial lesion (SUVmax 9.77; 2.8 cm), a right adnexal mass (30×21 mm; SUVmax 6.12) with ipsilateral hydronephrosis, and a left proximal humeral lesion (SUVmax 4.05) later confirmed by MRI as non-infiltrative. Ultrasound-guided endometrial biopsy confirmed metastatic ILC (GATA3+, ER/PR+), prompting the multidisciplinary team to continue ribociclib (600 mg/day) and fulvestrant (500 mg/month) alongside urological intervention for hydronephrosis. ***Results:*** Critical insights emerged from this case. PET/CT detected uterine metastasis in an asymptomatic patient (ECOG 0), upstaging her disease from oligometastatic to polymetastatic and reorienting management toward systemic CDK4/6 inhibition over localized radiotherapy. The lesion's elevated SUVmax (9.77) and GATA3+/ER+ profile distinguished it from tamoxifen-associated endometrial carcinoma, which typically exhibits lower FDG avidity (mean SUVmax 5.2±2.1). Concurrent ovarian involvement (SUVmax 6.12) and probable skeletal lesions underscored ILC's multifocal dissemination tendency. Follow-up PET/CT at three months demonstrated metabolic stabilization, with a 14% reduction in uterine SUVmax (8.4), corroborating treatment efficacy. ***Conclusion:*** This case solidifies ^{18}F-FDG PET/CT's role in identifying atypical ILC metastases, particularly in hormonally treated patients with biomarker progression. Key implications include integrating routine pelvic imaging into ILC surveillance protocols regardless of symptomatology, employing SUVmax thresholds (>7.5) to prioritize uterine lesion biopsies, and mandating multidisciplinary evaluation to optimize therapy sequencing. Prospective studies are needed to establish optimal PET/CT intervals and validate SUVmax cutoffs for discriminating metastatic versus primary uterine malignancies in this population.

EP-0459

Dynamic F-18 fluorodeoxyglucose positron emission tomography with texture analysis for the differential diagnosis of ovarian masses

T. Shinya[1], *A. Shinya*[2], *T. Matsushita*[1], *Y. Hiroshima*[1], *J. Hiraoka*[1], *Y. Otomi*[1], *B. Zayabat*[1], *H. Inui*[1], *T. Kagawa*[1], *R. Kinouchi*[1], *K. Yoshida*[1], *M. Nishimura*[3], *T. Iwasa*[1], *M. Harada*[1];
[1]*Tokushima University Hospital, Tokushima-city, JAPAN,*
[2]*Tokushima Red Cross Hospital, Komatsushima-city, JAPAN,*
[3]*Tokushima Prefectural Central Hospital, Tokushima-city, JAPAN.*

Aim/Introduction: In PET examinations in ovarian tumours, imaging is typically started at 1 hour after intravenous administration of F-18 FDG. In recent years, the usefulness of dynamic PET/CT, which collects data early time after administration of F-18 FDG, has been reported in various tumours. However, there have been no report that have evaluated in detail the time-dependent accumulation dynamics of FDG after administration in ovarian tumours using maximum standardized uptake values (SUVmax). This prospective study assessed the diagnostic capacity of dynamic PET/CT in the differentiation between benign and malignant ovarian lesions. In addition, we introduce our research attempts on texture analysis (TA). ***Materials and Methods:*** Dynamic scans (5-15 min [1st phase], 15-25 min [2nd phase], 25-35 min [3rd phase] postinjection) and consecutive 1-h scan were undergone in eleven patients (4 endometrioid carcinomas; 1 high-grade serous carcinoma; 1 mucinous carcinoma; 1 granulosa cell tumour; 2 mature teratomas; 1 hemorrhagic ovarian cyst; 1 endometriotic cyst) between Jane 2023 to March 2025. We statistically compared the diagnostic capacity of SUVmax for each phase in the discrimination between benign and malignant ovarian lesions using receiver operating characteristic (ROC) curve analysis. In addition, we performed TA for dynamic and 1-h PET/CT. ROC analysis was performed on the features which showed a significant difference of $p<0.05$ between the malignant and benign groups. Finally, we compared the ROC curves from TA and SUVmax to evaluate the diagnostic performance. Statistical significance was set at $p < 0.05$. This study was approved by the Ethics Committee of the Hospital. ***Results:*** SUVmax gradually decreased or remained similar with minimal fluctuations in four cases of benign ovarian lesions and two cases of malignant ovarian tumours. In contrast, SUVmax had been increasing over time in five cases of malignant ovarian tumours. The areas under the curve (AUC) are higher than 0.857 in all analyses and AUC yielded the highest values at 0.929 on dynamic 1st phase. 37 of 102 TA features showed a significant difference of $p<0.05$ between the malignant and benign groups and have high AUC of higher values than 0.893. Especially, 20 of 37 TA features had highest diagnostic performance with a sensitivity of 100% and a specificity of 100%. Delong's test did not reveal any significant differences between TA-derived ROC curves and SUVmax-derived ROC curves. ***Conclusion:*** Dynamic F-18 FDG PET scans with TA have the potential to be good predictors of discriminating benign and malignant ovarian lesions.

EP-0460

Performance of 18F-FDG-PET/CT in Lymph Node Staging of Patients with Endometrial Cancer

J. Rodríguez Gomez[1], *C. F. Ortiz Muñoz*[1], *E. Noriega Alvarez*[2], *F. J. Pena Pardo*[1], *M. P. Talavera Rubio*[1], *V. M. Poblete García*[1];
[1]*Hospital General Univesitario Ciudad Real, Ciudad Real, SPAIN,*
[2]*Hospital Univesitario De Guadalajara, Guadalajara, SPAIN.*

Aim/Introduction: To evaluate the diagnostic accuracy of 18F-FDG-PET/CT in lymph node staging of patients with endometrial cancer (EC) and its concordance with histopathological findings. ***Materials and Methods:*** A retrospective observational study was conducted on patients with histologically confirmed EC who underwent staging 18F-FDG-PET/CT and surgery within 45 days, without neoadjuvant treatment. Lymph node involvement detected by 18F-FDG-PET/CT was compared with histopathological results. 18F-FDG-PET/CT scans were reported by two experienced nuclear medicine physicians; in case of discrepancy, a third reader was consulted. Suspicious lymph nodes were classified as left/right pelvic or extra-pelvic. Sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV), and overall accuracy were calculated. Concordance was assessed using the Chi-square test and Cohen's Kappa coefficient (κ). ***Results:*** A total of 22 consecutive patients were included from January 2018 to December 2022, with a mean age of 70 years (range 39-91). Of these, 10 patients (48%) showed suspected lymph node involvement on staging 18F-FDG-PET/CT (5/10 extrapelvic). Following surgery and pathological analysis (17 endometrioid tumours and 5 non-endometrioid), lymph node tumour involvement was confirmed in 7 patients. This corresponds to 7 true positives (TP), 12 true negatives (TN), 3 false positives (FP), and 0 false negatives (FN) on 18F-FDG-PET/CT. The diagnostic values were: Se 100%, Sp 80%, PPV 70%, NPV 100%, and accuracy 86.4%. Histopathological analysis of the 3 FP cases revealed reactive lymphadenitis (2 patients had a history of prior malignancy in complete remission). There was a statistically significant correlation between 18F-FDG-PET/CT and histopathological findings, with a Chi-square value of 12.32 ($p < 0.001$), and a high level of agreement ($\kappa = 0.718$; $p < 0.001$). ***Conclusion:*** 18F-FDG-PET/CT shows excellent diagnostic performance for both pelvic and extra-pelvic lymph node staging of EC patients, with high concordance with histopathology, despite limitations related to sample size.

Radiomic analysis of baseline 18-F FDG PET/CT to build machine-learning models able to predict treatment response in primary mediastinal B-cell lymphoma: results of a bicentric experience

S. Adamantiadis[1], *L. Urso*[1], *L. Manco*[2], *F. Esposito*[3], *G. Scribano*[2], *L. De Marchi*[3], *A. Venditti*[3], *M. Postorino*[3], *N. Urbano*[4], *R. Gafà*[1], *A. Cuneo*[5], *A. Chiaravalloti*[6], *M. Bartolomei*[7], *C. Cittanti*[1], *L. Filippi*[6];
[1]*Department of Translational Medicine, University of Ferrara, Ferrara, ITALY,* [2]*Medical Physics Unit, University Hospital of Ferrara, Ferrara, ITALY,* [3]*Hematology, Department of Biomedicine and Prevention, University of Roma Tor Vergata, Rome, ITALY,* [4]*Nuclear Medicine Unit, Department of Oncohaematology, Fondazione PTV Policlinico Tor Vergata University Hospital, Rome, ITALY,* [5]*Hematology Unit, University of Ferrara, Ferrara, ITALY,* [6]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Rome, ITALY,* [7]*Nuclear Medicine Unit, Onco-Hematology Department, University Hospital of Ferrara, Ferrara, ITALY.*

Aim/Introduction: Primary mediastinal B-cell lymphoma (PMBCL) is an uncommon, B-cell non-Hodgkin lymphoma. PMBCL often develops in the anterior-superior mediastinum and presents as bulky mass at diagnosis. [^{18}F]FDG PET/CT imaging is the gold standard for staging, interim and end-of-treatment (EoT) assessment, associated with the five-point Deauville score (DS). Aim of this bi-centric pilot study is to evaluate the predictive value of pre-treatment [^{18}F]FDG PET/CT radiomics in assessing treatment response in PMBCL. ***Materials and Methods:*** Two cohorts of PMBCL affected patients, 29 from Policlinico Tor Vergata University Hospital of Rome and 9 from Sant'Anna University Hospital of Ferrara, underwent [^{18}F]FDG PET/CT between January 2011 and January 2022. DS were collected. A total of 121 quantitative

radiomics features were extracted from manually segmented volume of interests (VOIs) in PET and CT images, according to IBSI. ComBat harmonization was applied to correct center variability of features, followed by class balancing with SMOTE. Two machine learning (ML) prediction models, the PET Model and the CT Model, were independently developed using robust RFts. For each ML model, two different algorithms were trained (i.e., Random Forest/RF and Support Vector Machine/SVM) using 10-fold cross validation, tested on the internal/external validation set. Receiver operating characteristic (ROC) curves, area under the curve (AUC), classification accuracy (CA), precision (Prec), sensitivity (Sen), specificity (Spec), true positive (TP), and true negative (TN) scores were computed. ***Results:*** The entire dataset was composed of 29 samples for the Rome cohort (23 from D1-D3 and 6 from D4/D5) and 9 samples for the Ferrara cohort (4 from D1-D3 and 5 from D4/D5). A total of 27 RFts were identified as robust for each imaging modality. Both the CT and PET models effectively predicted the Deauville score. The performance metrics of the best classifier (SVM) for the CT and PET models in external validation were AUC=0.75/0.80, CA=0.85/0.77, Prec=0.97/0.67, Sen=0.60/0.80, Spec=0.98/0.75, TP=75.0%/66.7%, TN=77.8%/85.7%, respectively. ***Conclusion:*** ML-models trained on radiomic features extracted from pre-treatment [^{18}F]FDG PET/CT may contribute to predict therapy response in PMBLC patients.

EP-0462

Prognostic Impact Of Metabolic Tumour Volume On Survival In Patients With Diffuse Large B-Cell Lymphoma Treated With Chimeric Antigen Receptor T-Cell Therapy

L. Henrich Malizia[1], *A. Gomez Lopez*[1], *F. Arraut Serrano*[1], *A. Garin Rodriguez*[1], *N. Etxabeguren Gallo*[1], *I. Cillero Etxebeste*[1], *B. Mendibil Esquisabel*[2], *I. Zeberio Etxetxipia*[2], *I. Olazabal Eizaguirre*[2], *V. Rodriguez Ortega*[1], *I. Sanchez Oscoz*[1], *S. Sanchez Eguiguren*[1], *I. Jauregui Larrea*[1], *G. Rodriguez Rodriguez*[1], *I. Leon Zubizarreta*[1], *A. Iztueta Iturbe*[1], *I. Lopez Sanchez*[1], *A. Roteta Unceta Barrenechea*[1]; [1]*Hospital Universitario Donostia - Onkologikoa, San Sebastian, SPAIN,* [2]*Hospital Universitario Donostia, San Sebastian, SPAIN.*

Aim/Introduction: Chimeric Antigen Receptor T-cell Therapy (CAR-T) has improved the treatment of haematologic malignancies, but patient response is variable. Identifying prognostic biomarkers is crucial. Metabolic Tumour Volume (MTV), measured by Positron Emission Tomography-Computed Tomography (PET/CT), is a promising biomarker, as high levels are associated with poorer prognosis in lymphomas. This study evaluated the association between pre-treatment MTV and survival in patients with Diffuse Large B-Cell Lymphoma (DLBCL) treated with CAR-T therapy at our institution. ***Materials and Methods:*** A descriptive retrospective study was conducted on 36 patients with DLBCL who received CAR-T therapy between 2023 and 2024. MTV was calculated from the baseline pre-infusion PET/CT scan. For this calculation, only lesions with a volume greater than 3 cm^3 and SUVmax greater than 4 were measured. Patients were then stratified into 3 groups (low, intermediate, high) using the Youden index. SUVmax (maximum Standardised Uptake Value) and Dmax (maximum distance) were also analysed. The intermediate MTV group was further subdivided according to SUVmax (<16 vs ≥16) to assess if stratification improved. Progression-Free Survival (PFS) was analysed using Kaplan-Meier curves and the MTV groups compared with the log-rank test. ***Results:*** The median age was 64 years. 58.3% received CAR-T as a third line of treatment. At the end of follow-up, 25% had died, and 41.7% had progressed. The MTV groups were: Group 1 (MTV=0, n=16), Group 2 (0 < MTV ≤ 36.8, n=6), and Group 3 (MTV > 36.8, n=14). Significant differences in PFS were observed between the groups (p=0.002). Group 3 (high MTV) had the worst PFS, with a median of 4.5 months. An additional exploratory analysis, subdividing Group 2 by SUVmax (<16 vs ≥16), showed even stronger prognostic separation among four groups (p<0.001), identifying a subgroup with intermediate MTV but SUVmax > 16 (n=2) with very poor survival (median PFS 1 month). ***Conclusion:*** Baseline PET/CT-derived MTV is a significant predictor of PFS in this cohort of DLBCL patients treated with CAR-T therapy. High MTV levels are associated with a poorer prognosis. Incorporating SUVmax may further refine risk stratification in the intermediate group. These findings suggest that Baseline MTV could be a useful tool to predict prognosis in patients with DLBCL treated with CAR-T therapy. However, the main limitation of this study is the small number of patients; therefore, these results require validation in larger cohorts.

EP-0463

Automated AI-based total Metabolic Tumor Volume in lymphoma- a RECOMIA-tool

M. Sadik[1], *J. Mörk*[1], *J. Lopez Urdaneta*[1], *M. Lewold*[2], *M. Larsson*[3], *O. Enqvist*[4], *S. F. Barrington*[5], *L. Edenbrandt*[1], *E. Trägårdh*[2]; [1]*Medicine, Gothenburg, SWEDEN,* [2]*Clinical Physiology and Nuclear Medicine, Malmö, SWEDEN,* [3]*Eigenvision AB, Lund, SWEDEN,* [4]*Electrical Engineering, Gothenburg, SWEDEN,* [5]*Clinical PET Centre, London, UNITED KINGDOM.*

Aim/Introduction: Increasing evidence suggests that total metabolic tumor volume (tMTV) measured at baseline before treatment in lymphoma patients undergoing FDG-PET/CT can predict prognosis. However, there is a lack of fast, reliable, and easy-to-perform multilesional segmentation tool with an urgent need to improve tMTV segmentation workflow in clinical practice. Here, we test an AI-based tool that automatically calculates tMTV in untreated lymphoma patients undergoing FDG-PET/CT. ***Materials and Methods:*** The RECOMIA AI-based tool is a 3D U-Net convolutional neural network trained on a 1500 lymphoma patient cohort, mean age 52 years (range 10-88), 44% were female. The model was optimized to segment metabolically active tumor regions across the FDG-PET/CT scans, enabling automated and reproducible tMTV measurements. The test group consists of all untreated Hodgkin lymphoma (HL) patients and all Diffuse large B-cell lymphoma (DLBCL) patients who underwent FDG-PET/CT at Sahlgrenska University Hospital between 2017-2018 and 2019-2022, respectively. There were 117 patients with mean age 50 years (range 7-90), 39% were female. A group of nine nuclear medicine specialists manually segmented lesions for tMTV calculations; each patient was independently segmented by two specialists. ***Results:*** The median of the manual tMTV was 321 m^3 (interquartile range [IQR]: 92-689 cm^3) and the median of the difference between two tMTV values segmented by different specialists for the same patient was 26 cm^3 (IQR: 9-86 cm^3). In 85 of the 117 patients, the manual tMTV value was closer to the AI tMTV value than to the other manual tMTV value segmented by the second specialist. In 15 of the remailing 32 patients, the difference between the AI tMTV and the manual tMTV was small (<26 cm^3, which was the median difference between two manual tMTV values from the same patient). ***Conclusion:*** The results of this study indicate that the RECOMIA AI tMTV-tool could be used without any major manual adjustments in 85% (100/117) of the untreated lymphoma patients. This demonstrates the feasibility of using AI to support physicians measuring tMTV for assessment of prognosis in clinical practice. ***References:*** Measuring Total Metabolic Tumor Volume from ^{18}F-FDG PET: A Reality Check. EP-0464

The Value of F-18 FDG PET/CT Quantitative and Semi-Quantitative Parameters in Predicting Treatment Response and Prognosis in Hodgkin Lymphoma

S. Aksu[1], *G. Uçmak*[1], *B. B. Demirel*[1], *M. S. Dal*[2]; [1]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Hematology, Ankara, TÜRKIYE.*

Aim/Introduction: Hodgkin lymphoma (HL) is generally considered a favorable lymphoid malignancy, typically exhibiting a robust response to standard chemotherapy regimens. However, in some cases, a complete metabolic response (CMR) is not achieved. This study aims to evaluate the prognostic value of

F-18 FDG PET/CT metabolic parameters in predicting complete metabolic response in patients - prognosis with HL. ***Materials and Methods:*** This retrospective study included 150 patients aged 18 years and older, diagnosed with HL, who underwent F-18 FDG PET/CT for initial staging and treatment response assessment following standard chemotherapy regimens. All patients had a minimum follow-up period of 36 months. Clinical, pathological, and PET/CT metabolic parameters were recorded. Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were derived from baseline PET/CT scans using three threshold methods: SUV 2.5, SUV 4.0, and 41% of SUVmax. For each threshold, total MTV and TLG were calculated by summing the values across all nodal and extranodal lesions. Regression analyses were conducted to identify parameters predictive of treatment response and prognosis. A p-value < 0.05 was considered statistically significant. ***Results:*** Of the 150 patients, 138 (92%) achieved a complete metabolic response to standard chemotherapy, whereas 12 (8%) did not. In univariate analysis, total MTV at the 41% SUVmax threshold (p=0.003, OR: 0.994, 95% CI: 0.990-0.998) and total TLG at the same threshold (p=0.023, OR: 1.000, 95% CI: 0.999-1.000) were significantly associated with treatment response. Multivariate analysis identified total MTV at the 41% threshold (p = 0.025, OR: 0.988, 95% CI: 0.977-0.998) as the sole independent predictor of metabolic response. Using the Youden index, a cutoff value of 101 mL for total MTV 41% provided a sensitivity of 75% and specificity of 70%. Notably, 75% of patients who did not achieve CMR had a total MTV 41% value exceeding this cutoff. During the follow-up period, 132 patients (88%) remained disease-free, while 18 (12%) experienced relapse. The mean disease-free survival was 30 months (range: 7-56 months). No PET/CT parameter was found to be a statistically significant predictor of disease-free survival. ***Conclusion:*** This study demonstrates that total MTV derived from baseline F-18 FDG PET/CT at the 41% SUVmax threshold is the only significant metabolic parameter predictive of treatment response in HL. Our findings suggest that patients with elevated total MTV 41% values (>101 mL) may benefit from modifications to standard treatment regimens to potentially improve clinical outcomes.

EP-0465

Variability factors of hepatic SUVmax and SULmax in patients with FDG avid lymphoma during chemotherapy

H. Habchi[1], *S. Mensi*[2,3], *B. Daoud*[4], *K. Chatti*[3,5];
[1]*Department of Biophysics and Medical Imaging, Higher Institute of Medical Technologies of Tunis, University of Tunis El Manar, Tunis, TUNISIA,* [2]*Nuclear Medicine department, CHU Sahloul, Sousse, TUNISIA,* [3]*Department of biophysics, School of medicine of Sousse, University of Sousse, Sousse, TUNISIA,* [4]*University of Texas, MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA,* [5]*School of Medicine of Monastir, University of Monastir, Monastir, TUNISIA.*

Aim/Introduction: ^{18}F-FDG PET/CT scan is the gold standard imaging modality for initial staging and therapeutic response assessment in lymphoma by using the liver uptake as a threshold. However, hepatic SUVs are likely prone to intra and inter patient variability. The aim of this study was to identify the factors that vary hepatic SUVmax and SULmax between baseline (PET1) and end of treatment (PET2) in patients followed for FDG-avid lymphoma. ***Materials and Methods:*** A retrospective study was conducted on seventy-five patients treated for avid FDG lymphoma who underwent ^{18}F-FDG PET/CT scans at initial assessment and post-treatment. Linear regression models were utilized to evaluate the variability of hepatic SUVmax and SULmax. The correlation between SUVmax, SULmax, and various clinical and technical factors such as age, fasting blood glucose, injected activity, body mass index (BMI), time to acquisition, sex, initial Ann Arbor stage, and histological type of lymphoma was analyzed. During the second PET scan, residual tumor SUVmax and hepatic SUVmax were compared, particularly in patients with a Deauville score of 3 and 4. ***Results:*** The hepatic SUVmax and SULmax values substantially increased (p < 0.0001) between PET1 and PET2 scans. The hepatic SUVmax values demonstrated significant correlations with age, BMI, and the amount of injected activity. Comparable results were found for hepatic SULmax yet with slightly weaker correlation coefficients. The strongest association with hepatic SUVmax was observed with BMI (r = 0.587 to r = 0.693, respectively). Age exhibited the highest correlation with hepatic SULmax (r = 0.516 to 0.533, respectively). The multivariate analysis revealed that BMI and age were the only significant factors. Other factors showed either fragile or no significant relationships with SUVs. Hepatic SUVs were largely unaffected by the histological type or fasting blood glucose concentrations and remained statistically significant. In PET2, the residual tumor SUVmax was less than the hepatic SUVmax but more than the hepatic SULmax in patients with a Deauville score of 3. ***Conclusion:*** Hepatic SUVmax and SULmax demonstrate similar variability, with a more robust correlation for hepatic SUVmax. Despite its major variability, SUVmax seems to be more suitable than SULmax for assessing therapeutic response according to Deauville criteria. These findings should be considered when evaluating therapeutic response based on the Deauville criteria, particularly when the hepatic SUVmax value is employed as a threshold to distinguish between responder and non-responder patients.

EP-0466

Lymphoma Therapy Response Assessment with Low-Dose [^{18}F]FDG Total-Body PET/CT

C. Mingels[1], *F. Sen*[2], *K. J. Chung*[2], *H. Nalbant*[2], *Y. Abdelhafez*[2], *N. S. Esteghamat*[3], *J. Tuscano*[3], *A. Rominger*[1], *R. D. Badawi*[2], *B. Spencer*[2], *L. Nardo*[2];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA,* [3]*Department of Internal Medicine, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Total-body (TB) PET/CT's improved sensitivity offers the possibility to reduce injected activities. Theaim of our study was to define a lower limit of dose reduction for lymphoma therapy assessment. ***Materials and Methods:*** 3.0 MBq/kg [^{18}F]FDG injections of n=24 prospective lymphoma patients served as a referencestandard (RS). Images simulating low-dose injections of 1.0, 0.5, 0.25 and 0.125 MBq/kg werereconstructed at 1-/2-hours post-injection (p.i.). Liver's coefficient of variation (CoV) was assessed. Lymphoma lesions were compared to RS using standardized uptake values (SUV), metabolic tumorvolume (MTV) and total-lesion glycolysis (TLG). Parameters were normalized to liver and blood pool by tumor-to-background (TBR_{Liver}/TBR_{BP}) and contrast-to-noise ratios (CNR_{Liver}/CNR_{BP}). Therapy response was assessed by Deauville criteria. ***Results:*** Overall, 191 lymphoma lesions were analyzed. SUV_{max} trended towards statistically significant increase at 1h p.i. in the lowest dose (1h SUV_{max}: RS: 6.28±5.87 vs. 0.125 MBq/kg: 7.76±6.69, p=0.07 and at 2h: 7.14±7.16 vs. 8.67±7.62, p=0.13). SUV_{max}, MTV and TLG did not differ significantly. CoV increased significantly with lower dose (p<0.01). TBR_{Liver} did not differ statistically. Thus, TBR_{BP} was significantly higher in the lowest dose (p<0.01) at 2h p.i. only. CNR significantly decreased with decreasing doses. Deauville scores did not differ significantly up to an injection of 0.25 MBq/kg for 1h and 1.0 MBq/kg for 2h p.i. Below this limit, we noted significantly lower Deauville scores for lower-dose reconstructions (p<0.01). ***Conclusion:*** Dose reduction with [^{18}F]FDG TB PET/CT for therapy assessment in lymphoma patients is possibleand does not result in significant different MTV, TBR and TLG. SUV_{max} and Deauville scores were comparable to the RS to a lower limit of 0.25 MBq/kg for 1h p.i. and 1.0 MBq/kg for 2h p.i. imaging.

EP-0467

A Radiomic and Semiquantitative PET Approach to Post-Treatment Mediastinal Residuals in cHL and PMBCL: From Classification to PrognosiSA Radiomic and Semiquantitative PET Approach to Post-Treatment Mediastinal Residuals in cHL and PMBCL: From Classification to Prognosis

E. Abenavoli[1], *A. Lombardo*[2], *F. Mungai*[3], *M. Palazzo*[4], *L. Nassi*[4], *B. Puccini*[4], *B. Sordi*[4], *R. Sciagrà*[1], *S. Valente*[1], *A. M. Vannucchi*[4], *V. Berti*[1];
[1]*Nuclear Medicine Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY,* [2]*Nuclear Medicine Unit,Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY,* [3]*Department of Radiology, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY,* [4]*Division of Hematology, Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY.*

Aim/Introduction: Interpreting residual FDG-avid mediastinal masses after end-of-treatment (EoT) PET in lymphoma is challenging, as uptake may reflect either malignancy or benign processes. Not all uptake indicates active disease, and distinguishing residual malignancy from benign causes, such as thymic rebound or inflammation, is often uncertain. This study aimed to assess the value of semiquantitative and radiomic PET features in improving non-invasive characterization and relapse prediction in patients with classical Hodgkin lymphoma (cHL) and primary mediastinal B-cell lymphoma (PMBCL). ***Materials and Methods:*** 113 patients with bulky mediastinal involvement at baseline (cHL n=73, PMBCL n=40) underwent EoT FDG PET/CT. Semiquantitative metrics (SUVmax, SUVmean, MTV, TLG) and radiomic features were extracted using Life7.3 software. A two-step analysis was conducted:(1)a discriminant analysis in patients with residual FDG uptake to differentiate physiological from pathological activity;(2)assessment of the prognostic value of significant variables in the full cohort, regardless of residual uptake. ***Results:*** For relapse prediction, in cHL, DS, TLG and MTV (both with threshold = 4, p<0.001),Intensity_Coefficient_of_Variation (cutoff 0.243, p=0.04), and GLCM_Sum_Entropy (p=0.001) were significant. In PMBCL,both TLG (threshold = 4) and SUVmax (cutoff 12.5,p<0.05)retained prognostic value.Radiomic features identified as predictive included GLCM_Sum_Average, Intensity_Absolute_Median_Deviation, and Intensity_Robust_Mean_Absolute_Deviation.These features were consistently associated with progression-free survival(p<0.05),reflecting complementary aspects of intralesional heterogeneity. ***Conclusion:*** A two-step PET-based strategy combining conventional and radiomic analysis improves the post-treatment assessment of bulky mediastinal disease in both cHL and PMBCL.In cHL, the DS remains the clinical reference; however, radiomic features and metabolic burden parameters such as TLG and MTV enhance prognostic accuracy, particularly in equivocal DS3-4 cases. This supports more individualized therapeutic decisions by helping to distinguish inflammatory from metabolically active residual disease.In PMBCL, where high residual uptake is frequent, the combination of radiomic features with TLG and SUVmax (cutoff 12.5) improves both classification and relapse prediction. These findings support the integration of advanced PET biomarkers,.

EP-0468

Inter-reader variability of FDG PET/CT measurements in lymphoma patients

E. Tragardh[1,2], *M. Lewold*[1,2], *J. Lopez Urdaneta*[3], *M. Larsson*[4], *O. Enqvist*[4,5], *L. Edenbrandt*[3], *S. F. Barrington*[6], *M. Sadik*[3];
[1]*Skåne University Hospital, Malmo, SWEDEN,* [2]*Lund University, Malmö, SWEDEN,* [3]*Sahlgrenska Academy at the University of Gothenburg, Gothenburg, SWEDEN,* [4]*Eigenvision AB, Lund, SWEDEN,* [5]*Chalmers University of Technology, Gothenburg, SWEDEN,* [6]*School of Biomedical Engineering and Imaging Sciences Kings College, London, UNITED KINGDOM.*

Aim/Introduction: The Deauville score is a crucial predictive factor in Hodgkin lymphoma (HL) and diffuse large B-cell lymphoma (DLBCL) during interim or end-of-treatment PET/CT evaluations. However, additional measurements such as metabolic tumour volume (MTV), total lesion glycolysis (TLG), and the maximum distance between hypermetabolic lymphoma lesions (Dmax) may offer enhanced prognostic power, also at baseline. This study aims to investigate the inter-reader variability of these variables, providing insights into the reliability of measurements taken by different physicians. ***Materials and Methods:*** This study included 117 patients with untreated HL or DLBCL who underwent [18F] fluorodeoxyglucose PET/CT scans. Nine nuclear medicine physicians manually segmented lesions. The segmentations were performed in the online tool Recomia (www.recomia.org). No specific instructions were provided other than to segment lymphoma related tumours. MTV, TLG, and Dmax were calculated from these segmentations. MTV was defined as the summed volume in cm3, TLG as MTV multiplied with SUVmean and Dmax as the distance between the centroids of the two farthest lesions, measured in the 3D reconstruction. Each patient was independently segmented by two physicians. Bland-Altman statistics were used to assess the bias between observers and the upper and lower limits of agreement. Pearson correlation coefficients were also calculated. ***Results:*** The mean age of the117 patients was 50 years (range 7-90), 39% female. The mean (standard deviation) values were 501 (782) cm3 for MTV, 3836 (5165) cm3 for TLG, and 400 (290) cm for Dmax. The bias between observers was 4 cm3 for MTV, -1.6 cm3 for TLG and 9.6 cm for Dmax, with limits of agreement of ± 422 for MTV, 1329 for TLG and 415 for Dmax. Pearson correlation coefficients were 0.93 for MTV, 0.99 for TLG and 0.74 for Dmax (p<0.001 for all). ***Conclusion:*** The study demonstrates high inter-reader reliability for MTV and TLG measurements, as indicated by strong Pearson correlation coefficients and narrow limits of agreement. However, Dmax showed moderate variability between observers. Despite the lack of standardization in MTV and TLG measurements, they appear more robust than Dmax. If Dmax is to be used, physicians need clear instructions to add small lesions that may not contribute significantly to MTV but which might affect measurement of disease dissemination.

EP-0469

Correlation analysis of PET parameters and clinical characteristics in 91 patients with diffuse large B-cell lymphoma

S. Chen, *W. Chen, Y. Zhang;*
Fuzhou University Affiliated Provincial Hospital, Fuzhou, CHINA.

Aim/Introduction: This study aims to explore the correlation between ^{18}fluoro-fluorodeoxyglucose (^{18}F-FDG) PET/CT parameters and clinical characteristics in patients with diffuse large B-cell lymphoma (DLBCL). ***Materials and Methods:*** A retrospective analysis was conducted on the baseline and mid-term ^{18}F-FDG PET/CT of 91 patients with DLBCL who received R-CHOP or similar regimens and underwent baseline and interm PET/CT examinations at Fujian Provincial Hospital from January 2012 to June 2022 Parameters and related clinical indicators. The selection of lesions and the post-processing of images were carried out in accordance with the standards recommended by the European Association for Nuclear Medicine (EANM). The relative threshold method was adopted. The VOI of the largest lesion in each patient was delineated with 41% of the maximum standardized uptake value (SUVmax) as the boundary. SUV≥41%SUVmax was used as the threshold to obtain the tumor metabolic volume (MTV). When a patient has multiple metabolic lesions, the MTVS of all the lesions are added together to obtain the total tumor metabolic volume (TMTV). Record the SUVmax with the highest metabolic activity among all positive lesions in baseline PET and mid-term PET as

the baseline SUVmax and mid-term SUVmax. The volume division is automatically performed by the built-in software of the nuclear medicine imaging workstation Xeleris3.0 of the American GE Company to obtain semi-quantitative metabolic parameters. And the relationship between PET metabolic parameters and clinical parameters was explored through point-two-column correlation coefficient analysis. Statistical processing was performed using Pearson correlation analysis. ***Results:*** The research results showed that there were mild to moderate statistical associations between multiple clinical indicators and PET metabolic parameters (P<0.05). The expression of BCL6 protein was negatively correlated with mid-term TMTV (r=-0.221, P=0.048), ΔTMTV% (r=-0.282, P=0.009), and baseline SUVmax (r=-0.244, P=0.025), but was significantly positively correlated with ΔTLG (r=0.221). (P=0.044) Ki67 was positively correlated with ΔSUVmax% (r=0.224, P=0.033); The Performance Status (PS) score, BCL2, CD3 and CD5 of the Eastern Oncology Collaboration Group were positively correlated with the mid-term SUVmax (PS: r=0.212, P=0.049;) BCL2: r=0.251, P=0.020; CD3: r=0.227, P=0.046; CD5: r=0.219, P=0.041. ***Conclusion:*** This study found that there were statistical associations between multiple clinical characteristics of patients with DLBCL and PET metabolic parameters, further supporting the potential importance of BCL6 in regulating the tumor metabolic process of patients with DLBCL and confirming the association between high expression of BCL2 and chemotherapy resistance.

EP-0470

The impact of increased sensitivity of LAFOV PET/CT on DS assessment in lymphoma patients: implication and perspectives

A. Franchini[1], *C. Romano*[2], *S. Capitanio*[1], *A. Spataro*[1], *A. Scarale*[1], *L. Airo' Farulla*[1], *G. Cabrini*[1], *E. Gay*[1], *C. Rossetti*[1];
[1]*Nuclear Medicine Unit, Dipartimento Ematologia, Oncologia e Medicina Molecolare, ASST GOM Niguarda, Milan, ITALY,* [2]*S.C. Fisica Sanitaria, ASST GOM Niguarda, Milan, ITALY.*

Aim/Introduction: The Deauville Score (DS) is routinely used for lymphoma qualitative response assessment using PET/CT imaging. However, variability in DS due to differences in acquisition time and inter-observer interpretation may impact clinical decision-making. The recent introduction of long axial field-of-view (LAFOV) PET/CT scanners offers significantly higher sensitivity than conventional short axial field-of-view (SAFOV) systems. These scanners reduce acquisition time and radiopharmaceutical dose, improving image quality. The purpose of this study is to evaluate the impact of LAFOV PET/CT technology on DS assessment, with a focus on acquisition time and observer variability. ***Materials and Methods:*** Twenty-one patients with lymphoma (both Hodgkin and Non-Hodgkin lymphoma) underwent whole-body PET/CT scans using a uMI Panorama GS scanner for assessment of treatment response. Data were acquired over 5 minutes and reconstructed at 5, 3, 1 minutes, and 30 seconds, with and without point spread function (PSF) modeling. Three independent observers assigned DS values for each reconstruction. Inter-observer DS concordance was analyzed. Additional quantitative metrics included SUVmax, SUVmean, SUVpeak, and liver coefficient of variation (COV). ***Results:*** DS discordances were observed in 4/21 patients. In particular, in one of these, DS varied between 2 and 3. In the remaining three patients, DS varied between 3 and 4, potentially affecting further treatment. Specifically, in one of these, all observers assigned DS 4 with PSF and DS 3 without PSF at acquisition times ≥1 minute. In another, DS was 4 with PSF, but showed inter-time variability (DS 3 or 4) without PSF. In the third case, two observers noted a shift from DS 3 at 3-5 minutes to DS 4 at 30 seconds and 1 minute. Across all patients, no inter-observer variation in DS was observed in PSF reconstructions at 3 and 5 minutes. In all patients, liver COV remained below 15% for acquisition times of 1, 3, and 5 minutes; liver SUVmax was significantly higher in PSF reconstruction at all time points, whereas liver SUVmean did not. Lesion SUVpeak instead was significantly higher in PSF reconstructions compared to non-PSF. ***Conclusion:*** New generation LAFOV PET/CT scanner significantly improves image quality and allows shorter acquisition times. However, it may also introduce variability in Deauville scoring, particularly with very short acquisitions (30 seconds to 1 minute). Further studies are needed to determine the optimal combination of acquisition time and reconstruction method for accurate assessment of treatment response in FDG-avid lymphomas.

EP-0471

Effect on Deep-Learning Time-of-Flight (DL-ToF) image enhancement compared to non-Time-of-Flight (non-ToF) Positron Emission Tomography (PET) images on clinical outcome for response assessment in lymphoma.

C. Low*, O. Adesanya, N. Rao, V. Leung, A. Vasiljevic, C. Lim, L. Rowley;*
University Hospital Coventry and Warwickshire NHS Trust, Coventry, UNITED KINGDOM.

Aim/Introduction: To assess if using DL-ToF PET images will affect the maximal Standardised Uptake Value (SUVmax) and Deauville scoring when compared to non-ToF PET images will cause a stage migration in response assessment for lymphoma. ***Materials and Methods:*** Total of 34 F18-FDG PET-CT scans for response assessment in lymphoma were included in this study between 1/1/2025 to 15/04/2025. All PET-CT images had both DL-ToF and non-ToF reconstructions for comparisons. The highest SUVmax for lymphoma lesions were obtained for both reconstructions. Background mediastinal blood pool and liver SUVmax were also obtained with regions of interest within the aortic arch and the liver respectively for both PET reconstruction images. Deauville scoring was also compared between the 2 PET reconstructed images. ***Results:*** Out of the 34 studies, 11 had Hodgkin Lymphoma (HL), 18 had Diffuse Large B-cell Lymphoma (DLBCL), 2 had Follicular Lymphoma (FL), 2 had T-Cell Lymphoma (TCL) and 1 had Marginal-Zone Lymphoma (MZL). 16 studies were performed for interim response adaptive assessment and 18 studies were for end of treatment response assessment. Based on non-TOF PET images, the number of studies as categorised by Deauville classifications are as follow: Deauville 1 (1), Deauville 2 (9), Deauville 3 (9), Deauville 4 (7) and Deauville 5 (8). Out of the 34 studies, 10 studies had a change in Deauville score between non-TOF and DL-ToF images: 6 studies demonstrate an increased in Deauville score (5 studies from Deauville 4 to 5; 1 study from Deauville 3 to 4) which 4 studies demonstrate a decrease in Deauville score (from Deauville 3 to 2). The average change for SUVmax in lymphoma lesions is 1.76 (-0.8 to 13.3). The average change for background SUVmax in mediastinal blood pool and liver are 0.06 (-0.8 to 0.5) and 0.32 (-1.4 to 0.9) respectively. ***Conclusion:*** Findings show that 10 studies demonstrated a change of Deauville score between non-ToF and DL-ToF images but only 1 study will cause a change in clinical management (Deauville 3 to 4). There are also small changes in SUVmax within lymphoma lesions and background SUVmax for mediastinal blood pool and liver. Findings from this small study demonstrate that DL-ToF images are consistent with non-ToF images for Deauville scoring and can be use in lymphoma treatment response assessment. ***References:*** Mehranian A, Wollenweber SD, Walker MD et al. Deep learning-based time-of-flight (ToF) image enhancement of non-ToF PET scans. EJNMMI, (2022)Vol. 49,11 3740-3749. doi:10.1007/s00259-022-05824-7.

Prognostic Role of Volumetric and Dissemination Parameters from ^{18}F-FDG PET/CT in Follicular Lymphoma.

F. López-Bermejo García[1], *M. Contreras Ameduri*[1], *J. Rodríguez Gómez*[1], *E. Noriega Álvarez*[2], *J. Gatón Ramírez*[1], *F. Pena Pardo*[1], *D. Martínez Osorio*[1], *M. Talavera Rubio*[1], *V. Poblete García*[1];
[1]*Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN,* [2]*Hospital Universitario de Guadalajara, Guadalajara, SPAIN.*

Aim/Introduction: To analyse the prognostic value of maximum tumour dissemination (Dmax), metabolic tumour volume (MTV), and total lesion glycolysis (TLG) measured by ^{18}F-FDG PET/CT in patients with follicular lymphoma (FL). ***Materials and Methods:*** A retrospective observational study was conducted including consecutive patients diagnosed with FL between January 2016 and August 2020, with histopathological confirmation and staging by PET/CT. Dmax was determined by measuring the distance between the two most distant lesions, corrected by body surface area (SDmax) and height (HDmax). MTV and TLG were assessed using PET VCAR software, with semi-automatic segmentation of all hypermetabolic lesions and a SUVmax threshold of 2.5, consistent with previous studies. Clinical and laboratory variables collected included Ann Arbor stage, FLIPI index, lactate dehydrogenase (LDH), and beta-2 microglobulin (B2M). Statistical analysis was conducted using SPSS v29: Pearson's bivariate correlation was used to assess associations between quantitative parameters and overall survival (OS) and disease-free survival (DFS). Cox regression was applied for survival analysis, and Kaplan-Meier curves were generated. Finally, ANOVA was performed to assess the association between the occurrence of death (dependent variable) and the main quantitative PET/CT-derived parameters, as well as clinical and laboratory variables. ***Results:*** A total of 108 patients (59 men) with a mean age of 60.3 years (range 31-86) were evaluated. During follow-up, 20 patients (18.5%) died and 29 experienced disease progression. Pearson's correlation demonstrated a statistically significant negative correlation between OS and both MTV (-0.264) and TLG (-0.265). DFS also showed a negative correlation with MTV (-0.199). LDH was negatively correlated with both OS (-0.319) and DFS (-0.266), while B2M correlated negatively with OS (-0.262). Ann Arbor stage and FLIPI index were associated with DFS. Furthermore, B2M and MTV showed a negative correlation between the dependent variable 'death' and TLG (p 0.04) and B2M (0.02) in ANOVA analysis; these results reject the null hypothesis. Dmax values (corrected and uncorrected) did not show a significant correlation. ***Conclusion:*** Metabolic tumour volume and total lesion glycolysis demonstrate a superior prognostic value in follicular lymphoma compared to dissemination PET/CT parameters.

EP-0473

Diagnostic value of Metabolic Tumor Volume (MTV) as a prognostic criterion in Follicular Lymphoma

Y. Sauchuk*;*
Minsk Oncology Center, Minsk, BELARUS.

Aim/Introduction: Follicular lymphoma (FL) is the second most frequent non-Hodgkin lymphoma subtype. To date, according to the NCCN Guidelines® in B-Cell Lymphomas, there are several first lines of chemotherapy for patients with FL. The choice of chemotherapy line is based on the FLIPI clinical criteria (FLIPI score). However, according to these criteria, the total tumor volume of the affected lymph nodes is not taken into account. And although these scores are a prediction basis for the patient prognosis, they have not yet been established as a means of selecting treatment options. The topic of this research is learning of the prognostic criteria, based on evaluation of Metabolic Tumor Volume (MTV) in FL. ***Materials and Methods:*** Was analyzed baseline and interim PET-CT of 132 patients with FL before and after chemoimmunotherapy induction treatment: R-B (Bendamustine plus Rituximab) versus R-CHOP (Rituximab combined with Cyclophosphamide, Doxorubicin, Vincristine and Prednisone). ***Results:*** Median age was 54 years. 37 (28%) patients had a stage I-II of disease and 95 (72%) patients had a stage III-IV of disease. 33 (25%) patients had a FLIPI2 score 0-2 (Low Risk Group) and 99 (75%) patients had a FLIPI2 score ≥3 (Intermediate and High-Risk Groups). The presence of a high TMTV (≥510 cm^3) was significantly associated with stage III-IV of disease (including number of involved nodal sites ≥5 and bone marrow involvement) + higher FLIPI2 scores. On multivariable analysis, MTV (p=0.002) and FLIPI2 score (p=0.002) were independent predictors of 3-year progression-free survival (PFS). In combination, they identify two risk groups: high TMTV (≥511 cm^3) and high FLIPI2 score (≥3) with 3-year PFS - 26% (p=0.001) and low MTV (<511 cm^3) and low-to-intermediate FLIPI2 score (0-2) with 3-year PFS - 74% (p=0.001). ***Conclusion:*** Baseline MTV is a strong independent predictor in FL. In combination with FLIPI2 score, it identifies patients at high risk of early progression. It can be useful in choosing the most optimal first-line chemotherapy regimen in FL. ***References:*** 1. EP-0474

Concordance and Discordance Between FDG PET/CT and Bone Marrow Biopsy in Detecting Bone Marrow Involvement in Lymphoma: A Retrospective Analysis.

L. Goriparti[1]*, C. S*[1]*, J. Krishna P.*[1]*, V. Goenka*[2]*, D. Khan*[1]*, S. Sagar*[1]*, S. Sharma*[1]*, B. S. Nayak*[1]*, R. Karna*[1]*, A. Dhiman*[1]*, R. Kumar*[1]*;*
[1]All India Institute of Medical Sciences, New Delhi, INDIA, [2] All India Institute of Medical Sciences, Jodhpur, INDIA.

Aim/Introduction: Lymphomas represent a heterogeneous group of malignant neoplasms originating from lymphocytes, broadly classified into Hodgkin lymphoma (HL) and non-Hodgkin lymphoma (NHL). Accurate staging is critical for prognosis and treatment planning, with bone marrow involvement (BMI) being a key determinant, as its presence upstages the disease to Stage IV. Traditionally, bone marrow biopsy (BMB) has been gold standard for detecting BMI. However, FDG PET/CT has emerged as superior, non-invasive alternative, offering comprehensive evaluation of the entire skeletal system and enhanced detection of focal lesions. This study aims to assess the concordance and discordance between FDG PET/CT and BMB in baseline lymphoma cases, providing insights into their diagnostic reliability. ***Materials and Methods:*** This retrospective analytical study utilized data extracted from institutional database. A cohort of 353 baseline and suspected lymphoma cases, spanning from 2022 to March 2025, with 258 cases confirmed as lymphoma via biopsy. Bone marrow involvement was evaluated histopathological using bone marrow biopsy. Histopathological data were available for 149 patients. The dataset was categorized into four groups: Positive on both FDG PET/CT and BMB. Positive on FDG PET/CT but negative on BMB. Negative on FDG PET/CT but positive on BMB. Negative on both modalities. Statistical analysis was performed to determine concordance rates and diagnostic discrepancies between the two techniques. ***Results:*** The study included 149 patients with confirmed lymphoma, comprising 95 males (63.8%) and 55 females (36.2%). The age range was 2 to 85 years, with a median age of 28. The cohort consisted of 88 Hodgkin lymphoma (HL) cases (59.1%) and 61 non-Hodgkin lymphoma (NHL) cases (40.9%).Concordant results (both FDG PET/CT and BMB agreeing on bone marrow involvement status) were observed in 113 cases (75.8%), yielding a concordant-to-discordant ratio of 3.1:1. Discordant results were noted in 36 cases (24.2%), with the following distribution, PET-positive/BMB-negative: 24 cases (19 in HL and 5 in NHL) and PET-negative/BMB-positive: 12 cases (7 in HL and 5 in NHL). Among HL cases, 62 (70.5%) were concordant, while 26 (29.5%) showed discordance. Among NHL cases, 51 (83.6%) were concordant, with 10 (16.4%) discordant. ***Conclusion:*** This study demonstrates a high concordance rate (75.8%) between FDG PET/CT and BMB in

detecting bone marrow involvement, supporting the role of PET/CT as a reliable non-invasive alternative. However, discordance occurred in 24.2% of cases, with a notable predominance in HL, suggesting potential limitations in sensitivity or specificity for certain subtypes, which needs further evaluation into factors influencing discordance.

EP-0475

Texture Analysis of Lymph Nodes on Initial FDG PET/CT for Predicting Interim Deauville Scores after Chemotherapy in Newly Diagnosed Non-Hodgkin Lymphoma Patients

A. Kibar, *K. Saglam, S. Asa, S. Sager, H. B. Sayman;*
Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: FDG PET/CT plays a critical role in staging and assessing treatment response in Non-Hodgkin Lymphoma (NHL). This study evaluates texture features derived from baseline FDG PET/CT scans in newly diagnosed NHL patients to determine their ability to differentiate between responders and non-responders based on interim Deauville scores and assess their predictive value for treatment response. ***Materials and Methods:*** A total of 21 NHL patients were included in the study. Following chemotherapy, 11 patients were classified as Deauville score 1 on interim FDG PET/CT, indicating a complete metabolic response, whereas 10 patients were categorized as Deauville scores 4-5, representing inadequate or no metabolic response. FDG PET images were analyzed with LIFEx software version 7.7.0 to extract texture features. The study aimed to assess whether there were statistically significant differences in texture parameters between responders (Deauville score 1) and non-responders (Deauville scores 4-5). For responders, the lesion with the highest SUVmax on baseline PET/CT was selected for analysis. For non-responders, the lesion with the highest FDG uptake on interim PET/CT was identified on the baseline PET/CT scan for texture analysis. ***Results:*** Of the 21 patients, 7 were female and 14 were male, with a median age of 61 years (range: 19-80 years). The median interval between baseline and interim PET/CT scans was 100 days (range: 43-151 days). All patients were at stage 3 or higher at diagnosis. Among the extracted texture parameters, 17 out of 38 showed statistically significant differences ($p < 0.05$) between responders and non-responders using the Mann-Whitney U test (Table 1). The parameter with the lowest p-value, GLCM_DifferenceVariance, was analyzed using Spearman correlation, revealing an inverse correlation with interim Deauville score ($p < 0.05$, rho = -0.598), indicating that higher Deauville scores correlated with lower GLCM_DifferenceVariance values. Receiver operating characteristic (ROC) analysis for this parameter yielded an area under the curve (AUC) of 0.845. ***Conclusion:*** FDG PET/CT plays a key role in NHL management. As automatic segmentation becomes a part of routine clinical practice in the future, texture features are likely to become more valuable in clinical decision-making. Predicting treatment response based on these features could help clinicians provide more tailored and beneficial care for patients.

EP-0476

Metabolic biomarkers assessed with ^{18}F-FDG PET/CT in patients with diffuse large B-cell lymphoma, with and without BCL-2 and MYC expression

Y. Sánchez Vera, *M. Olarte Casas;*
Unidad PET/CT /Unidad UNAM, Mexico, MEXICO.

Aim/Introduction: The most common lymphoma subtype in adults is diffuse large B-cell lymphoma (DLBCL), which shows heterogeneous characteristics due to the presence of rearrangements and oncoprotein expression. This study determined metabolic characteristics (maximum standardized uptake value (SUVmax), total lesion glycolysis (TLG), metabolic tumor volume (MTV), and Deauville score) assessed with ^{18}F-FDG PET/CT in DLBCL patients with and without BCL-2 and MYC protein expression. Because there is evidence that oncoprotein expression and translocations in BCL-2 and MYC have poorer outcomes, assessing the metabolic characteristics could enhance treatment decision-making. ***Materials and Methods:*** A retrospective, cross-sectional, and descriptive study was conducted. Inclusion criteria:1) patients older than 18 years with a diagnosis of DLBCL, 2) BCL-2 and/or MYC oncoprotein expression status was determined by immunohistochemistry. 3) PET/CT scans at end of therapy. Statistical analysis was performed using one-way analysis of variance and the Mann-Whitney U test. A p value ≤0.05 was considered statistically significant. ***Results:*** Fifty-one patients were included. 51% of the patients included were men and 49% were women. The Lugano classification included stage I in 4 patients (7.9%), stage II in 15 patients (29.4%), stage III in 6 patients (11.7%), and stage IV in 26 patients (51%). BCL-2 expression was positive in 37 patients (72.54%). MYC oncoprotein expression was positive in 3 patients. MUM-1 was positive for 19 patients. The mean SUVmax values in the groups with and without BCL-2 expression were 4.1 SUVmax and 1.1 SUVmax, respectively. These values were not statistically significantly different ($p>0.05$). However, there was a tendency for higher values to be present in the BCL-2-expressing group. The mean TLG in the BCL-2 and/or MYC-expressing group was 73.96 SUV-bwx cm3, and in the negative and/or undetermined group it was 13.87 SUV-bwx cm3, $p>0.05$. The mean MTV in the BCL-2 and/or MYC-expressing group was 38.24 cm3, and in the negative and/or undetermined group it was 8.11 cm3, $p=0.07$. ***Conclusion:*** In this study, higher values of metabolic parameters were observed in patients who expressed BCL2/MYC oncoproteins, although there were no statistically significant differences. This knowledge constitutes a preamble for personalized treatment strategies and further studies of associated genes poorer outcome.

EP-0477

Prognostic Value of ^{18}F-FDG PET/CT in CAR T-Cell Therapy for Relapsed/Refractory Non-Hodgkin Lymphoma

S. Gavriilidis[1], *N. Pianou*[1], *I. Tzannou*[2], *I. Baltadakis*[2], *P. Rontogianni*[1];
[1]*Nuclear Medicine Department, Evangelismos Hospital, Athens, GREECE,* [2]*Hematology Department – BMT Unit, Athens, GREECE.*

Aim/Introduction: Chimeric Antigen Receptor (CAR) T-cell therapy represents a groundbreaking advancement in the treatment of relapsed/refractory non-Hodgkin lymphoma (R/R NHL).18F-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography (^{18}F-FDG PET/CT) plays a critical role in assessing disease status before and after CAR T-cell administration. The aim of this study was to evaluate the prognostic impact of ^{18}F-FDG PET/CT in patients undergoing CAR T-cell therapy. ***Materials and Methods:*** We retrospectively analyzed 16 patients (56% male) with R/R NHL (87.5% with diffuse large B-cell lymphoma) treated at our institution, all of whom underwent ^{18}F-FDG PET/CT imaging at baseline, and at 1- and 3-months post-CAR T-cell therapy. Quantitative PET/CT parameters assessed included total metabolic tumor volume (TMTV), changes in maximum standardized uptake value (ΔSUVmax) between baseline and the 1-month scan, and the Deauville score (DS) at 1 month. The primary endpoints were progression-free survival (PFS) and overall survival (OS), and the association of the above parameters with PFS and OS. Survival estimates were calculated using the Kaplan-Meier method, and prognostic significance was assessed via Cox regression analysis. ***Results:*** Patients with a lower baseline TMTV < 25 mL demonstrated significantly improved overall survival (OS) ($p = 0.028$). A greater reduction in ΔSUVmax > 66.6% between baseline and 1-month post-treatment scans was significantly associated with improved progression-free survival (PFS) ($p =$

0.003). Additionally, a DS of ≤3 at 1-month post-CAR T-cell therapy was strongly correlated with both longer PFS ($p < 0.001$) and OS ($p = 0.02$). In multivariate Cox regression analysis, both ΔSUVmax and 1-month DS emerged as independent prognostic factors for survival outcomes. ***Conclusion:*** ^{18}F-FDG PET/CT serves as a valuable prognostic imaging modality in patients with relapsed/refractory NHL treated with CAR T-cell therapy. Quantitative and semi-quantitative PET/CT parameters—specifically baseline TMTV, early ΔSUVmax, and the 1-month DS—are significantly associated with PFS and OS. However, the small sample size of this study limits the generalizability of these findings. Despite this, the results support the integration of PET/CT-based metrics into post-treatment risk assessment and clinical decision-making.

EP-0478

Prognostic Role of Interim PET in Peripheral T-Cell Lymphoma

S. Pacella[1], *F. Rossi*[1], *N. Rampi*[1], *E. Domingo Domenech*[2], *C. Martinez-Ramos*[3], *D. Bonometti*[1], *F. Passamonti*[4], *M. Castellani*[1]; [1]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico di Milano, Milan, ITALY,* [2]*Institut Catala d'Oncologia, Hospital Duran i Reynals, IDIBELL, Hematology, Barcelona, SPAIN,* [3]*Hospital Universitari de Bellvitge, IDI, Nuclear Medicine, Barcelona, SPAIN,* [4]*Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico di Milano, Università degli Studi di Milano, Milan, ITALY.*

Aim/Introduction: 18-Fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) has become a very important tool for initial staging and for the response assessment in lymphoma. In peripheral T-cell lymphomas (PTCL) its use is recommended in staging, but the predictive role of interim PET during front-line therapy remains to be determined. The aim of this study is to evaluate the predictive role of interim PET in first-line treatment of PTCL. ***Materials and Methods:*** We retrospectively identified 68 patients diagnosed with PTCL and treated between 2014 and 2023. All patients were evaluated with PET at baseline, at interim (iPET) and at the end of treatment (ePET). Interim evaluation was performed after 3 cycles or after 4 cycles. Only 2 patients were evaluated after 2 cycles due to suspected progression. Interim-PET were qualitatively evaluated according to Deauville Score (DS), considering the study negative if DS ≤3 and positive in case of DS ≥4. The results of interim-PET according to DS were correlated with PFS and OS. ***Results:*** At iPET 39 (57%) patients were in complete metabolic response (CMR) with DS 1-3, 21 (31%) in partial metabolic response (PMR) with DS4 and 8 (12%) with progressive disease (PD) with DS5. With a median follow-up of 23 months (2-107), 36 (53%) patients relapsed or progressed. Median progression-free survival (PFS) was 20 months. According to the iPET, median PFS of patients with DS1-3, DS4 and DS5 were 28, 10 and 4 months respectively. In univariate analysis, beside known prognostic factors as ALK+ anaplastic subtype(p=0,02), extranodal involvement (0,01), bone marrow infiltration (0,005), advanced stage (0,006) and increased LDH (0,002), iPET impacted on PFS (DS1-3 vs DS4 vs DS5, p=0.001; DS1-3 vs DS4-5, p=0.003). Regarding the timing, iPET after 4 cycles was associated with better prognostic significance (DS1-3 vs DS4 vs DS5, p=0.0009) than after 3 cycles (DS1-3 vs DS4 vs DS5, p=0,32). Median OS was not reached. The estimated 2-year OS was 69% (95%CI, 55-80). According to iPET, the estimated 2-year OS for patients with DS1-3, for those with DS4 and for those with DS5 were respectively 75% (55-87), 64% (34-83) and 57% (22-81), without significant impact. ***Conclusion:*** Interim PET/CT is a good predictor of outcome in terms of PFS in patients with PTCL. Further studies in larger cohorts and also in multicenter trials are needed to better clarify this important prognostic impact of interim-PET in this histotype of lymphoma.

EP-0479

The Effect of MTV Value Evaluated in Staging FDG-PET/CT on Survival and Prognosis in Diffuse Large B-Cell Lymphoma

A. Tunç[1], *E. N. Durmazer*[2], *N. Akad Soyer*[3], *A. Gunes*[3], *A. M. Argon*[1]; [1]*Ege University Nuclear Medicine Department, Izmir, TÜRKIYE,* [2]*Yuksekova State Hospital, Hakkari, TÜRKIYE,* [3]*Ege University Hematology Department, Izmir, TÜRKIYE.*

Aim/Introduction: Today, as in many malignant diseases, F-18 FDG PET/CT is a functional and metabolic imaging modality that plays major role in staging, treatment response evaluation and residual/recurrence detection in NHL. In this study, we aimed to evaluate the predictive power of whole-body MTV value for median survival and progression-free survival in patients with DLBCL. ***Materials and Methods:*** We retrospectively analyzed 61 DLBCL patients who underwent baseline PET/CT at Ege University between January 2014 and September 2022 and had a minimum of 2 years of follow-up. ROC analysis was used to determine the cut-off value of MTV measurements for predicting progression and survival; cut-off values were determined by Youden index. Kaplan-Meier method was used to determine the overall progression-free survival and overall survival curves. Cox regression analysis method was used to calculate Hazard Ratio. ***Results:*** The mean patient age was 58.8±15.6 years (range: 23-85), with a mean follow-up duration of 48.2±25.1 months (median: 42 months). When evaluated according to survival status, cut-off values >556.6 for MTV and >403.9 for MTV when evaluated according to progression status were found to be significant. Our cohort was reclassified according to the cut-off values and descriptive statistics were performed. Of the 61 patients included in the study, death was observed in 10 (16.39%) and progression in 18 (29.1%). Overall survival and progression-free survival were analyzed according to the MTV value at diagnosis. Exitus was observed in 7 of 17 patients with MTV >556.6 and 3 of 44 patients with MTV ≤556.6. The presence of a 12.21-fold higher risk of death in patients with MTV>556.6 compared to those with MTV ≤556.6 was statistically significant. Progression/relapse was observed in 14 of 22 patients with MTV>403.9 and 4 of 39 patients with MTV ≤403.9. The presence of 11.88 times higher risk of progression/relapse in patients with MTV>403.9 compared to patients with MTV ≤403.9 was statistically significant. ***Conclusion:*** As seen in this study, it is thought that the inclusion of MTV values in various risk classifications will facilitate the identification of patients with high mortality and relapse risk and will allow the determination of patient-specific treatment modalities at the time of diagnosis. It is not possible to standardize these values due to individual factors as well as differences in imaging protocols and devices used between centers. Therefore, it would be more appropriate for each center to determine its own cut-off values and make treatment planning accordingly.

EP-0480

Metabolic Tumor Heterogeneity-Based Scoring System Predicts Prognosis in Hodgkin Lymphoma

S. Bayram[1], *E. M. Kaya*[1], *M. G. Tekin*[2], *M. Ayer*[3], *M. Kaya*[1], *B. Esen Akkaş*[1]; [1]*University of Health Sciences Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*University of Health Sciences, Tepecik Training and Research Hospital, Department of Haematology, Izmir, TÜRKIYE,* [3]*University of Health Sciences Basaksehir Cam and Sakura City Hospital, Department of Haematology, Istanbul, TÜRKIYE.*

Aim/Introduction: To investigate the impact of metabolic tumor heterogeneity and heterogeneity-based prognostic scoring system on treatment response and prognosis in patients with Hodgkin lymphoma (HL). ***Materials and Methods:*** We retrospectively enrolled 94 newly diagnosed adult HL patients

(57M, 37F; mean age:36.6±14.4). Staging ^{18}F-FDG PET/CT, clinical, histopathological and follow-up data were recorded. Cumulative SUV-volume histograms (CSH) were generated using voxel based dosimetry software by segmentation of tumor foci from staging PET/CT images. The area under the curve (AUC-CSH) was defined as heterogeneity index (HI), with lower values associated with more heterogeneous uptake. Based on follow-up PET/CT and clinical results, patients were grouped as: treatment-responsive and treatment-refractory/relapsed disease. The relationship between clinical-metabolic parameters, AUC-CSH and the presence of treatment-refractory/relapsed disease was investigated. An optimal cut-off value for the AUC-CSH was determined through receiver operating characteristic (ROC) analysis. A two-point prognostic scoring system including disease stage (1-2= 0, 3-4= 1) and HI (high >2568= 0; low ≤2568= 1), was constructed. Primary outcome measures were overall survival (OS) and progression-free survival (PFS). Cox regression models were used to perform survival analysis. ***Results:*** The median follow-up was 24.4 (range 6-60) months. Univariate Cox regression analysis showed that lower AUC-CSH value predicted both OS (p=0.034) and PFS (p=0.03). Additionally, advanced disease stage(3-4) was also associated with shorter PFS (p=0.038) and OS (p=0.02). There was no significant correlation between survival outcomes and other clinical parameters or SUVmax values. In our prognostic scoring system, 22 patients(23%) received a score of 2, indicating the presence of both advanced disease stage(n=37) and low AUC-CSH value(n=44). Median PFS and OS for 0-1 point group were not reached, whereas for 2 point group, were 26 and 44 months, respectively (log rank p <0.05; both). Multivariate Cox regression analysis demonstrated that this score was an independent prognostic factor, significantly associated with poorer outcomes in OS (HR=13.2, CI=2.73-64, p=0.001) and PFS (HR=3.12, CI=1.4-7, p=0.006). ***Conclusion:*** Metabolic tumor heterogeneity-based prognostic scoring system was identified as an independent predictor of PFS and OS in patients with HL. Lower AUC-CSH was significantly associated with worse outcome. Alone or combined with disease stage, heterogeneity index can serve as a novel prognostic marker for newly diagnosed HL patients and may support risk-adapted patient management.

EP-0481

Visual and quantitative assessment of interim ^{18}F-fluorodeoxyglucose-positron emission tomography/computed tomography in children with Hodgkin lymphoma

M. Dunaykin[1], *K. Chaurasiya*[1], *E. Kireeva*[1], *G. Shestopalov*[1,2], *M. Yadgarov*[1,3], *N. Myakova*[1], *Y. Likar*[1];
[1]*Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION,* [2]*Russian Children's Clinical Hospital, branch of the Federal State Autonomous Educational Institution of Higher Education " N.I. Pirogov Russian National Research Medical University", Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION,* [3]*Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: The generally accepted visual assessment of Hodgkin's lymphoma (HL) with a 5-point scale (Deauville score, "DS") on interim PET/CT but the method may be subject to inaccuracies. One suggested way to solve this problem may be the use of a quantitative evaluation technique (qPET). This study aimed to assess the discrepancies between visual scoring (vDS) and a quantitative evaluation technique (qDS) of visually identified foci on interim scans. ***Materials and Methods:*** We conducted a retrospective, single-center study involving 115 pediatric HL patients diagnosed and treated under the EuroNet-PHL-C1 and DAL/GPOH-HD protocols. The median follow-up was 35 months, with 16 cases (13.9%) of relapse or progression observed. Event-free survival at three years was 86.3±3.3%. We evaluated visually detected foci for DS using qPET analysis through HERMES Medical Solutions software. Both visual and qPET assessments were performed on interim scans for foci with the highest metabolic activity. ***Results:*** Our findings revealed a 30% discrepancy between vDS and qDS scores when analyzing interim PET/CT along with medical history, with no discrepancies when a DS5 score was assigned. Notably, 31 patients (27.0%) were overestimated by the visual scoring; specifically, 25 had a qDS score of 2 compared to a vDS score of 3, and 6 had a qDS score of 3 versus a vDS score of 4. Factors significantly associated with event-free survival included vDS score (hazard ratio: 2.49, p = 0.009) and the presence of bulk tumor mass (HR: 3.12, p = 0.048). ***Conclusion:*** Our study corroborates existing data showing that DS2 and DS5 scores reliably indicate metabolic remission and progression, respectively, serving as effective prognostic factors. However, for intermediate DS scores (DS3 and DS4), where visual assessment may be questionable, incorporating quantification software is recommended for improved accuracy.

EP-0482

Diagnostic accuracy of ^{18}F-FDG PET/CT in detecting bone marrow lesions in children with Hodgkin's lymphoma

M. Dunaykin[1], *G. Shestopalov*[1,2], *M. Yadgarov*[1,3], *K. Chaurasiya*[1], *E. Kireeva*[1], *N. Myakova*[1], *Y. Likar*[1];
[1]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION,* [2]*Russian Children's Clinical Hospital, branch of the Federal State Autonomous Educational Institution of Higher Education " N.I. Pirogov Russian National Research Medical University", Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION,* [3]*Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: The aim of this study to assess the diagnostic accuracy of ^{18}F-FDG PET/CT for detecting bone marrow lesions in children with Hodgkin's lymphoma (HL), using bone marrow biopsy (BMB) as the "gold standard." ***Materials and Methods:*** Children with newly diagnosed HL and who underwent both BMB and PET/CT imaging as part of pre-treatment staging were included in this retrospective analysis. We evaluated sensitivity, specificity, prognostic values, and overall diagnostic accuracy. ***Results:*** 118 children with HL were included based on the selection criteria, with a median age of 14.3 years (IQR 11.1-16.2) and an age range of 0 to 17 years. The cohort comprised 55.9% males. Among the participants, 1 patient had stage I, 40 had stage II, 39 had stage III, and 38 had stage IV disease. The median follow-up period was 29 months (IQR 14-47 months), revealing 13 cases of recurrence/progression (11.0%) and one mortality (0.8%). Bone marrow involvement was confirmed in 5 (4.2%) out of the 118 patients based on BMB results. Initial PET/CT scans indicated pathological bone marrow lesions in 28 (23.7%) patients. Notably, all patients who tested positive in BMB also showed positive findings on PET/CT. There were no statistically significant differences in event-free survival based on the presence of focal lesions (p=0.19). ***Conclusion:*** ^{18}F-FDG PET/CT can be a perfect alternative to BMB as a noninvasive diagnostic method with high sensitivity and specificity for assessing bone marrow lesions in children with HL. Based on our findings, BMB should not be performed in HL patients when initial PET/CT shows no evidence of bone marrow lesions or when clear signs of bone marrow involvement are present.

EP-0483

Prognostic Value of Total Metabolic Tumor Volume derived from baseline ^{18}F-FDG PET in Patients with Aggressive Non-Hodgkin Lymphoma

S. Hoberück[1], *P. Nikulin*[2], *F. Hofheinz*[2], *J. Kotzerke*[1], *R. A. Bundschuh*[1], *U. Dührsen*[3], *F. Kroschinsky*[4], *A. Braune*[2];

[1]Department of Nuclear Medicine, University Hospital Carl Gustav Carus, TU Dresden, Dresden, GERMANY, [2]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY, [3]Department of Hematology and Stem Cell Transplantation, University Hospital Essen, University of Duisburg-Essen, Essen, GERMANY, [4]Department of Internal Medicine I, University Hospital Carl Gustav Carus, TU Dresden, Dresden, GERMANY.

Aim/Introduction: Our goal was to investigate if the total metabolic tumor volume (TMTV) can improve the prognostic value of baseline PET in aggressive lymphoma. ***Materials and Methods:*** PET data from the PETAL Trial[1] were re-evaluated. Image data as well as maximum baseline SUV and maximum interim SUV (after 2 cycles of R-CHOP) were provided by the PETAL-Trial coordinators. Altogether, 520 patients could be included. In the corresponding baseline PET all affected lesions were delineated with a previously trained neural network. All AI-driven delineations were visually verified and corrected by an experienced nuclear medicine observer, if necessary. From the resulting VOIs TMTV was derived. Survival analyses with respect to event free survival (EFS) were performed for baseline ΔSUVmax and TMTV. ***Results:*** Survival analyses revealed ΔSUVmax and TMTV as prognostic factors for EFS (HR=4.29 and HR=2.81, respectively, p<0.001). In multivariate analysis, ΔSUVmax (p<0.001) and TMTV (p=0.005) remained significant for EFS indicating their independent prognostic value. 5years EFS for low and high risk was 71% vs. 25% for ΔSUVmax and 75% vs. 49% for TMTV. Extension of the two risk model for TMTV to a multi-risk model including clinical parameters further improved discrimination of low and high risk (5years EFS 92% and 35%, respectively). ***Conclusion:*** Our results show that TMTV derived from baseline PET allows a risk stratification close to the risk stratification by ΔSUVmax, which requires both a baseline PET and an interim PET. Prospective investigations are necessary to confirm these promising results. ***References:*** Dührsen U, Müller S, [⋯] Hüttmann A; PETAL Trial Investigators. EP-0484

^{18}F-FDG PET-Based Multidimentional Scoring System for Immune Adverse Events in PD-1 Inhibitor-Treated Refractory Hodgkin Lymphoma

Z. Wu*, X. Zhang, Z. Lin, Y. Deng, Z. Lin, D. Zheng, R. An, Y. Zhang, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Hodgkin lymphoma (HL) features Reed-Sternberg (RS) cells that express PD-1 receptors, contributing to the disease's notable responsiveness to immunotherapy. However, immune-related adverse events (irAEs), stemming from similar immune mechanisms, pose clinical challenges[1]. Reliable biomarkers for irAE prediction remain scarce. Given the non-invasive, systemic metabolic insights provided by ^{18}F-FDG PET/CT, we explored its integration with clinical variables to predict irAE risk. ***Materials and Methods:*** We retrospectively analyzed 54 HL patients (≥18 years) treated with PD-1 inhibitors and assessed with PET/CT before and after four treatment cycles (2017-2023). irAEs were defined by immune-mediated etiology, evaluated through clinical documentation and CTCAE v5.0 criteria. Predictive factors were identified using elastic net and multivariable logistic regression. ***Results:*** Among the cohort, 44.4% (24/54) developed irAEs, with liver dysfunction, fever, rash, diarrhea, and hypothyroidism being most common. Baseline metabolic tumor volume (MTV) and Ann Arbor stage were significantly associated with irAE incidence. Patients with irAEs had higher MTV (255 ± 320 vs. 152 ± 289, p = 0.0192) and were more likely to be stage IV. A predictive nomogram incorporating MTV and Ann Arbor stage achieved strong performance (AUC = 0.80 ± 0.06, p < 0.001; sensitivity: 70.83%, specificity: 76.67%). ***Conclusion:*** Our study proposes a novel PET/CT-based model for anticipating irAEs in HL patients receiving immunotherapy, aiding early risk stratification and clinical decision-making. ***References:*** 1. Naidoo J, Murphy C, Atkins MB, Brahmer JR, Champiat S, Feltquate D, et al. EP-0485

Early ^{18}F-FDG PET/CT as a predictor of metabolic response in large B-cell lymphoma patients following CAR T-cell therapy

C. Sachpekidis*[1], C. Neelsen[1], F. T. Kurz[2], P. Dreger[3], M.-L. Schubert[3], S. A. Klein[4], A. KoppSchneider[1], H.-P. Schlemmer[1], A. Dimitrakopoulou-Strauss[1];*
[1]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [2]Geveva University Hospitals, Geneva, SWITZERLAND, [3]University Hospital Heidelberg, Heidelberg, GERMANY, [4]University Hospital Mannheim, Mannheim, GERMANY.

Aim/Introduction: Chimeric antigen receptor (CAR)-T cells targeting CD19 represent the new standard of care for patients with relapsed or refractory (r/r) large B-cell lymphomas. This study aimed to assess the predictive value of early ^{18}F-FDG PET/CT in determining long-term metabolic response and progression-free survival (PFS) following CAR-T cell therapy. ***Materials and Methods:*** In this prospective, IRB-approved study, 19 patients with r/r B-cell lymphoma receiving CAR-T cell therapy underwent ^{18}F-FDG PET/CT before (PET-0), 1 month after (PET-1) and 3 months after CAR-T cell infusion. Metabolic responses were classified using the Lugano criteria as complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), or progressive metabolic disease (PMD), and further dichotomized by complete response rate ([CMR] vs. non-CMR=[PMR] + [SMD] + [PMD]), and at least partial response rate (responders = [CMR] + [PMR] vs. non-responders = [PMD] + [SMD]). Early metabolic findings (PET-1) were compared with late follow-up results (PET-2). The results of PET/CT were correlated with patients' PFS. ***Results:*** Eighteen patients had metabolically active lymphoma, while one patient showed no target lesions at baseline (PET-0). At 1 month (PET-1), 7 patients achieved CMR, 9 had PMR, 1 had SMD, and 1 had PMD. The patient without baseline target lesions remained in CMR in PET-1. By 3 months (PET-2), 13 patients (68%) showed concordant responses with PET-1, whereas 6 (32%) exhibited inconsistencies. In particular, all patients with early CMR maintained remission. Among the 9 patients with early PMR, 3 remained PMR, 1 patient achieved CMR, while 5 progressed to PMD on PET-2. The patient with early SMD developed PMD, while the PMD patient remained PMD at late follow-up. Median follow-up [95% CI] of the patient cohort from PET-1 was 13 months [7.4 months - NA]. Patients with CMR on PET-1 had significantly longer PFS (median: NA, 95% CI: 10.0 months - NA) compared to non-CMR (median: 1.5 months, 95% CI: 0.9 months- NA) (p= 0.02). The dichotomization based on at least PMR on PET-1 led to no significant PFS differences between responders and non-responders. ***Conclusion:*** Early CMR on PET/CT is a strong predictor of sustained metabolic response and patient survival. However, early PET/CT findings were inconclusive for patients with patients with PMR and SMD, as some experienced disease progression over time.

EP-0486

Prognostic Value of Diffusely Increased F-18 FDG Uptake in the Reticuloendothelial System and CBC Score in Patients with Aggressive B-Cell Lymphoma

Ü. Aksu*[1], S. Bayram[1], E. M. Kaya[1], M. Bayer[2], M. Kaya[1], B. E. Akkaş[1];*
[1]Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Basaksehir Cam and Sakura City Hospital, Department of Hematology, Istanbul, TÜRKIYE.

Aim/Introduction: The immune system and signalling molecules shape the tumour microenvironment and are crucial in cancer

development and progression. The inflammatory response is mainly regulated by the liver, spleen, and bone marrow. While focal F-18 FDG uptake in the spleen and bone marrow indicates disease involvement in lymphoma, diffuse uptake may reflect systemic inflammation. However, its clinical significance remains unclear. This study aimed to assess the association between diffuse FDG uptake in these organs and inflammatory markers, and to evaluate their prognostic value in lymphoma patients. ***Materials and Methods:*** A total of 305 newly diagnosed NHL patients who underwent staging PET/CT between 2020 and 2024 were reviewed. After excluding those with PET- or biopsy-confirmed bone marrow involvement, anemia, secondary malignancies, or indolent lymphoma, 54 patients with aggressive B-cell lymphoma (47 DLBCL, 2 Burkitt, 4 anaplastic large B-cell, 1 lymphoblastic) were included. Pre-treatment inflammatory indices—neutrophil-to-lymphocyte (Neu/Lym), platelet-to-lymphocyte (Plt/Lym), and lymphocyte-to-monocyte (Lym/Mono) ratios—were calculated to generate a CBC score. SUVmean values from the spleen, vertebral column, iliac bone, and proximal femur were obtained and normalized to liver SUVmean. The prognostic impact of these metabolic and inflammatory parameters was assessed for progression-free survival (PFS) and overall survival (OS). ***Results:*** The cohort included 54 patients (32 male, 22 female) with a mean age of 50 years (range: 6-84). Early-stage disease (Stage I-II) was present in 65%. Nine patients (18%) had B symptoms, and 24 patients (45.3%) had extranodal involvement. The median follow-up was 19.9 months (range: 1-50). Disease progression or relapse occurred in 16 patients; 13 patients died. Univariable analysis revealed that spleen-to-liver SUVmean, Neu/Lym, Plt/Lym, Lym/Mono, CBC score, and LDH levels were significant prognostic factors for both PFS and OS ($p < 0.05$). In multivariable analysis, the Neu/Lym ratio was the only independent predictor of OS ($p = 0.004$, HR: 9.34, 95% CI: 2.04-42.7). A strong positive correlation was observed between metabolic activity in the spleen and inflammatory parameters. A spleen-to-liver SUVmean cutoff of 0.86 yielded 93% sensitivity and 66% specificity for predicting PFS, and 91% sensitivity and 61% specificity for OS (AUC: 0.81 for PFS, 0.75 for OS). ***Conclusion:*** Our findings suggest that diffuse splenic FDG uptake correlates with systemic inflammatory markers in aggressive B-cell NHL. Spleen metabolic activity and CBC score may serve as prognostic indicators for PFS and OS; however, further validation with larger cohorts and longer follow-up is warranted.

EP-0487

A new prognostic nomogram based on ^{18}F-FDG PET/CT and clinical parameters in patients with newly diagnosed mucosa-associated lymphoid tissue lymphoma

Y. Han, *X. Zhang, Z. Gao;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Mucosa-associated lymphoid tissue (MALT) lymphoma is an indolent B-cell lymphoma originating from extranodal marginal zones, accounting for approximately 7-8% of non-Hodgkin lymphomas. Although its overall prognosis is favorable, a subset of patients may experience progression or relapse. Existing prognostic evaluation systems lack the incorporation of tumor metabolic information. Assessing the value of combining baseline ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) has emerged as an essential tool for evaluating Hodgkin lymphoma and aggressive non-Hodgkin lymphoma. Nevertheless, its role in MALT lymphoma remains incompletely understood. In this study, our objective is to evaluate the prognosis of patients with newly diagnosed MALT lymphoma by combining baseline ^{18}F-FDG PET/CT quantitative parameter SUVmax and clinical indicators. ***Materials and Methods:*** Patients diagnosed with MALT lymphoma by histopathology between January 2020 and December 2023 were retrospectively enrolled. All patients underwent baseline ^{18}F-FDG PET/CT before treatment. PET/CT parameter (SUVmax) and clinical indicators were collected. Least absolute shrinkage and selection operator (LASSO) regression combined with multivariate Cox regression was used to identify independent predictors of progression-free survival (PFS). A nomogram was constructed based on these predictors. Model performance was evaluated using time-dependent receiver operating characteristic (ROC) curves, calibration curves, decision curve analysis, and Kaplan-Meier survival curves. ***Results:*** A total of 65 patients (age range: 23-83 years; median age: 59) were included. During follow-up, 14 patients experienced progression or relapse, and 1 patient died. LASSO regression identified age, Eastern Cooperative Oncology Group (ECOG) score, SUVmax, platelet counts, neutrophil-to-lymphocyte ratio, and systemic immune-inflammation index as PFS-related factors. Multivariate Cox regression showed that age, SUVmax, ECOG score, and platelet counts were independent prognostic factors. The resulting nomogram showed good predictive accuracy for 1- and 3-year PFS, with the area under the ROC curve (AUC) of 0.905 and 0.884 respectively.The calibration curves for 1-year and 3-year PFS reported good consistency between predicted and observed probabilities for PFS. DCA demonstrated the net clinical benefit of this nomogram. Additionally, the PFS was significantly different according to the best cutoff of nomogram scores ($P < 0.001$). ***Conclusion:*** A multiparameter prognostic model combining PET metabolic parameters and clinical indicators provides robust discrimination, calibration, and clinical applicability for predicting outcomes in MALT lymphoma, offering a visual tool to support individualized treatment decisions.

EP-0488

Defining the optimal volume of interest for response assessment in lymphoma: Evidence from two prospective multicentre trials and a real-world cohort

C.-A. Voltin[1], *D. Hasenclever*[2], *U. Dührsen*[3], *A. Hüttmann*[3], *C. Hanoun*[3], *M. Dietlein*[1], *P. J. Bröckelmann*[1], *P. Borchmann*[1], *A. Drzezga*[1], *C. Mauz-Körholz*[4], *D. Körholz*[4], *O. Sabri*[5], *R. Kluge*[5], *L. Kurch*[5];
[1]*University Hospital Cologne, Cologne, GERMANY,* [2]*University of Leipzig, Leipzig, GERMANY,* [3]*University Hospital Essen, Essen, GERMANY,* [4]*University Hospital Giessen and Marburg, Giessen, GERMANY,* [5]*University Hospital Leipzig, Leipzig, GERMANY.*

Aim/Introduction: Positron emission tomography (PET) with 2-[^{18}F]fluoro-2-deoxy-D-glucose ([^{18}F]FDG) plays a key role in response evaluation of lymphoma, which is commonly based on the Deauville five-point scale. Quantitative approaches using lesion-to-liver standardized uptake value (SUV) ratios may yield more objective and reproducible results than purely visual assessment. However, the optimal size for lesion volumes of interest (VOIs) has not yet been specified. If chosen too large, it may include a substantial number of voxels surrounding the lesion, particularly in cases with small residuals. Therefore, the present study aimed to evaluate which VOI dimensions offer the most reliable basis for quantitative lymphoma response assessment. ***Materials and Methods:*** A total of 90 response assessment PET scans, visually classified as Deauville score 4, were evaluated in this study. Our analysis set consisted of patients with diffuse large B-cell and paediatric Hodgkin lymphoma (n = 30 each). These individuals were treated in the prospective multicentre trials PETAL and EuroNet-PHL-C2. Furthermore, a real-world cohort of adult patients with Hodgkin lymphoma (n = 30) was included. Maximum SUV and average [^{18}F]FDG uptake were determined in the hottest lesion using VOIs of four voxels, 0.2 mL, 0.5 mL, 1.0 mL, and 2.0 mL. We then calculated quantitative PET (qPET) signals as ratios between tumour and background, based on the mean liver SUV, for all six measurements. Signal shifts across VOI sizes, their clinical relevance, and the effects of correction factors were analysed with a linear mixed model fitted to log-transformed data. ***Results:*** Our

analysis revealed statistically significant changes in qPET signal across increasing VOI sizes ($P < 0.0001$), except for the comparison between a volume of four voxels and 0.2 ml ($P = 0.085$). When the published thresholds were applied, a considerable proportion of patients shifted to different quantitative Deauville scores. We observed the highest rates of misclassification for the 1.0-ml and 2.0-ml measurements, with 36 (40.0%) and 42 individuals (46.7%), respectively, being incorrectly classified as PET-negative. After implementation of the calculated volume-specific correction factors, quantitative Deauville scores remained acceptably stable up to 0.5 ml. For VOI sizes of 1.0 ml and above, variability increased and the adjusted values became less reliable. ***Conclusion:*** The qPET signal intensity systematically decreases with increasing VOI size. This effect can be compensated by adjustment factors, which allow acceptably precise quantitative Deauville classification for a volume of up to 0.5 ml. Larger VOIs introduce high variability and are not recommended in the context of lymphoma response assessment.

EP-0489

Prognostic Accuracy of Semiquantitative Analysis of Interim PET/CT in PMBCL

L. Henzlová[1], *V. Ičová*[1], *V. Hanáčková*[2], *K. Polgárová*[3], *D. Zogala*[4], *M. Trněný*[3], *T. Papajík*[2], *V. Procházka*[2], *M. Kamínek*[1];
[1]*Department of Nuclear Medicine, Palacky University and University Hospital Olomouc, Olomouc, CZECH REPUBLIC,* [2]*Department of Hematooncology, Palacky University and University Hospital Olomouc, Olomouc, CZECH REPUBLIC,* [3]*First Department of Internal Medicine, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague, CZECH REPUBLIC,* [4]*Institute of Nuclear Medicine, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague, CZECH REPUBLIC.*

Aim/Introduction: Primary mediastinal large B-cell lymphoma (PMBCL) is a rare and aggressive lymphoma primarily affecting young adults[1]. While interim PET/CT (iPET/CT) scans are routinely used to assess treatment response[2], their prognostic utility remains limited due to the low positive predictive value of standard visual assessment using Deauville scores[3]. ***Materials and Methods:*** This retrospective multicenter study analyzed 116 patients with PMBCL treated with anthracycline-based chemoimmunotherapy. 90 of them had iPET/CT performed on EARL accredited scanners. Semiquantitative parameters, including changes in maximum standardized uptake value (dSUVmax), metabolic tumor volume (dMTV), and total lesion glycolysis (dTLG), were assessed alongside event-free survival (EFS). All iPET/CT scans were independently reviewed by two nuclear medicine physicians blinded to outcomes. ***Results:*** Of the 90 patients, 62 (68.9 %) were iPET-positive (Deauville scores 4-5). Event-free survival (EFS) at 3 years was significantly higher in iPET-negative patients compared to iPET-positive patients (75 % vs. 29 %; $p < 0.01$). Semiquantitative analysis showed that evaluated parameters (dSUVmax, dMTV, and dTLG) provided enhanced predictive accuracy for EFS. Patients with values above optimized cut-off thresholds demonstrated significantly better outcomes (e.g., 3-y EFS: 11.1 % for dSUVmax < 80 % vs. 77.8 % for dSUVmax ≥ 80 %, $p < 0.01$). Semiquantitative analysis was superior in identifying high-risk patients compared to visual assessment alone. ***Conclusion:*** This study highlights the limitations of traditional iPET/CT assessment in PMBCL and underscores the value of incorporating semiquantitative parameters. Metrics such as dSUVmax, dMTV, and dTLG improve predictive accuracy and aid in identifying patients at high risk of treatment failure. Future prospective studies should focus on integrating semiquantitative parameters with clinical factors and exploring their utility as a surrogate endpoint in PET-guided treatment strategies. ***References:*** 1. EP-0490

Quantitative ^{18}F-FDG PET/CT parameters as predictors of CAR-T therapy response in large B-cell lymphoma: a preliminary study.

P. Stefaneli Mormandi*, M. Calls-Calahorro, B. Serrallonga, Y. Delisau, M. Velasco-Nuño, A. Fernández-León, J. Duch, S. Asadurova, V. Camacho, S. Castejon, G. Guzman, A. Flotats-Giralt;*
Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: The emergence of novel oncological treatments such as chimeric antigen receptor T-cell (CAR-T) therapy, creates a growing need to identify individual predictors of therapeutic response. This study was aimed to evaluate whether baseline quantitative ^{18}F-FDG PET/CT parameters (metabolic tumor volume [MTV], total lesion glycolysis [TLG], and SUVmax) could play that role. ***Materials and Methods:*** A retrospective analysis was performed on 35 patients with large B-cell lymphoma who received CAR-T therapy. All underwent baseline ^{18}F-FDG PET/CT prior to CAR-T infusion and a follow-up scan at 3 months post-treatment. Univariate logistic regression was used to assess the individual effect of each biomarker, followed by multivariate logistic regression to evaluate their combined predictive value. The model's discriminative capacity was assessed using a ROC curve, and an optimal probability cutoff was determined using the Youden index. ***Results:*** In the univariate analysis, none of the variables were statistically significant on their own ($p>0.05$), although MTV showed a positive trend. In contrast, the multivariate model showed that altogether the three variables were independently significant (all p-values $p<0.05$), suggesting their predictive value when combined. The model demonstrated good discriminative performance, with an area under the curve (AUC) of 0.8. The optimal probability threshold was 0.4, yielding a sensitivity of 94.4% and a specificity of 58.8% for predicting treatment response. ***Conclusion:*** Although MTV, TLG, and SUVmax individually show limited predictive power, their combination in a multivariate logistic regression model may effectively estimate the probability of response to CAR-T therapy. This model holds potential for clinical implementation through the development of a predictive calculator, enabling physicians to input PET/CT parameters and obtain an objective probability of treatment response, thereby supporting personalized therapeutic decision-making prior to CAR-T infusion. ***References:*** 1) Cohen D, Luttwak E, Beyar-Katz O, et al. EP-0491

Baseline PET/CT Metabolic Parameters as Predictors of Early Treatment Response in Pediatric Hodgkin Lymphoma

M. Cornide Carrallo*, P. Dauden Onate, A. Berardinelli Isea, C. Wakfie Corieh, M. Zapardiel Martinez-Falero, R. Couto Caro, M. Romero Porras, G. Cuesta Domingo, M. Vaillant Lopez, M. Cabrera Martín;*
HCSC, Madrid, SPAIN.

Aim/Introduction: To evaluate the prognostic value of clinical and metabolic parameters derived from baseline ^{18}F-FDG PET/CT (bPET) in predicting early treatment response in pediatric

patients with Hodgkin lymphoma (HL). ***Materials and Methods:*** A retrospective study was conducted in pediatric patients diagnosed with lymphoma who underwent PET/CT at our center between November 2015 and January 2024. From a total of 85 patients, 23 with confirmed HL diagnosis and both baseline and interim PET/CT (iPET) studies were selected. Clinical, analytical, and histopathological variables were collected. Quantitative PET parameters included SUVmax, metabolic tumor volume (MTV), and total lesion glycolysis (TLG), were calculated using automated segmentation software. Treatment response was assessed based on clinical and metabolic criteria, including the Deauville score on iPET. ***Results:*** Mean age at diagnosis was 13.8 ± 3.5 years, with a predominance of female patients (65%). The most frequent histologic subtype was classical Hodgkin lymphoma of the nodular sclerosis type (87%). Most patients were at stage II (65%) and had a low-risk prognostic index (IPS ≤3), without B symptoms (74%), bulky disease (83%), or extranodal involvement (78%). Induction chemotherapy with OEPA was administered in 91% of cases and 71% received consolidation treatment. Radiotherapy was used in 43%, and only 9% of patients underwent autologous stem cell transplantation. A statistically significant association was found between younger age and better metabolic response on iPET ($p = 0.002$). Higher TLG values on bPET were significantly associated with a lower likelihood of achieving complete metabolic response (CMR) ($p = 0.010$). A similar trend was observed for MTV, although statistical significance was not clearly reached ($p = 0.071$). ***Conclusion:*** These findings suggest that baseline TLG and MTV may provide valuable prognostic information in the initial assessment of pediatric HL. Younger age at diagnosis was also associated with improved early metabolic response. Despite the limitations of a retrospective design and small sample size, these results support the need for prospective studies to validate the role of these metabolic biomarkers in risk stratification.

EP-0492

Prognostic Value of Diffusely Increased FDG Uptake in Spleen and/ or Bone Marrow due to Reticuloendothelial System Activation in Lymphoma Patients

Y. Song, *Q. Zhao, W. Cai, Y. Dong, Y. Yang;*
General Hospital of Ningxia Medical University, Yinchuan, CHINA.

Aim/Introduction: The aim of this study was to evaluate the prognostic value of diffusely increased ^{18}F-FDG uptake in the spleen and/ or bone marrow due to the activation of reticuloendothelial system (RES) in lymphoma patients. The correlation between RES activation and inflammation were also explored. ***Materials and Methods:*** We retrospectively analyzed 629 newly diagnosed and untreated lymphoma patients confirmed by pathology between June 2018 and December 2024, all of whom underwent ^{18}F-FDG PET/CT. Patients with conditions affecting splenic or bone marrow metabolism (e.g., anemia) were excluded. Based on diffuse FDG uptake in the spleen and/ or bone marrow on PET/CT, patients were divided into two groups: diffuse FDG uptake (dFDG, n=67) and normal FDG uptake (nFDG, n=75). Hematological parameters (leukocytes, monocytes, neutrophils, platelets) and inflammatory markers (LDH, β2-microglobulin) were recorded within one week before or after PET/CT scan. Volumes of interest (VOIs) were delineated for the liver, spleen and bone marrow to calculate SUVmean, spleen-to-liver ratio (SLR) and bone marrow-to-liver ratio (BLR). Follow-up data were obtained via medical records or telephone. Prognostic results were assessed by correlation analysis, Cox-regression analysis, and Kaplan-Meier survival analysis. ***Results:*** Compared with nFDGgroup, the dFDG group showed more advanced-stage of disease (account for 83.6% vs. 52.0%, $p < 0.001$) and higher serum level of inflammatory markers (including leukocytes, LDH, β2-microglobulin, D-dimer; $p < 0.05$). SLR positively correlated with LDH, β2-microglobulin, and D-dimer ($p < 0.05$). SLR > 2.221 was an independent risk factor for progression-free survival (PFS) (HR=4.660, p=0.012). The diffuse bone marrow uptake may be caused by inflammation. Multivariate analysis identified SLR as an independent predictor of PFS. ***Conclusion:*** The diffuse pattern of FDG uptake in the spleen and bone marrow demonstrated a significant association with systemic inflammatory reactions, and SLR served as an independent prognostic factor for PFS in lymphoma patients. This study provides new insights into PET/CT-guided prognostic stratification in lymphoma.

EP-0493

Prediction Prognostic Models Based on ^{18}F-FDG PET/CT and Clinical Parameters for Diffuse Large B cell Lymphoma with Interim Deauville Scores of 2-4

S. Chen, *W. Chen, Y. Zhang;*
Fuzhou University Affiliated Provincial Hospital, Fuzhou, CHINA.

Aim/Introduction: To develop a prognostic model combining quantitative PET metrics with clinicopathological variables for refined PFS prediction in DLBCL patients with DS2-4, excluding DS1/DS5 extremes to mitigate analytical bias.Diffuse large B-cell lymphoma (DLBCL) represents 30%-40% of non-Hodgkin lymphomas, yet 30%-40% of R-CHOP-treated patients experience progression despite 60%-70% 5-year survival. While interim PET/CT (iPET) with Deauville scores (DS) stratifies metabolic response, conventional DS1-3/DS4-5 dichotomy inadequately addresses heterogeneous outcomes. ***Materials and Methods:*** Study Design: Retrospective diagnostic accuracy study integrating PET/CT metrics (SUVmax/TMTV/TLG/Δvalues, EANM-compliant), clinical indices , and IHC markers through multivariate Cox regression to develop a PFS prediction model, with progression confirmed by imaging/clinicopathology as the reference standard.Modalities/Interventions: Standard R-CHOP regimen; PET/CT scans (GE Discovery NM/CT 710) at baseline (pre-treatment) and interim (post-cycle 3-4).Data Collection: Retrospective retrieval (2012-2022) of clinical/PET data from electronic records, with follow-up through Dec 2024.Participants: Single-center cohort (n=91) meeting WHO 2022 DLBCL criteria.Statistical Analysis: ROC-optimized thresholds, Kaplan-Meier survival analysis, Bootstrap validation (B=500), with model performance assessed via C-index/calibration curves. ***Results:*** 91 patients (mean age 60±14 years; 50 males) with median PFS of 31 months (1-/3-year rates:82.4%/61.5%). Multivariate analysis identified Ann Arbor III-IV (HR=3.520,95%CI 1.154-10.737, P=0.027), BCL2+ (HR=10.018,3.239-32.040, P<0.001), ΔTMTV%>65% (HR=0.461,0.218-0.975, P=0.043), and interim SUVmax>4.1 (HR=9.737,3.802-24.936, P<0.001) as independent predictors. The combined model showed higher discrimination (C-index=0.743 vs. 0.724/0.578, P<0.05) and calibration (Bootstrap B=500). Time-dependent ROC confirmed 3-year AUC=0.75 (95%CI 0.66-0.84). ***Conclusion:*** Ann Arbor stage III-IV (HR=3.520, P=0.027), BCL2 positivity (HR=10.018, P<0.001), ΔTMTV% >65% (HR=0.461, P=0.043), and interim SUVmax >4.1 (HR=9.737, P<0.001) as independent predictors of PFS in DLBCL patients. The nomogram (BCL2/CD20/interim SUVmax) enables precise risk stratification for interim DS 2-4 patients, validated by sustained 3-year AUC=0.80.

Aim/Introduction: Peripheral T-cell lymphoma (PTCL) is a rare and heterogeneous group of aggressive non-Hodgkin lymphomas originating from mature T-cells. It accounts for approximately 10-15% of all lymphomas in adults. PTCL is often associated with poor prognosis and limited response to conventional chemotherapy, highlighting the need for accurate staging and response assessment tools to guide treatment strategies.The aim of this study is to evaluate the predictive value of [^{18}F]FDG PET/CT for response assessment during interim (iPET) and at the end of treatment (fPET) in patients with PTCL. ***Materials and Methods:*** Retrospective study including 47 patients diagnosed with PTCL (mean age: 62 years), all treated at our center with first-line therapy. All patients underwent baseline, interim, and end-of-treatment PET/CT scans. Total metabolic tumor volume (TMTV) and total lesion glycolysis (TLG) were measured using an SUV4 threshold. The percentage reduction in MTV (ΔMTV), Deauville Score (DS) and progression-free survival (PFS) were also analyzed. ***Results:*** The median baseline TMTV and TLG were 78.63 cm^3 (range 0-4833) and 540 cm^3 (range 0-54253.78), respectively. iPET was performed after 3 cycles in 23 patients (49%), after 4 cycles in 22 patients (47%) and after 2 cycles in 2 patients due to early progression. At interim, 30 patients (64%) achieved complete metabolic response (CMR, DS1-3), 11 (23%) had partial metabolic response (PMR, DS4) and 6 patients (13%) showed disease progression. Higher baseline TMTV and TLG were associated with DS4-5 on iPET. Forty patients (85%) showed a ≥90% reduction in MTV (ΔMTV), most frequently observed in those with iPET DS1-3.A total of 91% of patients completed treatment, achieving 68% CMR, 18% PMR, and 15% progression on fPET. Among patients with CMR on iPET, 74% maintained this response at the end of therapy. Additionally, 55% of those with PMR on iPET converted to CMR after completing treatment. Median PFS was 24 months. iPET negativity and ΔMTV >90% were both associated with significantly better PFS. ***Conclusion:*** Our study highlights the potential role of iPET in PTCL. Achieving early CMR and a ΔMTV >90% correlates with longer progression-free survival. Patients with iPET DS4 remain a challenge, as more than half may still achieve CMR after treatment completion. Further research with larger cohorts is needed to better define the prognostic value of baseline TMTV and ΔMTV in PTCL.

EP-0495

Evaluation of Bone Marrow in the Initial Staging of Peripheral T-cell Lymphoma: [^{18}F]FDG PET/CT vs Bone Marrow Biopsy

B. Hervás-Sanz[1], *C. Martínez-Ramos*[1], *E. Domingo-Domenech*[2], *M. Pudis*[1], *J. L. Vercher-Conejero*[1], *A. I. Fritsch-Medina*[1], *J. J. Robles-Barba*[1], *M. Crespí-Busquets*[3], *F. Climent-Esteller*[4], *E. M. González-Barca*[2], *A. Bagán-Trejo*[1], *B. Dacosta-Escobar*[1], *L. M. Gràcia-Sánchez*[1], *I. E. Sánchez-Rodríguez*[1], *M. Cortés-Romera*[1];
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Hematology, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN, [3]Radiopharmay Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [4]Anatomical pathology, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Peripheral T-cell lymphoma (PTCL) comprises a rare and diverse group of aggressive non-Hodgkin lymphomas derived from mature T-cells, representing about 10-15% of adult cases. Due to its clinical heterogeneity and poor response to standard therapies, accurate tools for disease assessment and early response evaluation are essential to improve patient outcomes and guide therapeutic decision-making. The objective of this study is to assess the utility of [^{18}F]FDG PET/CT and its concordance with bone marrow biopsy (BMB) in detecting bone marrow infiltration (BMI) in patients diagnosed with peripheral T-cell lymphoma (PTCL). ***Materials and Methods:*** Retrospective study of 40 patients diagnosed with PTCL (24 males, average age 63 years). Baseline PET/CT, interim (iPET), and post-treatment (fPET) scans were performed. All patients were candidates for chemotherapy according to their histological subtype. Visual analysis of bone marrow uptake on PET and its concordance with BMB were evaluated. PET was considered positive for BMI if focal (unifocal/bifocal/multifocal) and/or diffuse uptake (> liver uptake) was observed. Sensitivity (S), specificity (E), positive predictive value (PPV), and negative predictive value (NPV) of PET were calculated against BMB and/or follow-up. ***Results:*** Thirty of the 40 patients had BMB performed. PET/CT detected BMI in 18/40 patients (45%): 11 with focal uptake and 7 with diffuse uptake. BMB detected BMI in 11/30 patients (37%). There was concordance between PET/CT and BMB in 19/30 patients (63%), with 6 positive cases (3 focal and 3 diffuse) and 13 negative cases (43%). Discordance between PET/CT and BMB occurred in 11/30 patients (37%): 6 had positive PET/CT (3 focal and 3 diffuse) and negative BMB, while 5 had negative PET/CT and positive BMB. Sensitivity, specificity, PPV, and NPV were 55%, 68%, 50%, and 72%, respectively. Three patients with focal uptake on PET/CT had negative BMB. In 12 patients with a positive PET and negative BMB or no biopsy, 8 showed normalization on iPET. In 10 patients with no BMB study, 4 had negative PET/CT and were considered NPV, while 6 showed resolution of medullary foci on iPET, considered PPV. The sensitivity, specificity, PPV, and NPV of PET/CT after including these 10 patients were 71%, 74%, 67%, and 77%, respectively. ***Conclusion:*** The concordance between PET/CT and BMB in evaluating bone marrow in PTCL was good (63%), despite the limited number of patients. Ten percent of patients with focal uptake on PET/CT had negative BMB, and 27% with diffuse uptake had positive BMB.

EP-0496

The prognostic value of MTV is retained in new proposed SUV 4 threshold: an international comparison of follicular and Hodgkin patient survival

S. Chauvie[1], *F. Fallanca*[2], *R. Durmo*[3], *E. Bergalla*[1], *V. Talini*[1], *A. Gallamini*[4], *S. Luminari*[5], *L. Guerra*[6];
[1]S. Croce e Carle Hospital, Cuneo, ITALY, [2]IRCCS San Raffaele, Milano, ITALY, [3]IRCCS Reggio Emilia, Reggio Emilia, ITALY, [4]Lacassagne Cancer Center, Nice, FRANCE, [5]IRCCS Reggio Emilia & University of Modena and RE, Reggio Emilia, ITALY, [6]San Gerardo IRCC, Monza, ITALY.

Aim/Introduction: The objective of this study is to evaluate and compare the prognostic performance of three commonly used TMTV segmentation methods—SUV4, SUV41%, and SUV2.5—across distinct lymphoma patient cohorts, as these thresholds represent widely adopted yet methodologically diverse approaches to metabolic tumor delineation. ***Materials and Methods:*** Data from two large multicenter phase 3 trials were analyzed: 330 Hodgkin Lymphoma (HL) patients from HD0607 (NCT00795613) and 278 Follicular Lymphoma (FL) patients from FOLL12 (NCT02063685). The HL cohort included only PET-negative patients treated with six cycles of ABVD. Baseline FDG-PET/CT scans were segmented using three methods: a 41% SUVmax threshold and fixed thresholds at SUV=4 and SUV=2.5. Only lesions with metabolic tumor volume (MTV) greater than 3 ml were considered. TMTV cut-offs were determined using maximally selected log-rank statistics, and progression-free survival (PFS) was assessed via Kaplan-Meier analysis. ***Results:*** In the FOLL12 trial, 278 patients (124 male) with a median follow-up of 48 months and a median age of 60 years were analyzed. Ann Arbor stages were 33 stage II, 60 stage III, and 185 stage IV, with 173 patients having a FLIPI2 score of 1. In the HD0607 trial, 318 patients (149 male) with a median follow-up of 40 months and a median age of 32 years were analyzed. Ann Arbor stages were 114 stage II, 111 stage III, and 93 stage IV, with 127, 151, and 40 patients having high, intermediate, and low IPS, respectively.The median TMTV in FOLL12 were 164 ml, 236 ml, and 320 ml with SUV4, SUV41%, and SUV2.5 thresholds, respectively. The cut-offs were 405 ml, 479 ml, and 550 ml, discriminating low and high-risk populations with log-rank p-values of 0.00013, 0.0013, and <0.0001, respectively. The 3-year PFS for low and high TMTV were 0.87 and 0.72 with SUV4. In HD0607, the median TMTV were 116 ml, 136 ml, and 216

ml with SUV4, SUV41%, and SUV2.5 thresholds, respectively. The cut-offs were 134 ml, 411 ml, and 623 ml, discriminating low and high-risk populations with log-rank p-values of 0.018, 0.00089, and 0.003, respectively. The 3-year PFS for low and high TMTV were 0.84 and 0.79 with SUV4. ***Conclusion:*** SUV4 has recently been proposed as a standard for lymphoma lesion segmentation, given its reproducibility and practicality in clinical settings. Our results demonstrate that SUV4 offers prognostic value comparable to SUV41% and SUV2.5, reinforcing TMTV's potential as a robust and reproducible biomarker in lymphoma.

EP-0497

Immuno-metabolic stratification in newly diagnosed classical Hodgkin lymphoma: prognostic significance of FDG PET-derived tumor burden and immune-inflammatory parameters

Aim/Introduction: Total metabolic tumor volume (TMTV) derived from baseline [18F]FDG-PET/CT is a validated predictor of progression-free survival (PFS) in classical Hodgkin lymphoma (cHL). However, tumor burden alone may not capture the full biological variability at diagnosis. This study assessed whether immunological and inflammatory markers complement TMTV in predicting PFS and explores their underlying biological organization. ***Materials and Methods:*** We retrospectively included patients with newly diagnosed cHL (January 2016-April 2024) who underwent [18F]FDG-PET/CT for initial staging, prior to any systemic therapy, including corticosteroids (GR19-12370372). Eligible patients had available pre-treatment laboratory data and follow-up for PFS. TMTV was calculated on Syngo.via (Siemens Healthineers) by semi-automatic segmentation of all lesions applying the PERCIST liver threshold (SUV ≥ 1.5 × liver mean + 2 SD). Laboratory data included C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), fibrinogen, monocyte and neutrophil counts, CD4-positive, CD8-positive, CD19-positive lymphocytes, and natural killer (NK) cells. Principal component analysis (PCA) was used to identify latent biological dimensions. Kaplan-Meier curves and the log-rank test were used for survival analysis. ***Results:*** Ninety-two patients were analyzed (mean age: 38 years ±15.9; 54% female). Forty had advanced-stage disease and 52 limited-stage. The mean TMTV was 129.45 mL. Patients with TMTV ≥129.45 mL (n=40) had significantly lower 24-month PFS (66.7% vs. 85.5%; log-rank p=0.027). In multivariate Cox regression including TMTV, CD19-positive, CD8-positive, CD4-positive cells, and CRP, only TMTV was confirmed as independent predictor of poor prognosis (hazard ratio 1.005; 95% confidence interval 1.002-1.009; p=0.004). PCA identified four biological axes which contribute to the pathogenesis of Hodgkin lymphoma in an independent manner: systemic inflammation (CRP, ESR); adaptive immunity (CD4, CD8, CD19) tumor burden/innate cellular immunity (TMTV, monocytes, neutrophils); NK-specific cytotoxicity. TMTV was grouped within the component representing tumor burden and innate immunity, suggesting a shared biological signature with circulating myeloid cells. Among patients with high TMTV, CD19-positive lymphocytes <45.5 cells/mm^3 was associated with lower 24-month PFS (46.2% vs. 90.9%; log-rank p=0.053). Relapsed/refractory patients with high TMTV had significantly lower CD19-positive lymphocyte counts compared to patients without relapse [median 33, IQR 37.5 vs. median 61.5, IQR 50.5] cells/ mm^3 (p=0.03, Mann-Whitney U test). Among patients with low TMTV, CRP >14.7 mg/L was associated with significantly reduced PFS (log-rank p=0.001). ***Conclusion:*** PET-derived TMTV retains independent prognostic value in cHL. Immunological markers, particularly CD19-positive cells and CRP, further stratify PFS risk within TMTV subgroups. These findings support integrated metabolic-immunological assessment to improve early risk stratification in cHL patients.

EP-0498

To evaluate the role of ΔMTV at one month in assessing response after chimeric antigen receptor T-cell (CAR-T) therapy in diffuse large B-cell lymphoma.

C. Martínez*, B. Hervás-Sanz, A. Bagan-Trejo, J. Diaz Moreno, M. Zamorano Rivas, M. Tormo Ratera, A. Mussetti, M. Cortés-Romera; Hospital Universitario de Bellvitge, Barcelona, SPAIN.*

Aim/Introduction: [^{18}F]FDG PET/CT is the technique of choice for evaluating CAR-T therapy in patients with relapsed/refractory diffuse large B-cell lymphoma (DLBCL). A high tumor burden is an independent prognostic factor for overall survival and predicts early relapse. Our objective was to describe the role of 1-month ΔMTV in assessing response after CAR-T therapy in DLBCL. ***Materials and Methods:*** Adult patients (>18 years of age) with relapsed/refractory DLBCL treated with commercial anti-CD19 CAR-T therapy, referred to our center, and with [^{18}F]FDG PET/CT at baseline (pre-infusion) and at one month (1M PET) after treatment were included. Patients with a minimum of 6 months of follow-up after infusion were included. Demographic data and metabolic parameters were collected: metabolic tumor volume (MTV), calculating the ΔMTV at baseline and 1M PET. This was compared with the assessment of response using the Deauville criteria (DS) and with disease status at 6 months. Complete response (CR) was considered to be those with DS1-3 and partial response (PR) with DS4-5. ***Results:*** Fifteen patients (6M) were evaluated, mean age (61 years) range 49-75. It was observed that of the 8 patients with CR in PET1M, all achieved a ΔMTV100%, of them 5 maintained CR/PR (62%) and 3 progressed at 6 months. Of the 6 patients who achieved PR in PET1M, the mean ΔMTV was 84% (range 61-100), 2 maintained CR/PR and 4 (66%) progressed. One patient progressed in PET1M with an increase in ΔMTV leading to death. ***Conclusion:*** In this preliminary study, a ΔMTV of 100% at the one-month follow-up assessment after CAR-T therapy in patients with DLBCL who achieved CR does not guarantee maintenance of CR during follow-up. A larger number of patients with longer follow-up is needed.

EP-0499

Baseline ^{11}C-acetate PET/CT predicts 3-year relapse post complete remission for newly diagnosed multiple myeloma

S. Chen*, S. Cheung, Y. Wong, K. Wu, Y. Yip, K. Cheng, C. Ho; Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

Aim/Introduction: Multiple myeloma cells (MMC) are known to utilize raw acetate as a versatile carbon source to energize

intensive cellular activities, including overexpression of monocarboxylate transporters, acetyl-CoA synthetase and fatty acid synthase for immunoglobulin production, replication and lipid synthesis. Such biosynthetic framework forms the underlying basis for ^{11}C-acetate as a more appropriate biochemical probe in PET evaluation of MM than ^{18}F-FDG, especially for assessment of intramedullary MMC activities. Achievement of complete remission (CR) is the ultimate goal of treatment for MM, but many CR patients continue to relapse, even under the current definition of minimal-residual-disease (MRD) negativity. We had previously showed that baseline ^{11}C-acetate-PET/CT predicts CR, so called "molecular-CR". In this prospective study, we aimed to evaluate whether baseline ^{11}C-acetate-PET/CT might predict 3-year relapse post-CR, thus identifying MM patients who need close PET/CT follow-up. ***Materials and Methods:*** During the last 10 years, we consecutively recruited MM patients who satisfied ALL criteria listed below: (1) pretreatment dual-tracer (DT) PET/CT showing active MM disease without extramedullary involvement; (2) post-treatment serological-CR achieved; (3) post-treatment DT-PET/CT confirmed molecular-CR; (4) post-treatment DT-PET/CT within 3 years to evaluate for any relapse. We previously defined active/relapse MM as: (1) focal relapse with ^{11}C-acetate/^{18}F-FDG-avid focal bone lesions (FBLs); and/or (2) diffuse relapse diagnosed with L3 as index vertebra (^{11}C-acetate-SUV$_{max_}$L3>=3.8 or ^{18}F-FDG-SUV$_{max_}$L3>=3.0). The primary endpoint was relapse within 3 years. The parameters for statistical analysis in prediction of post-CR relapse included the following: (1) %clonal marrow plasma cells, (2) beta-2 microglobulin, (3) FISH risk-stratification, and pretreatment PET parameters (4) >3 ^{11}C-acetate-avid FBLs, (5) ^{11}C-acetate-SUV$_{max_}$L3, (6) >3 ^{18}F-FDG-avid FBLs, (7) ^{18}F-FDG-SUV$_{max_}$L3. ***Results:*** 46 myeloma patients (M:F=22:24; age=59.6±9.6 years, range:44-88 years) having achieved "serological+molecular-CR" were thereafter closely followed by PET/CT. 16/46 patients experienced relapse (by IMWG criteria) within 3 years. Multivariate analysis identified baseline "^{11}C-acetate-SUV$_{max_}$L3" as the only independent predictor for 3-year relapse post-CR (P=0.016). Patients relapsed within 3-years had a significantly higher "^{11}C-acetate-SUV$_{max_}$L3" than relapse-free patients (SUV$_{max_}$L3=7.09±1.87 vs. 4.65±1.99, P<0.01). ROC curve analysis calculated "SUV$_{max_}$L3>=5.55" as the threshold for 3-year relapse post-CR (AUC=0.856, P<0.01). Patients with baseline SUV$_{max_}$L3≥5.55 had a significantly higher 3-year relapse rate than those with SUV$_{max_}$L3<5.55 (71.4% vs. 4%, P<0.05). ***Conclusion:*** Pretreatment ^{11}C-acetate PET/CT is a surrogate biomarker of tumor burden and predictor of 3-year relapse post-CR for newly diagnosed MM patients. High-risk patients with baseline "^{11}C-acetate-SUV$_{max_}$L3≥5.55" are advised to have more frequent surveillance with serial ^{11}C-acetate PET/CT and MRD monitoring, even after achieving CR.

EP-0500

Head-to-head comparison of [^{18}F]florbetapir and [^{18}F]FDG PET for the early detection of amyloidosis in systemic amyloidosis and plasma cell dyscrasias

R. Ni[1], *Y. Kong*[2], *L. Cao*[1], *B. He*[2], *Z. Zhou*[2], *Q. Zhang*[2], *M. Zhang*[2], *W. Wang*[2], *Q. Wang*[2], *H. Zhu*[2], *J. Xiao*[2], *A. Rominger*[3], *Y. Guan*[2], *H. Tan*[2]; [1]*University of Zurich, Zurich, SWITZERLAND,* [2]*Fudan University, Shanghai, CHINA,* [3]*Inselspital, Bern, SWITZERLAND.*

Aim/Introduction: Amyloidosis is underdiagnosed in light-chain amyloidosis (AL) and hereditary transthyretin amyloidosis (hATTR), as well as plasma cell dyscrasias (PCD). We aimed to investigate the utility of [18F]florbetapir (FBP) and [18F]fluorodeoxyglucose (FDG) positron emission tomography (PET) for the early detection and evaluation of organ involvement in systemic amyloidosis. ***Materials and Methods:*** We retrospectively included 83 participants, including 38 AL patients, 8 hATTR polyneuropathy patients, 28 PCD patients and 9 healthy controls. Whole-body PET/CT using [18F]FBP was performed in all participants, [18F]FDG PET was performed in 37 patients with AL and PCD, and the results were analyzed by visual and quantitative assessment. Biochemical, serum, and urine assays and histological analysis of tissue biopsies were performed. ***Results:*** [18F]FBP SUV and TBR analysis showed comparable uptake in AL and hATTR-PN patients (p.A117S, p.V50M, p.K55N, p.T69A, or p.H76R mutation carriers) and greater uptake than in PCD patients and control patients. Different regional [18F]FBP and [18F]FDG distributions were observed among the PCD, AL, and hATTR-PN groups. Both [18F]FBP and [18F]FDG enabled the detection of amyloidosis in patients with PCD before clinical detection of AL. [18F]FBP SUV and visual analysis provide comparable measures of organ involvement and were comparable to [18F]FDG and clinical assessment. ***Conclusion:*** [18F]FBP PET detected organ amyloidosis in PCD, AL and hATTR-PN patients with high sensitivity and specificity. [^{18}F]FBP PET, through both visual and SUV$_{max}$ analysis, is more sensitive than [^{18}F]FDG PET and biospy based asessment for detecting organ amyloidosis in PCD and AL patients. It serves as a valuable noninvasive method for the early and accurate detection of systemic amyloidosis, with the potential to improve diagnostic precision and facilitate timely intervention in systemic amyloidosis patients.

EP-0501

FDG-PET/CT versus WB-MRI for bone disease assessment and management change in Smoldering and Symptomatic Multiple Myeloma.

D. Bezzi[1], *A. Rossi*[2], *A. Prochowski Iamurri*[2], *F. Matteucci*[1], *M. Celli*[3], *V. Rossetti*[3], *G. Feliciani*[4], *C. Cerchione*[5], *P. Caroli*[3]; [1]*Nuclear Medicine Unit, AUSL Romagna, Forli-Cesena, ITALY,* [2]*Radiology Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY,* [4]*Medical Physics Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY,* [5]*Hematology Unit, IRCCS Istituto Romagnolo per lo Studio dei Tumori (IRST) "Dino Amadori", Meldola, ITALY.*

Aim/Introduction: The aim of the study was to compare 18F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET) and whole-body magnetic resonance imaging (WB-MRI) for bone disease (BD) assessment in high-risk Smoldering (SMM) and Symptomatic Multiple Myeloma (MM), and to evaluate their relevance for patient management. ***Materials and Methods:*** SMM and MM patients were prospectively enrolled between October 2020 and January 2024. Within one month, all underwent FDG-PET and 3Tesla-WB-MRI, assessed by double-blind readers according to IMPeTUs criteria and MY-RADS respectively. BD was defined as the presence of either focal (FL) or non-focal patterns (NFPs) beyond classical CRAB-criteria: diffuse/micronodular infiltration on WB-MRI and diffuse uptake on FDG-PET. Patient management was established during weekly multidisciplinary meetings, with consensus decisions (IMWG criteria) serving as the reference standard. Patients were stratified by BD presence (FDG-PET+ and/or WB-MRI+) or absence (FDG-PET−/WB-MRI−) and correlated with laboratory data. ***Results:*** The cohort included 137 patients 73M/64F [53%/47%], mean age 66 y): 39 SMM and 98 MM (37 newly diagnosed, 37 post-ASCT, 24 relapsed/refractory). Within the SMM subgroup, WB-MRI detected BD in 10 patients (26%) vs. 4 (10%) with FDG-PET, showing only fair concordance (Cohen's κ=0.33). Most WB-MRI+ cases were NFPs (6/10); among 4 with FL on WB-MRI, only 2 showed focal-PET pattern. Within the MM subgroup, FDG-PET was positive in 60 patients(61%) and WB-MRI in 67(68%), with 91% agreement (κ=0.80). WB-MRI showed higher detection for NFPs: in 9 cases (7 diffuse,2 micronodular), PET was negative or discordant in 6. Regarding FL, FDG-PET detected 55 cases (56%) and WB-MRI 58 (59%), with 97% agreement and excellent concordance (κ=0.94). In the overall cohort, patient management changed in

49% of cases (67/137); attributed to WB-MRI in 95% (64/67) and FDG-PET in 81% (54/67), suggesting a greater impact of WB-MRI (p=0.02), particularly in SMM (3 additional cases), with added clinical value from incidental findings (2 malignancies,1 spinal cord compression). A complementary role emerged in post-ASCT suspected relapse (13 changes based on both, 11 on FDG-PET, 10 on WB-MRI). Furthermore, double-negative patients (FDG-PET–/WB-MRI–) showed less aggressive disease features: in SMM, lower paraprotein (19.8 vs. 29.8g/L, p=0.01); in MM, lower paraprotein (7.4 vs. 19.3g/L, p=0.007) and higher hemoglobin (12.5 vs. 11.2g/dL, p=0.002). ***Conclusion:*** FDG-PET and WB-MRI are central to BD assessment, with WB-MRI showing higher detection of non-focal patterns. Both significantly influenced clinical management. Their complementarity was evident in post-ASCT relapse, with WB-MRI having greater overall impact—especially in SMM—supporting combined use in clinical practice.

EP-0502

[18F]FDG vs [68Ga]Ga-PSMA-11 PET/CT in Multiple Myeloma(MM): Agreement Analysis in Staging and Response Assessment

M. Di Franco[1], *D. Bezzi*[2], *M. Stasolla*[1], *M. Talarico*[3], *E. Zamagni*[3], *V. Cabitza*[4], *F. Lodi*[4], *S. Fanti*[1,4], *C. Nanni*[4];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Unit, AUSL Romagna, Cesena, ITALY,* [3]*Seràgnoli Institute of Hematology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: MM lesions can show a variable uptake on [18F]FDG PET/CT(FDG-PET/CT), with 10% of FNs. Prostate-specific membrane antigen(PSMA) can be overexpressed on the endothelium of neoangiogenic blood vessels, including in MM lesions. The aim of this study is to compare [68Ga]Ga-PSMA PET/CT(PSMA-PET/CT) and FDG-PET/CT in the assessment of MM before and after treatment. ***Materials and Methods:*** Patients with newly-diagnosed symptomatic MM were prospectively enrolled to undergo paired FDG-PET/CT and PSMA-PET/CT within 14 days. Patients with a positive baseline PSMA-PET/CT underwent post-treatment paired FDG- and PSMA-PET/CT. Per-patient and per-lesion analyses were conducted, using Cohen's kappa test, and the McNemar's test. Clinical trial: NCT06835244. ***Results:*** 51 patients were enrolled. A)Pre-treatment: 40/51(78%) patients had concordant FDG and PSMA-PET/CT scans, 23(45%) both positive and 17(33%) both negative; 11/51(22%) patients had discordant scans: 9/5(18%) had a positive FDG-PET/CT only, 2/51(4%) had a positive PSMA-PET/CT only (k=0,57). Overall, 309 focal lesions(FLs) were detected across both scans. Excluding the outlier subject(155 FLs; 137 FDG-positive only; 18 positive at both tracers), FDG-PET/CT detected 116/154(75%) and PSMA-PET/CT detected 72/154(47%) FLs. Eighty-two(53%) FLs were FDG-positive only, whereas 38(24%) were PSMA-positive only (n=7 patients). In the per-lesion analysis, Cohen's kappa showed a strong negative agreement (k= -0.509, p < 0.0001). McNemar's test confirmed significant asymmetry in lesion detection (p < 0.001), in favor of FDG. The median SUVmax of FLs was 5.7 for FDG, 5.2 for PSMA. Overall, 13 paramedullary(PM) lesions were detected, all FDG-positive, 12(92%) PSMA-positive. B)Post-treatment: 17/26 patients, all FDG- and PSMA-positive at baseline, underwent post-treatment paired scans. Therapies were chemotherapy only (n=2) or chemotherapy plus autologous stem cell transplant (n=15). Clinical responses were: complete response(n=7), very good partial response(VGPR)(n=8), partial response(n=1), not-evaluable(n=1). 15/17 patients had concordant negative scans, 1/17(VGPR) was positive at both tracers, 1/17 (VGPR) had FDG-negative/PSMA-positive scans due to the persistence of a PSMA-positive FL (k=0,63). Five patients progressed (4/5 within one year from treatment initiation): at baseline, all had both FDG- and PSMA-positive FLs; in 3/5 PSMA detected more lesions than FDG (22/38 PSMA-positive-only FLs). ***Conclusion:*** Our study showed a systematic disagreement between FDG- and PSMA-PET/CT in the pre-treatment assessment of MM, suggesting that the different biological processes targeted by the two tracers may rarely coexist. FDG-PET/CT significantly outperformed PSMA in lesion detection. However, in the post-treatment assessment, the two tracers showed good concordance in identifying responding patients. A negative prognostic value of PSMA is suggested by the follow-up data, although still limited.

EP-0503

Prospective Comparison of [18F]FDG PET/CT and Whole-Body Diffusion-Weighted Magnetic Resonance for Staging and Treatment Response Assessment in Multiple Myeloma

M. Di Franco[1], *D. Bezzi*[2], *M. Stasolla*[1], *M. Talarico*[3], *E. Zamagni*[3], *A. Cattabriga*[4], *F. Galuppi*[4], *S. Brocchi*[4], *C. Mosconi*[4], *S. Fanti*[1,5], *C. Nanni*[5];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Unit, AUSL Romagna, Cesena, ITALY,* [3]*Seràgnoli Institute of Hematology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [5]*Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: This is a prospective, single-center, non-pharmacological interventional study comparing [18F]FDG PET/CT(FDG-PET/CT) and Whole-body Diffusion-Weighted Magnetic Resonance(WB-MRI) in assessing patients with smoldering multiple myeloma(SMM) or newly diagnosed multiple myeloma(NDMM) at staging and pre-maintenance. The aims are to compare the two modalities' positivity rates and to investigate their pre- and post-treatment prognostic value. ***Materials and Methods:*** FDG-PET/CT and WB-MRI were performed at diagnosis of SMM/NDMM. Positive techniques were repeated after ASCT (pre-maintenance) or after 1 year of treatment. IMPeTuS criteria and MY-RADS criteria were used for image interpretation. Protocol: 364/2022/Oss/AOUBo. ***Results:*** Up to April 2025, 205 patients were enrolled (n=74 SMM; n=131 NDMM). In NDMM, baseline FDG-PET/CT and WB-MRI were concordant in 109/131(83,2%) patients: 90/131(68,7%) were both positive and 19/131(14,5%) were both negative. Discordant scans were found in 22/131(16,8%) patients: 4/22 were FDG+/WB-MRI- due to BM DS4 diffuse uptake; 18/22 were WB-MRI+/FDG- due to the presence at MRI of up to 3 FLs in 10 patients, 3-10 FLs in 2, more than 10 FLs in 5, bone marrow involvement in 1 (DS2 by FDG-PET/CT). Notably, 11/18 WB-MRI+/FDG- discordant patients had DS3 BM diffuse uptake at FDG-PET/CT (borderline positivity). In terms of positivity/negativity, the two modalities showed moderate agreement (kappa=0,53; IC95% 0,37-0,7). Overall, FLs were detected more frequently by WB-MRI than by FDG-PET/CT (FLs' k=0,48; p<0,05), while bone marrow involvement(DS4) was seen more frequently at FDG-PET/CT (k=0,40; p<0,05). PM lesions were detected in 30 patients by FDG-PET/CT, in 39 by WB-MRI (k=0,74). Forty-six patients were evaluated after 1 year of treatment/pre-maintenance. Hematologic responses were: n=24(52,2%) complete response, n=17(37,0%) very good partial response, n=4(8,7%) partial response, n=1(2,2%) not-evaluable. Thirty-one out of 46 patients underwent post-treatment FDG-PET/CT: 27(87,1%) had complete response, 1(3,2%) partial response, and 3(9,7%) progressive o stable metabolic disease. Forty patients underwent post-treatment WB-MRI: n=36(90%) RAC1-2, n=2 RAC3, n=1 RAC4, n=1 RAC=5. Responders at both modalities were 27/31(FLs/BM DS<4 and RAC 1-2), while non-responders were 2/31(FLs' DS>4 and RAC 3-5); 2/31 patients had discordant response categories at FDG-PET/CT and WB-MRI (n=1 FDG-positive and WB-MRI-negative; n=1 FDG-negative and WB-MRI-positive)

(k=0,63). ***Conclusion:*** Concordance between the two modalities was moderate in terms of positivity/negativity. WB-MRI detected a greater number of FLs than FDG-PET/CT, whereas PET/CT more frequently identified diffuse BM infiltration. Further follow-up data are needed to assess the prognostic significance of these findings. Preliminary data indicate good agreement between PET/CT and WB-MRI for treatment response evaluation, despite the small sample sizes' limitations.

EP-0504

Prognostic Value of [^{18}F]FDG PET/CT in Acute Lymphoblastic Leukemia

M. Stasolla[1], *M. Di Franco*[1], *C. Sartor*[2,3], *C. Papayannidis*[3], *J. Nanni*[2], *A. Curti*[3], *A. Romagnoli*[2], *C. Nanni*[4];
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Dipartimento di Scienze Mediche e Chirurgiche, Università di Bologna, Bologna, ITALY, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "Seràgnoli", Bologna, ITALY, [4]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Acute lymphoblastic leukemia (ALL) is a hematological malignancy characterized by the uncontrolled proliferation of immature lymphocytes in the bone marrow and peripheral blood. This condition represents the most common type of leukemia in children but can also affect adults of all ages. Positron emission tomography with fluorodeoxyglucose (PET-FDG) is an imaging technique that allows the assessment of the metabolic activity of both medullary and extramedullary tumor cells. We seek to investigate the potential prognostic value of PET-FDG imaging in predicting overall survival (OS) and progression-free survival (PFS) in patients with ALL. ***Materials and Methods:*** 63 patients (43 men and 20 women) diagnosed with ALL underwent a staging PET-FDG scan. Of these patients, 40 underwent a follow-up PET-FDG scan after the first cycle of therapy. The PET variables considered were hepatic SUVmax, hepatic SUVmean, bone marrow (BM) SUVmax, BM SUVmean and extramedullary lesions. For the subsequent multivariate analysis, additional variables such as OS months, PFS days, white blood cells (WBC), hemoglobin, platelets, LDH BM blasts were included. Statistically significant cut-off values were identified for PET variables (both staging and post-therapy). The log-rank test was performed, followed by Kaplan-Meier survival curves for variables with statistically significant p-values in the univariate analysis ($p < 0.05$). Finally, a multivariate Cox regression analysis was conducted, incorporating both staging and post-therapy PET parameters along with the aforementioned variables. ***Results:*** Statistically significant cut off values were identified for some of the PET variables considered. The log-rank test and Kaplan-Meier survival curves showed that the post first cycle PET-FDG results significantly dichotomize the patient outcomes. Multivariate analysis revealed that both the post first cycle PET-FDG results and LDH levels are prognostic factors in terms of PFS ($p = 0.037$ and $p = 0.039$, respectively). ***Conclusion:*** PET-FDG imaging provides valuable prognostic information in patients with ALL. The identified cut-off values for PET-FDG parameters can help in stratifying patients based on their metabolic activity, potentially guiding therapeutic decisions and improving clinical outcomes.

EP-0505

Prognostic Value of ^{18}F-FDG PET/CT Brain-to-Liver Uptake Ratio in Multiple Myeloma

C. D. Ramos, *T. P. Santos, M. E. S. Takahashi, C. Cralcev, M. D. S. Silva, F. C. Souza, E. Miranda, C. A. Souza;
University of Campinas, Campinas, BRAZIL.*

Aim/Introduction: ^{18}F-FDG PET/CT is routinely used for staging and response assessment in multiple myeloma (MM). Reduced cerebral FDG uptake has been observed in advanced malignancies, potentially linked to metabolic alterations like the Warburg effect and elevated lactate levels. This study investigated the prognostic significance of the brain-to-liver standardized uptake value ratio (BLR) in MM patients. ***Materials and Methods:*** We analyzed 82 MM patients (diagnosed March 2011-May 2019) with median 25-month follow-up (range: 0.1-113). All underwent diagnostic ^{18}F-FDG PET/CT after ≥6-hour fasting (glucose <180 mg/dL), receiving 0.1 mCi/kg ^{18}F-FDG 60 minutes pre-scan. Automated whole-brain segmentation and liver spherical VOIs generated SUVmean values for BLR calculation. Overall survival (OS) and progression-free survival (PFS) analysis used Kaplan-Meier and log-rank tests (SPSS v24), with data updated through January 2025. ***Results:*** The cohort (55% male, median age 64 years) showed 67% ISS stage III, 16% ECOG ≥2, and 88% with bone lesions. Most (94%) received chemotherapy (27% bortezomib), with 71% achieving ≥PR. Progression occurred in 47%, mortality in 69%. Five-year OS/PFS rates were 35%/10%.BLR correlated significantly with sex ($p=0.006$), overweight status ($p=0.007$), ISS stage ($p=0.04$), and β2-microglobulin ($p<0.0001$). Patients with BLR >2.7 had superior OS (50% vs 13%, $p=0.006$) and PFS (3% vs 0%, $p=0.006$). ***Conclusion:*** BLR at diagnosis demonstrates strong prognostic value for MM outcomes, with 2.7 as a clinically relevant cutoff. Its association with β2-microglobulin and advanced disease suggests BLR reflects tumor glycolytic activity. Reduced brain uptake in aggressive MM may indicate lactate-mediated metabolic adaptation, positioning BLR as a potential biomarker of disease burden and metabolic dysregulation.

Assessing the relationship between quantitative ^{18}F-FDG PET/CT and DWI MRI parameters in bone marrow imaging of multiple myeloma

Ö. Kilic[1,2], *M. Hajiyianni*[3], *M. Wennmann*[1,4], *E. K. Mai*[3], *L. John*[3], *N. Weinhold*[3], *M. Grözinger*[4], *S. Sauer*[3], *M. S. Raab*[3], *H. Goldschmidt*[3], *A. Dimitrakopoulou-Strauss*[1], *C. Sachpekidis*[1];
[1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [2]Medical Faculty Heidelberg, Heidelberg University, Heidelberg, GERMANY, [3]Internal Medicine V, Hematology, Oncology and Rheumatology, German-Speaking Myeloma Multicenter Group (GMMG), Heidelberg University Hospital, Heidelberg, GERMANY, [4]Division of Radiology, German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Aim/Introduction: In multiple myeloma (MM), imaging plays a critical role in assessing bone marrow (BM) involvement. ^{18}F-FDG PET/CT reflects metabolic activity, while diffusion-weighted MRI (DWI) provides insights into tissue microstructure via the apparent diffusion coefficient (ADC). This study explores the relationship between quantitative imaging biomarkers—ADC and PET-derived SUVmax—and established clinical indicators of disease burden. ***Materials and Methods:*** Fifty-seven newly diagnosed MM patients (36 ISS-I, 10 ISS-II, 11 ISS- III; 28% with high-risk cytogenetic features) underwent whole-body ^{18}F-FDG PET/CT and MRI —including DWI, T1-, and T2-weighted sequences—, both at baseline and after induction therapy. All patients were enrolled in the open-label, multicentre, randomized phase 3 GMMG-HD7 trial at the Myeloma Center Heidelberg and received either isatuximab plus lenalidomide, bortezomib, and dexamethasone or the standard regimen without isatuximab. A total of 114 paired measurements per time point were obtained from anatomically matched regions in the os ilium and lower lumbar spine to assess diffuse BM involvement. SUVmax and ADC values were extracted from corresponding sites. Correlation was assessed using Spearman's rank coefficient ($p < 0.05$). ***Results:*** At baseline, a weak but statistically significant correlation was observed between ADC and SUVmax ($r = 0.19$). Longitudinally, changes in ADC moderately correlated with changes in SUVmax from baseline to follow-up ($r = 0.20$). Both baseline SUVmax and ADC values significantly correlated with β2-microglobulin levels (SUVmax: $r = 0.40$; ADC: $r = 0.38$), plasma cell infiltration rate (SUVmax: $r = 0.30$; ADC: $r = 0.38$), and hemoglobin levels (SUVmax: $r = -0.20$; ADC: $r = -0.31$).

Additionally, both parameters increased significantly across ISS stages. ***Conclusion:*** Functional imaging modalities provide complementary insights into BM involvement in MM. ADC may serve as a valuable alternative to PET/CT in longitudinal disease assessment, particularly in settings with limited PET availability. These findings support a multimodal imaging approach to improve diagnostic precision and treatment monitoring in MM.

EP-0507

Prognostic Value of Tumor Dissemination (Dmax) Derived from ^{18}F-FDG PET/CT in Patients With Multiple Myeloma

S. Pellegrino[1], *E. Di Donna*[1], *M. Lamagna*[2], *R. Della Pepa*[2], *S. Del Vecchio*[1], *R. Fonti*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY,* [2]*Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.*

Aim/Introduction: The aim of our study was to test whether the largest distance between two ^{18}F-FDG avid lesions (Dmax) may predict overall survival (OS) in patients with multiple myeloma (MM). ***Materials and Methods:*** Thirty-two MM patients (18 men, 14 women) who had undergone ^{18}F-FDG PET/CT scan showing at least two positive focal bone lesions were included in the study. All lesions were segmented using an automated contouring program setting an absolute threshold for SUV at 2.5. The largest distance between two ^{18}F-FDG avid lesions (Dmax) in each patient was measured. Then the hottest focal lesion was selected and SUVmax, SUVmean and Coefficient of Variation (CoV) were determined along with total MTV (MTV_{TOT}) and whole-body TLG (TLG_{WB}) from all malignant lesions. Patients were subjected to a mean follow-up period of 49 months. Univariate and multivariate analyses of clinical and imaging variables were performed using Cox proportional hazards regression whereas Kaplan-Meier method and log-rank tests were used for survival analysis. ***Results:*** A total of 311 bone focal lesions were segmented and mean Dmax value was 49.64±29.13 cm. In 32 hottest focal lesions, average values of SUVmax, SUVmean and CoV were 10.96±7.55, 4.86±1.94 and 0.36±0.14, respectively, whereas mean values of MTV_{TOT} and TLG_{WB} were 52.26±64.5 ml and 284.68±370.56 g, respectively. Univariate analysis showed that OS was predicted by haemoglobin (p=0.0458), plasma cell percentage in the bone marrow (p=0.0468), Dmax (p<0.0001), MTV_{TOT} (p=0.0030), TLG_{WB} (p=0.0017) as well as by SUVmax (p=0.0339), SUVmean (p=0.0325) and CoV (p=0.0062) of targeted lesions. At multivariate analysis only Dmax was retained in the model for the prediction of OS (p=0.0028). By Kaplan-Meier analysis, patients with Dmax ≤ 48.7 cm had significantly better OS as compared to patients with Dmax > 48.7 cm (p=0.0001). When we combined Dmax with MTV_{TOT}, in all possible arrangements, a statistically significant difference was found among the survival curves (p=0.0002). In particular, patients with Dmax > 48.7 cm and MTV_{TOT} > 39.4 ml had the worst prognosis. ***Conclusion:*** Dmax, by reflecting tumor dissemination, can predict overall survival in MM patients. Moreover, the combination of Dmax with MTV_{TOT}, that represents the whole metabolically active tumor burden, may improve the risk stratification of these patients.

EP-0508

Diagnostic Value of Whole-Body ^{18}F-FDG PET/MRI versus PET/CT in Systemic Histiocytosis: A Prospective Comparative Study

M. Pudis[1], *G. Rocamora Blanch*[2], *J. A. Narváez*[3], *X. Solanich-Moreno*[2], *B. Hervás-Sanz*[1], *J. Diaz-Moreno*[1], *A. Bagan-Trejo*[1], *M. Zamorano-Rivas*[1], *C. Martínez-Ramos*[1], *J. J. Robles-Barba*[1], *J. J. Marcuartu*[1], *M. Cortés-Romera*[1];
[1]*Nuclear Medicine - PET (IDI), Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [2]*Internal Medicine, Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, SPAIN,* [3]*Radiology Department, Bellvitge University Hospital - IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Histiocytoses such as Erdheim-Chester Disease (ECD), Langerhans Cell Histiocytosis (LCH), and Rosai-Dorfman Disease (RDD) are rare multisystem disorders characterised by histiocyte proliferation. Accurate disease staging is crucial for diagnosis, biopsy guidance, and treatment planning. While ^{18}F-FDG PET/CT is widely used, PET/MRI may offer improved soft-tissue contrast and lesion characterisation. This prospective study aimed to assess the diagnostic performance of whole-body ^{18}F-FDG PET/MRI compared to PET/CT in patients with systemic histiocytosis. ***Materials and Methods:*** Between 2022 and 2024, fifteen patients with histologically confirmed systemic histiocytosis (ECD n=9, LCH n=2, RDD n=2, mixed n=2) underwent sequential whole-body ^{18}F-FDG PET/CT and PET/MRI following a single radiotracer injection. Lesions were evaluated by a multidisciplinary team regarding anatomical definition, metabolic uptake, and disease extent, and were correlated with clinical, laboratory, histopathological, and follow-up data. ***Results:*** PET/CT and PET/MRI showed concordant findings in 14 of 15 patients (93%). One patient presented with a discordant finding: PET/MRI detected a brainstem lesion missed by PET/CT, altering management. A total of 38 lesion sites were identified, of which 35 (92%) were attributed to histiocytosis. PET/MRI demonstrated improved anatomical delineation in 60% of cases and better lesion characterisation in 33%, particularly for CNS, cardiac, renal, and skeletal involvement. Additional lesions were detected by PET/MRI in 33% of patients. PET/MRI revealed higher metabolic uptake and more extensive disease in 73% of cases, suggesting increased sensitivity. However, PET/CT was superior for pulmonary lesion characterisation. ***Conclusion:*** This prospective study supports the integration of ^{18}F-FDG PET/MRI into the diagnostic workflow for systemic histiocytosis. PET/MRI provides superior soft-tissue contrast, improved lesion delineation, and enhanced sensitivity in detecting disease burden, potentially guiding more accurate clinical decisions and reducing radiation exposure—especially relevant for patients requiring repeated follow-up imaging.

EP-0509

Comparison of 68Ga-Pentixafor and ^{18}F-FDG PET/CT for initial evaluation of patients with newly diagnosed multiple myeloma.

S. Kumar, *H. Kaur;*
PGIMER, Chandigarh, INDIA.

Aim/Introduction: ^{18}F-FDG PET/CT is seen to have limitations in evaluation of multiple myeloma due to low hexokinase expression. Additionally, it is seen to underestimate diffuse marrow involvement. CXCR4 targeting 68Ga-Pentixafor is increasingly used in evaluation of myeloma. We compared the performance of 68Ga-Pentixafor and ^{18}F-FDG PET/CT in newly diagnosed multiple myeloma. ***Materials and Methods:*** In this prospective study we recruited 84 patients with newly diagnosed multiple myeloma from February 2021 to April 2023. 84 patients underwent 68Ga Pentixafor PET CT and 77 underwent 18F FDG PET CT. IMPeTUs criteria was used to evaluate ^{18}F-FDG PET/CT and uptake≥ twice liver was considered positive on 68Ga-Pentixafor. Patterns of disease involvement were assessed. Positivity rate on both modalities and degree of marrow involvement were compared. ***Results:*** Eighty-four (54 Male and 31 Female) patients were recruited in the study and underwent 68Ga-Pentixafor PET/CT among them, 77 (47 male and 30 female) underwent both ^{18}F-FDG and 68Ga-Pentixafor PET/CT. Positivity rate was 89.2% (75/84) on 68Ga-Pentixafor PET/CT. Among 77 patients who underwent both modalities, 68Ga-Pentixafor PET/CT was positive in a higher number of patients (90.9%, n=70/77) compared to ^{18}F-FDG PET/CT (68.8 %, n=53/77) (p<0.01) using Deauville score≥ 4 as the criteria. However, no difference was noted between the modalities when using Deauville score≥ 3 as the criteria (90.9% vs 87.0% n=67/77) (p=0.581). On 68Ga-Pentixafor PET/CT 26 (30.9%) had only marrow involvement, 41 (48.8%) had both marrow and focal lytic lesions and 10 (11.9%) had only focal lytic lesions. On 18 -FDG PET/CT 17 (22.0%) had only marrow involvement, 31 (40.2%)

had both marrow and focal lytic lesions and 21 (27.2%) had only focal lytic lesions. 68Ga-Pentixafor PET/CT showed a higher rate of marrow involvement i.e. 79.2% (61/77) compared to 49.3% (38/77) on ^{18}F-FDG PET/CT (p<0.01), among patients who underwent both investigations. 68Ga-Pentixafor PET/CT also demonstrated a higher SUVpeak (11.6 vs 5.5) , SUV mean (7.8 vs 4.1) and SUV max (16.2 vs 6.5) compared to 18 F -FDG PET/CT (p<0.05). No significant difference was noted in detection of paramedullary disease (21 vs 19) and extra medullary disease (4 vs 6) (p>0.05) on 68Ga-Pentixafor and ^{18}F-FDG PET/CT respectively. ***Conclusion:*** 68Ga-Pentixafor PET/CT is a promising modality for assessment of disease extent in newly diagnosed patients with multiple myeloma. It demonstrates a higher detection rate and SUV values compared ^{18}F-FDG PET/CT and shows a higher degree of marrow involvement.

EP-0510

PETBOT: An AI-Powered Patient-Centric Chatbot for Cancer Staging and Treatment Guidance according to NCCN from PET/CT Reports

S. Sagar[1], *D. Khan*[1], *N. Kundu*[1], *A. Roy*[1], *A. Mahalik*[1], *L. Goriparti*[1], *A. Tilak*[1], *J. Krishna P.*[1], *A. Dhiman*[1], *A. Singh*[2], *A. Rout*[2], *S. K V*[1], *R. Babu*[1], *J. Pathak*[1], *R. Kumar*[1];
[1]*AIIMS, Delhi, INDIA,* [2]*AIIMS, Bhubaneswar, INDIA.*

Aim/Introduction: Patients undergoing PET/CT scans often struggle to interpret complex cancer staging reports, leading to anxiety, misinterpretation, and delayed decision-making. With the growing accessibility of AI tools, there is a unique opportunity to empower patients directly using structured summaries derived from their imaging reports.To develop and evaluate a Python-based chatbot application (PETBOT) that automatically extracts TNM staging, NCCN-based treatment options, and simplified explanations from uploaded PET/CT reports, with an interactive feedback mechanism. ***Materials and Methods:*** We developed a Streamlit-based application integrated with a text extractor (for PDF/DOCX), a fine-tuned NER model (spaCy with BioBERT backbone) for extracting named entities such as tumor site, lymph node involvement, and metastases, and a custom rule-based TNM staging engine (modularized by cancer type). The application supports six cancer types: esophageal, gallbladder, breast, lung, colorectal, and head & neck. Extracted features were mapped to AJCC-like TNM rules, and treatment guidance was aligned with NCCN recommendations. The chatbot interface allowed users to select predefined questions about their diagnosis and download personalized summaries. A CSV-based feedback system captured user responses on helpfulness and emotional impact which will be used for analyzing patient parameters later. ***Results:*** The chatbot successfully identified and staged six major cancer types—esophageal, gallbladder, breast, lung, colorectal, and head & neck—from unstructured PET/CT reports using rule-based logic and NER-assisted feature extraction. For these cancers, PETBOT generated accurate TNM classification, NCCN-aligned treatment suggestions, and plain-language summaries. However, when reports of unsupported cancer types (e.g., pancreatic, ovarian, or hematological malignancies) were uploaded, the system either failed to extract meaningful features or returned misleading outputs, underscoring the need for strict cancer-type validation. The tool is accessible for demonstration and testing at: https://petbot1.streamlit.app. ***Conclusion:*** PETBOT demonstrates the feasibility of a lightweight, deployable, patient-centered tool for AI-assisted cancer education and empowerment using PET/CT reports while underlining the requirement for an indigenous Large Language Models(LLM) to deduce TNM staging from imaging reports. Future enhancements include multilingual support, physician feedback loop, and broader cancer type integration.

EP-0511

Extramedullary Involvement in Multiple Myeloma: Can FDG PET/CT and Disease-Related Parameters Provide New Insights into Clinical Outcome?

K. Toplutas*, A. B. Dere, E. M. Kaya, B. Esen Akkaş;*
University of Health Sciences, Basaksehir Çam and Sakura City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Multiple myeloma (MM) is a complex hematologic malignancy with various clinical stages. Although definitions vary, extramedullary disease (EMD) is generally described as soft tissue or organ involvement without direct bone contact. EMD is usually associated with poor prognosis. This study aimed to evaluate the prognostic significance of FDG PET/CT findings and associated clinical and biochemical parameters in MM patients with EMD. ***Materials and Methods:*** MM patients who underwent FDG PET/CT between 2021 and 2025 were retrospectively screened for EMD. PET/CT findings (lesion localization and SUVmax), Durie-Salmon Plus (DSP) scores, bone marrow immunophenotyping, biochemical markers, progression-free survival (PFS), and overall survival (OS) were analyzed. Statistical analyses were performed using Jamovi v2.3.28. ***Results:*** Among 424 patients, EMD was identified in 21 cases (4%). Eleven had primary and ten had secondary EMD. Eight patients died during follow-up. The mean SUVmax for EMD lesions was 6.85±5.28, and for intramedullary disease (MD), it was 6.02±5.30 (p>0.05). Paramedullary disease (PMD) was present in 57% of cases, with a higher mean SUVmax (8.81±4.70). The most common EMD sites were lymph nodes (42.9%) and pleura-lung (19%); rare sites included orbit, sphenoid sinus, brain, and jejunum. Median PFS was 8 months and OS was 13 months. No significant correlation was found between SUVmax and PFS/OS in Cox regression analyses (p>0.05). However, a borderline significant OS difference was observed by EMD location (log-rank p=0.05), with longest survival in lymph node involvement (26 months) and shortest in lung (8 months) and spleen (3 months) involvement. DSP score correlated positively with both MD SUVmax (rho=0.562, p=0.008) and EMD SUVmax (rho=0.443, p=0.044). No significant differences were observed based on light/heavy chain status (p>0.05). Albumin levels were inversely associated with mortality (HR: 0.89, p=0.022). CD138 positivity was significantly associated with better survival outcomes (p=0.013). ***Conclusion:*** FDG PET/CT provides useful information in identifying EMD, particularly in atypical sites. However, FDG PET/CT-associated metabolic parameters did not show a significant relationship with survival outcomes in this cohort.Notably, patients with splenic and pulmonary involvement exhibited shorter overall survival compared to those with lymph node involvement. CD138 negativity and low albumin levels were also associated with worse prognosis. Further studies with larger cohorts are needed to validate these findings. ***References:*** Vicentini, J. R., & Bredella, M. A. (2022). Role of FDG PET in the staging of multiple myeloma. Skeletal Radiology, 51(1).

From Volume to Dissemination: Dmax and TMTV Drive Prognostic Assessment in Newly Diagnosed Multiple Myeloma Over Advanced Radiomic Approaches

L. Raffy[1], *C. Etchegaray*[2], *E. Hindie*[1], *O. Saut*[2], *C. Hulin*[3], *A. Schmitt*[4], *C. Mesguich*[1];
[1]*Department of nuclear medicine, University of Bordeaux, Bordeaux, FRANCE,* [2]*Inria, Univ. Bordeaux, CNRS, Bordeaux INP, IMB, UMR 5251, Talence, FRANCE,* [3]*Department of onco-hematology, University of Bordeaux, Bordeaux, FRANCE,* [4]*Department of onco-hematology, Institut Bergonié, Bordeaux, FRANCE.*

Aim/Introduction: ^{18}F-FDG PET/CT (FDG-PET) has consistently demonstrated prognostic value in the evaluation of newly diagnosed multiple myeloma (NDMM). However, current standard

FDG-PET biomarkers fall short in assessing tumor heterogeneity and spatial dissemination, critical features that radiomic analysis could quantify. This study aimed to identify prognostic FDG-PET radiomic biomarkers in NDMM. ***Materials and Methods:*** Between 2014 and 2022, 146 NDMM patients underwent FDG-PET imaging at two medical centers. The associations between clinical, biological, and standard PET variables - referred to as 'standard parameters'- were assessed using Cox regression analysis. Random Forest models were trained using three distinct datasets to predict two-year PFS: (1) standard parameters, (2) PET radiomic features, and (3) CT radiomic features. A voting classifier combined the best-performing models from each dataset. ***Results:*** Multivariate analysis revealed that both total metabolic tumor volume (TMTV) and Dmax were significantly associated with PFS (HR=2.17, p=0.003 ; HR=1.89, p=0.01, respectively) and OS (HR=2.23, p=0.04 ; HR=2.69, p=0.01, respectively). The standard parameters model demonstrated promising predictive performances of two-year PFS with an AUC of 0.749 (IC95% 0.679-0.792) and a Brier Score of 0.198 (IC95% 0.178-0.218). PET and CT radiomics models showed poor performance. The voting classifier presented an AUC of 0.624 (IC95% 0.564 - 0.684), and a Brier Score of 0.221 (IC95% 0,207-0,233). ***Conclusion:*** Both Dmax and TMTV are robust and independent prognostic biomarkers in NDMM. The models utilizing PET and CT radiomic features yielded poor performance, highlighting the current limitations of this approach in multiple myeloma prognostic assessment.

FDG PET/CT in Multiple Myeloma Staging: Standardization and Prognostic Impact of Imaging Parameters

M. Havel[1,2], *L. Muronova*[3,4], *G. Havlova*[1], *D. Zihala*[3,4], *T. Popkova*[3,4], *G. Kascakova*[1], *S. Bobkova*[1], *K. Bukovansky*[1], *J. Mihalyova*[3,4], *H. Plonkova*[3], *J. Golisova*[1,2], *R. Hajek*[3,4], *T. Jelinek*[3,4];
[1]*Department of Nuclear Medicine, University Hospital Ostrava, Ostrava, CZECH REPUBLIC,* [2]*Department of Imaging Methods, Faculty of Medicine, University of Ostrava, Ostrava, CZECH REPUBLIC,* [3]*Department of Hematooncology, University Hospital Ostrava, Ostrava, CZECH REPUBLIC,* [4]*Department of Hematooncology, Faculty of Medicine, University of Ostrava, Ostrava, CZECH REPUBLIC.*

Aim/Introduction: ^{18}F-FDG PET/CT has become a crucial imaging modality in the diagnosis, staging, treatment response evaluation, and detection of relapse in multiple myeloma (MM). Given the complexity of this hybrid technique, standardization of examination protocols and reporting is essential. In 2023, the Czech Myeloma Working Group and the Czech Society of Nuclear Medicine introduced procedural guidelines for MM imaging and reporting using FDG PET/CT. This study aims to determine the prognostic significance of parameters assessed according to the latest Czech guidelines in hybrid imaging during MM staging. ***Materials and Methods:*** The study cohort comprised 77 patients (41 men, median age 66), all of whom underwent FDG PET/CT for MM staging. Patients were monitored through regular clinical assessments, with clinically determined disease progression serving as the study endpoint. PET/CT evaluations adhered to the recommended standardized protocol, capturing 30 defined imaging parameters recorded by an experienced nuclear medicine specialist. Key assessed parameters included the number, location, characteristics (e.g. paraskeletal and extramedullary), and metabolic activity of FDG-avid lesions, as well as the presence, quantity, and distribution of lytic lesions on CT. Statistical analysis was performed to identify significant predictors of patient outcomes. ***Results:*** The median follow-up duration was 39 months. Metabolically active lesions were detected in 57 patients (74.0%), while significant lytic lesions were observed in 58 patients (75.3%). At least one active paramedullary lesion was identified in 37 patients (48.1%), and at least one extramedullary lesion in 4 patients (5.2%).Univariate Cox regression analysis showed significant associations between poor outcomes and high metabolic lesion counts (>10 lesions; P=0.033), metabolically active lesions in the skull (P=0.025), and appendicular skeleton (P=0.017). Although the number of subjects with extramedullary lesions was low, 2 out of 4 patients experienced worse outcomes. Among lytic lesions, skull involvement was a notably unfavorable prognostic factor (P=0.016). Additional negative prognostic indicators included high bone marrow metabolic activity (DS > 4; P=0.049). No other assessed parameters demonstrated statistical significance in predicting disease progression during follow-up. ***Conclusion:*** A standardized, comprehensive reporting system is essential for complex imaging modalities such as FDG PET/CT. Our findings suggest that peripheral skeletal involvement is associated with adverse outcomes, potentially reflecting extensive tumor spread beyond the axial skeleton. ***References:*** Havel, M. & Jelínek, T. et al. AI-based vs Manual Segmentation in Multiple Myeloma: Are They Equally Prognostic?

M. Stasolla[1], *D. Bezzi*[2], *M. Di Franco*[1], *S. Proto*[1], *M. Talarico*[3], *E. Zamagni*[3], *C. Malizia*[4], *S. Fanti*[4,1], *C. Nanni*[4];
[1]*Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY,* [2]*Nuclear medicine unit AUSL Romagna, Forlì-Cesena, ITALY,* [3]*Seràgnoli Institute of Hematology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,* [4]*Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: Multiple myeloma is a neoplastic disorder characterized by the uncontrolled proliferation of a plasma cell clone in the bone marrow. It can occur as both intramedullary and extramedullary disease with different prognostic values. Aim of our study was to test the prognostic value of AI-based method to calculate active disease volume as compared to standard manual segmentation. ***Materials and Methods:*** 130 patients (78 men and 52 women) diagnosed with symptomatic multiple myeloma performed a staging positron emission tomography with fluorodeoxyglucose (PET-FDG) scan. The variables considered were focal lesions (FL), paramedullary lesion (PM), extramedullary lesion (EM) and total tumor burden. For each of these variables, metabolic tumor volume (MTV) and total tumor glycolysis (TLG) were calculated both manually by an operator (using a threshold corresponding to liver SUV peak) and through an artificial intelligence (AI) program (uOmnispace). The median was calculated for each parameter, then used to perform the Wilcoxon test for paired data. Additionally, MTV and TLG of each variable (FL, PM, EM and total) were analyzed to determine optimal cut-off values using ROC (Receiver Operating Characteristic) curves. These cut-offs were used to dichotomize each variable into two categories: high and low MTV or TLG. Only variables with statistically significant p-values ($p < 0.05$) in univariate analysis were considered for dichotomization. The dichotomized data were then correlated with overall survival (OS) and progression free survival (PFS) using Kaplan-Meier analysis. ***Results:*** The results showed significant differences between manual and AI measurements for total MTV (p=0.001), total TLG (p=0.002), FL MTV (p=0.016), FL TLG (p=0.030), PM MTV (p=0.002) and PM TLG (p=0.002), with AI tending to overestimate compared to manual method. EM parameters (MTV and TLG), on the other hand, didn't show significant differences between manual and AI measurements (p=0.123 and p=0.213, respectively), most likely due to the small number of findings. Statistically significant cut-offs were identified for MTV and TLG parameters, which were able to dicothomize the popolation into better and worse prognosis groups. Although with different cut-offs, both measurements were good stratificators of PFS and OS especially for MTV-FL, TLG-FL, MTV-PM, TLG-PM, MTV-Total and TLG-Total. ***Conclusion:*** AI-assisted segmentation is easier

and faster and could be considered in the future as a parameter to sistematically report. Additionally, it may be more accurate in characterizing total tumor burden. Tumor volumes obtained by both manual and AI segmentation methods, although slightly different, are predictive of prognosis.

EP-0515

Improved Initial Staging and Risk Stratification of Newly DiagnosedMultiple Myelomaby Targeting Chemokine Receptor CXCR4 using [^{68}Ga]Ga-Pentixafor PET/CT

J. Chen, *C. Li, Y. He;*
Zhongnan Hospital of Wuhan University, Wuhan, CHINA.

Aim/Introduction: This study aimed to evaluated the diagnostic performance and risk stratification capabilities of C-X-C motif chemokine receptor 4 (CXCR4)-targeted [^{68}Ga]Ga-Pentixafor PET/CT in newly diagnosed multiple myeloma (NDMM): a head-to-head comparison with [^{18}F]FDG PET/CT. ***Materials and Methods:*** Sixty-one NDMM patients underwent both [^{68}Ga]Ga-Pentixafor and [^{18}F]FDG PET/CT within two weeks. Clinical staging was performed based on the Durie-Salmon PLUS system, Revised International Staging System (R-ISS), and the Second R-ISS (R2-ISS). Maximum and mean standardized uptake values (SUVmax and SUVmean), metabolic tumor volume (MTV), total lesion glycolysis (TLG), total lesion volume (TLV), total lesion uptake (TLU), and a total burden score (TBS) were recorded and calculated. Univariate and multivariate logistic regression, along with receiver operating characteristic (ROC) analysis were used to assess the predictive indicator for risk stratification in NDMM. ***Results:*** [^{68}Ga]Ga-Pentixafor PET/CT demonstrated a significantly higher detection rate than [^{18}F]FDG PET/CT (83.6% vs. 55.7%, P = 0.001) in NDMM. Positive [^{68}Ga]Ga-Pentixafor findings correlated with more serious R-ISS and R2-ISS stage, lower hemoglobin, and higher β2-microglobulin (β2-MG) and bone marrow plasma cell percentage (BMPC%) (all P < 0.05). For staging, [^{68}Ga]Ga-Pentixafor better identified advanced disease (Durie-Salmon PLUS stage III) than [^{18}F]FDG PET (P < 0.001). [^{68}Ga]Ga-Pentixafor PET aligned better with R-ISS (62.3% vs. 27.9%, P < 0.001) and R2-ISS (57.4% vs. 24.6%, P = 0.001) than [^{18}F]FDG PET/CT. Multivariate analysis identified TBS_{CXCR4} and β2-MG as significant predictive indicators. ROC analysis revealed that the combined model of TBS_{CXCR4} and β2-MG achieved the highest diagnostic performance for R-ISS risk stratification (AUC = 0.901). For R2-ISS, ROC analysis demonstrated that $TBS_{CXCR4,}$ β2-MG and their combined model exhibited strong and comparable diagnostic performance, with AUCs ranging from 0.830 to 0.915. ***Conclusion:*** [^{68}Ga]Ga-Pentixafor PET/CT outperforms [^{18}F]FDG PET/CT in diagnostic accuracy, staging, and risk stratification in NDMM. TBS_{CXCR4} derived from [^{68}Ga]Ga-Pentixafor and β2-MG are the predictive indicators of high-risk status in NDMM.

Inter-reader Agreement of The IMPeTus Criteria ın Multipl Myeloma Patients

A. Tunç, *F. Avci, R. H. Tokac, Z. Burak;*
Ege University Nuclear Medicine Department, Izmir, TÜRKIYE.

Aim/Introduction: Multiple Myeloma (MM) accounts for 1% of all cancers and 10% of hematologic cancers. FDG PET/CT is a functional imaging procedure with proven good performance in MM patients. It is a valuable tool in the evaluation of patients with newly diagnosed or relapsed/refractory MM, especially in the detection of paramedullary and extramedullary soft tissue masses or solid organ involvement. However, a standardized interpretation criterion for the evaluation of FDG PET/CT findings in MM has not yet been accepted. Some groups base their image interpretation on semiquantitative findings, some on visual assessment, and another group on both two methods, which hinders the reproducibility of the result. Recently, an Italian group proposed new visual interpretation criteria, the IMPeTuS criteria, to standardize FDG PET/CT interpretation in MM patients. In this study, our aim was to evaluate the inter-reader agreement of the IMPeTuS criteria in MM patients. ***Materials and Methods:*** The study included 32 patients whose treatment response images were available in our archive. All PET scans were reviewed by three nuclear physicians blinded to each other and to patient names. Diffuse bone marrow involvement in terms of Deauville scoring, hypermetabolism in limbs and ribs if present, PET positive focal bone lesions, localization of these lesions and Deauville value of the hottest lesion, number of lytic lesions, presence of fracture, presence of paramedullary involvement, presence and locations of extramedullary involvement (nodal and extranodal) and the Deauville value of the hottest extramedullary lesion were reported using the IMPeTUs criteria. Fleiss Kappa method was used to assess inter-reader agreement using SPSS v25. ***Results:*** There was moderate agreement between readers for bone marrow involvement in long bones and ribs, number of lytic bone lesions and supraclavicular lymph node involvement (0.31-0.40), while there was no agreement for skin involvement (-0.01). For other criteria, there was good to excellent agreement between readers (0.42-1). ***Conclusion:*** In this study where the number of cases was limited, it was shown that the agreement between PET-CT readers was moderate to high when IMPeTus criteria were used. It is thought that by applying these criteria to larger series and simplifying them by removing some non-prognostic parameters, a standardized PET reporting system that can be used routinely in MM cases can be achieved.

Machine learning based on ^{18}F-FDG PET/CT parameters for prediction of lymph node metastasis in cutaneous stage I-III melanoma

Y. Jin[1], *L. Lu*[2], *X. Chu*[3], *T. Long*[1], *Y. Yang*[1], *S. Hu*[1,4,5];
[1]*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [2]*Department of Dermatology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [3]*Department of Oncology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [4]*National Clinical Research Center for Geriatric Disorders, Xiangya Hospital, Changsha, Hunan, CHINA,* [5]*Key Laboratory of Biological Nanotechnology of National Health Commission, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA.*

Aim/Introduction: Malignant Melanoma (MM) is the most lethal malignancy among skin tumors. The five-year survival rate of patients with lymph node metastasis (LNM) is significantly reduced. Early detection of melanoma LNM facilitates promptly optimization of treatment strategies. This study aims to integrate pertinent clinical data, pathological markers, and Fluorine-18 Fluorodeoxyglucose Positron Emission Tomography/Computed

Tomography (^{18}F-FDG PET/CT) parameters to develop an effective and predictive machine learning model, in order to improve the diagnostic efficacy of lymph node metastasis. ***Materials and Methods:*** A total of 45 patients were included in the analysis, who underwent ^{18}F-FDG PET/CT examinations before surgical treatment at Xiangya Hospital between December 2016 and January 2024. LNM diagnosis was confirmed through postoperative biopsy or follow-up. Clinical data, primary pathological markers and ^{18}F-FDG PET/CT metabolic parameters of melanoma were collected. Eight machine learning models were constructed using R programming language for data analysis and performance comparison. After cross-validation and model fitting, the models were ranked based on Area Under the Curve (AUC) with interpretations via SHapley Additive exPlanations (SHAP). Subsequently, the 45 patients were randomly divided into training validation sets in a 6:4 ratio to evaluate model sensitivity and specificity, with model performance assessed using calibration and decision curve analysis (DCA). ***Results:*** Among eight machine learning models, the Naive Bayes model demonstrated the highest performance, achieving an optimized AUC of 94.6%. SHAP analysis revealed that exceeding specific threshold values for certain characteristics (MTV = 0.57, TIL3 = 1, SUVmax = 7.5, TLG = 2.8, SULavg = 4.1, SULmax = 6.3, SULpeak = 2.4, SUVpeak = 2.8, SUVavg = 4.8, Breslow = 2) increased the likelihood of LNM. The model's performance metrics for the training set showed sensitivity of 0.58, specificity of 0.93, and accuracy of 0.78. For the validation set, the sensitivity, specificity and accuracy were 0.625, 0.90 and 0.78 respectively. The calibration curve indicated a strong alignment between the predicted and actual observed values. DCA demonstrated that the Naive Bayes model offers a better net benefit when the threshold probability exceeds 0%. ***Conclusion:*** The Naive Bayes model, based on ^{18}F-FDG PET/CT parameters, can greatly improve specificity, sensitivity, and accuracy of identifying LNM in MM patients,playing a pivotal role in guiding sentinel lymph node biopsy (SLNB) and lymph node dissection decisions. It provides valuable insights for clinical staging and treatment planning in melanoma patients.

EP-0518

First Evaluation of [^{68}Ga]FAPI PET/CT Imaging to Assess Fibroblast Activation Protein Expression in Melanoma Patients

Y. Yang, *J. Su, X. Chen, S. Su;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Malignant melanoma (MM) is characterized by high malignancy, early metastasis, and poor prognosis. While immunotherapy has improved survival in advanced MM, over 50% patients fail to respond effectively, highlighting the urgent need for novel strategies to predict therapeutic response. This study aimed to identify key molecular predictors of immunotherapy response based on the mechanisms of tumor immunosuppressive microenvironment and to enable their noninvasive visualization through molecular imaging techniques. ***Materials and Methods:*** Spatial transcriptomics was performed on tumor samples from twenty-two MM patients who received neoadjuvant immunotherapy. Key targets were identified by integrating single-cell RNA sequencing (scRNA-seq) data and validated by immunohistochemistry. A prospective head-to-head imaging study was then conducted in five melanoma patients, each undergoing both ^{18}F-FDG and ^{68}Ga-FAPI PET/CT scans (whole-body range: vertex to toe). The mean injected doses were 4.1 ± 0.24 mCi for ^{68}Ga-FAPI and 6.62 ± 0.15 mCi for ^{18}F-FDG, respectively. The diagnostic performance of both tracers was compared for detecting primary lesions, lymph nodes, and distant metastases. ***Results:*** Spatial transcriptomic analysis revealed significantly higher enrichment of cancer-associated fibroblasts (CAFs) in non-responders compared to responders ($p < 0.05$), with spatial co-localization of CAFs and tumor cells negatively correlated with treatment efficacy. scRNA-seq confirmed fibroblast activation protein (FAP) as a CAF-specific marker and FAP+ CAFs were highly expressed in responders than non-responders ($p = 0.045$), which were negatively correlated with the prognosis of MM patients with immunotherapy ($p = 0.027$). Immunohistochemistry further confirmed the higher expression of FAP in melanoma tissues than that in its adjacent tissues (2.46 ± 0.65 vs. 0.18 ± 0.18, $p = 0.005$). The primary lesions showed slightly higher SUVmax on ^{68}Ga-FAPI (9.30 ± 2.95) than on ^{18}F-FDG (7.49 ± 3.23). In metastatic lymph nodes, ^{68}Ga-FAPI uptake was significantly higher in pathology-positive nodes than in negative ones (11.18 ± 2.82 vs. 0.97 ± 0.10, $p = 0.028$), while ^{18}F-FDG showed no statistically significant difference between groups (8.23 ± 2.99 vs. 2.42 ± 0.44, $p = 0.164$). In distant metastases, both tracers successfully identified a total of 116 metastatic lesions in the lungs, pleura, bones, adrenal glands, pancreas, and subcutaneous tissue. ***Conclusion:*** FAP, as a characteristic marker of CAFs, serves as a promising predictor of resistance to immunotherapy in MM. ^{68}Ga-FAPI PET/CT can successfully visualize and identify primary tumors, lymph nodes and distant metastatic sites in MM patients.

EP-0519

Prognostic Value of TMTV and SUVmax from ^{18}F-FDG PET/CT at Multiple Time Points in Melanoma Patients on Immunotherapy

K. Zevnik[1], *A. Doma*[1], *A. Studen*[2,3], *K. Strašek*[2], *K. Škalič*[1], *R. Jeraj*[2,4], *M. Reberšek*[1], *N. Hribernik*[1];
[1]*Oncology Institute Ljubljana, Ljubljana, SLOVENIA,* [2]*Faculty of Mathematics and Physics University of Ljubljana, Ljubljana, SLOVENIA,* [3]*Jozef Stefan Institute, Ljubljana, SLOVENIA,* [4]*Department of Medical Physics University of Wisconsin School of Medicine and Public Health, Madison, WI, UNITED STATES OF AMERICA.*

Aim/Introduction: To investigate whether MTV and SUVmax derived from ^{18}F-FDG PET/CT at multiple time points (baseline, week 4, and week 16) are associated with clinical outcomes in melanoma patients treated with immunotherapy. ***Materials and Methods:*** 37 patients with metastatic melanoma who received immune checkpoint inhibitors (ICIs) as part of a previous prospective, single-arm study were retrospectively included in this analysis. Patients underwent serial ^{18}F-FDG PET/CT imaging at baseline, week 4 (W4), and week 16 (W16) following initiation of ICI therapy. Tumour lesions were manually segmented by two nuclear medicine specialists using an open-source medical imaging software. A threshold of SUVmax >2.5 was applied for lesion segmentation. Quantification of FDG uptake and calculation of the two imaging biomarkers - SUVmax and total metabolic tumour volume (TMTV) - were performed at all three time points (baseline, W4, and W16), resulting in six parameters: bSUVmax, bTMTV, W4 SUVmax, W4 TMTV, W16 SUVmax, and W16 TMTV. Patients were stratified into two groups based on overall survival (OS), using a cut-off of 600 days. The association between each imaging parameter and OS was assessed using logistic regression with the Wald test. Receiver operating characteristic (ROC) analysis was performed to evaluate classification performance, and Youden's index was applied to determine the optimal thresholds. ***Results:*** The median OS of the cohort was 22.4 months (range: 1.7-43.3 months), with 19 patients alive at the time of analysis. 18 pts had OS less than 600 days, and 19 pts exceeded the cut-off. Among all evaluated parameters, only W16 SUVmax demonstrated a statistically significant association with OS ($p < 0.05$). ROC analysis revealed the highest area under the curve (AUC) for W16 SUVmax at 0.70, with an optimal threshold of 14.7. AUCs for the remaining parameters were as follows: bTMTV (0.62), bSUVmax (0.58), W4 TMTV (0.50), W4 SUVmax (0.67), and W16 TMTV (0.60). ***Conclusion:*** In our study SUVmax at week 16 emerged as the only imaging biomarker significantly associated with overall survival in metastatic melanoma patients treated with immune checkpoint inhibitors. These findings suggest that delayed metabolic response assessment (at 4 months) may offer valuable prognostic information and could support clinical

decision-making during immunotherapy. Further studies in larger, independent cohorts are warranted to validate these results. ***References:*** Hribernik, Nežka, et al. "Early-time-point 18F-FDG-PET/CT and other prognostic biomarkers of survival in metastatic melanoma patients receiving immunotherapy." Radiology and Oncology 59.1 (2025): 43-53.

EP-0520

FDG avid bone metastases in patients with stage IV melanomas under immune checkpoint inhibitors (ICI) therapy: comparison with low dose CT

J. Heinen, *C. Sachpekidis, J. Hassel, L. Pan, A. Dimitrakopoulou-Strauss;*
Deutsches Krebsforschungszentrum, Heidelberg, GERMANY.

Aim/Introduction: To evaluate the diagnostic utility of ^{18}F-FDG PET/CT in comparison to low-dose CT for detecting bone metastases in patients with metastatic melanomas or choroidal melanoma undergoing treatment with immune checkpoint inhibitors (ICI). ***Materials and Methods:*** We retrospectively analyzed data from a cohort of 371 patients diagnosed with AJCC Stage IV malignant including choroidal melanomas, all of whom received treatment with ICIs (Ipilimumab, Nivolumab, and/or Pembrolizumab) and underwent ^{18}F-fluorodeoxyglucose (^{18}F-FDG) positron emission tomography combined with low-dose computed tomography (PET/CT). Of these, 83 patients (22.37%) had one or more skeletal lesions with pathological ^{18}F-FDG uptake suspicious for bone metastases. A total of 225 such lesions were analyzed by measuring their standard uptake values (SUVs) as volumes of interest (VOIs) in PET, assessing CT findings, and quantifying Hounsfield units (HU) at baseline and up to three follow-up (FU1-FU3) examinations. Metabolic response to ICI therapy was evaluated according to EORTC criteria and categorized into four groups: complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD). ***Results:*** At baseline, 176 of 225 lesions were detectable on PET. 70 out of 176 (39.77%) PET-positive lesions were detectable on low-dose CT. In the most recent follow-up, 90 lesions (52.27%) were visible on CT, with a gradual increase observed over time (51.14% at FU1, 63.04% at FU3). Notably, 76 lesions (43.18%) were never detectable on CT at any time point. Overall, 26 lesions (14.77%) were classified as PMD at the latest follow-up. Of these, 9 lesions (34.62%) remained undetectable on CT, with the proportion decreasing over the course of therapy (30.30% at FU1, 44.44% at FU2, 20.0% at FU3). Additionally, 49 lesions were not visible on either PET or CT at baseline but appeared in later therapy cycles. Only 8 of these 49 lesions (16.33%) were visible on CT at their first PET-positive scan, and 13 of 49 (26.53%) were detectable on CT at the most recent follow-up. ***Conclusion:*** In patients with metastatic malignant or choroidal melanoma, ^{18}F-FDG PET/CT demonstrates higher sensitivity than low-dose CT alone for detecting osseous metastases. Many bone metastases remain undetectable on CT throughout the course of the disease. Furthermore, lesions may become visible on CT only during later stages of therapy, potentially representing new or enlarging lesions despite evidence of metabolic response on PET.

EP-0521

Adjuvant Therapy and FDG-PET/CT Follow-Up in High-Risk Patients with Cutaneous Melanoma: A Five-Year Retrospective Analysis

J. Aço, *I. P. Carvalho, H. Nunes, P. Pereira, E. Gouveia, E. Sousa, D. Fraga, P. Jorge, D. Rombo, J. Pais, L. Salgado;*
Instituto Português de Oncologia de Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: Adjuvant therapy has improved recurrence-free survival in stage III cutaneous melanoma. Despite treatment, recurrence risk remains high, particularly during the first year. Early detection is crucial, and FDG-PET/CT, although limited by potential false positives in patients under immunotherapy, remains a valuable tool for this purpose. We describe a 5-year single-center follow-up experience. ***Materials and Methods:*** A single-center retrospective study of 34 patients with resected high-risk stage III cutaneous melanoma, without known metastasis prior to sentinel lymph node biopsy, who received adjuvant therapy, and underwent FDG-PET/CT follow-up every six months between 2019 and 2023. The systemic therapy (anti-PD1 immunotherapy, or dabrafenib plus trametinib) was chosen according to clinical and molecular features. Four patients were excluded due to loss to follow-up. All recurrences identified by FDG-PET/CT were confirmed either by biopsy or in subsequent imaging studies. Data were analyzed using descriptive statistical methods. ***Results:*** A total of 30 patients were included, with a median age of 56 years (range: 24-86). The cohort comprised 19 males, and 11 females. The primary melanoma sites were: trunk (47%), upper limbs (23%), head and neck (17%), lower limbs (10%), and scrotum (3%). Most patients were staged as IIIB and IIIC (93%). BRAF V600E/K mutation was present in thirteen patients (43%). Twenty-four patients received anti-PD-1 immunotherapy (80%), while six were treated with dabrafenib plus trametinib (20%). Therapy was discontinued in two patients owing to adverse events — one experienced gastrointestinal toxicity, and the other developed muscular and renal toxicities. Recurrence occurred in 13 patients (43%), 5 during and 8 following completion of adjuvant therapy. The mean time between the beginning of therapy and relapse was 23 months. Disease relapsed in lymph nodes (7 patients), central nervous system (5), subcutaneous tissue (3), lungs (3), and pleura (1). Sixty percent of patients were asymptomatic at relapse. False-positive findings were observed in nine patients (30%), including therapy-related pneumonitis, two patients with reactive lymph-nodes, an ovarian adnexal follicle, two patients with colon polyps, a benign bone tumor, an infected sebaceous cyst, and nonspecific pancreatic uptake. Seven of these patients were undergoing immunotherapy. ***Conclusion:*** FDG-PET/CT enables early detection of recurrences, which is crucial in the management of these patients. However, the high rate of false positives—particularly in patients undergoing immunotherapy—must be carefully considered during image interpretation, and should also prompt further research into novel radiotracers with greater specificity given the critical importance of timely relapse diagnosis.

EP-0522

Prognostic Value of Clinical and Metabolic Parameters from ^{18}F-FDG PET/CT in Malignant Melanoma: Impact on Overall and Progression-Free Survivalv

L. Cagua Ruiz, *T. Aroui Luquin, J. Villa-Palacios, A. Piñero Donis, E. Dominguez-Polanco, R. Sánchez Sánchez;*
Servicio Medicina Nuclear Hospital universitario Virgen de las Nieves, Hospital universitario virgen de las Nieves, SPAIN.

Aim/Introduction: To evaluate the prognostic value of clinical, histopathological, and metabolic parameters obtained through ^{18}F-FDG PET/CT in overall survival (OS) and progression-free survival (PFS) in patients with malignant melanoma. ***Materials and Methods:*** A retrospective study of 100 patients with malignant melanoma (59 men, 41 women; mean age: 64.9 ± 15.1 years) who underwent ^{18}F-FDG PET/CT for initial staging between 2015 and 2016. Clinical characteristics (histological type, location, Breslow index, mitotic count, ulceration, LDH, and S100 protein) and metabolic parameters (SUVmax, SUVmean, TLG, and MTV) were analyzed. Associations with OS and PFS were assessed using Kaplan-Meier survival curves and Cox regression models. ***Results:*** Nodular melanoma was the most common histological subtype (35%), and the lower extremities were the most frequent location (25%). Fifty-three percent of patients were in stage III. PET/CT was positive in 40 patients and negative in 60. The mean follow-up was 73.7 ± 41.4 months. The mean OS was 85.6 months (95% CI: 75.5-95.6). High Breslow index, LDH, S100 protein, and TLG were significantly associated with shorter OS ($p < 0.05$), with TLG being

the strongest independent predictor (HR = 1.1; 95% CI: 1.06-1.13; p < 0.05). The median PFS was 20 months (95% CI: 13.6-26.3). The lentigo maligna subtype and the presence of nodal metastases on PET/CT were significantly associated with shorter PFS (p < 0.05). ***Conclusion:*** ^{18}F-FDG PET/CT is a key tool for prognostic stratification in malignant melanoma. TLG is an independent predictor of OS, while PET/CT-detected nodal metastases significantly impacted PFS. These findings support the integration of metabolic parameters into the clinical evaluation of patients with malignant melanoma.

EP-0523

The Pseudoprogression Challenge in FDG PET/CT Response Evaluation of Malignant Melanoma Patients Receiving Immunotherapy:Which Immune Related Response Criteria Should We Trust?

G. Gedikli Turgut, *S. Ince, U. M. Turan, H. Peker Yalcın, A. O. Karacalioglu;*
Gulhane Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: In recent years, immunotherapy agents have become increasingly used in the treatment of malignant melanoma. In addition to the four basic response categories (complete metabolic response [CMR], partial metabolic response [PMR], stable disease [SD], and progressive metabolic disease [PMD]), concepts such as pseudoprogression (PP), hyperprogression (HP), mixed response, and durable response have emerged with the use of immunotheraphy. The aim of this study is to emphasize the concept of PP in interim PET and determine which immune-related response criterion is safer, more practical, and more accurate in predicting final outcomes in MM patients receiving immunotheraphy. ***Materials and Methods:*** This study included 23 patients with biopsy-confirmed MM who underwent FDG PET/CT scans: baseline (pre-treatment), interim (4-8 weeks after treatment initiation), and post-treatment (4-8 weeks after therapy completion), with a total of 80 lesions evaluated. For target lesion selection, up to five lesions with the highest SULpeak values were selected, ensuring each tumor's SULpeak was at least 1.5 times that of liver SULpeak. The sum of the SULpeak values of these lesions was used as the "total SULpeak." ***Results:*** Significant differences were found between baseline and interim PET/CT in SUVmean, total SULpeak, and TLG values (p<0.05), but not in MTV. Among the IT criteria, iPERCIST was found to be significantly superior in predicting final response (p<0.022). ***Conclusion:*** In patients receiving immunotheraphy, the concept of progression should be reconsidered during response evaluation. iPERCIST was the most accurate, practical, and reliable method among the response criteria studied. Reinterpreting interim PMD as iuPMD and confirming with a follow-up PET in 4-8 weeks is a safe strategy to avoid premature discontinuation of beneficial treatment due to PP. imPERCIST5 was found less practical due to the need for more complex calculations. Additionally, response evaluation should not rely solely on imaging but also take clinical findings into account. If the clinical condition is improving, findings on interim PET, including new lesions, should be suspected as pseudoprogression. ***References:*** 1. Lopci E, Hicks RJ, Dimitrakopoulou-Strauss A, et al. Immune-Related Adverse Events in Metastatic Melanoma Patients Treated with Combination Immunotherapy: The Role of PET/CT

G. Horvatic Herceg[1], *V. Sabaric*[2], *K. Blazicevic*[2], *M. Ciglar-Hlasc*[1], *D. Herceg*[2];
[1]*Department of Nuclear Medicine and Radiation Protection, University Hospital Zagreb, Zagreb, CROATIA,* [2]*Department of Oncology, University Hospital Zagreb, Zagreb, CROATIA.*

Aim/Introduction: Immune checkpoint inhibitors (anti-PD-1 and anti-CTLA4), especially combination treatment with nivolumab and ipilimumab, have revolutionized metastatic melanoma treatment. Compared with monotherapy combination immunotherapy with dual checkpoint inhibitors have shown surge in immune-related adverse events (irAE). The aim of our study was to to explore the utility of the 18FDG-PET/CT for treatment monitoring in patients with metastatic melanoma receiving ipilimumab and nivolumab and to determine the incidence of irAE during immunotherapy. ***Materials and Methods:*** 33 subjects with metastatic melanoma were enrolled:mean age 59.5 (range: 31- 75)y, 10 women, 23 men.All 33 enrolled subjects were evaluable for their response to dual therapy with ipilimumab and nivolumab. A baseline scan of the whole body of each patient with ^{18}F-FDG PET/CT was performed before the planned treatment initiation. The patients were examined again with PET/CT three and six months later to evaluate the therapy response. The therapy response was assessed according to the imPERCIST (immunotherapy-modified PERCIST). ***Results:*** Four patterns of response to ipilimumab and nivolumab were observed: 19 patients had a response in baseline lesions, among them 7 had a complete response. Stable disease or steady decline in total tumor volume was recorded in 5 patients. Responses after an initial increase in total tumor burden (pseudo-progression) was notified in one patient. Eight patients had progressive metabolic disease, and two patients among them died. Out of 33 patients we detected irAE in 22 patients (81%), and among them in 11(50%) patients PET/CT findings were suggestive for irAE. PET/CT signs preceded the clinical symptoms in 6 cases (3 thyroiditis, 2 colitis and single case of pneumonitis and hepatitis). The most common irAE was hepatitis (41%) followed by dermatitis (19%), thyroiditis (13%), hypophysitis (9%), nephritis (9%), colitis (6%) and single cases of pneumonitis, meningitis, arthritis, type I diabetes and immune thrombocytopenia. All irAE were reported within 22 weeks from start of the treatment and most grades were 2 and 3 with no deaths reported due to irAE. ***Conclusion:*** Even though combination immunotherapy regimen ipilimumab and nivolumab demonstrated long term results in overall survival of metastatic melanoma patients, irAE remain a major concern during and after the treatment. On small cohort of patients we detected irAE in 22 of them (81%), and PET/CT findings preceded clinical symptoms in 27% of cases.Therefore, it is of great importance when interpreting PET/CT to pay attention to possible irAEs and alert clinicians to findings that may be of life-threatening importance.

Streamlined Monitoring of Immunotherapy Response in Metastatic Melanoma via Longitudinal PET Quantification and SemiAutomatic Tumor Delineation

C. Sachpekidis[1], *T. P. Vagenas*[2], *J. C. Hassel*[3], *A. Dimitrakopoulou-Strauss*[1], *G. K. Matsopoulos*[2];
[1]*German Cancer Research Center (DKFZ), Heidelberg, GERMANY,* [2]*Biomedical Engineering Laboratory, School of Electrical and Computer Engineering, National Technical University of Athens, Athens, GREECE,* [3]*National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: Metastatic melanoma (MM) is a highly aggressive malignancy characterized by extensive spread and lesion heterogeneity, which together drive poor survival outcomes.

Although immunotherapy has shown encouraging efficacy, its rapid dynamics necessitate timely and accurate assessment of treatment response. Manual delineation of lesions on FDGPET/CT scans is laborious and time-consuming. In this study, we adapt a semiautomatic segmentation pipeline for longitudinal PET imaging to streamline response evaluation. Quantitative PET biomarkers are extracted from baseline and followup scans and evaluated against the novel PET Response Evaluation Criteria for Immunotherapy (PERCIMT), demonstrating potential for efficient and reproducible immunotherapy monitoring. ***Materials and Methods:*** We employed a two-stage segmentation pipeline validated in [1], to analyze paired FDGPET/CT scans (baseline and followup) from 40 MM patients. The pipeline clusters highuptake regions in multimodal FDGPET/CT images and classifies them using extracted imaging features and a deeplearning model. After manual correction for physiologic uptake and misclassified regions, lesion masks were finalized for biomarker extraction. Key quantitative PET metrics - total metabolic tumor volume (TMTV), total lesion glycolysis (TLG), SUV_{mean}, and SUV_{peak} - were computed and their percentage changes evaluated. We assessed correlations between these metrics and PERCIMT response using Spearman's rank correlation and compared metric differences between responders and non-responders using the Wilcoxon signed-rank test. ***Results:*** Moderate to strong correlations were observed between percentage changes in PET-derived metrics and PERCIMT classification (SUV_{max}: ρ=0.62; SUVmean: ρ=0.58; SUV_{peak}: ρ=0.58; TLG: ρ=0.71; TMV: ρ=0.74; all p<0.001), indicating that greater increases from baseline to follow-up scans are associated with poorer metabolic response outcomes. Additionally, Wilcoxon tests confirmed that responders had significantly lower follow-up metrics and smaller changes than non-responders (Wilcoxon rank-sum tests, all p<0.01), with TLG and TMV providing the strongest discrimination between groups. ***Conclusion:*** This study demonstrates that semi-automatic segmentation combined with PET-derived biomarkers enables accurate and efficient assessment of immunotherapy response in metastatic melanoma. The strong concordance with PERCIMT criteria supports its clinical utility for streamlined, reproducible treatment monitoring. ***References:*** [1] T. P. Evaluating the Clinical Accuracy of Half-Time[^{18}F]FDG PET/CT Acquisition: A Quantitative Assessment of Liver and Lesion Metrics in Oncology Imaging

N. AL Makhmari*, S. Kheruka, N. AL Maymani, I. Collado, S. Al Rashdi, K. Al Riyami;*
Radiology and Nuclear Medicine Department, Sultan Qaboos Comprehensive Cancer Care and Research Center, University Medical City, Muscat, OMAN.

Aim/Introduction: Reducing PET acquisition time has the potential to enhance patient comfort and clinical efficiency. However, it is essential to maintain the integrity of quantitative imaging biomarkers and diagnostic image quality. This study aimed to assess whether a half-time PET acquisition protocol using TRUEX+TOF 4i4G reconstruction could yield comparable results to standard full-time acquisition for both liver and lesion metrics. ***Materials and Methods:*** A total of 28 liver background regions and 28 lesions were evaluated from patients who underwent ^{18}F-FDG PET/CT scans with full-time (1.8mm/sec) and half-time speed. For both liver and lesion, SUVmax, SUVmean, TLG, MTV , signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR were analyzed .Median values and interquartile ranges (IQR) were reported. Statistical comparisons were made using the Wilcoxon signed-rank test. ***Results:*** Quantitative liver parameters demonstrated strong consistency between full- and half-time acquisitions. Median SUVmax increased modestly from 2.09 (IQR: 0.40) to 2.22 (IQR: 0.5), and SUVmean rose from 1.67 (IQR: 0.42) to 1.73 (IQR: 0.46). TLG showed a slight increase from 3.95 (IQR: 3.3) to 4.71 (IQR: 3.4), while MTV remained stable at 2.9 (IQR: 2.3) in both protocols. For lesions, median SUVmax was comparable 5.89 (IQR: 4.43) in full-time vs. 5.56 (IQR: 4.26) in half-time scans. SUVmean and TLG also showed minimal variation, with SUVmean increasing slightly from 3.38 (IQR: 2.30) to 3.51 (IQR: 1.85), and TLG from 7.44 (IQR: 18.97) to 8.63 (IQR: 24.09). MTV remained consistent (2.03 vs. 2.08). Image quality metrics revealed a minor decline with SNR decreased from 15.51 (IQR: 3.81) to 12.09 (IQR: 3.14), and CNR from 20.47 (IQR: 12.88) to 13.60.63 (IQR: 14.59). The Wilcoxon signed-rank test showed not significant difference in SNR and CNR between two protocols with p-value 0.29 and 0.05 respectively. ***Conclusion:*** This study demonstrates that half-time acquisition using digital PET with TRUEX+TOF reconstruction retains excellent quantitative reliability in both liver and lesion evaluations. While there is a modest decline in SNR and CNR, the core imaging biomarkers remain stable, supporting the feasibility of adopting half-time protocols in clinical practice—particularly for routine follow-up or high-throughput workflows. ***References:*** Al-Fatlawi M, Pak F, Farzanefar S, Salehi Y, Monsef A, Sheikhzadeh P. Novel Role of PSMA PET/CT Versus FDG PET/CT in Hepatocellular Carcinoma: A Comparative Diagnostic Study

S. Shekhar Singh[1]*, P. Wadhwa*[2]*, A. K. Chaudhary*[1]*, A. K. Singh*[1]*, R. K. Pawar*[1]*, S. K. Tandon*[1]*;*
[1]*Globe Healthcare, Lucknow, INDIA,* [2]*United Imaging Healthcare, Delhi, INDIA.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is typically evaluated using contrast-enhanced CT (CECT) and MRI. While FDG PET/CT is primarily used for metastatic staging, its utility is limited in well-differentiated HCC due to variable FDG avidity. Emerging evidence suggests that PSMA PET/CT, which targets tumor neovasculature, may improve HCC detection. This study compares 68Ga-PSMA PET/CT and ^{18}F-FDG PET/CT in HCC diagnosis, assessing lesion detection, metabolic parameters, and clinical impact. ***Materials and Methods:*** This prospective analysis included 30 biopsy-proven HCC patients (median age 62, range 50-68; 80% male, 20% female) who underwent both FDG and PSMA PET/CT within one week. Scans were performed on a uMI 550 PET/CT scanner, with comparisons based on: Lesion detection rate (primary tumor, intrahepatic, and extrahepatic metastases) Metabolic activity (SUVmax, target-to-background ratio [TBR]) Management impact (changes in treatment strategy). ***Results:*** Lesion Detection: PSMA PET/CT detected 160 lesions vs. 102 with FDG PET/CT ($p < 0.01$). Liver lesions: PSMA identified 50 vs. FDG 18 ($p < 0.001$). Bone metastases: PSMA detected 28 vs. FDG 10 ($p < 0.01$). No significant difference in lung or lymph node metastases. Metabolic Parameters: PSMA showed higher SUVmax

and TBR in 98% of lesions, including intrahepatic (PSMA TBR 5.2 vs. FDG 3.4) and metastatic sites. Clinical Impact: PSMA PET/CT altered management in 30% of cases (vs. 10% with FDG), primarily due to detection of additional primary tumors or occult skeletal metastases. ***Conclusion:*** PSMA PET/CT outperforms FDG PET/CT in HCC detection, particularly for primary liver lesions and bone metastases, with superior sensitivity and higher metabolic contrast. These findings suggest PSMA PET/CT could be a better modality for staging in HCC patients and in cases where FDG PET/CT yields equivocal results. ***References:*** Thompson, Scott M., et al. "PSMA as a Theranostic Target in Hepatocellular Carcinoma: Immunohistochemistry and 68Ga-PSMA-11 PET Using Cyclotron-Produced 68Ga." Hepatology communications 6.5 (2022): 1172-1185.

EP-0528

Potential of [89Zr]Zr-girentuximab PET/CT for the routine clinical management of patients with suspicious, unspecified renal lesions

S. Rasul, *I. Huebner-Resch, E. Patronas, L. Nics, S. F. Shariat, M. Schmidinger, M. Hacker;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: The radioactive tracer [^{89}Zr]Zr-girentuximab used for positron emission tomography (PET) targets the hypoxia-induced enzyme carbonic anhydrase IX (CAIX). Recently, the role of [^{89}Zr]Zr-girentuximab PET/CT for the non-invasive identification of non-specific renal lesions in 300 adult patients was investigated in the ZIRCON study, an open-label, multicenter trial. Results suggested that [^{89}Zr]Zr-girentuximab is a very accurate and promising tracer to facilitate the differentiation between clear cell renal cell carcinoma (ccRCC) and other malignant and benign renal lesions. Here, we report our initial real-world clinical experience with this PET tracer for the routine clinical care of patients with non-specific renal lesions. ***Materials and Methods:*** As part of an early access program, PET/CT imaging of patients with uncertain renal lesions received 37 MBq (±10%) [^{89}Zr]Zr-girentuximab intravenously to non-invasively characterize lesions in place of biopsy. We performed [^{89}Zr]Zr-girentuximab PET/CT imaging on day 5 (±2 days) after [^{89}Zr]Zr-girentuximab administration in 6 patients with a total of 9 undetermined renal lesions. ***Results:*** All patients tolerated the tracer very well and no undesirable reactions were reported. Four patients, which had a total of 4 lesions, showed no CAIX expression. These results were later comparable with MRI and contrast-enhanced CT images. These patients were placed on active surveillance and follow-up with conventional imaging. The other 2 patients with a total of 5 renal lesions (size between 1.1 and 1.5 cm axial diameter) showed a significantly high focal CAIX expression with a maximum standardized uptake value of 58.4. In one of them, the postoperative histological result confirmed the presence of ccRCC. Since the other patient had undergone nephrectomy for renal cell carcinoma several years ago, systemic therapy with immunotherapeutic and antiangiogenic treatments was recommended for that patient. ***Conclusion:*** Despite our limited experience, we were able to recognize the distinct clinical potential of the [^{89}Zr]Zr-girentuximab PET/CT scan in the management of patients with unspecified renal lesions ***References:*** [89Zr]Zr-girentuximab for PET-CT imaging of clear-cell renal cell carcinoma: a prospective, open-label, multicentre, phase 3 trialShuch, Brian et al. The Lancet Oncology, Volume 25, Issue 10, 1277 – 1287.

EP-0529

Comparison of response assessment using morphological (iRECIST) and metabolic criteria (iPERCIST) in patients being treated with Immune checkpoint inhibitors in solid tumors.

D. Malik, *M. Koley, J. Gupta, D. Thakrani, A. Uppal, N. Rana, P. Thakral, I. B. Sen;*
Fortis Memorial research institute (FMRI), Gurugram, INDIA.

Aim/Introduction: The primary purpose of imaging in patients undergoing immunotherapy is to differentiate treatment non-responders from the responders who would benefit from an earlier change in therapeutic management and also from those who have initial increase in tumor burden due to pseudo progression. The CT based iRECIST, followed by FDG PET CT based iPERCIST criteria designed to better account for these patterns. F18-FDG PET tracks changes in metabolic activity of tumor, which often occurs much before changes in size are evident on morphological imaging, thus providing superior response evaluation in solid tumours as to CT based criteria. ***Materials and Methods:*** 94 patients with solid tumors undergoing immune checkpoint inhibitor (ICI) therapy were included. 1st follow up scan was performed after 3/4 cycles of (ICI) therapy as per referring physician discretion and subjects were classified into Response (complete and partial), progression or Stable disease on CT and PET by iRECIST and iPERCIST criteria respectively and clinical data. 2nd follow up scan was performed following 3-4 more cycles of ICI therapy. Final response was ascertained by a combination of PET and CT. Cohen's kappa coefficients with quadratic weights were used to assess concordance between ratings obtained at baseline and follow up separately for iRECIST and iPERCIST. Z-test for two independent kappa values were calculated to determine if statistically significant differences exist. ***Results:*** At first follow up, 49/94 patients had metabolically responding disease by iPERCIST criteria. Out of these patient, 32 patients had ongoing response in second follow up PET CT, whereas 16 patients who showed an initial response, progressed at second follow up, indicating an early treatment failure in these patients.In contrast, only 37/94 patients were found to have a morphologically responding disease in the first follow up PET CT by iRECIST criteria. Further on second follow up, 25 were found to have ongoing treatment response, while only 11 patients were found to have progressive disease. Therefore, fewer treatment failures (16 vs 11) were picked up by CT based criteria.The quadratic weighed kappa at 1st follow up and at 2nd follow up for iPERCIST was 0.6925 (substantial correlation), and for iRECIST was 0.3137 (fair correlation). This difference was statistically significant (p=0.022) when tested using a two-tailed Z-test. ***Conclusion:*** iPERCIST criteria was found to be superior to iRECIST criteria for evaluation of patients undergoing immunotherapy and prediction of true disease progression, early in the course of treatment with immune checkpoint inhibitors.

EP-0530

18F-FDG-PET/CT for staging Muscle-Invasive Urothelial Bladder Carcinoma: Impact on management using modified Deauville Score

O. Ajuria Illarramendi, *P. Gajate Borau, A. Martinez Lorca, P. Azpeitia Hernandez, P. Guerrero Serrano, M. Gutierrez Guerrero, J. Brasero Burgos, I. Hernandez Perez, F. Lopez Campos, U. Vera Schmülling, P. Paredes Rodriguez, T. Navarro Martinez, M. Orduña Diez;*
H. U. Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: To evaluate the role of 18F-FDG-PET/CT in staging muscle-invasive urothelial carcinoma(MIUC) with inconclusive nodal findings on contrast-enhanced Computed Tomography(ceCT), using modified Deauville Score(DS), and its impact on clinical decisions. Standard management of MIUC includes radical cystectomy and pelvic lymphadenectomy, often preceded by neoadjuvant cisplatin-based chemotherapy(neoQT). However ceCT has limited sensitivity for nodal metastases, leading to potential under-staging and suboptimal treatment. ***Materials and Methods:*** Retrospective review of MIUC patients (≥pT2) with indeterminate nodal status on ceCT who underwent staging with 18F-FDG-PET/CT between 01/01/2021-01/04/2025. Treatment decisions (neoQT, surgery, systemic therapy(QT)) were guided by 18F-FDG-PET/CT results. Patients with evidence of locoregional

nodal were administered neoQT and underwent follow-up 18F-FDG-PET/CT scan. Findings on initial and post neoQT were interpreted using modified Deauville Score(DS1-2 negative, DS3-5 positive) and were correlated with histopathology when available. Nodal SUVmax was recorded n initial and post neoQT scans. ***Results:*** 46 patients: 8 women and 38 men; mean age 73. Staging scan revealed: 21 cN0M0, 9 cN2M0, 3 cN3M0, 8 cN3M1a, and 5 cM1b (2 cN0M1b, 2 cN2M1b, 1 cN3M1b).The presence of cM1b in 5/46 ruled out surgery, as well as in 4/46 cN3M1a and were given chemotherapy.9/46 cN0M0 (3/9 underwent surgery that confirmed absence of disease pN0; VPN100% and 6/9 received RT or QT-RT due to comorbilities)28/46 (12 cN0M0, 9 cN2M0, 3 cN3M0, 4 cN3M1a) received neoQT. 8/28 are pending of follow up scan. 3/28 (2 ycN3M1a, 1 ycN2M0) continued systemic treatment due to persistence of disease in follow up scan. 17/20 achieved metabolic response (17 ycN0M0). Among these patients: 13/17 underwent surgery (12 ypN0, 1 ypN1. VPN92%) and 4/17 were ineligible for surgery and received chemotherapy. Mean SUVmax for pathological nodes(DS ≥3) in staging scan was 5,43 (±DS 2,6). Post-treatment mean SUVmax in responders (DS ≤2) was 1,57 (± 0,73) and 3,13 (±DS 0,11) in non-responders. ***Conclusion:*** 18F-FDG-PET/CT, using modified Deauville Score, improved nodal staging accuracy in MIUC and impacted management by identifying surgery candidates and assessing neoadjuvant therapy response. Its high negative predictive value supports its role as a reliable, non-invasive tool for response evaluation.

EP-0531

Flow cytometry to validate the efficacy of multi-target PET tracer in early monitoring of ICI in lung cancer

R. Meng, *F. Kang;*
Military Medical University First Affiliated Hospital of No.4 Military Medical University, Shaanxi Xi'an, CHINA.

Aim/Introduction: Immune checkpoint inhibitors (ICIs) are a new class of anti-cancer drugs that are able to turn the immune system back on to fight cancer. However, the efficacy of ICI varies greatly in different patients because of the complex immune microenvironment, in which the neutrophil/lymphocyte ratio may play a key role. Studies have shown that imaging of granzyme B (GZB) with 68Ga-DOTA-grazytracer and myeloperoxidase (MPO) with 68Ga-NOTA-bis-5HT could predict the ICI responders of lung cancer, which are the effective protein of CD8+ T cell and the core protein of neutrophil trapping net (NETs), respectively. In this study, the effector molecule granzyme B (GZB) targeting CD8+ T cells and myeloperoxidase (MPO), the core protein of neutrophil capture network (NETs), were used to predict ICI responders in lung cancer, and the effectiveness of multi-target PET tracer detection was verified by enzyme-linked immunosorbent assay and flow cytometry. ***Materials and Methods:*** LLC tumor-bearing mice were treated with intraperitoneal injection of PD-L1 mAb (200μg) every 3 days. Subsequently, microPET /CT dual PET probes were used to detect the uptake before and after treatment. The tumor tissues of LLC mice were collected after immunotherapy, and the proportion of cell types and the secretion of MPO and GZB were detected by flow cytometry and ELISA respectively. ***Results:*** ELISA experiments showed that after PD-L1 treatment, MPO secretion in the Responder and Nonresponder groups was significantly different, consistent with the PET/CT results, while GZB was not. Flow cytometry results showed that after PD-L1 treatment, neutrophils and PD-L1 were significantly different between the Responder and Nonresponder groups, while CD8+T cells were not, indicating the importance of activated neutrophils in immunotherapy monitoring. The expression of PD-L1 was higher in the Nonresponder group than in the responder group, which was inconsistent with the theoretical results, indicating that PD-L1 alone was not sufficient to predict immunotherapy response. ***Conclusion:*** GZB expression in tumor was increased by PD-L1 stimulation and the change of MPO had the potential to predict the immunotherapy response of lung cancer. The use of immunotherapy to treat lung cancer needs to satisfy both T cell activation and neutrophil inactivation, which can mobilize endogenous immune pathways. ***References:*** Zhang J, Shao S, Wu P, et al. Diagnostic performance of 68Ga-PSMA PET/CT in the detection of prostate cancer prior to initial biopsy: comparison with cancer-predicting nomograms. EP-0532

Head to head comparison of ^{68}Gallium-FAPI-PET/CT and ^{18}Fluor-FDG-PET/CT for the assessment of single site cancer of unknown primary

M. Röhrich[1], *D. Driess*[1], *A. Spektor*[1], *S. Zapata*[1], *A. Desuki*[1], *M. Schreckenberger*[1], *U. Haberkorn*[2], *A. Krämer*[3];
[1]*University hospital Mainz, Mainz, GERMANY,* [2]*University hospital Heidelberg, Heidelberg, GERMANY,* [3]*University hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: For the assessment of cancer of unknown primary of the head and neck (HNCUP), ^{68}Gallium FAPI-PET/CT has shown highly promising results and appears superior to ^{18}Fluor-FDG-PET/CT. However, to date no data on the diagnostic performance of ^{68}Gallium FAPI-PET/CT compared to ^{18}Fluor-FDG-PET/CT for patients with single site CUP (SSCUP) exists. In this pilot study, we compare detection rates, signal intensities and diagnostic accuracy of both PET techniques in 24 patients with SSCUP. ***Materials and Methods:*** 24 patients with SSCUP underwent ^{18}Fluor-FDG-PET/CT and additional ^{68}Gallium FAPI-PET/CT for optimized SSCUP staging. All PET-positive lesions were delineated by isocontouring and lesionwise SUVmax, SUVmean were extracted and target to background ratios (lesional SUVmax/bloodpool SUVmean) were calculated. Lesions were classified according to radiological appearance, clinical course and - if available - histological confirmation. Receiver-operating-characteristic curves for the differentiation of malignant and benign lesions and corresponding estimates of area under the curve, including 95% CIs, were calculated. ***Results:*** Primary tumors were detected in 6/24 (^{68}Gallium FAPI-PET/CT) and 3/24 cases (^{18}Fluor-FDG-PET/CT). ^{68}Gallium FAPI-PET/CT detected 12 metastases in 9 patients, ^{18}Fluor-FDG-PET/CT 9 in 6 patients. FAPI-uptake was almost equal to FDG-uptake in primaries (SUVmax/mean 7.49+/-1.54/4.76+/-1.09 versus 8.17+/-1.75/5.01+/-1.96), but significantly higher in metastases (SUVmax/mean 18.07+/-8.58/7.28+/-5.24/ versus 6.13+/-2.32/3.58+/-1.47, p values 0.009 (SUVmax) and 0.035 (SUVmean)). TBRs for primaries were 3.22+/-0.38 (^{68}Gallium FAPI-PET/CT) and 4.12+/-1.61 (^{18}Fluor-FDG-PET/CT), for metastases 6.42+/-0.92 (^{68}Gallium FAPI-PET/CT) and 2.64+/-1.31 (^{18}Fluor-FDG-PET/CT). ROC analyses showed higher area under curve values for ^{68}Gallium FAPI-PET/CT compared to ^{18}Fluor-FDG-PET/CT (SUVmax 78% versus 68%, SUVmean 71% versus 65%). ***Conclusion:*** In SSCUP, ^{68}Gallium FAPI-PET/CT detected more primary sites and metastases than ^{18}Fluor-FDG-PET/CT. Signal intensities of both tracers were mostly equal in primaries, however metastases showed higher ^{68}Gallium FAPI- than ^{18}Fluor-FDG-uptake. Diagnostic accuracy for the differentiation of malignant and benign lesions was higher for ^{68}Gallium FAPI-PET/CT than for ^{18}Fluor-FDG-PET/CT. Overall, ^{68}Gallium FAPI-PET/CT improved the diagnostic assessment of SSCUP compared to ^{18}Fluor-FDG-PET/CT, especially with respect to accurate and high-contrast detection of metastases.

EP-0533

Treatment monitoring of immunotherapy and targeted therapy using cluster of CD70-targeted positron emission tomography/computed tomography (PET/CT) in patients with advanced clear cell renal cell carcinoma(ccRCC)

Q. Wu, *G. Huang, J. Liu, W. Wei;*
Renji Hospital School of Medicine Shanghai Jiao Tong University, Department of Nuclear Medicine Institute of Clinical Nuclear Medicine, Shanghai, CHINA.

Aim/Introduction: CD70 is a potential biomarker for ccRCC. Using [^{18}F]RCCB6 (a ^{18}F-labelled single-domain antibody radiotracer targeting CD70) immunoPET/CT to assess the efficacy of immune checkpoint inhibition (ICI), targeted therapy (TT), and combinations thereof for advanced ccRCC, and comparing with Response Evaluation Criteria in Solid Tumours (RECIST). ***Materials and Methods:*** Thirteen postoperative advanced ccRCC patients were included between May 2023 and November 2024 who underwent [^{18}F]RCCB6 PET/CT for response assessment to ICI or TT or combinations thereof using baseline and follow-up scans (median time between scans, 5 mo). [^{18}F]RCCB6 PET/CT parameters (i.e., maximum standardized uptake value (SUVmax), CD70-derived tumour volume (CD70-TV) and total lesion uptake of the CD70 tracer (CD70-TLU)) were acquired in all extra-renal lesions. Treatment efficacy was assessed using [^{18}F]RCCB6 PET/CT and RECIST. ***Results:*** In thirteen patients with advanced ccRCC, 182 lesions were detected on baseline [^{18}F]RCCB6 PET/CT with a median SUVmax of 4.4. The median total CD70-TV and total CD70-TLU for patients were 4.9 and 36.3. Patients were then treated with ICI or TT or combinations thereof. In the follow-up scan by [^{18}F] RCCB6 PET/CT, three patients showed a decrease in the number of lesions (mean 4.3), with a mean decrease in total CD70-TV and total CD70-TLU of 2.0 and 74.4. Whereas in nine patients, the number of lesions increased (mean 18.0), with a mean increase in total CD70-TV and total CD70-TLU of 17.4 and 97.4. In five of 13 patients, the [^{18}F]RCCB6 PET/CT follow-up results were inconsistent with the results of RECIST. All five were considered to have stable disease by RECIST, while 3 of them were considered to have progressive disease and two were considered to be partial remission by [^{18}F] RCCB6 PET/CT. ***Conclusion:*** [^{18}F]RCCB6 PET/CT targeting CD70 may provide valuable information for the monitoring of patients with advanced ccRCC treated with ICI and TT.

EP-0534

Improving Clinical Management of von Hippel-Lindau Syndrome with [^{89}Zr]Zr-DFO-Girentuximab PET Imaging

F. Gelardi[1], *A. Larcher*[1,2], *L. Antunovic*[1], *F. Cei*[2,1], *C. Re*[2,1], *F. Belladelli*[2,1], *G. Guazzarotti*[1], *G. Brembilla*[1], *S. Calloni*[1], *N. Tenace*[1], *A. Piai*[1], *A. Tudda*[1], *U. Capitanio*[1], *F. Montorsi*[2,1], *A. Salonia*[2,1], *M. Sollini*[2,1], *A. Chiti*[2,1];
[1]*IRCCS Ospedale San Raffaele, Milan, ITALY,* [2]*Università Vita-Salute San Raffaele, Milan, ITALY.*

Aim/Introduction: Von Hippel-Lindau syndrome (VHL) is a rare inherited disease caused by mutations in the VHL tumour suppressor gene, resulting in upregulation of hypoxia-inducible factor 1α and carbonic anhydrase IX (CAIX), and subsequent tumour development. Imaging plays a central role in disease surveillance and patient management. We aim at evaluating the utility of CAIX-targeted PET imaging for comprehensive whole-body evaluation in patients with VHL syndrome. ***Materials and Methods:*** Adult patients with genetically confirmed VHL syndrome who are under regular surveillance at our institution are enrolled in a compassionate use programme. Each participant receives a single intravenous dose of [^{89}Zr]Zr-DFO-Girentuximab, followed by whole-body PET/CT imaging five days after injection. Conventional imaging - including abdominal and brain MRI - is performed according to clinical practice. PET/CT images are independently interpreted by two experienced nuclear medicine physicians. Lesions with increased tracer uptake are reported and detection rates are calculated both per patient and per region. Follow-up conventional imaging and/or histopathology are used as reference standards. ***Results:*** We report preliminary findings in two patients with VHL syndrome and suspicious renal, cerebral and pancreatic lesions on MRI. Patient 1 presented with bilateral renal lesions associated with polycystic kidney disease, which resulted in challenging MRI interpretation. The patient also had a known pancreatic neuroendocrine tumour (NET) and multiple cerebellar hemangioblastomas. [^{89}Zr]Zr-DFO-Girentuximab PET/CT showed high uptake in multiple bilateral renal lesions with a high degree of discrimination, outperforming MRI in terms of the number of lesions detected. High uptake was also observed in the pancreatic isthmus, corresponding to the known NET, whereas cerebellar lesions showed only mild uptake. Patient 2 presented with suspected bilateral renal lesions, multiple cerebellar hemangioblastomas, and pancreatic cysts with mural enhancement suggestive of adenoid cystic lesions. PET/CT showed high uptake in the renal and cerebellar lesions, but no uptake in the pancreatic cysts. ***Conclusion:*** This preliminary experience suggests that CAIX-targeted PET imaging may offer significant advantages in detecting and characterising VHL-associated tumours, particularly in anatomically complex or ambiguous settings. The ability of [^{89}Zr]Zr-DFO-Girentuximab PET/CT to identify different lesions subtypes supports CAIX as a promising imaging biomarker for improved surveillance and personalised management in VHL syndrome. Acknowledgements: This research is supported by the Italian Ministry of Health and the European Union for the project "CAT-VHL - Exploring the role of Carbonic Anhydrase IX as diagnostic and Theranostic target in Von-Hippel Lindau disease" (PNRR-POC-2023-12377493).

EP-0535

Diagnostic Utility of [18F]F-FAPI PET-CT in Patients with Carcinoma of Unknown Primary: A Prospective Multicentre Study in the Netherlands

S. Veldhuijzen van Zanten[1], *E. Droogers*[1], *M. Hendriks*[2], *E. Verburg*[3], *D. Robbrecht*[3], *A. Glaudemans*[4], *A. Glaudemans*[4], *M. van Kruchten*[5], *W. Vogel*[6], *S. Marchetti*[6], *S. Marchetti*[6], *M. Lam*[7], *H. Nienhuis*[7], *A. Timmer-Bonte*[8], *M. van Rijk*[8], *J. Nin*[9], *C. Mitea*[9], *A. van den Hoven*[10], *W. Kool*[2], *S. Veldhuijzen van Zanten*[3], *FAPI for CUP study team;*
[1]*Erasmus Medical Center, Rotterdam, NETHERLANDS,* [2]*Northwest Clinics, Alkmaar, NETHERLANDS,* [3]*Erasmus MC, Rotterdam, NETHERLANDS,* [4]*UMC Groningen, Groningen, NETHERLANDS,* [5]*UMC Grongingen, Grongingen, NETHERLANDS,* [6]*AvL, Amsterdam, NETHERLANDS,* [7]*UMC Utrecht, Utrecht, NETHERLANDS,* [8]*Radboud UMC, Nijmegen, NETHERLANDS,* [9]*Maastricht UMC, Maastricht, NETHERLANDS,* [10]*Antonius Ziekenhuis, Nieuwegein, NETHERLANDS.*

Aim/Introduction: Carcinoma of unknown primary (CUP) is a heterogeneous group of metastatic malignancies where the primary tumour site remains unidentified despite extensive diagnostic work-up. This impedes personalised, tumour-specific treatments and contributes to poor prognosis, with a median overall survival of only two months. [^{18}F]FDG PET-CT, the most sensitive imaging modality, fails to detect the primary tumour in two-thirds of cases. Fibroblast activation protein inhibitors (FAPI) represent a promising class of radiotracers targeting cancer-associated fibroblasts, offering high tumour specificity and favourable tumour-to-background contrast. This study aims to evaluate the clinical performance of [^{18}F]F-FAPI PET-CT in CUP patients. The study was initiated in collaboration with the Dutch patient advocacy group Missie Tumor Onbekend, now part of the international World CUP Alliance, highlighting the urgent need and potential societal impact of improving diagnostics for CUP patients. ***Materials and Methods:*** This patient-driven, investigator-initiated, prospective multicentre study involves 50 adult CUP patients across six Dutch centres. Eligible patients are identified through the national CUP referral pathway following standard diagnostics, including [^{18}F]FDG PET-CT. Each patient undergoes a single [^{18}F]F-FAPI-74 PET-scan (3.0 MBq/kg, 60-minute acquisition post-injection), followed by CECT. Imaging is centrally reviewed by two blinded experts, with discordant reads resolved through consensus. A multidisciplinary Truth Panel assesses whether suspected primary lesions on [^{18}F]F-FAPI PET-CT are confirmed by follow-up diagnostics (e.g., histopathology, imaging,

or molecular analysis) within six months post-scan. ***Results:*** The primary endpoint is defined as the proportion of CUP patients in whom the primary tumour is identified by [^{18}F]F-FAPI PET-CT. Secondary endpoints include sensitivity, specificity, PPV, and NPV. Tertiary outcomes assess the clinical impact on diagnostics and treatment, tracer safety, incidental findings, and comparative uptake metrics between [^{18}F]FAPI/[^{18}F]FDG. Subgroup analyses based on age, sex, histology, metastasis site, and performance status are also planned. As of April 2025, over half of the target population has been enrolled (first patient: July 2024). All [^{18}F]F-FAPI PET-CT scans have been reviewed within protocol timelines, and primary tumours have been identified following [^{18}F]F-FAPI imaging. The Truth Panel is actively reviewing eligible cases (≥6 months follow-up or deceased) to determine study endpoints. ***Conclusion:*** This study demonstrates that [^{18}F]F-FAPI PET-CT has the potential to improve primary tumour detection in CUP patients, informing clinical management. Through rigorous prospective evaluation and national collaboration, the study aims to establish the diagnostic performance and clinical utility of FAPI imaging in this high-need patient population. Preliminary results will be available at the time of EANM'25.

EP-0536

Head-to-Head Radiomics Comparison between ^{18}F-PSMA and ^{18}F-FDG PET/CT Imaging in Desmoid Tumor

C. D. Ramos, *T. L. Reis, M. E. S. Takahashi, B. J. Amorim, M. C. L. Lima, C. A. Souza, J. B. C. Carvalheira;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Desmoid tumors (DTs) are rare, locally aggressive soft-tissue neoplasms arising from myofibroblasts. While they lack metastatic potential, their infiltrative growth can cause substantial morbidity due to compression of adjacent structures. ^{18}F-FDG PET/CT, which reflects tumor glycolytic activity, has shown utility in assessing disease activity and predicting clinical outcomes [1]. More recently, uptake of radiolabeled Prostate-Specific Membrane Antigen (PSMA) has been reported in DTs, likely reflecting PSMA expression in tumor neoangiogenesis [2]. This study aimed to compare the uptake characteristics and intratumoral radiomic features of ^{18}F-FDG and ^{18}F-PSMA PET/CT in abdominal DTs. ***Materials and Methods:*** Four patients with histologically confirmed abdominal DT underwent both ^{18}F-FDG and ^{18}F-PSMA PET/CT imaging within a one-day interval. Lesions were assessed visually, and maximum standardized uptake values (SUVmax) were recorded for each radiotracer. Radiomic analysis included extraction of Haralick texture features and voxel-wise intensity metrics. Intra-patient percentage deviations were calculated to quantify differences between the two imaging modalities. ***Results:*** All DT lesions demonstrated mild-to-moderate uptake (above mediastinal blood pool) for both tracers. The index lesion size ranged from 4.4 to 9.2 cm (mean ± SD: 6.4 ± 2.4 cm). In three of four patients, ^{18}F-FDG showed more homogeneous intratumoral distribution than ^{18}F-PSMA; the reverse was observed in one patient. SUVmax values ranged from 2.3 to 9.8 for ^{18}F-FDG and 2.4 to 9.0 for ^{18}F-PSMA (mean ± SD: 6.4 ± 3.9 and 5.8 ± 2.7, respectively). Radiomic analysis revealed notable deviations (>25%) in several features, including SUV standard deviation, SUVpeak, contrast, difference variance, cluster shade, correlation measure 2 (MC2), sum variance, and variance. MC2, reflecting texture complexity and redundancy, showed an exceptionally high mean deviation (~5000%). ***Conclusion:*** Abdominal desmoid tumors demonstrate uptake of both ^{18}F-FDG and ^{18}F-PSMA, with inter-lesional and intra-lesional variability in tracer intensity and spatial distribution. While ^{18}F-FDG generally presents more uniform uptake, ^{18}F-PSMA reveals greater heterogeneity in most cases. Radiomic texture analysis highlights substantial differences between the two modalities, particularly in MC2, suggesting that each tracer captures distinct biological aspects of DT. These findings support a potential complementary role of PSMA imaging in the evaluation of desmoid tumors. ***References:*** [1] Liu DN, et al. Volume-based ^{18}F-FDG PET/CT predicts prognosis and outcome of active surveillance for intra-abdominal desmoid tumor. Abdom Radiol (NY). 2024;49(3):958-963.[2] Orevi M, et al . False positive findings of [^{18}F]PSMA-1007 PET/CT in patients after radical prostatectomy with undetectable serum PSA levels. Front Surg. 2022;9:943760.

Baseline Intelligence: Predicting Treatment Response in Esophageal Cancer via Machine Learning on PET/CT

D. Khan, *S. Sagar, N. Kundu, J. Krishna P., A. Tilak, L. Goriparti, A. Roy, A. Mahalik, S. K V, J. Pathak, R. Kumar;*
AIIMS Delhi, Delhi, INDIA.

Aim/Introduction: Accurate early prediction of treatment response in esophageal cancer is critical for timely clinical decision-making. While FDG PET/CT offers valuable metabolic insights, interpretation remains largely qualitative and subjective. This study aimed to develop and evaluate machine learning (ML) models that predict final treatment response using only baseline PET/CT features in patients with esophageal cancer. ***Materials and Methods:*** From an initial dataset of 951 esophageal cancer PET/CT scans, a cohort of 88 patients diagnosed with esophageal cancer having baseline, interim and response assessment scan was curated. After excluding cases with incomplete data, 82 patients with complete baseline features were included in the analysis. Quantitative features including Esophagus SUVmax, Nodal SUV, Metastasis SUV, Age, and Sex were extracted and used to train Random Forest and XGBoost classifiers. Response labels were derived from follow-up scan impressions, categorized into responders (CMR/PR) and non-responders (SD/PD). Both models were evaluated using stratified 5-fold cross-validation. SHAP-based interpretability was implemented to visualize feature impact per patient. ***Results:*** The Random Forest model achieved an average AUC of 0.65 and recall of 0.76, while XGBoost yielded similar performance (AUC 0.66, recall 0.74). Both models demonstrated consistent results across folds, with Esophagus SUV and Age emerging as top predictors. The models were integrated into a user-friendly Streamlit interface supporting Excel uploads, SHAP plots, and PDF report generation. ***Conclusion:*** This study demonstrates the feasibility of predicting esophageal cancer treatment response from baseline PET/CT features using ML. The workflow offers a scalable, interpretable, and clinically relevant tool for early response stratification, potentially enhancing personalized care.

EP-0538

99mTc-PSMA SPECT/CT in the detection of metastatic lesions in renal cell carcinoma

Y. Sánchez Vera, *J. González Díaz;*
Centro Médico Nacional Siglo XXI, IMSS, Mexico, MEXICO.

Aim/Introduction: Overexpression of prostate-specific membrane antigen (PSMA) has been demonstrated in the neovasculature of various malignant tumors, including Renal Cell Carcinoma (RCC). The objective of this study was to explore the usefulness of SPECT/CT with 99mTc-PSMA in the detection of metastases in patients with RCC. ***Materials and Methods:*** A retrospective, observational, and descriptive study was conducted. A total of 12 patients diagnosed with clear cell RCC were selected, who had undergone 99mTc-PSMA SPECT/CT, were clinically suspected, and/or had demonstrated metastasis by other diagnostic methods. SPECT/CT was performed from the vertex of the skull to the mid-thigh using a Phillips Precedence 16P hybrid scanner. ***Results:*** Twelve studies were included of patients with a mean age of 56 years; 3 women and 9 men, with a histopathological diagnosis of RCC. Lesions with 99mTc-PSMA uptake were detected in 66% (8/12) of the SPECT/

CT scans performed, and the remaining 33% (4/12) showed no lesions. Fifty-nine lesions with abnormal 99mTc-PSMA uptake were documented, of which 37.3% (22/59) were found in bone, 32.2% (19/59) in lung, 20.3% (12/59) in lymph nodes, 3.4% (2/59) in soft tissue, 3.4% (2/59) in retroperitoneum, and 3.4% (2/59) in the central nervous system. ***Conclusion:*** 99mTc-PSMA SPECT/CT detected metastatic disease in 66.6% of patients, including new lesions. Results showed potential for complementary use in the staging and restaging of RCC. Further studies are needed to determine its effectiveness in other histological subtypes. Additionally, SPECT/CT with 99mTc-PSMA can be a diagnostic method identifying metastatic disease and with potential theragnostic use in RCC.

EP-0539

Implementing Gallium - 68 FAPI PET/CT in Kenya: Initial experience in a tertiary cancer centre.

N. Harish[1,2], *K. Kallur*[1], *D. Muriuki*[1], *H. Ryatt*[1], *R. Prashanth*[1], *K. Rajkumar*[1], *T. Harsha*[1], *J. Kariuki*[1];
[1]*HCG CCK Cancer Centre, Nairobi, KENYA,* [2]*Kenyatta University Teaching Referral and Research Hospital, Nairobi, KENYA.*

Aim/Introduction: Molecular imaging has revolutionized oncology by assessing tumor biology over and above dependency on morphological anatomy like traditional radiologic imaging. Positron Emission Tomography/Computed Tomography (PET/CT), among molecular imaging modalities, is a hybrid imaging tool yielding structural and functional information in a way that enables visualization non-invasively of physiological and pathological processes at a cellular and subcellular level. In Kenya, PET/CT has existed for over six years with most using Fluorine-18 Fluorodeoxyglucose (^{18}F-FDG) as the go-to radiotracer in oncologic imaging. However, ^{18}F-FDG has its drawbacks, particularly when identifying tumors with low glucose metabolism or confidently differentiating malignant from benign processes like infection and inflammation. Additionally, the ^{18}F-FDG protocol requires fasting and may be cumbersome in diabetic and pediatric patients. Recently, our institution introduced Gallium-68 Fibroblast Activation Protein Inhibitor (^{68}Ga-FAPI), a novel radiotracer for fibroblast activation protein (FAP) overexpressed in cancer-associated fibroblasts (CAFs). The first-of-a-kind tracer in Kenya and the entire East African region has numerous advantages over ^{18}F-FDG, including high tumor-to-background contrast (TBR), minimal uptake in normal tissues, no dietary preparation requirement, and shorter uptake time. It is extremely useful in detecting primary and metastatic tumors, especially in malignancies with high fibroblast content. ***Materials and Methods:*** It is a retrospective study that aimed to assess the clinical application of ^{68}Ga-FAPI PET/CT in cancer diagnosis and therapy. A total of 141 patients with confirmed histopathological diagnoses were scanned with ^{68}Ga-FAPI PET/CT scans between February and March 2025 for several indications, such as staging, post-treatment follow-up, re-staging, surveillance, and detecting the primary tumor in cancers of unknown primary. The injected dose was between 120 to 185 MBq with an uptake of 20 minutes, and images were taken using a GE Discovery PET/CT IQ scanner. ***Results:*** Amongst all cancers, the highest SUVmax (>15) was seen in breast, esophageal, sarcoma, and lung carcinomas. Low uptake (SUVmax <6) was seen in renal cell and gallbladder carcinomas, and moderate uptake (SUVmax 6-15) in colorectal, nasopharyngeal, oral squamous cell carcinoma, and melanomas. ***Conclusion:*** Initial experience with ^{68}Ga-FAPI PET/CT in Kenya is promising. The technique boasts high contrast image, ease of use, and enhanced patient comfort. While not a replacement for ^{18}F-FDG, ^{68}Ga-FAPI is an adjunct modality that may have a significant impact on clinical decision-making as well as oncology care in the nation. ***References:*** FAPI-PET/CT: Mean intensity of tracer-uptake (SUV) in 28 different kinds of cancer. DOI:10.2967/jnumed.119.227967.

EP-0540

Organ-wise changes in ^{18}F-AraG immunoPET uptake before and after ICI Therapy

T. Nobashi*, Y. Shimizu, K. K. Miyake, R. Sakamoto, S. Yasumura, Y. Kitano, R. Nakamoto, H. Ajimizu, T. Nomizo, H. Yoshida, H. Ozasa, M. Nomura, C. Katada, M. Muto, Y. Nakamoto;*
Kyoto University Hospital, Kyoto city, JAPAN.

Aim/Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy, offering significant benefits across various malignancies. However, their overall response rate remains limited, ranging from 20% to 40%[1]. ImmunoPET has emerged as a powerful non-invasive imaging modality that visualizes the in vivo distribution of immune-related molecules. Among these, ^{18}F-AraG—a radiolabeled form of the T-cell-targeting prodrug nelarabine—selectively accumulates in activated T cells[2,3]. This study aimed to evaluate organ-specific changes in ^{18}F-AraG uptake following ICI initiation in cancer patients, with a particular focus on immune-related and irAE-prone organs. ***Materials and Methods:*** This investigator-initiated clinical study was approved by the Japan Registry of Clinical Trials (jRCTs051220109 and jRCTs051240253) in October 2022 and January 2025, respectively. Eligible patients were aged 20-85, had an ECOG performance status of 0-2, and were scheduled to receive ICI therapy approved in Japan. ^{18}F-AraG PET/CT scans were acquired at baseline and during the early phase of ICI treatment. Uptake changes were quantitatively analyzed in immune-related tissues (e.g., spleen, tonsils, upper pharynx) and irAE-associated organs (e.g., pituitary, thyroid, liver, pancreas, intestines) using paired t-tests. ***Results:*** Nine patients (1 female, 8 males; aged 69-82) were included: six with non-small cell lung cancer, two with esophageal cancer, and one with small cell lung cancer. Post-treatment PET/CT was performed 19 ± 7 days after ICI initiation. ^{18}F-AraG (228.3 ± 53.1 MBq) was injected manually without adverse events. Scanning was conducted 60.9 ± 8.5 minutes post-injection from mid-thigh to vertex. High tracer uptake was observed in the kidneys, liver, pancreas, and stomach; low accumulation was seen in the bladder, blood, and brain. Moderate to intense uptake occurred in the pituitary, salivary glands, heart, choroid plexus, and adrenal glands. Notably, the spleen exhibited a significant increase in both SUVmax (p=0.024) and SUVmean (p=0.019) after ICI, suggesting a rise in activated T cell populations. ***Conclusion:*** This pilot study demonstrated dynamic organ-wise changes in ^{18}F-AraG PET/CT uptake among Japanese cancer patients undergoing ICI therapy. The observed increase in splenic uptake may reflect systemic immune activation, highlighting the potential of ^{18}F-AraG PET as a biomarker for early immune response monitoring. ***References:*** 1. N Engl J Med. 2019;381:2020-31.2. Cancer Res. 2017;77:2893-902.3. Cancer Res. 2019;79:3455-65.

EP-0541

Use of ^{18}F-FDG PET/MR as an initial staging procedure for malignant tumors

Y. Xu*;*
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: This study aimed to evaluate the clinical utility and cost-effectiveness of PET/MR compared to PET/CT and conventional work-up (CWU) for initial staging of malignant tumors. ***Materials and Methods:*** From January 2018 to December 2023, 5850 patients with histologically confirmed malignancies were enrolled. Among them, 1250 patients underwent PET/MR prior to treatment, 1780 underwent PET/CT, and the remaining 2820 received CWU. Costs were calculated based on 2022 pricing guidelines from the National Health Insurance Agency of China. All patients were followed for ≥1 year, with final clinical staging as the reference standard. Incremental cost-effectiveness ratio (ICER) was used to assess the cost per percentage reduction in missed or misdiagnosed cases. ***Results:*** Missed/misdiagnosis rates were

5.2% for PET/MR, 10.8% for PET/CT, and 22.6% for CWU (p<0.001). The mean interval from diagnosis to treatment initiation was 5.3 days (PET/MR), 9.7 days (PET/CT), and 15.4 days (CWU) (p<0.001). Mean per-patient costs were $1620 (PET/MR), $890 (PET/CT), and $520 (CWU). Compared to CWU, ICER values for PET/MR and PET/CT were $62 and $28 per percentage reduction in misdiagnosis, respectively. The ICER between PET/MR and PET/CT was $173. ***Conclusion:*** PET/MR demonstrated superior diagnostic accuracy and expedited treatment initiation compared to PET/CT and CWU in malignancies. Additionally, PET/MR significantly reduced radiation exposure, a critical consideration for long-term cancer survivors. Despite higher upfront costs, PET/MR may offer cost-effectiveness in initial staging by minimizing diagnostic errors and optimizing therapeutic planning.

EP-0542

Evaluation of metastatic clear cell renal cell carcinoma: a head-to-head comparison of [^{18}F]PSMA-1007 PET/CT and standard-of-care CT

D. Khodakova, *A. Khalimon, V. Bobrov, A. Lokhova, G. Khamadeeva, M. Khodzhibekova, T. Lazutina, I. Pylova, A. Nikiforuk, A. Leontev;*
P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: The aim of this study was to perform a head-to-head comparison of [^{18}F]PSMA-1007 PET/CT and standard-of-care chest, abdominal, and pelvic CT for the evaluation of metastatic disease in clear cell renal cell carcinoma (ccRCC). ***Materials and Methods:*** This prospective, single-center study involved 20 patients with histologically verified ccRCC during primary staging, recurrence evaluation, and treatment response assessment. All patients underwent [^{18}F]PSMA-1007 PET/CT, which included non-contrast CT (NCCT) and dual-phase contrast-enhanced CT (CECT) from vertex to mid-thigh. Metastatic lesions were evaluated independently using PET/CT, NCCT, and CECT. Focal tracer uptake, as well as CT findings by NCCT part of PET/CT, that were typical for metastatic disease, were considered PET/CT-positive. The diameters of the lesions were assessed on CECT. ***Results:*** A total of 149 lesions were evaluated. The majority of lesions (n=147;98,7%;20,4mm [95%CI16,8;24,0]) were detected by CECT, while 133 (89,3%;20,7mm [95%CI16,8;24,6]) and 112 (75,2%;22,5mm [95%CI18,0;27,0]) lesions were identified by PET/CT and NCCT, respectively. 131 lesions (87,9%) were detected by both PET/CT and CECT, 16 lesions (10,7%;18,2mm [95%CI11,4;25,0]) - only by CECT, 2 lesions (1,3%) - only by PET/CT. Of the 16 lesions detected solely by CECT, 6 were located in the kidneys, 7 in the liver, 2 in the pancreas and 1 in the adrenal gland. The diameters of the two PET/CT-negative lesions in the pancreas were 4mm and 5mm. The PET/CT-negative liver lesions had diameters ranging from 7 to 26mm, while the diameters of PET/CT-positive liver lesions ranged from 26 to 161mm. The two lesions detected only by PET/CT were found in bones with no changes observed on CT. PET/CT identified 21 lesions that were not detected on NCCT: 2 in the brain, 8 in skeletal muscles, 3 in cardiac muscle, 4 in the pancreas, 2 in bones, 1 in the peritoneum, and 1 in subcutaneous adipose tissue. In two patients, PET/CT led to a change in treatment compared to NCCT. However, there were no changes in treatment when comparing PET/CT and CECT. ***Conclusion:*** The main causes of PET/CT false-negative results were small lesion size or high physiological [^{18}F]PSMA-1007 uptake nearby the evaluated lesions, which were associated with equivocal findings from NCCT as part of the PET/CT. There was no evidence that PSMA PET/CT provides additional value in evaluating metastatic disease compared to standard multiphase CECT in patients with ccRCC; however, it could serve as an alternative imaging modality when there are contraindications to CECT and MRI.

EP-0543

Head to Head Comparison of F18 FDG with GA68 FAPI 2286 in Staging and Restaging Evaluation in Various Solid Malignancies

J. Bal[1], *S. Jha*[2], *P. Dougall*[2], *K. Shanker*[2], *V. Semwal*[2];
[1]*Max Super Specialty Hospital, Delhi, INDIA,* [2]*Max superspeciality hospital, Delhi, INDIA.*

Aim/Introduction: Our study aims to compare the application of Gallium-68-fibroblast activation protein inhibitor (^{68}Ga-FAPI-2286) positron emission tomography/computed tomography (PET/CT) and Fluorine-18-fluorodeoxyglucose (^{18}F-FDG) PET/CT in primary and metastatic lesions of various solid malignancies to determine the superior diagnostic tool. In the past 30 years, ^{18}F-FDG tracers, which take advantage of the tumours' aberrant glucose metabolism, have become increasingly available and are now the most widely used PET imaging tool. 18F-FDG-PET is frequently used to diagnose malignancies, evaluate the effectiveness of tumour treatment, and predict prognosis. However, recent research has revealed that FDG tracers have limitations in the diagnosis of various gastrointestinal cancers and are unable to differentiate between inflammation and malignancy. Recent studies have also uncovered a correlation between increased fibroblast activation protein (FAP) levels in cancer-associated fibroblasts and tumour growth, metastasis, and prognosis. Fibroblast activation protein inhibitor (FAPI) has therefore emerged as a new cancer imaging molecule. ***Materials and Methods:*** 58 patients (mean age 56 ± 10 SD) with various solid malignancies underwent both gallium-68-fibroblast activation protein inhibitor (^{68}Ga-FAPI-2286) positron emission tomography/computed tomography (PET/CT) and fluorine-18-fluorodeoxyglucose (^{18}F-FDG) PET/CT for staging and restaging evaluation from November 2023 to August 2024. Histopathologic examination, morphologic imaging, and/or follow-up imaging served as the reference standard. The maximum standardized uptake value (SUVmax) of the primary tumor and nodal and distant metastases between ^{18}F-FDG and 68Ga-FAPI PET/ CT were compared using the paired-sample t test. ***Results:*** The sensitivity of [68Ga]FAPI PET/CT was higher than that of [^{18}F] FDG PET/CT for detecting primary tumors (36/36-100% vs. 81%), nodal (35/36-98% vs. 87%), and distant metastases (34/36-98% vs. 79%) in our subset of cases. SUVmax values of primary lesions and metastases ranged from 0- 9.8 in ^{18}F-FDG PET/CT and from 3.9 to 17.0 in ^{68}Ga-FAPI-2286. ***Conclusion:*** Our results showed that gallium 68-labelled fibroblast-activation protein inhibitor (68Ga-FAPI) PET/CT was superior to fluorine 18 fluorodeoxyglucose (18F-FDG) PET/CT for detecting the primary tumor and nodal and distant metastases in participants with biliary tract cancer (BTC). 68Ga-FAPI PET/CT findings led to an upstaging or changing the management in the staging or restaging in 17 participants compared with ^{18}F-FDG PET/CT. However, PET/ CT results were derived from studies with small sample sizes. Therefore, our observations need to be validated by a more extensive and comprehensive prospective study.

EP-0544

Head to head comparison of [^{68}Ga] FAPI PET/CT and [^{18}F] FDG PET/CT in Urothelial carcinoma : A prospective study

H. Ng, *A. Arya, M. Ora, S. Gambhir;*
Sanjay Gandhi Postgraduate Institue of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: Bladder carcinoma is the most prevalent malignancy of the urinary tract, with urothelial carcinoma accounting for over 90% of cases. Precise imaging is especially important in muscle-invasive bladder cancer (MIBC) to guide staging and treatment decisions. While [18F]-fluorodeoxyglucose positron emission tomography/computed tomography ([18F]-FDG PET/CT) is a widely accepted oncological imaging tool, its use in bladder cancer is limited due to urinary excretion of FDG,

which can obscure lesions within the urinary tract. Fibroblast activation protein inhibitor (FAPI) PET/CT has recently emerged as a promising alternative. By targeting FAP-expressing tumor-associated fibroblasts and being independent of glucose metabolism, [68Ga]-FAPI PET/CT achieves low background uptake, improving lesion contrast and potentially increasing diagnostic accuracy. Previous studies have demonstrated improved lesion detection and tumor-to-background ratios with [68Ga]-FAPI compared to FDG PET/CT in bladder cancer patients. This study aimed to assess the diagnostic performance of [68Ga]-FAPI PET/CT in bladder cancer and compare its ability to detect lesions with that of [18F]-FDG PET/CT. ***Materials and Methods:*** In this single-center prospective study, 25 patients with histologically confirmed urothelial carcinoma of the bladder were enrolled. All patients were initially referred for [18F]-FDG PET/CT for purposes of staging, restaging, or treatment response evaluation. Each patient then underwent a [68Ga]-FAPI PET/CT scan within 7 days, with no intervening therapy. Lesion detectability was compared between the two modalities across primary tumors, lymph nodes, lung nodules, and bone lesions using SUVmax values and total number of lesions. Exclusion criteria included secondary malignancies, concurrent prostate cancer, pregnancy, or lack of consent. ***Results:*** [18F]-FDG PET/CT demonstrated significantly higher SUVmax values in primary tumors (10.07 ± 7.49 vs. 7.68 ± 7.32; p = 0.007) and lymph nodes (5.00 ± 5.02 vs. 3.30 ± 3.94; p = 0.031) when compared to [68Ga]-FAPI PET/CT. However, no statistically significant differences were found in detection of lung nodules (p = 0.180), bone lesions (p = 0.655), or overall lesion counts (2.12 ± 1.30 vs. 1.92 ± 1.29; p = 0.170). ***Conclusion:*** Although [18F]-FDG PET/CT remains more sensitive for detecting primary and nodal lesions, [68Ga]-FAPI PET/CT offers comparable performance in identifying lung and bone metastases. With its low background activity, FAPI PET/CT presents as a promising complementary imaging technique in urothelial carcinoma. Further research with larger patient cohorts is warranted to validate these findings.

EP-0545

^{18}F-FDG PET/CT in Suspected Paraneoplastic Syndromes: Clinical and Imaging Correlation

A. Mestre Fusco*, S. Abouzian, D. A. López-Mora, L. Lozano-Murgas, J. C. Martín-Miramón, A. A. Rodríguez-Revuelto;*
Parc Taulí Hospital Universitari, Sabadell, SPAIN.

Aim/Introduction: ^{18}F-FDG PET/CT employed in patients with paraneoplastic syndrome, which often presents with toxic syndrome and a range of neurological, dermatological, endocrine, or hematological symptoms, remains challenging. This study aims to determine the prevalence of ^{18}F-FDG PET/CT findings in this patient population and evaluate the sensitivity and the specificity. Additionally, it seeks to analyze the relationship between ^{18}F-FDG PET/CT findings and tumor markers, acute-phase reactants, and findings from prior conventional imaging. ***Materials and Methods:*** Fifty-two patients (27 women, 25 men; mean age: 64 y/o; range: 39-89) with toxic syndrome (n=26) or other paraneoplastic symptoms (n=21) were prospectively included in the study from October 7, 2024, to April 4, 2025. All patients underwent ^{18}F-FDG PET/CT. Prior laboratory tests (acute-phase reactants, tumor markers, specific antibodies [anti-GAD, anti-HLA, ANA, ANCA, p155, anti-CV2, RS3-PE, anti-RF, anti-TPO, MD5, RO52, antineuronal]), conventional imaging (CT, MRI, ultrasound, or scintigraphy), and pathological findings were analyzed. ***Results:*** Toxic syndrome was present in 50% of patients (n=26), with or without additional symptoms, while the remaining 50% (n=26) presented exclusively with neurological, dermatological, endocrine, or hematological symptoms (e.g., dermatomyositis, sclerodermiform lesions, purpura, polymyalgia, encephalitis, sclerosis, pericarditis, pleural effusion, hemoptysis, myelitis, stiff-person syndrome, panhypopituitarism, vasculitis). Conventional imaging was performed in 71% of cases (n=37), all with negative findings, while it was not performed in 29% (n=15). Positive autoantibodies were detected in 39% (n=20), elevated acute-phase reactants in 35% (n=18), and tumor markers in 19% (n=10). ^{18}F-FDG PET/CT identified a primary tumor in 9 out of 52 patients (17%), with negative findings in 43. In 44% of patients (4 out of 9) with tumor markers the ^{18}F-FDG PET/CT demonstrated cancer. Biopsy confirmed malignancy in all PET-positive cases (lung, pleura, prostate, urinary tract, lymphoma, myeloma, colon, seminoma). One false-negative ^{18}F-FDG PET/CT case (gastric linitis plastica) was identified. These findings correspond to a 90% sensitivity and 100% specificity for ^{18}F-FDG PET/CT. No differences were found between ^{18}F-FDG PET/CT results and prior imaging or acute-phase reactants, tumor markers and antibodies. ***Conclusion:*** The prevalence of ^{18}F-FDG PET/CT positivity in patients with paraneoplastic syndrome was 17%, consistent with existing literature, with high sensitivity and specificity. Although positive autoantibodies, elevated acute-phase reactants, and tumor markers were frequently observed, no correlation was found between these biomarkers and ^{18}F-FDG PET/CT findings. These results underline the diagnostic value of ^{18}F-FDG PET/CT in selected cases, but its definitive role in the diagnostic algorithm for paraneoplastic syndromes remains to be clearly defined.

EP-0546

Prospective Evaluation of ^{68}Ga-Trivehexin in Solid Tumors: A Pan-Cancer Study in Comparison with ^{18}F-FDG PET/CT

L. Li*, H. Wu, Z. Liu, C. Li, Y. He;*
Department of Nuclear medicine, Zhongnan Hospital, Wuhan University, Wuhan, CHINA.

Aim/Introduction: Integrin αvβ6, a biomarker overexpressed in aggressive epithelial malignancies but absent in healthy tissues, drives metastasis and correlates with poor prognosis. While ^{18}F-FDG PET/CT faces specificity challenges, the αvβ6-targeted tracer ^{68}Ga-Trivehexin demonstrates superior tumour-to-background contrast in pilot studies. This study aimed to: (1) compare the diagnostic performance of the αvβ6-targeted tracer ^{68}Ga-Trivehexin with ^{18}F-FDG PET/CT across solid tumors, and (2) explore the correlation between ^{68}Ga-Trivehexin uptake and αvβ6 expression. ***Materials and Methods:*** In this single-center trial, 61 treatment-naïve patients with suspected/confirmed solid tumors underwent sequential ^{68}Ga-Trivehexin and ^{18}F-FDG PET/CT within 72 hours. Final diagnoses were confirmed by histopathology or ≥6-month follow-up. Quantitative parameters (SUVmax, SUVpeak, SUVmean) and tumor-to-background ratios (T/L, T/B) were compared using paired t-tests. αvβ6 expression was assessed via immunohistochemistry (IHC) in 26 surgical specimens. The study protocol was approved by the institutional ethics committee. ***Results:*** In a cohort of 61 patients with diverse solid tumors (14 anatomical sites, 19 subtypes), ^{68}Ga-Trivehexin demonstrated comparable overall lesion detection to ^{18}F-FDG (94.7% vs. 96.1%, p=0.68), with a trend toward improved primary tumor identification (69 vs. 64 lesions). Notably, ^{68}Ga-Trivehexin exhibited significantly higher tumor-to-background contrast, reflected in elevated tumor-to-liver ratios (7.3 ± 2.1 vs. 2.4 ± 0.9, p<0.001), particularly in αvβ6-rich pancreatic carcinomas (SUVmax: 9.4 ± 2.1 vs. 5.8 ± 1.7, p<0.001). Despite lower SUVmax in metastatic lesions (4.2 ± 1.1 vs. 7.5 ± 2.3, p<0.001), ^{68}Ga-Trivehexin maintained diagnostic utility through higher tumor-to-liver ratios (5.9 ± 1.7 vs. 2.6 ± 0.9, p<0.001). Crucially, ^{68}Ga-Trivehexin outperformed ^{18}F-FDG in specificity (92% vs. 68%, p<0.001), correctly reclassifying 78% (32/41) of inflammatory lesions misdiagnosed by ^{18}F-FDG. Additionally, A trend toward correlation was observed between αvβ6 expression in primary tumor lesions and both SUVmax and SUVpeak derived from ^{68}Ga-Trivehexin (r = 0.466 and 0.441, respectively, all p < 0.05). ***Conclusion:*** ^{68}Ga-Trivehexin PET/CT provides αvβ6-targeted imaging with enhanced tumor specificity

and inflammation discrimination compared to ^{18}F-FDG. Its high contrast across diverse malignancies supports potential applications in precision staging and therapy guidance.

EP-0547

Serum vascular endothelial growth factor helps identify patients with clear cell renal cell carcinoma who benefit more from [68Ga]Ga-PSMA PET/CT

M. Zhang;
Xijing Hospital, the Fourth Military Medical University, Xi'an, CHINA.

Aim/Introduction: To validate the application of serum vascular endothelial growth factor (VEGF) in the selection and prognosis of patients with clear cell renal cell carcinoma (ccRCC) using 68Ga-PSMA. ***Materials and Methods:*** The analysis encompassed radiological parameters and angiogenesis indicators. The correlation of VEGF and PSMA was evaluated, and the efficacy of VEGF in selecting high PSMA uptake lesions of ccRCC. ***Results:*** 44 patients with ccRCC who had serum VEGF levels assessed prior to [68Ga]Ga-PSMA PET/CT and surgery were included in this study. Serum VEGF was 86.7 ± 34.4 pg/mL, mean SUVmax was 15.3 ± 8.97, TBR (tumor to liver) was 3.25 ± 1.89, VR was 0.32 ± 0.28, median PSMA ICH staining was 2, and median visual score was 2. VEGF was significant different in low (0-1) and high group (2-3) (P=0.029). VEGF was a good predictor of PSMA PET visual score with AUC value of 0.707 (P=0.043), and stratified by the critical value of VEGF, 67.71 pg/mL, the sensitivity and specificity for predicting PSMA visual scores (0-1 vs. 2-3), were 85% and 78%. Patients had high pre-operation VEGF might show high PSMA uptake. 19 patients measured VEGF post-operation and the median of follow-up was 81 days. All patients imaging examination and clinical signs were normal during follow-up time, VEGF of 9 patients increased. Compared the pre-operative PSMA uptake characteristics between VEGF increased and decreased group, SUVmax was no statistically difference (P=0.464), the VR showed significantly difference (P=0.049), patients with increased VEGF had lower VR. ROC curve analysis found that using VR to predict postoperative VEGF changes, with AUC value of 0.750 (P=0.143), the sensitivity and specificity were 50% and 100%. Patients with preoperative VR≤0.42 were likely to have increased VEGF postoperative. VEGF was associated with patient prognosis, and results suggested that patients with low VR (high intra-tumor heterogeneity) may have poor prognosis. ***Conclusion:*** Serum VEGF was indicative of [68Ga] Ga-PSMA PET/CT uptake characteristics for ccRCC. Pre-operative serum VEGF levels have the potential to serve as a screening tool to identify patients who are more likely to benefit from PSMA imaging, and VR demonstrated potential as a prognostic predictor for tumor risk.

EP-0548

The Impact of a Short-Time Fasting on Gastrointestinal Uptake in ^{99m}Tc-FAPI-46 Scintigraphy: Mitigating Interpretation Pitfalls

N. Raeisi, *A. Saber Tanha, K. Aryana;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This study aims to evaluate the effect of a short fasting period on gastrointestinal tract uptake in patients undergoing ^{99m}Tc-FAPI-46 scintigraphy. ***Materials and Methods:*** In this study, 40 patients who underwent ^{99m}Tc-FAPI-46 scintigraphy were included. The cohort comprised individuals with various cancers, including papillary and medullary thyroid cancer, gastric, colon, breast, nasopharyngeal, bladder, rectal, ovarian and renal cancers, paratesticular rhabdomyosarcoma, cholangiocarcinoma, fibrosarcoma, glioblastoma multiforme, and cancers of unknown primary origin. Whole-body scans were acquired one hour post-injection. Patients were categorized into four subgroups based on fasting status: two main groups—one with fasting and one without—each further divided into subgroups based on the presence or absence of gastrointestinal uptake. ***Results:*** All patients exhibited gallbladder uptake, consistent with normal physiological patterns, except for six individuals with a history of cholecystectomy. In the fasting group, 18 out of 22 patients (82%) demonstrated no or minimal non-tumoral bowel uptake, while in the non-fasting group, only one out of 18 patients (6%) showed similar findings. The uptake patterns in both groups were generally non-focal. Notably, in one patient from the fasting group with no gastrointestinal uptake, a focal uptake in the anterior abdominal wall raised suspicion for bowel uptake or peritoneal deposit. Delayed imaging confirmed the diagnosis of peritoneal deposit, highlighting the importance of the absent bowel uptake in more accurate diagnosis in this case. ***Conclusion:*** Our findings support the recommendation of a short fasting period of approximately 4-6 hours prior to ^{99m}Tc-FAPI-46 scintigraphy, as it significantly reduces radiotracer accumulation in the bowel. This reduction aids in minimizing interpretation challenges, particularly in cases where the cancer's origin may be in abdominal region or when the investigation aims to assess the presence or extent of peritoneal involvement.

Combination of Targeted Axillary Dissection (TAD) and Selective Sentinel Lymph Node Biopsy (SSNGB) in patients with metastatic axillary involvement prior to systemic treatment

M. García Aragón, *A. Suazo Montero, B. Jaramillo López, F. Sebastian Palacid, M. González Soto, M. Alonso Rodríguez, M. Moral Cano, P. Suarez Mansilla, R. Ruano Pérez;*
Hospital Universitario Clínico Valladolid, Valladolid, SPAIN.

Aim/Introduction: To evaluate the combination of 125I seed labeling in pathological lymph nodes prior to neoadjuvant chemotherapy (NAC) with selective sentinel lymph node biopsy (SLNB) in patients eligible for conservative surgery. The objective is to determine the efficacy of these procedures in assessing axillary involvement, their impact on surgical planning, and subsequent therapeutic strategy. ***Materials and Methods:*** Prospective study of 78 patients diagnosed with advanced breast cancer undergoing treatment with NACT, who responded and were candidates for radioguided surgery using 125I seeds. Of these, 45 (mean age 57.65 +/- 10.53 years) had axillary involvement prior to treatment. Two to three days prior to surgery, previously pathological lymph nodes (coil-labeled) that responded were labeled with 125I seeds, and in selected cases, a SLNB was completed.The concordance between the SLN and the 125I seed labeling, the histological type, and the radiological response after NACT were assessed. ***Results:*** 84.4% (38/45) of the patients did not express the HER2 protein; all but two of these were infiltrating ductal, and of these, 22 were luminal B.In 46.7% (21/45) of the patients, only the axilla was marked, and in the remaining 53.3% (24/45), the breast lesion was also marked for conservative surgery.The radiological response was complete in 71.1% (32/45), major partial in 24.4% (11/45), minor partial in 2/45, and no response in the remaining case.In 53.3% (24/45), there was concordance between the SLN and marked adenopathy.The final pathology was negative in 57.8% (26/45) of the lymph nodes, while lymphadenectomy was performed in 19/45. ***Conclusion:*** The results suggest that the

combination of both techniques (DAD and SLNB) is effective in patients with metastatic lymph node involvement prior to NAT before surgery. This strategy helps improve the accuracy of lymph node status and optimize the surgical approach, minimizing the need for extensive lymph node dissection.

EP-0550

Relevance of SPECT/CT in the combined technique of lymphoscintigraphy and axillary labeling with 125-I seeds in breast cancer with axillary response after neoadjuvant chemotherapy

M. García Aragón, *B. Jaramillo López, A. Suazo Montero, C. Gamazo Laherran, F. Sebastian Palacid, M. González Soto, S. Cortes Pérez, M. Moral Cano, R. Ruano Pérez;*
Hospital Universitario Clínico Valladolid, Valladolid, SPAIN.

Aim/Introduction: To evaluate the usefulness of SPECT/CT in the presurgical localization of the sentinel lymph node (SLN), in combination with axillary labeling with 125-I seeds, in patients with pathological lymphadenopathy who have responded to neoadjuvant chemotherapy (NACT). ***Materials and Methods:*** Prospective study of 38 patients with breast cancer with axillary response after NACT. 125-I labeling of the biopsied lymphadenopathy was performed 2-3 days before surgery. Lymphoscintigraphy was performed the day before, acquiring planar images and SPECT/CT. Axillary nodes that uptake 99mTc-nanocolloid were identified, and their concordance with nodes with 125-I seed was evaluated. A gamma detector probe was used in the operating room, selecting the peak of both isotopes. ***Results:*** Drainage was observed in at least 1 SLN in 25/35 (71.43%) cases (50% had >3 nodes). In the 7 cases without drainage despite reinjection, the 125-I-labeled node was removed. Metastasis was present in 5/7 cases, and lymphadenectomy was performed (positive in 4/5).SPECT-CT showed concordance between the SLN and the 125-I-labeled node in 60.7% (17/28).At least 3 nodes were removed in the operating room: the seed-labeled node and 2 or 3 with activity (99mTc+).In 64.3% (18/28), the result was negative for metastasis in the removed nodes, and lymphadenectomy was not performed. Lymphadenectomy was performed in 35.7% (10/28), and was positive in other lymph nodes (7 cases). There was concordance (125I and 99mTc positive) in 5/12; only the 125I-labeled lymph node was metastatic in 6/12; only the 99mTc-labeled lymph node was metastatic in 5/12 cases.The 125I seed was recovered in all cases. ***Conclusion:*** SPECT/CT allows assessment of the concordance of the sentinel lymph node imaged with seed-labeled lymph nodes, facilitating preoperative planning. The combination of both techniques is the best strategy for staging advanced breast cancer after NACT treatment.

EP-0551

Implementation and Outcomes of the ROLL Technique in Radioguided Surgery

Y. Delisau[1], *M. Velasco-Nuño*[1], *S. Alfonso*[2], *A. Giménez*[2], *I. Pérez*[3], *I. Casado*[3], *J. Duch*[1], *M. Calls-Calahorro*[1], *P. Stefaneli*[1], *B. Serrallonga*[1], *D. Selva*[2], *G. Guzmán*[1], *V. Camacho*[1], *A. Flotats*[1];
[1]*Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [2]*Radiology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN,* [3]*General Surgery Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

Aim/Introduction: To analyse our experience with the ROLL (Radioguided Occult Lesion Localization) technique for the surgical localization of lesions. ***Materials and Methods:*** This retrospective study included 67 patients (35 women and 32 men; mean age: 62.6 years) who were candidates for radioguided surgery using the ROLL technique for the localisation of pulmonary and extrapulmonary lesions (including lymph node lesions, suspected tumour recurrences, and parathyroid adenomas). Radiotracer placement was performed by injecting [99m]Tc-albumin macroaggregates (37-111 MBq) under ultrasound or computed tomography guidance. SPECT/CT imaging was used to confirm radiotracer localisation. A hand-held or laparoscopic gamma probe was used intraoperatively to detect the radioactive signal and guide lesion excision. The analysis included lesion size and accuracy of radiotracer placement (intralesional vs. perilesional). Procedural complications, intraoperative localisation success, and surgical complications were recorded. ***Results:*** The ROLL procedure was successfully completed in 65 patients. In 2 patients with pulmonary lesions, complete radiotracer placement was not possible due to procedural complications. A total of 67 lesions were marked: 35 pulmonary and 32 extrapulmonary (including 23 lymph node lesions, 6 suspected tumour recurrences, and 3 parathyroid adenomas). Two patients had two lesions each. All targeted lesions were successfully localised intraoperatively. The mean lesion size was 11.2 mm for pulmonary lesions and 15.1 mm for extrapulmonary lesions. Radiotracer placement was intralesional in 54 lesions (81% overall; 74% of pulmonary and 87% of extrapulmonary lesions) and perilesional in 13 lesions (19% overall; 26% of pulmonary and 13% of extrapulmonary lesions). In the pulmonary lesion subgroup, 5 patients experienced significant procedural complications (pneumothorax), preventing completion of the procedure in 2 of them. No significant procedural complications were observed in 12 patients (10 with minimal asymptomatic pneumothorax and 2 with pleural contamination by the radiotracer). No intraoperative complications were reported. In the extrapulmonary lesion subgroup, no significant procedural complications were observed. One intraoperative complication (carotid artery injury) was reported. ***Conclusion:*** The ROLL technique has been successfully implemented in our institution as a reliable method for preoperative lesion marking and surgical localisation. It has demonstrated a high rate of accurate intralesional placement and intraoperative identification, with a low rate of complications.

EP-0552

Radioguided Localization of Non-palpable Breast Lesions Using I-125 Radioactive Seeds: Initial 5 Months Experience

P. Paez Vargas, *R. Salvador-Arthur, G. Martinez-Arias, M. Parra-Rina, A. L. Tardin-Cardoso, D. Nogueira-Souto, P. Razola-Alba, M. M. Delgado-Castro, L. Cáncer-Garza, T. Escalera-Temprado, A. Andres-Gracia;*
Hospital Clinico Universitario Lozano Blesa, Zaragoza, SPAIN.

Aim/Introduction: Radioguided localization of non-palpable breast lesions with I-125 seeds has emerged as a novel alternative to other techniques, such as hookwire localization.I-125 seed use has demonstrated clear advantages, such as patient comfort, better surgical planning, improved cosmetic outcomes, and lower rates of positive margins and re-excision. The aim of this study was to assess the usefulness of I-125 seeds in the radioguided localization of non-palpable breast lesions, taking into account the rate of margin positivity and re-excision. ***Materials and Methods:*** Descriptive analysis of patients with non-palpable breast lesions who underwent preoperative marking with I-125 seed under ultrasonographic guidance over a 5-month period. These patients underwent lumpectomy guided by gamma probe detection of the I-125 seed. The presence of the seed was verified through specimen radiography in order to assess the need for margin widening during the same surgical procedure. The utility of the technique was evaluated by calculating the rate of margin positivity through histopathology and the rate of surgical reinterventions. These results were compared with those published in the literature. ***Results:*** 49 patients were analyzed, median age of 61 years (44-83 years). A total of 60 I-125 seeds were implanted: 58 in non-palpable lesions in patients with a previous diagnosis of breast cancer (96.67%), 1 in a phyllodes tumor (1.67%) and 1 in a lesion with atypical ductal hyperplasia (1.67%). After

radioguided lumpectomy and pathological analysis of the surgical specimens, 77.55% of the samples had clear margins, whereas 22.45% had involved margins. In this last group of patients, 3 (27.27%) underwent a second surgical procedure, and margin enlargement was perfomed in 8 (72.73%) patients during the same surgical procedure These results are similar to those reported in previous studies, where the rate of involved margins was 5.5% for I-125 seeds vs 7.8%in the case of wire guidance, and the rate of reinterventions was 13.9% vs 18.9%, respectively.(1). ***Conclusion:*** Our preliminary results support the feasibility and potential benefits of I-125 seed localization in reducing the incidence of involved margins and reoperations in patients with non-palpable breast lesions. Further studies with larger cohorts and direct comparisons with conventional techniques are necessary to validate these findings. ***References:*** 1. Intraoperative Radiolabelling of Pulmonary Nodules Using Electromagnetic Navigation Bronchoscopy

L. León Ramírez[1], *C. González Roiz*[2], *M. zapardiel*[1], *E. Fernández*[1], *C. Fraile*[1], *A. Berardinelli*[1], *P. Dauden*[1], *G. Cuesta*[1], *M. Vaillant*[1], *M. Cabrera Martin*[1], *S. Vidal-Sicart*[3];
[1]*Hospital Clínico San Carlos, Madrid, SPAIN,* [2]*Hospital Puerta del Sur, Madrid, SPAIN,* [3]*Hospital Clínic de Barcelona, Barcelona, SPAIN.*

Aim/Introduction: The diagnostic and therapeutic management of peripheral pulmonary nodules remains a clinical challenge, particularly in cases involving small, non-palpable lesions in anatomically complex regions. Electromagnetic navigation bronchoscopy (ENB) allows access to peripheral areas of the lung that are beyond the reach of conventional bronchoscopy. ROLL, a technique widely validated in breast oncology, has been successfully adapted for pulmonary applications. This study describes the technical application of radioguided localisation usingENB to facilitate minimally invasive resection of pulmonary nodules. ***Materials and Methods:*** A prospective, observational, single-centre study was conducted between 2022 and 2025. A total of 36 patients, older than 18 years, who required minimally invasive pulmonary resection with radioguided localisation were included. The marking procedure was performed intraoperatively under general anaesthesia using bronchoscopy and electromagnetic navigation. A dose of 37-185 MBq of 99mTc-MAA was administered. Resection was performed via VATS or thoracotomy, with intraoperative localisation guided by gamma probe and portable gamma camera. ***Results:*** The mean age of patients was 64.3 years (range: 21-86). Male gender represented 76% of the cohort.The mean size of the nodules was 23.6 mm (range 5 -25mm). A 100% intraoperative localisation rate was succesfull in all cases. No procedure-related complications were observed. ***Conclusion:*** Intraoperative radiolabelling with ENB is a safe and effective technique for localising challenging pulmonary nodules. It enables appropriate resection margins, reduces complications, and enhances surgical efficiency. This approach is proposed as a viable alternative to percutaneous techniques in selected patients. ***References:*** Ho ATN, et al. Pulmón. 2023;201(1):85-93.Krochmal R, et al. EP-0554

HPA Axis Activation Evaluated by ^{18}F-FDG PETCT in Lung Cancer: From Clinical Discovery to Preclinical Validation

M. Liang[1,2], *C. Cui*[1], *X. Li*[1], *J. Guo*[3], *C. Yan*[3,2], *Z. Wu*[3,2];
[1]*Shanxi Medical University, Taiyuan, CHINA,* [2]*Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA,* [3]*Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

Aim/Introduction: This study aimed to evaluate hypothalamic-pituitary-adrenal (HPA) axis activity in lung cancer patients using ^{18}F-FDG PET/CT and access the potential of HPA axis as a therapeutic target. ***Materials and Methods:*** Clinical data and ^{18}F-FDG PET/CT from 151 lung cancer patients and 94 healthy controls were retrospectively analyzed. Metabolic activity in HPA-associated organs (brain, pituitary, adrenal glands, thyroid, gonads, muscle, and fat) was compared. Spearman's correlation and Kaplan-Meier analyses assessed HPA axis impact on prognosis. To further verify the effect of HPA activity on lung cancer, an A549 lung cancer mouse model was established and treated with chemotherapy, propranolol and combination therapy. Tumor size, glucose metabolism, and motor function were evaluated. ***Results:*** Lung cancer patients exhibited higher SUVmax, SUVmean, and MTV in adrenal glands, gonads, muscle, fat, and pituitary compared to controls ($P<0.05$). Hypermetabolism in subthalamic nuclei, thalamus, and amygdala, and hypometabolism in frontal gyri and insula were observed. SUVmean of bilateral adrenal glands independent risk factor for lung cancer prognosis. In mice, combination therapy showed improved body weight, motor function, and decreased glucose metabolism compared to chemotherapy alone ($P<0.05$). ***Conclusion:*** ^{18}F-FDG PET/CT imaging revealed increased metabolic activity in HPA axis-related organs among lung cancer patients, particularly in the adrenal glands and may worsen prognosis. Preclinical models demonstrated improvement in overall survival using combination of β-blockers with chemotherapy in tumor-bearing models which highlight the potential of HPA axis as a therapy target in lung cancer. ***References:*** 1. 125I seeds implantation in malignant-suspected ^{18}F-FDG PET/CT lymph nodes. Histopathological correlation.

E. Domínguez Polanco, *J. Villa-Palacios, A. Piñeiro Donis, L. Cagua Ruiz, E. Triviño-Ibáñez, A. Salmerón Ruiz, N. Muñoz Pérez, C. Ramos-Font;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To evaluate the malignant predictive value of ^{18}F-FDG PET/CT in patients with suspected malignant lesions and their labelling with 125I seeds towards radioguided surgery. ***Materials and Methods:*** Observational, prospective, and analytical study that included a cohort of patients with suspicious lesions, referred to the Nuclear Medicine department for ^{18}F-FDG PET/CT and subsequent labelling with 125I seeds. Data from both procedures and their histopathological correlation

after surgery were collected. Finally, we analyzed the malignant predictive value of the metabolic rate quantitative parameters through binary logistic regression analysis. ***Results:*** A total of 41 patients were included (mean age: 52.56±16.83 years, 51.2% women). They had a history of previous neoplastic pathology in 17/41 (41.5%) cases. Except for two cases, these were suspected malignant lymphadenopathies. The most frequent site was latero-basocervical 21/41 (51.2%), followed by axillary 11/41 (26.8%) and inguinal location 7/41 (17.1%). The 125I seed was placed inside the lymph node in 36/41 (87.8%) of the cases. The pathological result was malignant in 10/41 cases (24.4%). 87.8% (36/41) of the cases had undergone a previous PET/CT, in which the lymph node was identified with a mean SULpeak of 2.90±1.87. The only factor associated with malignancy in the lymph node pathological result was the SULpeak (OR1.65, p= 0.028). No complications related to the surgical removal of the lymph node or the extraction of the 125I seed were recorded. ***Conclusion:*** Radioguided surgery with 125I seeds is a feasible and safe procedure that allows accurate diagnosis of suspected lesions and minimizes the risk of reinterventions. When selecting the lesion, the metabolic rate quantified in the ^{18}F-FDG PET/CT constitutes the only factor associated with the probability of malignancy.

EP-0556

Safety and Diagnostic Yield of ^{18}F-FDG PET/CT-Guided Biopsy in Solitary Pulmonary Nodule

D. Saraswat, *P. Malik, R. Kumar, B. R. Mittal;*
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: A solitary pulmonary nodule (SPN) is a single, well-defined pulmonary opacity with a diameter of <3 cm surrounded by normal lung tissue that is not associated with atelectasis or adenopathy. Positron-emission tomography-computed tomography (PET/CT) primarily used for solid nodules ≥8 mm, assesses metabolic activity, aiding accurate targeting and reducing diagnostic errors. PET/CT-guided biopsy improves sample quality and reduces repeat procedures. We report the first extensive experience with ^{18}F-FDG-PET/CT-guided biopsies of SPNs, achieving accurate histopathological diagnoses through precise metabolic targeting. ***Materials and Methods:*** In this single-centre retrospective study, data from 80 patients with SPN who underwent ^{18}F-FDG-PET/CT between 2018 and March 2025 was analysed. FDG avidity more than mediastinal blood pool was considered as PET-positive and less than that was defined as PET-negative. Fifty-six patients were PET-positive and subsequently underwent PET/CT-guided-biopsy. The remaining 24 patients were monitored according to the Fleischner Society guidelines. Procedure-related complications and histopathologic outcomes were documented to assess the safety and diagnostic yield of the biopsy approach. ***Results:*** A total of 56 participants (mean age 56.8 ± 13.3 years; 39 males and 17 females) underwent PET/CT-guided-biopsy. The mean lesion size was ~ 1.8 × 1.5 cm, with a mean SUVmax of 10.8 ± 6.7. Histopathological evaluation revealed primary lung malignancy in 29 patients (51.8%), metastatic lesions in 13 (23.2%), and infective aetiologies in 9 (15%). Three patients demonstrated no histological evidence of malignancy or infection, while single cases of sarcoidosis and hamartoma were also identified. Among the primary lung malignancies, adenocarcinoma was the most common histologic subtype (16/29; 55.1%), followed by squamous cell carcinoma (8/29, 27.5%), small cell carcinoma (2/29), adenosquamous carcinoma (1/29), neuroendocrine tumour (1/29), and angiosarcoma (1/29). Among patients with metastatic disease, the most frequent primary sites included the hypopharynx (2/13), tongue (2/13), anorectum (2/13), and cervix (2/13). Post-procedural complications were observed in 2 of 56 patients (3.6%), comprising mild pneumothorax in one and moderate pneumothorax in another. Both cases were managed conservatively without the need for intervention. ***Conclusion:*** This study highlights the clinical utility and diagnostic accuracy of ^{18}F-FDG-PET/CT-guided-biopsy in the evaluation of SPNs. By enabling precise metabolic targeting, this technique enhances histopathological yield, improves subtype classification, and reduces the need for repeat procedures. The low complication rate further supports its safety and feasibility. These findings underscore the value of incorporating PET/CT-guided biopsy into routine clinical practice, particularly for FDG-avid SPNs, where conventional image-guided techniques may be limited by lesion size and metabolic heterogeneity.

EP-0557

Characterisation of a Fluorescent Dye Library using a Dual-Labelled PSMA-617-based Tracer

P. Minges[1,2,3], *L.-C. Domogalla*[1,2], *B. Thomas*[4], *N. Steinacker*[1,2], *H. Müller*[4], *M. Sulewska*[1,2], *A. Dietzel-Schaarschmidt*[5], *P. Meyer*[1,2], *M. Eder*[1,2], *A.-C. Eder*[1,2];
[1]*University Medical Center Freiburg, Freiburg im Breisgau, GERMANY,* [2]*German Cancer Consortium (DKTK), Freiburg im Breisgau, GERMANY,* [3]*University of Freiburg, Freiburg im Breisgau, GERMANY,* [4]*XION GmbH, Berlin, GERMANY,* [5]*Henke-Sass, Wolf GmbH, Tuttlingen, GERMANY.*

Aim/Introduction: In the field of dual-labelled tracers and fluorescence-guided surgery (FGS), ICG and IRDye800CW have been established as the most commonly used dyes. However, fluorescent dyes have continued to evolve and more photostable dyes with higher quantum yields and diverse chemical characteristics are now available. In order to investigate the suitability of such new dyes for potential clinical application, a library of dyes was conjugated to a PSMA-617-based tracer (DP). By characterising these dual-labelled PSMA-617-based hybrid molecules, the aim was to identify a candidate with the most promising pharmacokinetic and optical properties to improve precise real-time feedback during surgery. ***Materials and Methods:*** A library of 20 different dyes was conjugated to a PSMA-617-based PSMA inhibitor. All compounds were subsequently radiolabelled with ^{68}Ga or ^{177}Lu and characterised for serum stability and solubility. Internalisation rates and binding kinetics in LNCaP^{PSMA+} cells were determined. In addition, the pharmacokinetic behaviour was assessed in BALB/c nu/nu mice bearing LNCaP^{PSMA+} xenografts by µPET/MRI at 1h and 2h after injection of 0.5 nmol (2.8 kDa - 3.2 kDa) of the ^{68}Ga-labelled hybrid molecules. Fluorescence was determined ex vivo as well as organ distribution 2 h p.i.. ***Results:*** The three most promising candidates showed serum stability above 95% after 48 h with logD values ranging between -2.5 and -1.8. Internalisation rates and binding affinities decreased by 4-7-fold after dye conjugation (from 2.2 %AA to 0.3-0.6 %AA and from K_i 13.2 nM to 50-80 nM, respectively). In vivo studies revealed different pharmacokinetic profiles depending on the conjugated dye. Two candidates showed rapid clearance 1 h p.i. with high tumour uptake 2 h p.i.: DP-09 (9.14 %ID/g tumour, 26.27 %ID/g kidney) and DP-15 (7.67 %ID/g tumour, 7.68 %ID/g kidney). In contrast, DP-24 showed a slower clearance at 1 h p.i., but three times higher tumour accumulation compared to the others (22.94 %ID/g tumour, 61.97 %ID/g kidney). Only negligible accumulation in background organs was observed. ***Conclusion:*** The three candidates identified were shown to have a promising pharmacokinetic profile after conjugation with the fluorescent dyes, making them suitable for further investigation. With improved photostability and higher quantum yields compared to ICG and IRDye800CW, the selected candidates may lead to an advantage in FGS.

EP-0558

Needle in the hotspot: Integrating SUVmax, Necrosis, and Technical Factors in PET-CT-Guided Biopsies

S. Shamim, *B. Jain, Y. Khandelwal, S. Rastogi, P. Baberwal, P. Naranje, A. S. Bhalla, N. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: PET-CT-guided biopsies have emerged as a pivotal tool in oncological diagnostics, offering real-time metabolic and anatomical guidance. This study aimed to evaluate the diagnostic yield, scan characteristics, and technical considerations associated with PET-CT-guided biopsies in a cohort of 68 patients with suspicious lesions. ***Materials and Methods:*** This retrospective analysis included 68 patients who underwent percutaneous PET-CT-guided biopsies with ^{18}F FDG from March 2023 to April 2025, carried out using robotic positioning sytem (MAXIO) and semiautomatic biopsy gun, 18G for soft tissue lesions and 11G for bony lesions. Parameters recorded included age, gender, lesion site, lesion size, Standardized Uptake Value (SUV), necrosis, depth from skin, access type (oblique/direct), complications, and final histopathological diagnosis. Descriptive statistics and predictive modeling were employed to assess patterns and distributions. ***Results:*** The study population had a near-equal gender distribution (55% male, 45% female) with a mean age of approximately 48 years. The most common biopsy sites were the abdomen and thorax. Tissue sampling was successful in 88.2 % cases. Malignancy was confirmed in 38 cases (55.9%), followed by inflammatory lesions in 10 cases (14.7%), normal tissue in 8 cases (11.8%), and repeat biopsies in 8 cases (11.8%), benign tumor and necrotic tisue was also reported in individual cases. Higher SUV and necrosis was commonly reported in malignant lesions. The mean lesion size was 2.86 cm, and the average depth from skin was 4.18 cm. Necrosis was observed in 26 lesions (38.3%). The average SUV was 10.67, with 49 patients (72.1%) showing SUV > 5—most of which correlated with malignant pathology. Oblique access was used in 16 cases (23.5%), while direct or perpendicular access was preferred in 52 (75%). Minimal complications were reported, and most biopsies yielded sufficient tissue for diagnosis. Lesions requiring repeat biopsies tended to have lower SUV, deeper location, or higher necrotic components. Samples requring repeat sampling or non-diagnostic cases, showed more necrosis and higher target depth suggesting their potential impact on sample adequacy. ***Conclusion:*** PET-CT-guided biopsy demonstrates high diagnostic accuracy, particularly for metabolically active lesions. Technical parameters such as lesion depth, necrosis, and access angle may influence tissue adequacy and the need for repeat procedures. With minimal complication rates, PET-CT guidance offers a safe, effective approach for targeting challenging lesions.

EP-0559

Robotic arm-assisted, FDG-PET/CT guided percutaneous core-needle biopsies: Initial experience with inclusion of Pyrexia of unknown origin (PUO) patients.

B. Nayak, *M. Tripathi, S. K. Velliangiri, M. Soneja, N. Nischal, G. Arora, V. Jain, S. Jain, A. Tyagi, A. Kakkar, N. A. Damle, A. Kumar, M. C. Sharma, A. Aravindh, C. Bal;*
All India Institute of Medical Sciences, New Delhi, New Delhi, INDIA.

Aim/Introduction: PET/CT-guided, robotic arm navigated optimal trajectory definition for manual needle placement, offers an opportunity to target metabolically active lesions thus increasing the diagnostic yield. We sought to evaluate the efficacy, feasibility, diagnostic success rate and safety of image guided percutaneous core-needle biopsies performed by robotic arm assisted spatial positioning and orientation. ***Materials and Methods:*** This prospective study included patients who were referred for PET guided biopsies and were found to have FDG-avid lesions which could be accessed for percutaneous core-needle biopsy. The coagulation profile (i.e., platelet count, PT and INR) of each patient was evaluated within 48 hours before the procedure. The study was approved by the Institute of Ethics committee, procedure details, potential risks, benefits, and available alternatives were explained to all patients and written informed consent was obtained from each patients. The patient were injected with a dose of 74-111 MBq (2-3 mCi) of F-18 FDG and positioned on the scanner after 20-30 minutes. Single bed acquisition of both CT and PET images was followed by transfer to the robotic arm positioning system (Maxio, Perfint Healthcare) console, where the fused images were used for defining trajectory to the FDG-avid target lesion along with entry point. Planned needle insertion site was cleaned with betadine and spirit followed by administration of local anesthetic. The Biopsy needle was placed in a needle adaptor in the robotic arm and navigated to the target lesion along the planned path following which the needle-tip position was confirmed using regional low-dose CT. At least four cores were sampled from the lesion and fixed in both formalin (10%) and normal saline before sending them to pathology for histopathology analysis. End-of procedure regional check-CT was taken if indicated. ***Results:*** A total of 81 patients (45 males and 36 females, mean age 49+18.7 years) were included (including 10 patients with previous negative biopsy). The indications for biopsy were broadly categorized into four groups (Table 1) and the sites biopsied (Table 2). Size of lesions varied from 0.9x0.9cm to 5.6x5.7 cm. Minimal bleeding during the biopsy was seen in 3 patients but this was not associated with hematoma formation. No other complications were noted during any procedure. ***Conclusion:*** FDG-PET guided percutaneous biopsies targeting metabolically active lesions performed by robotic arm assisted needle positioning is technically feasible, safe, and effective, ensuring adequate sampling of the target lesions and has potential utility in PUO along-with the neoplastic aetiologies.

Sentinel Lymph Node Biopsy Results in Head and Neck Tumors

E. Domínguez Polanco, *A. Piñeiro Donis, J. Villa-Palacios, L. Cagua Ruiz, E. Triviño-Ibáñez, T. Balibrea-Zuñiga, S. Faílde Balea, C. Ramos-Font;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To analyze the results of patients undergoing sentinel lymph node biopsy (SLNB) with head and neck tumors at the Virgen de las Nieves University Hospital in Granada. ***Materials and Methods:*** Observational and prospective study that included patients with early-stage head and neck tumors (T1 and T2) who underwent SLNB between February 2021 and October 2024. Statistical, technical, imaging parameters and results of the pathological anatomy study were collected. All patients underwent SLNB during the validation period of the procedure and cervical lymphadenectomy was performed in those whose sentinel lymph node was positive. ***Results:*** A total of 80 patients were included (mean age: 66.42±13.98 years, 52.5% men). 62.5% presented well-differentiated squamous cell carcinoma, with ulceration in 70% of cases and cT1 being the most frequent stage (60%). In 18 cases (22.5%), the result of the pathology study of the sentinel lymph node was positive. The false negative rate was 1/17 (5.9%). The factors associated with a higher probability of positive sentinel lymph node, in the binary logistic regression

model, were tumor grade (OR: 3.67, p=0.020) and deep of invasion (DOI) (OR: 1.21, p=0.026). 13.8% (11/80) of patients had a relapse of the disease. The median time to relapse is 44 months. Factors associated with a shorter time to relapse included: a positive result in lymphadenectomy (HR: 5.33; p=0.033) and DOI (hr: 1.28, p=0.011). ***Conclusion:*** Selective sentinel lymph node biopsy is a feasible technique in patients with head and neck cancer, potentially avoiding unnecessary lymphadenectomies, especially in cases with lower tumor grade and DOI.

EP-0561

Sentinel Lymph Node Biopsy as a Reliable Staging Tool Post-Neoadjuvant Chemotherapy in Breast Cancer- A Comparative Study from Northern India

P. Rawat, *M. L. Narayan, F. Huda, M. Negi, N. Chowdhury;*
All India Institute of Medical Sciences, Rishikesh, INDIA.

Aim/Introduction: Sentinel lymph node biopsy (SLNB) is a standard, minimally invasive method for axillary staging in early breast cancer, particularly in treatment-naïve patients. However, its accuracy post-neoadjuvant chemotherapy (NACT) remains under investigation. This study evaluates SLNB's performance in both treatment-naïve and post-NACT patients, focusing on identification rates, nodal positivity, ALND avoidance, and its utility in guiding axillary irradiation. Conducted at a tertiary care center in Northern India, this study also explores SLNB's applicability across varied healthcare settings. ***Materials and Methods:*** A prospective study was conducted on 33 breast cancer patients (mean age 47.0 ± 11.3 years), including 23 post-NACT (AJCC stage I-III C) and 10 treatment-naïve (AJCC stage I-II B) cases. SLNB was performed using a dual-tracer approach: peri-areolar and intra-tumoral injections of 99mTc-sulfur colloid with SPECT/CT imaging and gamma probe localization, complemented by methylene blue dye. Intraoperative frozen section was used to assess SLN metastasis and determine the need for ALND. Outcomes assessed included SLN identification rate, nodal positivity, ALND avoidance, and guidance for post-surgical axillary irradiation. ***Results:*** SLNB demonstrated high identification rates, achieved in 31/33 patients (93.9%) overall—21/23 (91.3%) post-NACT patients and 10/10 (100%) treatment-naïve patients. The dual-tracer approach with SPECT/CT and gamma probe ensured reliable nodal localization. Among post-NACT patients, 43.5% (11/23) achieved a pathological complete response (pCR) in the primary tumor, which did not always correspond to nodal response. For post-NACT cases, SLN metastasis was detected in 18.8% (3/16) of patients, demonstrating SLNB's effectiveness in assessing nodal status after chemotherapy. For treatment-naïve patients, SLN metastasis was identified in 10.0% (1/10) of cases, further highlighting SLNB's role in evaluating nodal involvement in early-breast cancer. SLNB findings guided axillary irradiation planning, enabling node-negative patients to avoid unnecessary treatment while supporting targeted radiation for node-positive cases. The avoidance of axillary lymph node dissection (ALND) was achieved in 82.6% (19/23) of post-NACT patients and 90.0% (9/10) of treatment-naïve patients, significantly reducing surgical morbidity. ***Conclusion:*** SLNB demonstrates high reliability for axillary staging in both treatment-naïve and post-NACT breast cancer patients, with strong identification rates, reduced ALND requirement, and low lymphedema risk. It also effectively guides axillary irradiation, enabling targeted treatment in node-positive cases while minimizing overtreatment. These findings support broader adoption of SLNB in post-NACT protocols, particularly in resource-limited settings. Further large-scale studies are warranted to standardize its use post-NACT.

EP-0562

Sentinel Lymph Node Biopsy in Head and Neck Melanoma Malignum: Our Institutional Experience

N. Kelemen[1], *E. Kristóf*[1], *M. Piroska*[1], *P. Prekopp*[2], *K. Dános*[2], *E. Birtalan*[2], *G. Forgács*[2], *B. Baksa*[1], *T. Györke*[1];
[1]*Semmelweis University, Medical Imaging Centre, Department of Nuclear Medicine, Budapest, HUNGARY,* [2]*Semmelweis University, Department of Otorhinolaryngology, Head and Neck Surgery, Budapest, HUNGARY.*

Aim/Introduction: About 10% to 25% of malignant melanoma is found in the head and neck region. The localization in itself, the complex lymphatic drainage and the surgically challenging anatomy are risk factors for progressive disease. Sentinel lymph node biopsy (SLNB) is recommended as part of staging in order to detect occult nodal metastasis in clinical stage T1b-T4b, N0 and M0. However, precise implementation of SLNB is burdened by several anatomical and technical factors. Our aim was to get a closer insight into the optimal staging procedure, timing, imaging and surgical technique of SLNB through our single-center experience. ***Materials and Methods:*** 77 head and neck melanoma patients with negative primary staging had SLNB in our institute between 2021 and 2024. Staging was performed with ultrasound and in high-risk patients also with FDG-PET/CT. Epidemiological, imaging, intraoperative and histological data were collected and analyzed to establish correlation with SLNB detection rate and progression free survival. Survival related data was compared to a control group (no SLNB, only observation) and literature data. ***Results:*** SLNB was performed in 77 cases (31 female, 46 male, average age: 61 years). Micrometastasis was found in 7 patients (9,1%, stage T2a-T4a; 1 in parajugular and 6 in superficial regions). One macrometastasis was identified. So far, progression was confirmed in 5 cases (6,5%, median follow-up time: 1,8 years); in 2 of those indeterminate lesions were present at staging; and in further 3 cases technical issues limited the SLNB. General surgical success rate was 89% both in one and two day protocol. SLNB was planned but not performed in 9 further patients; in which progression was confirmed in 5 cases so far. ***Conclusion:*** According to our experience, adequate primary staging, proper timing and implementation of SLNB and integrated evaluation with clinical data improves the diagnostic power of SLN scintigraphy and surgical effectiveness. This approach aims personalized patient management strategies and leads to a better patient survival. According to higher rates of superficial lymph node metastasis in the head and neck region, subsequent completion lymph node dissection may not be beneficial in case of a positive sentinel lymph node. Long-term follow-up is needed to further evaluate how progression free survival and overall survival is influenced by SLNB; and to further optimize SLNB protocol.

EP-0563

Hybrid SPECT/CT sentinel node mapping impact in early and post-neoadjuvant breast cancer: our experience

M. Mihaylova[1], *E. Piperkova*[1], *L. Chavdarova*[1], *M. Zaharinov*[1], *V. Mitova*[2];
[1]*USHATO "Prof. Ivan Chernozemski", Department of Nuclear medicine, Sofia, BULGARIA,* [2]*USHATO "Prof. Ivan Chernozemski", Department of Breast surgery, Sofia, BULGARIA.*

Aim/Introduction: Accurate axillary lymph node (ALN) staging in breast cancer (BC) is essential for prognosis and treatment planning. Sentinel lymph node biopsy (SLNB) is considered the gold standard for staging in early BC with clinically negative ALNs and is also increasingly used after neoadjuvant chemotherapy (NACT) to avoid overtreatment. This study aims to assess the efficacy of hybrid SPECT/CT SLN imaging in early BC as well as after NACT, highlighting its diagnostic value and intraoperative success. ***Materials and Methods:*** We retrospectively analysed data of 80 patients with early-stage BC (T1-T2), diagnosed by core-needle biopsy (85%) or lumpectomy (15%), including 17 patients post -NACT, who underwent hybrid SPECT/CT SLN lymphoscintigraphy in our department between January 2024 and March 2025. Histological types included invasive ductal carcinoma (IDC) in 71 patients (1 bilateral), invasive lobular carcinoma in 8, and other in 1. Parameters evaluated: SLN detection by lymphoscintigraphy, lymphatic drainage patterns, surgical SLN detection, histological status, and short-term clinical outcomes. ***Results:*** Hybrid imaging with subsequent SLNB was successful in 77 of 80 patients (96.25% detection rate; mean age 58.03 ± 12.03 years). A single SLN was identified in 58 patients (72.5%), two in 17 (21.3%), and three in

2 (2.5%). Intraoperative SLN identification was successful in 74 patients (92.5%): 1 node (6.3%), 2 nodes (43.8%), 3 nodes (28.7%), 4 nodes (8.8%), and 5 nodes (5%). ALND (>5 nodes) was performed in 6 cases (7.6%). Twenty-seven patients (33.8%) underwent SLNB after NACT—11 with complete tumour response and 15 with partial response and ALN-negative status. SLNB post-lumpectomy was performed in 12 cases (15%). ALN metastases were histologically confirmed in 11 patients (6 macro, 5 micro), including 4 post-NACT cases (2 macro, 2 micro). During the short follow-up period, no cases of recurrence or lymphedema were observed. All patients continued adjuvant treatment according to post-surgical staging and tumour characteristics. ***Conclusion:*** In our study hybrid SPECT/CT-guided SLN imaging demonstrated high detection rates, with supportive data for its feasibility in post-lumpectomy, and post-NACT settings, with consistent intraoperative success, due to the standardized interdisciplinary collaboration in our centre. These results support wider clinical adoption to improve axillary staging accuracy, reduce overtreatment, and enhance patient outcomes in BC care across Bulgaria.

EP-0564

Can SPECT/ CT Lymphoscintigraphy Influence Surgical Approach for Sentinel Lymph Node Biopsy in Head and Neck Melanoma

L. Radosavcev, *M. Rajovic, M. Radulovic, B. Miljus, M. Rabrenovic, L. Kandolf;*
Military Medical Academy, Belgrade, SERBIA.

Aim/Introduction: Surgeons found routine use of SPECT/ CT very useful in operation planning (surgical team, patient s position, extent of incision). Preoperative lymphoscintigraphy in head and neck melanoma patients was important in more accurate localizing the SLN and in determining the relationship with deferent structures of surgical interest. We evaluated potential predictors to SLN metastatic involvement in patients with cutaneous head and neck melanoma. ***Materials and Methods:*** Patients who underwent SLN biopsy for head and neck melanoma between March 2021.and February 2025. were included. Preoperative planar SLN mapping (PL) was performed for all patients (n=56), followed by SPECT/CT (n=46). ***Results:*** Detection rate of SLN was 92.8. (SNL not visualized on preoperative lymphoscintigraphy in two patients, also not found in other two patients on operation). There were no patients with SLN seen only on SPECT/ CT.In total 98 lymph nodes were harvested (range 1-5; median 2 per patient). Nodal basins identified were parotid/preauricular, neck, occipital /postauricular and supraclavicular in 19, 19, 10 and 6 patients respectively. Metastases were found is 19.2 %. Location of primary, number on lymph nodes harvested and drainage to two different basins, were not significantly associated with SLN status. Location of primary associated with drainage to parotid /preauricular region was face, scalp and ear in in 9 ,7 and three patients respectively. Hystopathology sampling revealed parotid gland tissue in 3 out of 19 patients. ***Conclusion:*** Surgeons found routine use of SPECT/CT very useful in operation planning (surgical team, patient s position, extent of incision). Preoperative lymphoscintigraphy in head and neck melanoma patients was important in more accurate localizing the SLN and in determining the relationship with deferent structures of surgical interest.

Standardised Protocol for Radioguided Surgery of Non-Palpable Breast Lesions Using Iodine-125 Seed: Experience at Our Centre

M. Ottino, *P. Azpeitia Hernández, A. Martínez Lorca, O. Ajuria Illarramendi, M. Gutiérrez Guerrero, P. Paredes Rodríguez, T. Navarro Martínez, U. Vera Schmülling, I. Hernández Pérez, A. Torres Consiglieri, E. Pérez de los Ríos, M. Orduña Diez;*
Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: This study describes the multidisciplinary protocol implemented for radioguided surgery in the management of non-palpable breast lesions using iodine-125 (^{125}I) seed localisation, with or without targeted axillary dissection (TAD). The workflow for the safe administration and retrieval of radioactive material is detailed. ***Materials and Methods:*** A retrospective descriptive study was conducted on cases treated between November 2020 and November 2024 that required ^{125}I seed localisation for non-palpable breast lesions. The ^{125}I seed(s) were implanted under ultrasound or stereotactic guidance, with position confirmed by mammography. In TAD cases, an axillary seed was inserted under ultrasound guidance and its location confirmed by SPECT-CT. Preoperative skin marking was also performed.In the operating theatre, the surgeon used a gamma probe for localisation. Surgical specimens containing seeds were radiographed and subsequently sent to the Pathology Department for seed identification and retrieval by the pathologist, with support from the nuclear medicine physician if required. ***Results:*** A total of 556 cases were analysed: 493 (89%) involved a single ^{125}I breast seed, and 63 (11%) involved two seeds. TAD was performed in 17 patients (3%). Correct seed localisation was confirmed in 100% of cases via mammography and/or SPECT-CT. Preoperative skin marking enabled successful intraoperative identification of the sentinel lymph node and seed(s) in 100% of cases, without the need for the nuclear medicine physician to be present in theatre.The pathologist successfully identified the ^{125}I seed in the surgical specimen in 537 cases (97%), with nuclear medicine assistance required in 19 cases (3.5%). ***Conclusion:*** The use of ^{125}I seed localisation has proven to be an effective and safe technique for the accurate identification of non-palpable breast lesions and marked axillary nodes. Detailed preoperative planning and skin marking optimise the surgical procedure and minimise the need for intraoperative assistance from nuclear medicine. These findings support the integration of this protocol into the multidisciplinary approach to breast cancer management.

EP-0566

Sentinel Node Biopsy in Laryngeal Cancer: A Systematic Review and Meta-Analysis

P. Sahafi[1], *R. Sadeghi*[1], *E. Askari*[1], *A. Sahebkari*[1], *M. Ghahraman*[1], *V. Dabbagh*[1], *S. Harsini*[2];
[1]*Ghaem Hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*BC Cancer Research Institute, Vancouver, BC, CANADA.*

Aim/Introduction: Sentinel lymph node (SLN) biopsy offers a minimally invasive approach to staging lymph node involvement in laryngeal squamous cell carcinoma (SCC). Despite its adoption in other cancers, its accuracy in laryngeal SCC remains under investigation. This systematic review and meta-analysis evaluates the diagnostic performance of SLN mapping in laryngeal cancer. ***Materials and Methods:*** A systematic search of MEDLINE, Scopus, and Google Scholar was conducted using the keywords "(larynx OR laryngeal) AND sentinel", with no date or language restrictions. Studies reporting SLN detection rates and/or sensitivity in laryngeal SCC were included. A random-effects model was applied for data pooling, and subgroup analyses were performed based on tumor location (supraglottic versus transglottic) and mapping material (radiotracer versus blue dye). Publication bias was assessed using funnel plots and statistical methods. ***Results:*** Nineteen studies, encompassing 366 patients, were analyzed. The overall pooled SLN detection rate was 90.8% (95% CI: 86-94.1), and sensitivity was 88% (95% CI: 81-94). Supraglottic tumors demonstrated superior outcomes (detection rate: 93.7%, sensitivity: 96%) compared to transglottic tumors (detection rate: 84.7%, sensitivity: 71%). Radiotracers significantly outperformed blue dye, with detection rates of 90.8% versus 81.5% and sensitivities of 88% versus 77%. ***Conclusion:*** SLN mapping is a reliable technique for staging laryngeal SCC, particularly for supraglottic tumors, where high detection rates and sensitivity were observed. Radiotracers offer

superior performance compared to blue dye, underscoring their clinical value. These findings support the feasibility and accuracy of SLN biopsy in laryngeal cancer, while emphasizing the importance of tumor location and mapping material.

EP-0567

Accuracy of sentinel node mapping in Marjolin ulcer: Comparison of three different injection techniques

P. Sahafi, *R. Sadeghi, V. Dabbagh;*
Ghaem Hospital, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Marjolin ulcer is a specific type of squamous cell cancer that can benefit from the use of lymphoscintigraphy. The purpose of this study was to evaluate 3 different injection techniques for sentinel node biopsy in patients with Marjolin ulcer. ***Materials and Methods:*** Forty-eight patients with Marjolin ulcer (27 male and 21 female) ranging in age from 24 to 85 years were included in our study. Intratumoral (IT), peritumoral (PT) and periscar (PS) tissue injections of radiotracer were done in 9, 10, and 29 patients respectively. Injections were done 2-4 h before surgery. Lymphoscintigraphy was done for mapping the lymphatic drainage. During surgery, lymphatic mapping and sentinel node biopsy was performed using a handheld gamma probe. After harvesting sentinel nodes, regional lymph node dissection was done. ***Results:*** Sentinel node detection rate was higher in the PS group as compared to the IT and PT groups (89.6% vs. 50% and 22.2%) respectively. False negative rate was 0%. Pathologically involved sentinel nodes were detected in 16% of the included patients of our study which led to management change. None of the patients with pathologically non-involved sentinel nodes developed regional lymph node recurrence. ***Conclusion:*** Lymphatic mapping and sentinel node biopsy is feasible in Marjolin ulcer with high detection rate and low false negative cases which by detection of regional lymph node involvement can potentially change the management of patients. Injection site may be an important factor influencing the success of the procedure and injection of the mapping material in the peri-scar normal skin proximal to the lesion is the best technique.

EP-0568

Ex Vivo Sentinel Lymph Node Mapping in Colorectal Cancer Using [99mTc-HMPAO] Patent Blue Liposomes: A Hybrid Radiotracer/Dye Approach

P. Sahafi, *H. Abbasian, K. Sadri, R. Sadeghi;*
Ghaem Hospital, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Colorectal cancer (CRC) remains a leading cause of cancer-related morbidity and mortality worldwide, with lymph node (LN) status serving as a critical prognostic factor. Accurate sentinel lymph node (SLN) detection is essential for optimal staging and treatment planning. This study introduces a novel hybrid radiotracer—[99mTc-HMPAO] patent blue liposomes—designed to combine the advantages of visual (blue dye) and gamma probe (radiotracer) detection in a single injection, offering a streamlined and efficient approach for SLN mapping in nuclear medicine. ***Materials and Methods:*** A prospective study was conducted on 40 colorectal cancer patients undergoing surgical resection. Post-resection, the novel radiopharmaceutical—comprising either 99mTc-HMPAO-non-PEGylated liposomes or 99mTc-HMPAO-PEGylated liposomes—was injected peritumorally in an ex vivo setting. SLNs were identified using dual-modality detection: visual confirmation of blue dye and gamma probe quantification of radiotracer uptake. Pathological evaluation was performed to validate findings. ***Results:*** Among the 40 patients—19 (47.5%) with colon cancer and 21 (52.5%) with rectal cancer—SLNs were not found in six cases (15%). Of the remaining 34 cases, 29 (85.3%) showed no SLN involvement, while 5 (14.7%) had pathological involvement. In two cases without SLN involvement, other non-sentinel lymph nodes were affected. The study demonstrated a total detection rate of 85%, with sensitivities of 80% for colon cancer and 50% for rectal cancer. The false negative rate was calculated at 28%. ***Conclusion:*** Patent blue liposome labelled by Tc-99m HMPAO can be used for sentinel node mapping in colorectal cancers with success. Both blue dye visual detection and radiotracer count detection simultaneously can be used by single injection in this technique. Lymphoscintigraphic mapping of SLNs in colorectal cancers using [99mTc-HMPAO] liposomes enhances the accuracy of pathological staging and achieves a notable detection rate of SLNs, particularly in colon cancers.

EP-0569

Tc-99m-nanocolloid scintigraphy in sentinel lymph node detection in patients with a history of conservative resection and prior lymph node biopsy.

A. Velidaki, *S. Episkopopoulou, I. Sevaslidou, I. Vagios, N. Prosotsianiotis, E. Dagrakis, A. Kolindou;*
Laiko General Hospital of Athens, Athens, GREECE.

Aim/Introduction: Breast cancer is the most common malignancy in women with local recurrence occurring in less than 3% in the decade, after conservative resection and radiation. The value of sentinel node approach in breast cancer has been proven in several studies but its role in case of local relapse has not been sufficiently studied. Maybe the biopsy of a new sentinel node, which takes on the role of sentinel, can modify the new treatment. The aim of this study is to investigate whether imaging of a new sentinel lymph node is possible in patients with a history of conservative resection with previous sentinel lymph node biopsy and adjuvant radiotherapy. ***Materials and Methods:*** Twenty seven (27) women were included in this study with an average age of 67 years (38-82). The interval from the end of treatment was at least six months. The technique involved peritumoral injection of 1-2 mCi Tc-99m-nanocolloid. Planar and SPECT images were obtained 15 minutes post injection and the first hot spot of the lymphatic drainage (SLN) was marked on the skin as a guide for the surgeon. Planar and SPECT results were compared to the surgical findings. ***Results:*** Radioisotope administration revealed radiopharmaceutical uptake in a new sentinel node in 78% of patients. In 88% of the cases, the new sentinel lymph node was located in the unilateral armpit, 8% was located in the contralateral armpit while in 1 case (4%) sentinel node was detected at the cervical area. ***Conclusion:*** Tc-99m-nanocolloid scintigraphy is useful for detecting the sentinel lymph node also in patients with a history of conservative resection with previous sentinel lymph node biopsy and adjuvant radiotherapy. This fact will help unnecessary lymph node dissection and its subsequent morbidity even in this group of patients.

EP-0570

Feasibility of Sentinel Lymph Node Lymphoscintigraphy in Cutaneous Head and Neck Squamous Cell Carcinoma

P. Sahafi, *A. Aghaee, K. Sadri, E. Soltani, E. Hasanzadeh Haddad, B. Rasoulian, R. Sadeghi;*
Ghaem Hospital, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Non-melanoma skin cancers, particularly squamous cell carcinoma (SCC), are among the most common malignancies worldwide. Risk factors include ultraviolet (UV) exposure, advanced age, immunosuppression, genetic disorders, and exposure to carcinogens. Cutaneous SCC (cSCC) predominantly occurs in the head and neck region and may metastasize to lymph nodes, worsening the prognosis. Accurate diagnosis and staging—using techniques such as sentinel lymph node biopsy (SLNB), lymphoscintigraphy, and blue dye mapping—are crucial. These minimally invasive and highly accurate methods can potentially replace elective neck dissection in clinically node-

negative (cN0) patients. Surgical excision remains the mainstay of treatment. In cases with nodal involvement, neck dissection with or without radiotherapy is recommended. Currently, no consensus exists on the optimal management of high-risk node-negative patients. ***Materials and Methods:*** This prospective study included 42 patients with a primary histopathologic diagnosis of head and neck cutaneous SCC, all without clinical or radiologic evidence of cervical metastasis. After eligibility confirmation, patients underwent tumor resection and elective neck dissection. Prior to surgery, 99mTc-Phytate was injected subcutaneously around the lesion. Lymphoscintigraphy with gamma camera and SPECT/CT was performed to identify sentinel lymph nodes (SLNs). During surgery, a gamma probe was used to localize SLNs, which were then excised and sent for pathological analysis. If metastasis was confirmed in SLNs, neck dissection was completed. Results were verified with both frozen and permanent sections. ***Results:*** Of the 42 enrolled patients, 36 had confirmed cutaneous SCC of the head and neck (27 males, 9 females), all clinically and radiologically node-negative, with a mean age of 68 years. SLNs were successfully detected in 31 of the 36 patients (detection rate= 86.1%). Pathologic evaluation showed SLN involvement in only one patient, who subsequently underwent neck dissection and parotidectomy. In the remaining 30 patients with negative SLNs, no metastases were found in non-sentinel nodes, resulting in a calculated false negative rate of zero. During the two-year follow-up period, no cases of lymphatic recurrence were observed among the patients. ***Conclusion:*** This study suggests that SLNB, due to its high detection rate and sensitivity, is a reliable method for accurate pathological assessment of cervical lymph nodes in patients with clinically node-negative cutaneous SCC of the head and neck.

Added value of ^{18}FDG PET-CT in modern radiotherapy planning for Hodgkin Lymphoma: A Dosimetric Comparison

M. Ben Nasr*, L. Zaabar, S. Yahyaoui, E. Zaidi, A. Mhiri;*
Salah Azaiez Institute of Tunis, Tunis, TUNISIA.

Aim/Introduction: To evaluate the clinical benefit of integrating ^{18}FDG PET-CT into modern radiation therapy (RT) planning for Hodgkin's lymphoma (HL), with a focus on optimizing dose distribution and enhancing protection of organs at risk (OARs)." ***Materials and Methods:*** A retrospective, descriptive study was conducted at the Salah Azaiz Institute (Tunis) including 15 patients (4 children, 11 adults) with histologically confirmed HL treated with combined modality therapy. All patients underwent initial and/or end-of-treatment ^{18}FDG PET-CT. Treatment indications and doses followed the Tunisian MDH 2015 protocol (adults) and EuroNET-PHL-C1 (children). Each patient had a simulation CT in treatment position with personalized immobilization cast. Positioning CT was performed under free-breathing conditions. Two RT plans were generated: a conformational plan using 3D-CRT based on IFRT and contrast CT alone, and an ISRT plan using VMAT incorporating PET-CT data. Target volumes and OARs were delineated by the same radiation oncologist using Eclipse® software. Dosimetric comparisons were performed using dose-volume histograms (DVH), and parameters were statistically analyzed via the Wilcoxon test ($p < 0.05$ considered significant). ***Results:*** The average patient age was 31 years (range: 5-52), with a male predominance (sex ratio 1.5). Stage II HL was most frequent (53%). Five patients had at least two nodal regions involved. The initial PET-CT modified irradiated fields in 4 patients without changing disease staging. Mediastinal RT was performed in six cases, cervical in nine, axillary in three, and one child received supra- and sub-diaphragmatic RT. In total, 30 RT plans were analyzed (15 3D-CRT, 15 VMAT). A total of 75 OARs were contoured. PET-CT and VMAT use led to decreased mean doses in 65% of the structures. V95 to the PTV was significantly improved with PET-based VMAT planning. Compared to 3D-CRT, VMAT significantly reduced heart mean dose and V30, as well as doses to the anterior interventricular artery during mediastinal RT. Lung V20 was also significantly reduced ($p = 0.02$). In women, breast V5 was lower with VMAT. VMAT also reduced spinal cord maximum dose and parotid mean doses (except contralateral parotid in unilateral cervical RT, which was better with IFRT). No significant difference was observed for thyroid or esophagus. ***Conclusion:*** ^{18}FDG PET-CT enhances modern RT planning by allowing more precise targeting and better sparing of OARs. The use of VMAT guided by PET imaging provides significant dosimetric advantages, especially in mediastinal HL, by enhancing cardiac and breast protection and thereby potentially lowering long-term toxicity.

Upright and Supine artefact locations in Myocardial Perfusion Imaging using a cardiac-dedicated CZT gamma camera

A. Carradus*[1,2], M. Ulyatt[1], K. Jones[1,2], C. Paterson[1,2], J. Robinson[1,2], A. Laird[1], R. McDade[1], S. Han[1,3];*
[1]DCPB, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM, [2]College of Medical, Veterinary & Life Sciences, University of Glasgow, Glasgow, UNITED KINGDOM, [3]School of Infection & Immunity, University of Glasgow, Glasgow, UNITED KINGDOM.

Aim/Introduction: Attenuation correction of SPECT-MPIs remains a challenge, particularly as CZT cardiac-dedicated gamma cameras do not typically offer hybrid SPECT/CT imaging. Previous studies have localised common areas of artefact in supine, semi-reclined, and forward-leaning positions[1][2]. This study aims to identify the frequency of localised artefacts in upright and supine positions, and investigate any trends with sex. ***Materials and Methods:*** 100(53F) patients with upright and supine stress MPI were retrospectively individually reported by an experienced operator using a 17 segment polar-map, to give an upright-SSS and supine-SSS. Artefact score was then quantified by subtracting upright-SSS from supine-SSS and vice-versa (i.e. assuming if a defect is present in only one position, it is an attenuation artefact). ***Results:*** The average upright artefact score was 1.65 (F=1.89,M=1.38), and the average supine artefact score was 1.23 (F=0.91,M=1.60). 45% of patients had more artefact on their upright images (F=53%,M=36%), and 36% of patients had more artefact on their supine images (F=25%,M=49%). Upright artefacts were located primarily inferiorly and apically, with the most artefacts located distal inferiorly (26%). These were more common in female patients (36%), whereas male patients had more artefacts mid-basal inferolaterally (13%-15% vs 6%-8% respectively). Supine artefacts were located primarily anteriorly and inferiorly. Anterior artefact frequency was similar for male and female patients, however inferior artefacts were seen predominantly in male patients (basal/mid/distal inferior artefact frequency F:2%/8%/4%,M:34%/23%/13%). ***Conclusion:*** Dual-

position stress MPI is locally preferred on CZT cameras in order to identify attenuation artefacts. This work shows the locations of where we might expect attenuation artefacts. It follows that rest imaging should be performed in the position with less attenuation artefact, which we show here to generally be supine, although 36% of male patients had less artefact in the upright position compared to 49% having less artefact while supine. We are currently discussing how to implement these results - the options being a)acquire all rest imaging supine, b)acquire rest imaging upright for males and supine for females, or c)assess each patient's images for attenuation artefacts individually prior to rest imaging. This work partially agrees with the supine results of Chopra et al.[1], however we also see inferior artefacts in male patients which is in line with previous non-CZT based studies[3]. ***References:*** [1]Chopra, S et al. Myocardial Blood Flow and Ejection Fraction Measurement in Rb82-PET/CT shows high inter-observer reliability

S. Stolte, *H. Geiger, O. Maas, F. Forrer;*
Kantonsspital St Gallen, St Gallen, SWITZERLAND.

Aim/Introduction: Myocardial perfusion PET/CT e.g. using Rb-82 enables the measurement of absolute myocardial blood flow (MBF) including the flow-reserve which is a useful tool in assessing myocardial ischemia as well as microvascular disease. However, the values might depend on the observer's analysis i.e. e.g. the observer's experience. We investigated the inter-observer reliability of MBF measurements in Rb-82-PET/CT. ***Materials and Methods:*** 30 consecutive patients who underwent Rb-82-PET/CT for suspected myocardial ischemia were analysed. Stress conditions were simulated using 400 µg Regadenoson. MBF was measured using Corridor 4DM software. Flow-reserve (FR) is the ratio of absolute flow measurements under stress and rest conditions. Four different physicians on different levels of experience (two senior physicians and two residents) investigated the MBF. The experience of the residents was one year and a couple of weeks respectively. Intraclass correlation coefficients (ICC) were calculated for MBF and FR in the three main vascular territories and in the whole left ventricle as well as for the ejection fraction (EF). ***Results:*** The evaluation of MBF showed an excellent correlation between all observers indicated by a low inter-observer-variability. Comparing the two different levels of experience, senior physicians showed an even slightly higher accordance in MBF-assessment (ICC ranging from 0.9 to 0.98) than residents (ICC ranging from 0.86 to 0.94). The FR-calculations showed a slightly lower reliability due to the accumulation of variability in rest and stress measurements (ICC between 0.78 and 0.81), still indicating a good reliability. EF-calculations also showed a good reliability among different observers (ICC 0.83). ***Conclusion:*** Measurement of MBF, FR and EF in Rb-82-PET/CT shows an excellent inter-observer reliability demonstrating the robustness of the method. A slightly higher inter-observer reliability was found for more experienced physicians.

EP-0574

Myocardial Prone Imaging In The SPECT/CT Era - The Need Is Still There: When CT-Attenuation Correction Is Not Enough

C. Fragkaki[1], *S. Maragkoudakis*[2], *G. L. Lilikaki*[2], *A. T. Archontaki*[3];
[1]*Nuclear Medicine Department, Athens General Anti-Cancer/Oncology Hospital "Agios Savvas", Athens, GREECE,* [2]*Cardiology Department, Chania General Hospital "St. George", Chania, GREECE,* [3]*Nuclear Medicine Department, Chania General Hospital "St. George", Chania, GREECE.*

Aim/Introduction: In myocardial imaging, SPECT systems, can provide only non-attenuation corrected (NAC) images that are susceptible to attenuation artifacts, usually to anterior and inferior wall, known as "breast" and "diaphragmatic" attenuation artifacts, respectively. In hybrid systems, attenuation correction (AC) with CT will improve the accuracy of SPECT images most of the times, but not always. ***Materials and Methods:*** In July 2023, the Nuclear Medicine Department of Chania General Hospital "St. George", acquired a new dual-headed SPECT/CT γ-camera. Since then, all myocardial perfusion studies, using ^{99m}Tc-MIBI, were performed using the suggested CT-AC protocol. For a 20-month period, a total of 1336 studies were performed. Stress Prone imaging acquisition was performed, after the Stress Supine acquisition, when there was still reduced or questionable perfusion in the anterior wall (101patients) and in the inferior wall (120patients) and before a second radiopharmaceutical injection, needed for the Rest imaging acquisition, was performed. ***Results:*** From 1336 studies, 576 patients showed normal myocardial perfusion and left without any further imaging, 221 patients needed a Stress-Prone imaging acquisition, in order to clarify their attenuation artifact and 169 of those (105 females and 64 males) avoided an unnecessary radiation exposure from the Rest acquisition dose injection, since the stress prone images, showed normal myocardial perfusion in the suspicious area. The rest, concluded the whole Stress-Rest protocol. ***Conclusion:*** It seems, that even though SPECT/CT images in myocardial imaging are definitely superior to SPECT images alone, a 16,5% of the patients examined, still needed an "old-fashioned" Prone imaging as well. Therefore, our conclusion is that if there is any doubt, Prone Imaging could still be a very useful tool in everyday practice. ***References:*** Alwan, M, Sayed, A, Ahmed, A. et al. The impact of utilization of attenuation correction and prone positioning on stress-only imaging in cardiac spect mpi: an observational study. JACC. 2025 Apr, 85 (12_Supplement) 2044.

Analysis of factors affecting persistent perfusion defects in patients with pulmonary embolism

S. Niu[1], *J. Cao*[2], *H. Liu*[1], *J. Cao*[3];
[1]*First Hospital of Shanxi Medical University, Taiyuan, CHINA,* [2]*First Hospital of Shan Xi Medical University, Taiyuan, Shanxi, CHINA,* [3]*First hospital of Shan Xi medical university, Taiyuan, Shanxi, CHINA.*

Aim/Introduction: Acute pulmonary embolism is a common and potentially life-threatening condition. Some patients continue to have residual blood clots in the lungs long after the diagnosis of pulmonary embolism, which may lead to a poor long-term prognosis. In this study, we collected and analyzed a variety of meaningful ancillary laboratory markers during the acute phase of the disease, with the aim of evaluating the correlation between these markers and persistent perfusion defects in patients with pulmonary embolism. ***Materials and Methods:*** A total of 276 patients with acute pulmonary embolism who underwent pulmonary perfusion imaging were included in the study, and basic clinical data, serologic indices, and symptoms in the acute phase were collected. After 3-6 months of oral anticoagulant therapy, the patients were again subjected to pulmonary perfusion imaging, and were divided into two groups based on the results, the group with recovery of pulmonary perfusion flow and the group with persistent perfusion defect (patients with a first diagnosis of pulmonary embolism who had little change in embolism of the original lung segment or new embolisms in other segments of the lungs after 3-6 months of pharmacologic anticoagulant therapy). ***Results:*** Compared with the pulmonary perfusion blood flow recovery group, a significantly higher proportion of the persistent perfusion defect group had a smoking history, and the difference was statistically significant (χ^2=5.981, P=0.014); the incidence of dyspnea, hemoptysis, and chest pain

in the persistent perfusion defect group was significantly higher than that in the pulmonary blood flow perfusion recovery group, and the difference was statistically significant (χ^2=5.333, P=0.021; χ^2=10.530, P=0.001 ; χ^2=6.617, P=0.010); the blood uric acid level in the persistent perfusion defect group (361.33±117.32) was higher than that in the pulmonary blood flow perfusion recovery group (330.76±104.09), with a significant difference (t=-2.087, P=0.038). ***Conclusion:*** Patients with acute pulmonary embolism are more likely to have persistent pulmonary perfusion defect if they have a long history of smoking, early symptoms of dyspnea, hemoptysis, chest pain, or high blood uric acid levels. ***References:*** 1. EP-0576

Dual-position Myocardial Perfusion Imaging: reducing the number of rest scans performed while increasing reporter confidence

M. Ulyatt[1], *K. Jones*[1,2], *A. Carradus*[1,2], *J. Robinson*[1,2], *A. Laird*[1], *S. Han*[1,2], *C. Paterson*[1,2];
[1]*Department of Clinical Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM,* [2]*College of Medical, Veterinary and Life Science, University of Glasgow, Glasgow, UNITED KINGDOM.*

Aim/Introduction: The Nuclear Cardiology department at Glasgow Royal Infirmary (GRI) follows a one-day Myocardial Perfusion Imaging (MPI) protocol, wherein rest imaging is performed only if stress imaging indicates a perfusion defect. Scanning uses cardiac SPECT-only CZT gamma cameras: due to the lack of CT attenuation correction, attenuation artefacts may be misidentified as areas of reduced perfusion. This may cause patients to unnecessarily receive a rest scan, increasing patient dose. Literature suggests that dual-position imaging reduces the number of required rest scans due to increased confidence in identification of position-dependent attenuation artefacts [1][2][3]. Dual-position imaging (upright and supine) has recently been introduced at GRI: the impact this has had on the number of rest scans performed has been assessed. ***Materials and Methods:*** 30 anonymised dual-position studies were processed into two sets: one displaying upright only stress images and another displaying both upright and supine stress images. Two experienced operators assessed both sets to determine if a rest scan was required. In addition, 100 consecutive patient reports from both before and after the protocol change were audited to determine the number of rest scans performed in practice, and to assess the frequency of normal outcomes (i.e scans demonstrating no reversibility or previous myocardial infarction), and of these, how many normal studies had rest imaging. ***Results:*** The assessment of 30 anonymised patients found operators required fewer rest scans when viewing dual-position imaging, vs upright alone (53% vs 87%). The audit found dual-position imaging reduced the overall number of rest scans performed in practice (99% to 84%), increased the overall number of normal studies reported (16% to 49%), and lowered the rate of rest scans among patients with normal scan results (94% to 67%). ***Conclusion:*** Dual-position imaging reduces the number of rest scans performed when using a SPECT-only cardiac gamma camera, resulting in lower patient dose and reduced imaging time. Previously we were unable to rule out small areas of mild reversibility in equivocal scans: dual-position imaging has both increased confidence in identifying defects as attenuation using only the stress part of the study, without requiring a rest scan, and also in reporting images as within normal limits. ***References:*** [1] Ben-Haim, S. et al. 2014, 21:478-485. EP-0577

Assessment of Reversible Ischemia and Left Ventricular Function in Relation to SCORE2 Risk, COVID 19 History, and Vaccination: A Retrospective MPS Study

S. Demirtas Senlik[1], *B. Bozca*[1], *A. Celik Arslan*[1], *S. Gulbahar Ates*[2], *O. Ozmen*[1];
[1]*Ankara Etlik City Hospital, Ankara, TÜRKIYE,* [2]*Gazi University Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: This study aimed to assess the association between a history of COVID-19 infection, vaccination status, and cardiovascular risk as determined by the SCORE2 with the presence of reversible ischemia on Tc99m-sestamibi myocardial perfusion scintigraphy (MPS), and to evaluate the relationship between ejection fraction (EF) and cardiovascular risk categories. ***Materials and Methods:*** This retrospective study included 438 patients referred for MPS between January and March 2025. Demographic, clinical, and cardiovascular risk data, along with history of COVID-19 and vaccination, were collected. Patients were stratified into low-to-moderate or high risk using the SCORE2 algorithm, based on age, smoking status, cholesterol, and blood pressure(1). Individuals aged ≥70 or with cardiovascular disease or diabetes were classified as high-risk. Patients were also grouped based on reversible ischemia presence on MPS. Associations between ischemia, SCORE2 risk categories, COVID-19 history, and vaccination were assessed. EF, calculated on MPS, was categorized as low (≤50%) or normal (>50%), and the relationship between EF and cardiovascular risk groups was analyzed. ***Results:*** Among the 438 patients, 201 (45.9%) were male and 237 (54.1%) female, with a median age of 63 years (IQR: 55-69). Except for known coronary artery disease, no significant association was found between other risk factors, including diabetes, and reversible ischemia on MPS. A total of 105 patients were in the low-to-moderate risk group, and 333 in the high-risk group. Myocardial ischemia was present in 17 patients (16.2%) in the low-to-moderate group and 87 patients (26.0%) in the high-risk group, with a significant difference ($p = 0.037$). Similarly, a significant difference was found between the groups in reduced EF ($p = 0.021$). No significant association was observed between COVID-19 history or vaccination and ischemia or left ventricular EF among risk groups***. Conclusion:*** No significant association was found between individual risk factors and reversible ischemia on MPS, but a significant correlation was observed between low-to-moderate and high-risk groups when cardiovascular risk was classified using the SCORE2 algorithm. Although the role of COVID-19 infection as a risk factor remains debated, our study found no significant increase in reversible ischemia associated with a history of infection or vaccination. Additionally, a significant association was observed between SCORE2 risk categories and EF, supporting the clinical utility of SCORE2 not only in ischemia prediction but also in assessing left ventricular function. These results suggest that SCORE2 may be related to both reversible ischemia and impaired EF on MPS. ***References:*** 1. doi: 10.1093/eurheartj/ehab309. PMID: 34120177; PMCID: PMC8248998.

EP-0578

Prognostic Impact of Reverse Redistribution in Myocardial Perfusion Imaging, particularly in non-obstructive CAD

W. Yu, *Y. Wang, X. Su;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: Reverse redistribution (RR) is an imaging characterization in myocardial perfusion imaging (MPI), characterized by reduced radiotracer uptake in specific myocardial

regions on rest images compared to the corresponding stress images, which clinical significance remains unclear. The purpose of this study is to investigate the clinical and prognostic significance of RR. ***Materials and Methods:*** A retrospective study included suspected coronary artery disease (CAD) patients who underwent stress-rest MPI and coronary angiography (CAG) within 3 months at the Third Affiliated Hospital of Soochow University from January 2018 to April 2023. Reversible myocardial ischemia and myocardial infarction were excluded. Clinical data such as sex, age, cardiovascular risk factors, chest pain symptoms, medication use, Angio-based Microvascular Resistance (AMR) and echocardiography were collected. RR is defined as a ≥1-point increase in perfusion score at rest compared to stress imaging within the same myocardial segment, observed across ≥3 consecutive layers in two distinct imaging axes. Major adverse cardiovascular events (MACE) was defined as cardiac death, non - fatal myocardial infarction, late coronary revascularization (≥ 3 months) after MPI, after-hospitalization for angina with repeat coronary angiography, heart failure, and stroke. ***Results:*** A total of 305 patients were enrolled, including 59 (19.3%) RR patients and 246 (80.7%) normal perfusion patients. Compared with the normal perfusion group, patients in the RR group had a lower proportion of obstructive CAD (35.6% vs. 53.7%, P=0.013), a higher proportion of positive electrocardiogram of stress test (32.2% vs. 16.3%, P=0.005) and higher AMR [3.49±0.62 vs. 3.05±0.40, P=0.005]. Non-obstructive CAD (OR=2.08, 95%CI: 1.14-3.79, P=0.017) and hyperlipidemia (OR=1.85, 95%CI: 1.03-3.36, P=0.041) were independent factors for RR in MPI. With a follow-up period of 43 (40, 46) months, a total of 29 MACE events occurred. Multivariate Cox regression analysis showed that RR (HR=2.57, 95%CI: 1.06-6.20, P=0.036) and obstructive CAD (HR=3.91, 95%CI: 1.57-9.71, P=0.003) were independent risk factors for MACE. In patients without obstructive CAD, those with RR had a worse prognosis than normal MPI (9.4% vs. 3.1%, Log rank P=0.014). Obstructive CAD affected the relationship between RR and MACE (P for the interaction=0.03) with an interaction effect. RR independently predicted MACE in non-obstructive CAD (HR=6.18, 95%CI: 1.16-32.97, P=0.03), but demonstrated no significant prognostic impact in obstructive CAD. ***Conclusion:*** Among patients with suspected CAD, 19% exhibited RR, with non-obstructive CAD and hyperlipidemia as independent influencing factors. RR was significantly associated with MACE, particularly in the non-obstructive CAD subgroup.

EP-0579

GATED-SPECT-Based Nomogram for Early Prediction of Major Cardiac Events in Ischemic Heart Disease

R. Zambrano Infantino, *J. F. Piñerúa-Gonsálvez, B. M. Jaramillo López, F. Sebastian Palacid, Á. R. Suazo Montero, N. Álvarez Mena, M. Alonso-Rodríguez, R. Ruano-Pérez;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Coronary artery disease is one of the leading causes of death worldwide. Although several imaging parameters are currently available as prognostic indicators, few predictive models integrate multiple variables derived from nuclear cardiology tests. The aim of this study is to develop a nomogram model for the early prediction of major cardiac events (MCE) in patients with ischemic heart disease using quantitative variables from Gated-SPECT myocardial perfusion imaging with 99mTc-SESTAMIBI. ***Materials and Methods:*** A retrospective study was conducted using data from the Nuclear Medicine Department at Hospital Clínico Universitario de Valladolid between January 2020 and January 2021. Consecutive patients who underwent Gated-SPECT myocardial perfusion imaging with 99mTc- SESTAMIBI after pharmacological stress, for the diagnostic or prognostic evaluation of ischemic heart disease, and who demonstrated evidence of myocardial ischemia, were included. Patients with arrhythmias, atrial fibrillation, left bundle branch block, right bundle branch block, pacemakers, or previous resynchronization therapy were excluded. Data on MCE occurring within 12 months after the imaging procedure, such as death, heart failure, acute myocardial infarction (AMI), and coronary revascularization (CR), were obtained from medical records. The selection of quantitative variables to create the predictive nomogram was performed using partial least squares (PLS) regression analysis, with the aim of correcting multicollinearity among the variables. The performance of the nomogram was evaluated using the ROC curve and concordance index (C-index). ***Results:*** Of the 185 patients referred to the department with suspected myocardial ischemia, 53 patients were included in the study. The cohort had a mean age of 68.9 ± 8.9 years. 39.6% of patients experienced MCE, with CR being the most frequent event (22.6%), followed by AMI at 9.4%. The PLS regression analysis identified that the end-systolic volume (ESV), left ventricular ejection fraction (LVEF), and standard deviation (SD) and bandwidth (BW) were independent variables for predicting MCE. Using these four variables, a predictive nomogram was developed, which showed an AUC of 0.72 (95% CI: 0.57-0.85) and a C-index of 0.71. ***Conclusion:*** The predictive nomogram developed in this study, based on quantitative variables derived from Gated-SPECT myocardial perfusion with 99mTc-SESTAMIBI, appears to be an effective tool for the early prediction of MCE in patients with ischemic heart disease. The model showed robust performance, identifying key predictors as ESV, LVEF, SD and BW. These findings highlight the clinical value of the Gated-SPECT based nomogram in risk stratification and therapeutic decision-making in this population.

EP-0580

Prognostic Significance of Transient Ischemic Dilatation with Adenosine 99mTc Sestamibi SPECT/CT in Diabetic Patients with Normal Myocardial Perfusion

M. Juweid*;*
University of Jordan, Amman, JORDAN.

Aim/Introduction: To investigate the prognostic significance of non-attenuation (NAC) and attenuation-corrected (AC) TID in diabetic patients with normal perfusion on adenosine ^{99m}Tc-sestamibi imaging. ***Materials and Methods:*** We analyzed 790 diabetic patients with normal perfusion on 2-day adenosine stress/rest ^{99m}Tc-sestamibi SPECT/CT between 1/2019-9/2023. 51 patients with Framingham 10-year coronary heart disease risk <10% were used to derive abnormal AC and NAC TID thresholds (derivation group or DG). The significance of TID at these thresholds was validated in the remaining 739 patients (validation group or VG) followed for cardiac events for 33.6 ± 17.4 (mean ± SD) months. Events were defined as cardiac death, nonfatal MI, coronary revascularization and congestive heart failure. ***Results:*** Mean NAC TID in the DG was 1.09 ± 0.13 while AC TID was 1.07 ± 0.14. Three definitions of an abnormal TID were used: > mean + 2SD (NAC TID ≥ 1.36, AC TID ≥ 1.36), > mean + 1SD (NAC TID ≥ 1.22, AC TID ≥ 1.21) and a TID in the DG's highest quartile (NAC TID ≥ 1.17, AC TID ≥ 1.18). Of the VG, 205 (27.7%), 134 (18.1%) and 36 (4.9%) had NAC TID ≥ 1.17, 1.22 and 1.36, respectively, while 147 (19.9%), 114 (15.4%) and 31 (4.2%) had AC TID ≥ 1.18, 1.21 and 1.36, respectively. On multivariate analysis, NAC TID ≥ 1.17 and 1.22 were predicted by rest LVEF (p <0.001 and .035, respectively). A ≥ 5% decrease in LVEF predicted NAC TID ≥ 1.22 (p < 0.001), NAC TID ≥ 1.36 (p = .002), AC TID ≥ 1.18 (p = .006) and AC TID ≥ 1.21 (p = .020). A ≥ 10% decrease in LVEF predicted NAC TID ≥ 1.22 (p = .030) and AC TID ≥ 1.36 (p = .023). Gender, known CAD, family history of coronary artery disease (CAD), hypertension, dyslipidemia, atrial fibrillation, thyroid disorders and post-stress LVEF did not predict abnormal AC or NAC TID at the tested thresholds. Cardiac event-free survivals were similar in patients with NAC TID ≥ and < 1.17 (2.9% vs. 5.6%, p = .157), ≥ and < 1.22 (1.5% vs. 5.6%, p = .059) and ≥ and < 1.36 (2.8% vs. 5.0%, p = .483). Similar results were found

using the respective AC TID cutoffs. ***Conclusion:*** TID, whether based on attenuation or non-attenuation corrected scans, does not confer adverse prognosis in diabetic patients with normal perfusion on adenosine 99mTc-sestamibi SPECT/CT.

EP-0581

Prevalence of Ischemia with Non Obstructive Coronary Artery disease (INOCA) in patients with positive myocardial perfusion SPECT.

A. Manrique[1], *M. Esnault*[1], *N. Coudrais*[1], *N. Catherine*[1], *P. Richard*[2], *R. Vincent*[1], *D. Agostini*[1];
[1]*CHU de Caen, Caen, FRANCE,* [2]*Hopital Privé Saint Martin, Caen, FRANCE.*

Aim/Introduction: INOCA refers to patients with inducible ischemia during a functional test and no significant epicardial coronary artery stenosis. It is associated with increased risks of major adverse cardiovascular events. ***Materials and Methods:*** In order to evaluate the prevalence of INOCA in patients referred to myocardial perfusion SPECT imaging (MPI), we retrospectively evaluated a series of consecutive patients without previously documented coronary artery disease who underwent a coronary angiogram within 1 month after a positive MPI. All MPIs were performed using a DSPECT CZT camera, a ^{99m}Tc-lebelled tracer and a one-day protocol. MPI and coronary angiogram results were retrieved from hospital records. INOCA was defined by at least one non-significant coronary lesion < 50% and no lesion ≥ 50%. ***Results:*** From January to December 2018, among 3595 patients undergoing MPI, 335 (age 68±10, male 67%) met the inclusion criteria. Symptoms included dyspnea (50%) and/or chest pain (28%) and pre-test likelihood of CAD was >15% in 62%. SPECT demonstrated reversible and non-reversible defects in 299 (90%) and 49 (15%) cases respectively. Coronary angio was normal in 53 (16%) cases and considered as false positive SPECT. Significant lesions (≥50%) were found in 193 (58%) and INOCA in 88 (27%) patients, including 36 (11%) with 30-50% lesions and 53 (16%) with < 30% lesions. Univariate analysis demonstrated that, compared to patients with >50% lesion, INOCA was associated to female gender (p<0.001), decreased rate of hypertension (p<0.01), of peripheral artery disease (PAD) (p<0.001), of dyslipidemia (p<0.05) or pre-test probability (PTP) range (p<0.05), younger age (p<0.01), higher LVEF (p<0.05), lower EDV (p< 0.05) and ESV (p<0.05) at stress and rest, and decreased number of segments with irreversible defects (p<0.001). Using logistic regression, the independent predictors of INOCA were female gender (OR: 4.84, p<0.01), hypertension (OR: 0.30, p<0.01, PTP range <0.15 (OR: 0.26, p<0.01) and irreversible perfusion defect <2 segments (OR 3.85, p<0.05). The extent of reversible perfusion defect was not associated with INOCA in this series. ***Conclusion:*** INOCA was present in ¼ of patients with positive SPECT referred to subsequent coronary angiography. They deferred from patients with significant coronary artery stenosis, with a higher prevalence of female gender with decreased rate of hypertension, a low pre-test probability of CAD and a lower rate of irreversible SPECT defects.

EP-0582

Change in myocardial perfusion does not correlate to change in peak oxygen uptake after coronary revascularization - a positron emission tomography study

A. Székely[1], *S. Akil Engblom*[1], *H. Mosén*[1], *K. Steding-Ehrenborg*[1], *C. Hindorf*[2], *F. Hedeer*[1], *H. Arheden*[1], *H. Engblom*[1];
[1]*Clinical Physiology, Department of Clinical Sciences Lund, Lund University, Skåne University Hospital, Lund, SWEDEN,* [2]*Department of Medical Radiation Physics, Lund University, Lund, SWEDEN.*

Aim/Introduction: Chronic coronary syndrome (CCS) is associated with reduced stress perfusion, which is a predictor of adverse cardiovascular outcome (1). To what extent the level of myocardial perfusion is related to cardiorespiratory fitness is not completely known. The aim of this study was to investigate if change in myocardial perfusion assessed by cardiac [^{13}N]NH_3 positron emission tomography (PET) correlates with change in VO_2 peak assessed with CPET before and after invasive coronary angiography (ICA) with revascularization. ***Materials and Methods:*** Sixty-two patients (median age 68 (range 46-86) years, 14 females) with suspected or established CCS underwent cardiopulmonary exercise testing (CPET) and [^{13}N]NH_3 PET before and after elective ICA. The angiographer was blinded to the results from CPET and PET. Thirty-five patients were revascularized. Myocardial perfusion at stress and myocardial perfusion reserve (MPR) were assessed from PET. VO_2 peak % of predicted and VO_2 peak ml/min/kg were assessed from CPET. Results are presented as median (range). ***Results:*** Global myocardial perfusion at stress increased significantly from baseline to follow-up if baseline global perfusion at stress was <2 ml/min/g (1.79 (1.01-1.86) ml/min/g vs 1.94 (1.09-2.61) ml/min/g, P=0.02), however not if baseline was ≥2 ml/min/g (2.42 (2.00-3.32) ml/min/g vs 2.57 (1.55-4.22) ml/min/g, P=0.09). Global MPR increased significantly from baseline to follow-up if baseline global MPR was <2.4 (2.23 (1.33-2.40) vs 2.63 (1.22-3.20), P=0.001), however not if baseline was ≥2.4 (2.89 (2.45-3.52) vs 3.07 (1.77-4.46), P=0.43; Figure 2). There were no significant correlations between change in VO_2 peak % of predicted and global myocardial perfusion at stress (R=0.08, P=0.64) or global MPR (R=0.07, P=0.69) from baseline to follow-up. Furthermore, there were no correlations between change in VO_2 peak ml/min/kg and global myocardial perfusion at stress (R=0.15, P=0.39) or global MPR (R=0.10, P=0.57, figure 3). No significant improvement in VO_2 peak % of predicted or VO_2 peak ml/min/kg was seen in patients undergoing revascularization of vessel territories with a significantly reduced perfusion at stress (<2.0 ml/min/g) (P=0.63 and P=0.94) or MPR (<2.4) (P>0.99 and P=0.96) at baseline. ***Conclusion:*** Change in myocardial perfusion after revascularization was not associated with change in VO_2 peak in patients with CCS, regardless of whether perfusion was decreased or normal in the culprit vessel territory prior to revascularization. ***References:*** 1.Knott KD, Seraphim A, Augusto JB, Xue H, Chacko L, Aung N, et al. The Prognostic Significance of Quantitative Myocardial Perfusion: An Artificial Intelligence-Based Approach Using Perfusion Mapping. Circulation. 2020;141(16):1282-91.

EP-0583

Comparison of LVEF derived using four cardiac softwares on CZT cardiac camera and 2D-Echocardiography

J. Krishna P.*, D. Khan, S. Sagar, L. Goriparti, R. Wakankar, C. Patel, B. Chandra, P. Gupta, A. Roy, S. Yadav, S. Agstam, N. Parakh;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To compare the left ventricular ejection fraction (LVEF) values derived using four cardiac quantitative softwares on Tc99m-MIBI Myocardial Perfusion SPECT (MPS) acquired on CZT camera with 2D-Echocardiography (ECHO). ***Materials and Methods:*** This prospective study included 112 patients with known or suspected CAD, referred for MPS and ECHO. Estimated LVEF of 60% or more on ECHO was considered normal. The MPS studies were processed using vendor provided individual softwares, namely Emory Cardiac Toolbox (ECTb), 4D-MSPECT, QGS/QPS (Cedars-Sinai) and Myometrix. LVEF was subsequently calculated and compared to ECHO, which was taken as the reference standard. Pearson's correlation was done to compare LVEF values between the softwares and normal cutoff values for each software program was obtained with receiver-operating characteristic (ROC) analysis. ***Results:*** Out of 112 patients [(94 M, 18 F), median age - 56 years], 47 were found normal and 65 abnormal based on ECHO findings. The mean LVEF on ECHO was 55±8.9%. The mean LVEF values for ECTb, 4D-MSPECT, QGS/QPS and Myometrix were 59.1±14.7%, 61.1±12.9%, 59.0±13.1% and

54.3±12.6%, respectively. A positive correlation was observed between LVEF values derived by ECHO and MPS software programs: ECTb ($r = 0.604$, $P < 0.001$), 4D-MSPECT ($r = 0.543$, $P < 0.001$), QGS/QPS ($r = 0.587$, $P < 0.001$) and Myometrix ($r = 0.595$, $P < 0.001$). Significant correlation was also seen for LVEFs among the four software programs ($P < 0.05$). Normal cutoff values for LVEF on ECTb, 4D-MSPECT, QGS/QPS and Myometrix were estimated to be 60%, 57%, 52%, 49% respectively. ***Conclusion:*** The study revealed a positive correlation for LVEF between cardiac softwares and ECHO and it also derived the normal cutoff values for each of them. However, the cutoff values were software specific and cannot be used interchangeably for routine clinical practice.

EP-0584

Evaluation of Myocardial Perfusion Imaging Using AUC Guidelines: Adherence and Diagnostic Yield at a High-Volume Tertiary Care Center in Central India.

B. Vamshi Naik, *M. Ravina, S. Singh, S. Raju, S. Thakur; All India Institute of Medical Sciences, Raipur, INDIA.*

Aim/Introduction: Myocardial perfusion imaging (MPI) is essential for diagnosing and managing coronary artery disease (CAD). However, inappropriate use can increase healthcare costs and radiation exposure. The Appropriate Use Criteria (AUC) were developed to help clinicians make informed, evidence- based decisions when ordering myocardial perfusion imaging (MPI). This study looks at how appropriately MPI is being used and how often perfusion defects are detected. With limited research available from India, this audit is expected to play an important role in understanding and improving clinical practice. ***Materials and Methods:*** A retrospective study of 475 MPI procedures conducted between February 2022 and August 2024 was performed. All patients referred for stress MPI were included. Clinical indications were reviewed and categorized as Appropriate, Rarely Appropriate, or Maybe Appropriate based on the 2013 ACCF/AHA/ASNC Appropriate Use Criteria. The frequency and percentage of each category were calculated to assess adherence, and MPI results were analysed for perfusion defects. ***Results:*** Among the 475 MPI studies analysed, 431 (90.74%) were deemed Appropriate, 43 (9.05%) Rarely Appropriate, and 1 (0.21%) Maybe Appropriate. These findings suggest a high level of compliance with AUC at the institution. Similar international audits have reported appropriate use rates ranging from 72% to 91%, placing our adherence at the higher end of global benchmarks. Perfusion defects were observed in 123 patients (25.89%) overall. Among the 431 appropriately indicated studies, 112 (25.99%) showed perfusion abnormalities. In contrast, defects were identified in approximately 11 (25.58%) of the 43 rarely appropriate cases, and none in the single maybe appropriate case. There was no statistical difference in the prevalence of perfusion defects between the appropriate and rarely appropriate groups (P-value ~0.79). ***Conclusion:*** The study highlights strong adherence to the Appropriate Use Criteria in myocardial perfusion imaging at a tertiary care centre in Central India, with most studies classified as appropriate. However, the relatively low detection rate of perfusion defects & no significant difference in the prevalence of perfusion defects between the appropriate and rarely appropriate groups- reveals a disparity between guideline-based indications and actual diagnostic yield. Additionally, this disparity underscores the limited clinical utility of MPI in scenarios deemed rarely appropriate by the guidelines. These findings emphasize the importance of balancing guideline adherence with clinical judgement to optimize the diagnostic yield of MPI.

EP-0585

Feasibility of functional analysis using myocardial perfusion SPECT/CT with a novel multifocal collimator, retrospective gating, and integrated corrections

S. Watanabe[1], *K. Nakajima*[1], *T. Shibutani*[2], *S. Yoshida*[3], *M. Onoguchi*[2], *S. Kinuya*[1], *F. Massanes*[4], *T. Shimizu*[4], *A. H. Vija*[4]; [1]*Department of Nuclear Medicine, Kanazawa University, Kanazawa, JAPAN,* [2]*Department of Quantum Medical Technology, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, JAPAN,* [3]*Department of Cardiovascular Medicine, Kanazawa University Graduate School of Medical Science, Kanazawa, JAPAN,* [4]*Molecular Imaging, Siemens Medical Solutions USA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA.*

Aim/Introduction: We have presented an iterative reconstruction method that mitigates the causes of image degradation, demonstrating effectiveness of integrated systematic corrections. We evaluated the accuracy of functional analysis using myocardial perfusion SPECT/CT with a novel multifocal SMARTZOOM high resolution and extended magnification volume (SZHRX) collimator compared with conventional SPECT. ***Materials and Methods:*** We prospectively studied patients who underwent myocardial perfusion imaging (MPI) for suspected coronary artery disease at Kanazawa University Hospital between February 2023 and November 2024, using a Symbia Intevo 16 SPECT/CT with SZHRX collimator (research setting) and ^{99m}Tc perfusion tracers. For SPECT/CT with SZHRX collimator, we used 256×256 matrix and 3° list-mode data sampling from continuous rotation over 360° scan range with either 180° or 76° camera configurations. The ordered subset conjugate gradient minimizer (OSCGM) reconstruction method was used with retrospective electrocardiography (ECG) gating and CT-based attenuation and energy window-based scatter corrections. Corrections for patient and organ motion between and within views were also applied to the gated reconstructions. For conventional SPECT, all patients underwent MPI with parallel-hole low-energy high-resolution collimator using the 3D-OSEM (Flash 3D) reconstruction method with prospective ECG gating without attenuation and scatter corrections, and data were also acquired over 360°. Left ventricular (LV) end-diastolic volume (EDV), end-systolic volume (ESV), ejection fraction (EF), and phase entropy were assessed at rest. Echocardiographic measurements of volume and EF within 3 months of an MPI study were used as reference. ***Results:*** Twenty-nine patients (age, 69 ± 10 years; male, 86%) were included. The integrated corrections used in the SZHRX collimator condition did not cause any harms or artifacts. Correlations of functional parameters between the SZHRX collimator condition and conventional SPECT were strong and significant ($p < 0.0001$) for all EDV ($R^2 = 0.96$), ESV ($R^2 = 0.96$), LVEF ($R^2 = 0.90$), and phase entropy ($R^2 = 0.55$). EDV and ESV were 1 and 8 mL higher, respectively, LVEF was 5% lower, and entropy was 6% higher for the SZHRX collimator condition compared with conventional SPECT. The correlations between these functional variables and echocardiographic values were higher for the SZHRX collimator condition than for conventional SPECT ($R^2 = 0.83$ and 0.78 for EDV, 0.93 and 0.86 for ESV, and 0.80 and 0.64 for LVEF, respectively) in 26 patients. ***Conclusion:*** Myocardial perfusion SPECT/CT with SZHRX collimator, retrospective gating, and integrated corrections showed good performance for functional analysis. More comprehensive studies are warranted to validate these findings. ***References:*** JNC. 2023;30: 2773-2789.

Prediction of Cardiac Events in Patients with Diabetes Using Stress Myocardial Blood Flow and Coronary Flow Reserve

M. Havel[1,2], *M. Kaminek*[1,3], *L. Quinn*[1], *L. Henzlova*[1], *V. Icova*[1], *G. Havlova*[2];
[1]*Department of Nuclear Medicine, University Hospital, Palacky University, Olomouc, CZECH REPUBLIC,* [2]*University of Ostrava and University Hospital Ostrava, Department of Nuclear Medicine, Ostrava, CZECH REPUBLIC,* [3]*International Clinical Research Center and Department of Internal Medicine/Cardiology, St. Anne´s University Hospital, Faculty of Medicine, Masaryk University, Brno, CZECH REPUBLIC.*

Aim/Introduction: Cardiovascular disease (CVD) is a major complication of diabetes mellitus (DM), encompassing macrovascular complications, diabetic cardiomyopathy, and microvascular dysfunction. Coronary flow reserve (CFR), derived from dynamic SPECT imaging, is a valuable marker for coronary artery disease (CAD) and microvascular involvement. However, acquiring CFR requires both stress and rest studies, increasing time and radiation exposure. This study evaluates the prognostic significance of dynamic SPECT-derived myocardial blood flow (MBF) during stress and rest and CFR in a cohort of patients with DM. ***Materials and Methods:*** A retrospective analysis was conducted on 49 patients with DM (26 men, mean age 65±10 years) who underwent rest-stress dynamic myocardial SPECT. Stress and rest MBF, along with CFR, were correlated with adverse cardiac events (CE) during follow-up, defined as sudden cardiac death, myocardial infarction, acute coronary revascularization, and hospitalization for heart failure. ***Results:*** Over a mean follow-up of 15 months, 11 CE (22.4%) were recorded. Patients with CE exhibited significantly lower stress MBF (1.90±1.16 vs. 2.61±0.81 ml/min/g, P=0.0025) and lower CFR (1.53±0.67 vs. 2.36±0.82, P=0.004), whereas rest MBF showed no significant difference (1.26±0.40 vs. 1.16±0.39, P=0.458). Cut-off values predicting CE were stress MBF ≤1.73 ml/min/g (sensitivity 73%, specificity 87%, AUC=0.75) and CFR ≤1.94 (sensitivity 73%, specificity 76%, AUC=0.79). Univariable Cox regression revealed both stress MBF and CFR as significant predictors (HR=9.0, P=0.001 and HR=5.7, P=0.011, respectively). However, in a multivariable model, only stress MBF remained significant (HR=5.72, P=0.026). ***Conclusion:*** CE in patients with DM can be predicted by low stress MBF and low CFR. However, the addition of CFR to stress MBF did not provide significant incremental value. These findings suggest a potential simplification of the dynamic SPECT protocol, favoring a stress-first or stress-only approach, which could enable broader MBF quantification for an increased number of patients. Supported by: MH CZ - DRO (FNOl, 00098892). ***References:*** Kaminek M, Havel M, Kincl V, Henzlova L, Hudson L. The prognostic value of CZT SPECT stress myocardial blood flow (MBF) quantification-opportunity for stress-first/stress-only protocol. Eur J Nucl Med Mol Imaging. 2024 Jan;51(2):344-345.

EP-0587

The Minimum Scan Time for Gated Myocardial Perfusion Imaging Using a Dedicated Ultrafast Solid-state Cardiac Camera

D. Zhao*, S. Sun, T. Wang, J. Song, X. Bi, T. Ye, Y. Wang, X. Xu, S. Yao, J. Liu, R. Wang;*
Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: The study aimed to determine the minimum scan time for gated myocardial perfusion imaging (MPI) using a standard dose and a dedicated ultrafast solid-state cardiac camera (Discovery NM 530c [DNM]). ***Materials and Methods:*** We performed a retrospective study which included 76 consecutive patients who were suspected coronary artery disease (CAD) referred for gated-MPI scan on the DNM camera. In the included 76 patients, 52 underwent a stress-only protocol and 24 underwent a two-day stress-rest protocol. Among them, 30 patients (15 male and 15 female) who received the stress-only scan were randomly selected as the test group and the remaining patients were assigned to the validation group. Patients were scanned 90-120 minutes (min) post-injection of [^{99m}Tc] Tc-sestamibi (about 555 MBq) for 6 min using list-mode. The List-mode raw data from the test group were reframed into 1-min, 2-min, 3-min, 4-min, 5-min datasets, while data from the validation group were reframed to generate the minimum scan time dataset. All datasets were quantified using automated quantitative perfusion and gated SPECT software (QPS/QGS). The minimum scan time was determined and validated by assessing the absolute agreement of quantitative parameters between reframed scan durations and original 6 min scan duration using intraclass correlation coefficient (ICC). ***Results:*** The minimum scan time was determined as 3 min in the test group based on the comparison of perfusion and function parameters and was confirmed in validation group with good to excellent agreement (ICC>0.87 for summed difference score and ICC>0.97 for summed stress score, summed rest score, ejection fraction, the end-diastolic volume and end-systolic volume). ***Conclusion:*** The minimum scan time was determined as 3 min in the test group based on the comparison of perfusion and function parameters and was confirmed in validation group with good to excellent agreement (ICC>0.87 for summed difference score and ICC>0.97 for summed stress score, summed rest score, ejection fraction, the end-diastolic volume and end-systolic volume).

EP-0588

Comparison of myocardial perfusion imaging and myocardial flow reserve using cadmium-zinc-telluride camera for the diagnosis of coronary artery disease

T. Niimi*, K. Hirayama;*
Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital, Nagoya, JAPAN.

Aim/Introduction: A cadmium-zinc-telluride (CZT) camera can simultaneously evaluate myocardial flow reserve (MFR) and myocardial perfusion imaging (MPI) without positron emission tomography. This camera has renewed the interest in single-photon emission computed tomography (SPECT)-MFR assessment in patients with coronary artery disease (CAD). However, there has been little discussion on the relationship and validity of the MFR with conventional indicators. This study evaluated the relationship between the MFR and left ventricular (LV) phase analysis indices, such as bandwidth, phase standard deviation (SD), and entropy, calculated from the MPI and their effectiveness in improving CAD diagnosis. ***Materials and Methods:*** We retrospectively analyzed the clinical images of 60 patients who underwent dynamic CZT SPECT to evaluate suspected CAD (43 men and 17 women, mean age; 66.9 ± 10.0 years) after injection of ^{99m}Tc-sestamibi for rest and stress imaging. To assess the severity of CAD, the combined effect of MFR and LV phase analysis indices on MPI was examined. Receiver operating characteristic (ROC) and multivariate ROC analyses were used to quantify, improvement of CAD diagnostic performance using MPI (summed stress score (SSS)) alone, if MPI and MFR were combined, and if MPI and LV phase analysis indices were combined. ***Results:*** The area under the ROC curve (AUC) if SSS using MPI alone was 0.86 (sensitivity; 0.76, specificity; 0.84), whereas that if SSS was combined with MFR was 0.93, confirming a significant difference if MFR was combined with SSS. (p = 0.03). The AUCs for bandwidth, phase SD, and entropy combined with SSS were 0.88, 0.85, and 0.88, respectively, with no significant differences because of the combination. However, combining all LV phase analysis indices confirmed a significant difference with an AUC of 0.94 (p = 0.04). Similar diagnostic accuracy for CAD was obtained by combining the SSS in the MPI with the MFR or LV phase analysis indices. ***Conclusion:*** Using SSS in MPI combined with LV phase analysis indices can provide diagnostic accuracy

similar to that of using MFR in combination, although not the absolute quantitative blood flow indices. LV phase analysis indices calculated from the MPI may be used as alternative indices if the MFR cannot be measured for CAD screening.

EP-0589

Evaluation and mitigation of false positives in inferior myocardial wall with CZT camera using complementary stress myocardial perfusion with hybrid Anger-type camera

F. Vauchot, *T. Paunet, J. Dubois;*
CHU Gui de Chauliac, Montpellier, FRANCE.

Aim/Introduction: Meta-analysis show the diagnostic performance of cardiac dedicated multi-pinhole CZT (Cadmium Zinc Telluride) myocardial perfusion imaging (MPI) with a sensibility around 0.9 and a specificity around 0.7. Specificity is lower for inferior myocardial wall (IMW) because of more artefact occurring in this territory, with addition of body attenuation and CZT camera-specific artefacts. The aim of the present study is to evaluate and prevent false positive in IMW with CZT camera and to enhance specificity without changing sensibility using complementary stress MPI with hybrid Anger-type camera. ***Materials and Methods:*** From march 2023 to march 2025, we recruited all patients (n=100) explored by MPI with [99mTc]Tc-tetrofosmin under multi-pinhole CZT (Discovery NM 530c, GE Healthcare), with potential inferior ischemia and without necrosis. Those patients were explored the same day at stress with hybrid Anger-type camera (Discovery 870 DR16, GE Healtcare) using attenuation correction.Potential inferior ischemia was defined as a difference between sum stress score (SSS) and sum rest score (SRS): Δ= SSS-SRS ≥ 1. SSS was estimated a second time with hybrid camera: SSSh. Wilcoxon rank sum test was used for statistical comparisons. ***Results:*** After the second acquisition at stress, only 15 patients remained with SSSh>0 and were explored by coronarography or known for ischemic cardiopathy. SSSh was equal to 0 for 85 patients, meaning 85% potential false positive. Despite very low major cardiologic adverse event rate associated to normal stress MPI, those patients underwent a complementary 6-month follow-up. Among the 100 patients: 24 of 30 patients with SSS≥3 (80%); 35 of 42 patients with SSS=2 (83%) and 26 of 28 patients with SSS=1 (93%) showed a SSSh=0.Only number of segments with average subtraction (NAS) > 5 on dedicated polar maps and quantitative value of this average subtraction (QAS) were predictive of ischemia (p-value=0.0004 and p-value=0.002 respectively). For ischemia arm, NAS was 4.1±1.4 (IC95 3.4-4.8) and QAS was 16.3±6.1 (IC95 13.2-19.3). For potential false positive arm, NAS was 2.5±1.5 (IC95 2.2-2.9) and QAS was 11.3±4.9 (IC95 10.2-12.3). Δ was not predictive of ischemia (p-value=0.097): Δ= 2.6±1.2 (IC95 2.0-3.6) for ischemia arm, and Δ= 2.0±1.0 (IC95 1.8-2.3) for potential false positive arm. ***Conclusion:*** This study showed an IMW ischemia evaluation significantly different between cardiac dedicated multi-pinhole CZT and hybrid Anger-type cameras, with 85% potential false positives, regardless of the reversible segment numbers Δ.

EP-0590

Post-PCI patients with persistent chest discomfort lacking immediate post-procedural caIMR-derived CMD and subsequent MPI-detected residual ischemia exhibited optimal prognosis

W. Yu, *Y. Wang;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: This study evaluated the prognostic value of immediate post-procedural coronary angiography-derived Index of Microcirculatory Resistance (caIMR) and Single photon emission computed tomography myocardial perfusion imaging (SPECT/MPI) during follow-up in post PCI patients with persistent chest discomfort. ***Materials and Methods:*** 214 prospective post-PCI inpatients with persistent chest discomfort were enrolled, then underwent SPECT/CT 1-3 months later. Post-procedural Coronary Microvascular Dysfunction (CMD, caIMR≥25) and subsequent residual ischemia (SPECT/MPI SDS≥2) were assessed. MACE included angina-related rehospitalization, cardiac death, late coronary revascularization, nonfatal MI, heart failure, and stroke. ***Results:*** Post-procedural CMD and subsequent residual ischemia occurred in 106 (49.5%) and 107 (50.0%) respectively. During the median follow-up period of 42 (24, 50.25) months, MACE occurred in 88 (41.1%). MACE group showed higher CMD [53 (60.2%) vs. 53 (42.1%)] and residual ischemia rates [57 (64.8%) vs. 50 (39.7%)], both P <0.05], with Kaplan-Meier analysis confirming elevated MACE risks (Log-rank P<0.05). Post-procedural CMD and subsequent residual ischemia were independently correlated with MACE after adjusting for confounding factors [HR (95%CI): 1.72 (1.12, 2.65) and 2.34 (1.50, 3.66), both P < 0.001]. Patients without subsequent residual ischemia or post-procedural CMD exhibited optimal prognosis compared with patients with one or both risk factors [7 (8.0%) vs. 24 (27.3%) vs. 28 (31.8%) vs. 29 (33.0%), P<0.001]. ***Conclusion:*** Both post-procedural caIMR-derived CMD and subsequent residual ischemia identified via MPI independently related to MACE in post-PCI patients with persistent chest discomfort. Patients with neither post-procedural caIMR-derived CMD nor subsequent MPI-detected residual ischemia exhibited optimal prognosis.

EP-0591

Long-term prognostic value in nuclear cardiology: Expert scoring combined with automated measurements vs. angiographic score

G. Angelidis, *S. Giannakou, V. Valotassiou, E. Panagiotidis, I. Tsougos, C. Tzavara, K. Sakellariou, D. Psimadas, E. Theodorou, C. Ziangas, J. Skoularigis, F. Triposkiadis, P. Georgoulias;*
University of Thessaly, Larissa, GREECE.

Aim/Introduction: The evaluation of myocardial perfusion imaging (MPI) studies is based on the visual interpretation, while automated analyses may contribute to the investigation. We aimed to investigate the long-term prognostic value of expert reading of summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS), combined with the automated measurements of these parameters, in comparison to the prognostic ability of the angiographic score for soft and hard cardiac events. ***Materials and Methods:*** The study was conducted at the Nuclear Medicine Laboratory, University of Thessaly, Larissa, Greece. 528 consecutive patients with known or suspected coronary artery disease (CAD) were enrolled. All participants were referred to our laboratory for the performance of stress/rest myocardial perfusion single photon emission computed tomography. Automated measurements of SSS, SRS, and SDS were obtained by Emory Cardiac Toolbox (ECTb (Version 3.0), Emory University, Atlanta, GA, USA), Myovation (MYO, Xeleris version 3.05, GE Healthcare, Chicago, IL, USA), and Quantitative Perfusion SPECT (QPS Version 4.0, Cedars-Sinai Medical Center, Los Angeles, CA, USA) software packages. Coronary angiographies were scored according to a 4-point scoring system (angiographic score; 0: normal study, 1: one-vessel disease, 2: two-vessel disease, 3: three-vessel disease). Follow-up data were recorded after phone contacts, as well as through review of hospital records. All participants were followed up for at least 36 months. ***Results:*** Data from 528 patients (61.6% males), with mean age 64.1 years (SD=9.5 years) were analyzed. Any cardiac event was recorded in 35.2% (n=186) of the sample and hard cardiac events in 10.8% (n=57) of the sample. The prognostic values of the angiographic score and of the expert scoring (all indexes combined) regarding hard cardiac events, as well as any cardiac event, were significant

(p<0.05). The prognostic ability of the angiographic score was significantly lower than the prognostic ability of the combination of expert scoring and automated analysis, for both hard events (p<0.001) and any cardiac event (p<0.001). The incremental prognostic value of the angiographic score to the prognostic value of the combination of the expert scoring and automated analyses was significant for hard events (p=0.014), whereas for any cardiac event it was not significant (p>0.05). ***Conclusion:*** The combination of expert reading and automated measurements of SSS, SRS and SDS shows a superior prognostic ability in comparison to the angiographic score.

EP-0593

Early Detection of Cardiac Involvement in Lipid Storage Myopathy:The Superior Role of Myocardial Perfusion Imaging

W. Zhengjie, *L. Jia, T. Fangfang, Z. Xiaoyang, L. Mengdan, P. Hua; The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.*

Aim/Introduction: Lipid storage myopathy (LSM), arising from defects in multiple enzyme functions or carnitine deficiency and resulting in impaired fatty acid metabolism, often involves cardiomyopathy as advanced stages of the disease across various genotypes. This study aims to investigate the utility of myocardial perfusion imaging (MPI) in patients with LSM, with a particular focus on its role in evaluating the extent of cardiac involvement. ***Materials and Methods:*** Fourteen patients Confirmed as LSM by muscle biopsy underwent rest/stress single-photon emission computed tomography MPI, echocardiography, and blood biochemical profiling. Four patients completed a follow-up MPI 3 months post-treatment. Left ventricle perfusion was evaluated using a 17-segment standardized model with a 5-point scoring system. The summed rest score (SRS) and summed stress score (SSS) for the left ventricle were calculated. Pearson's correlations between SSS and other cardiac function and biochemical parameters were evaluated. Paired t-tests were employed to analyze the pre- and post-treatment changes. ***Results:*** The cohort exhibited a mean SSS of 9.71. Cardiac abnormalities were detected in 12 out of 14 patients (85.7%), with 4 patients of severe abnormalities indicated by SSS, compared to 4 out of 14 (28.6%) by echocardiography. SSS also demonstrated a positive correlation with stress end-diastolic volume (EDV; r = 0.89) and a significant negative correlation with ejection fraction (EF; r = -0.87). There are no biochemical markers demonstrated correlation coefficients with SSS. As the disease progressed, patients demonstrated gradually increasing SSS on MPI, with radionuclide distribution defects transitioning from reversible to partially irreversible patterns. Post-treatment SSS also showed significant reduction (8.76 to 2.33). ***Conclusion:*** This study underscores the efficacy of MPI in the early detection and monitoring of myocardial damage associated with LSM. Specifically, it emphasizes the utility of SSS in assessing the extent of cardiac involvement, thereby furnishing essential evidence to inform clinical treatment decisions. ***References:*** 1. EP-0594

Triglyceride is associated with coronary microvascular dysfunction in patients with obstructive coronary artery disease

Y. Wang, *Y. Lu, X. Zhang;*
Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: Coronary microvascular dysfunction (CMVD) is one of the significant causes of myocardial ischemia, and is widely present in patients with obstructive coronary artery disease (OCAD) and non obstructive coronary disease (NOCAD). This prospective study sought to evaluate the CMVD though quantitative myocardial blood flow assessment derived by CZT-SPECT, and compare the difference of CMVD in patients with OCAD versus NOCAD at the patient level and the coronary vessel level, and to identify the risk factors associated with CMVD in patients with OCAD. ***Materials and Methods:*** Patients diagnosed with suspected or known CAD, and suspected of having CMVD, was underwent pharmacological stress and rest gated myocardial perfusion imaging (G-MPI), prospectively. They also completed dynamic acquisition for coronary flow reserve (CFR) assessment within three months before or after coronary angiography (CAG) or coronary computed tomography angiography (CCTA). CMVD was defined as the coronary stenosis < 50% and the CFR < 2.1. Multivariable logistic regression analysis was used to identify the risk factors associated with the co-occurrence of CMVD in patients with OCAD. ***Results:*** A total of 54 patients (mean age 58±9 years, 33 men) and 162 vessels were finally enrolled. Among the patients, there were 39 cases of OCAD and 15 cases of NOCAD. In the OCAD group, 57 coronary arteries had stenosis less than 50%, among which 14 were diagnosed with CMVD. In the NOCAD group, out of 45 coronary arteries, 15 were diagnosed with CMVD. (1) At the vessel level, there is no significant difference between the detection rate of CMVD in OCAD and NOCAD patients (24.6% vs. 33.3%,P > 0.05). At the patient level, there is no significant difference between the two groups (15.4% vs. 33.3%, P = 0.276). (2) In patients with OCAD, elevated triglyceride is an independent risk factor for the coexistence of CMVD (OR = 1.956, 95% CI: 1.031-3.712, P = 0.04). ***Conclusion:*** The detection rate of CMVD was similar between OCAD and NOCAD patients. For patients with OCAD, increased triglyceride is an independent risk factor for the presence of CMVD.

EP-0595

The prognosis value of coronary microvascular dysfunction in chronic coronary syndrome patients compared with global coronary flow reserve

Y. Wang, *Y. Zhao, X. Zhang;*
Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: Impaired global coronary flow reserve (CFR) and coronary microvascular disease (CMVD) is associated with adverse outcomes in coronary artery disease (CAD) patients. This prospective study sought to evaluate whether CMVD contributes to the worsened outcomes in chronic artery disease (CCS) patients and those with normal global left ventricular CFR. ***Materials and Methods:*** Patients diagnosed with CCS and suspected of having CMVD were prospectively enrolled. Individuals with prior myocardial infraction or revascularization were excluded. Participants underwent pharmacological stress and rest gated myocardial perfusion imaging (G-MPI) and completed dynamic acquisition for CFR assessment by using CZT-SPECT within three months before or after coronary angiography (CAG) or coronary computed tomography angiography (CCTA). CMVD was defined as having coronary stenosis < 50% along with impaired CFR (CFR < 2.1). The major adverse cardiac events (MACE) included rehospitalization for angina, repeat CAG, acute myocardial infarction, late revascularization, and all-cause death. Kaplan-Meier survival analysis and log-rank tests were used to compare outcomes between groups and to assess the prognostic value of impaired CFR and CMVD. ***Results:*** A total of 54 patients (mean age 58 ± 9 years, 33 men) were recruited for the study. Among these patients, 11 were diagnosed with CMVD, of which 8 exhibited impaired global CFR. In the 43 patients without CMVD, 7 were

diagnosed with impaired global CFR. Over a median follow-up duration of 164 days (interquartile range I77-232 days), 5 patients (9.26%) experienced cardiac events. Kaplan-Meier analysis showed significantly higher event rates in patients with impaired global left ventricular CFR (20%[3/15]vs. 5.13%[2/39],Log-rank = 4.564, P <0.05), in comparison with patients with normal CFR.. However, no significant difference was observed in the event rate between patients with and without CMVD (18.18% vs. 6.98%, P = 0.054). Among patients with normal global CFR, there was also no significant difference in the MACE rate between those with and without CMVD (P > 0.05). ***Conclusion:*** Among CCS patients, the presence of CMVD indicates a trend toward an increased risk of adverse outcomes. Although this trend is not statistically significant, it highlights the need for larger patient cohorts in future studies.

EP-0596

Decrease in Ejection Fraction between Rest and Stress on Myocardial Perfusion Imaging Studies: Frequency and Potential Clinical Significance

F. Naeem*, V. Pant, S. Salam, A. Chamnan, L. Yeung, S. Vinjamuri;*
Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM.

Aim/Introduction: Myocardial Perfusion Imaging (MPI) plays a crucial role in evaluating cardiac function, with resting Ejection Fraction (EF) commonly included in routine MPI assessments. Recent guidelines from the American Society of Nuclear Cardiology (ASNC) highlight the prognostic value of identifying a decline of 10% or more in EF between rest and stress phases, as this may independently signal a poor cardiac outcome. This study aimed to assess the frequency of such EF changes and their potential link to adverse cardiovascular events. ***Materials and Methods:*** We performed a retrospective review of MPI scans from 100 patients (60 female) conducted between July 2023 and January 2024. Reports and images were analyzed, and EF values were re-evaluated when required. We specifically looked for cases showing a drop in EF greater than 10% between stress and rest imaging. In the second phase, we followed these patients for 12 months, identifying any significant cardiac events or markers associated with poor prognosis. ***Results:*** Of the 100 patients reviewed, only 2 had both stress and rest EF values documented in their reports. One showed a >10% EF decline, while the other did not exhibit any significant change. An additional 16 patients (10 female) were identified during reanalysis to have an unreported EF drop of more than 10%. Among the remaining 82 cases, 37 had higher EF values during stress, 25 had a mild EF reduction (3-9%), and 19 had nearly identical stress and rest EF values (±3%). During the 12-month follow-up, 10 patients died. One of these individuals had a significant (>10%) EF drop that had not been reported initially. This patient, who experienced chest discomfort and breathlessness, had an otherwise normal MPI scan. The death was due to community-acquired pneumonia resulting in cardiorespiratory failure. Among the other nine deaths, two were caused by out-of-hospital cardiac arrests. One of these patients had reversible ischemia on their MPI and a history of coronary artery bypass surgery. ***Conclusion:*** Only a small percentage (2%) of patients had both EF values reported. While significant EF changes did not consistently predict cardiac death, we advocate for reporting both values routinely. EF data should be interpreted within the full clinical context, as a clear link between EF changes and major cardiac events remains uncertain in this limited study. ***References:*** Quality Metrics for Single-photon Emission Computed Tomography Myocardial Perfusion Imaging: An ASNC Information Statement.

EP-0597

Myocardial Perfusion Scintigraphy with Regadenoson and Correlation with the Findings of Coronary Angiography

M. Ilic Tomas*[1,2], K. Žepina[2], P. Stroglio[2], L. Fischer[1,2], I. Iskra[1,2], T. Bogović Crnčić[1,1];*
[1]Clinical Hospital Centre Rijeka, Rijeka, CROATIA, [2]University of Rijeka, Faculty of Medicine, Rijeka, CROATIA.

Aim/Introduction: Myocardial perfusion scintigraphy (MPS) using Regadenoson is a well-established, non-invasive method for evaluating myocardial ischemia, particularly in patients unable to perform adequate exercise stress testing. While MPS provides valuable functional insight into myocardial blood flow, invasive coronary angiography (CA) remains the anatomical gold standard for assessing coronary artery disease (CAD). This study aims to compare MPS results with CA findings in order to assess the diagnostic concordance between functional and anatomical assessments in detecting significant CAD and guiding clinical decisions. ***Materials and Methods:*** This retrospective study included 206 patients who underwent Regadenoson MPS. A fixed 400 µg dose of Regadenoson was administered for pharmacologic stress in individuals with contraindications to exercise. Among them, 109 patients (52.9%) also underwent invasive CA, allowing for direct comparison between perfusion abnormalities and anatomical lesions. MPS was considered positive in cases of reversible ischemia and negative in the presence of myocardial scarring. CA was deemed positive if it revealed significant obstructive lesions, occlusions, or high-grade stenoses. Statistical analysis included the chi-squared test to evaluate associations, Phi coefficient to assess the strength of association, and Pearson's correlation coefficient to determine linear correlation between MPS and CA. The Mann-Whitney U test was used to assess relationships between clinical variables, including symptoms, ECG changes, ejection fraction, myocardial contractility, heart rate response, and adverse effects. A p-value of less than 0.05 was considered statistically significant. ***Results:*** The median age of the study population was 69 years, with 64.1% being female. Regadenoson was generally well tolerated, with only mild and transient adverse effects reported. Among the 109 patients who underwent both MPS and CA, 62 (56.9%) had a positive MPS result. Of these, 16 (25.8%) had significant findings on CA, whereas 46 (74.2%) did not. A statistically significant association between positive MPS and CA findings was observed (p = 0.0346), with a Phi coefficient of 0.162 indicating a weak yet meaningful association. Pearson's correlation coefficient was r = 0.178 (p = 0.020), confirming a statistically significant but weak correlation between the two diagnostic modalities. ***Conclusion:*** Regadenoson MPS is a safe, well-tolerated, and effective tool for assessing myocardial ischemia in patients unable to perform exercise testing. Despite statistically significant correlations with CA, the weak association highlights the importance of combining both functional and anatomical imaging techniques for a more comprehensive and reliable CAD evaluation.

EP-0598

Head-to-head comparison of Left Ventricular Ejection Fraction and Volumes from 3D-ring CZT and dedicated Cardiac CZT SPECT Cameras

V. Roelants*[1], F. Dupont[2], A. Oulad Bouchetta[2], N. Laajimi[2], R. Lhommel[2], M. Hesse[2];*
[1]Cliniques universitaires Saint-Luc, Brussels, BELGIUM, [2]Cliniques universitaires Saint-Luc - Université Catholique de Louvain, Brussels, BELGIUM.

Aim/Introduction: The comparison between a 3D-ring CZT SPECT camera (3D CZT) and a dedicated cardiac CZT SPECT camera (cardiac CZT) in terms of left ventricular functional parameters derived from perfusion studies has yet to be

thoroughly investigated. In this study, we directly compared the left ventricular ejection fraction (LVEF), end-diastolic volume (EDV) and end-systolic volume (ESV) obtained from a 3D CZT to those obtained using a cardiac CZT, within the same patient cohort. ***Materials and Methods:*** Twenty-seven patients (19 male; age: 67 ± 15 years, BMI: 28 ± 6 kg/m2) with suspected or known coronary artery disease and referred for a two-day stress/rest myocardial perfusion SPECT imaging (MPI) have been included at this stage. ECG-gated (16 bins) acquisitions were performed 30-60 minutes after injection of 359 ± 18 MBq of a 99mTc-labeled perfusion tracer. Imaging was first conducted on the cardiac CZT (5-minute acquisition), followed immediately by the 3D CZT (12-minute acquisition). Stress and rest images were reconstructed with the manufacturer's iterative algorithms and settings specific to each camera, without applying attenuation correction. LVEF, EDV and ESV were calculated from each reconstruction using Quantitative Gated SPECT (QGS) software. Results were analyzed using linear regression and Wilcoxon Signed-Rank test, while Bland-Altman plots served to evaluate the level of agreement. ***Results:*** LVEF, ESV and EDV values were automatically obtained for 23 patients. Manual adjustment of the LV contour was required in the remaining 4 patients. The comparison between 3D CZT and cardiac CZT gave the following results: 60.6 ± 9.3 % vs 60.6 ± 8.9 % (p=0.79) for LVEF (range: 44-80 % vs 42-80 %), 99.3 ± 30.5 ml vs 100.5 ± 30.2 ml (p=0.38) for EDV and 41.0 ± 19.1 ml vs 41.5 ± 19.2 ml (p=0.66) for ESV. Linear correlation was strong for LVEF (R=0.85, p< 0.001) and excellent for both EDV (R=0.95, p<0.001) and ESV (R=0.94, p<0.001). Bland-Altman analysis revealed non-significant overall bias of 0.02 % for LVEF (95% limit of agreement: -9.92 to 9.97 %), of -1.19 ml for EDV (95% limit of agreement: -19.5 to 17.1 ml) and of -0.47 ml for ESV (95% limit of agreement: -13.9 to 13.0 ml). ***Conclusion:*** LVEF, EDV and ESV as determined by QGS software from gated 3D CZT 99mTc-labeled MPI agree over a wide range of clinically relevant values with cardiac CZT, without any significant bias.

EP-0599

Can Myocardial Perfusion Imaging Predict Heart Rhythm Disturbances After Coronary Revascularization?

L. Sobral Torres*, R. Albergueiro, P. Dias, P. Soeiro;*
Unidade Local de Saúde São João, Porto, PORTUGAL.

Aim/Introduction: Myocardial Perfusion Single Photon Emission Computed Tomography (MPS) is routinely used in the follow-up of ischemic heart disease when new symptoms emerge. However, its role in asymptomatic individuals after coronary artery bypass grafting (CABG) is less defined. Post-operative heart rhythm disturbances are common and have been linked to adverse long-term outcomes. This study aims to explore the potential of MPS as a tool for identifying asymptomatic post-CABG patients at increased risk for developing heart rhythm abnormalities. ***Materials and Methods:*** A retrospective analysis at a single tertiary care center was conducted, including asymptomatic adults who underwent MPS within three years of CABG between January and June 2013. Patients with non-coronary cardiac conditions or confounding treatments were excluded. MPS scans were assessed using QGS/QPS and SyncTool™ software to evaluate perfusion, wall motion, and left ventricular function. Patient demographics and clinical data were collected, and follow-up extended to December 2023 to document Major Adverse Cardiovascular Events (MACE) and the onset of rhythm disturbances such as conduction delays and supraventricular arrhythmias. Cox regression models were applied using R software, including both univariate and multivariate analyses with 16 imaging and functional parameters. ***Results:*** Fifty patients fulfilled the inclusion criteria, (mean age 66±9.2 years; 78% male), with MPS performed a mean of 10±10 months post-CABG. The average stress EF was 63±10%. Fifteen patients (30%) developed rhythm abnormalities over follow-up, primarily atrial fibrillation (66%), with a mean onset at 6.75±3.5 years post-surgery. In univariate analysis, elevated end-systolic eccentricity (ESE) was associated with a 5% increased risk of arrhythmia (HR = 1.05). A multivariate model including ESE, stress EF, and the anterior descending artery (ADA) motility SSS showed all variables were statistically significant. ESE and ADA SSS had hazard ratios of 1.11 (p=0.006) and 1.13 (p<0.001), respectively. ***Conclusion:*** Our findings suggest that MPS may be a valuable non-invasive tool for stratifying arrhythmic risk in asymptomatic patients post-CABG. These results support further prospective validation of MPS in post-operative rhythm surveillance.

Nothing Else Matters? — The Predominant Association of BHB and Myocardial Glucose Metabolism Suppression

T. Korhonen[1]*, A. Valve-Dietz*[1]*, T. Laitinen*[1]*, S. Hartikainen*[2]*;*
[1]*University of Eastern Finland, Kuopio, FINLAND,* [2]*Kuopio University Hospital, Kuopio, FINLAND.*

Aim/Introduction: The purpose of this study was to investigate if there were other metabolic or functional myocardial stress factors that predict the inadequacy of myocardial glucose metabolism suppression other than β-hydroxybutyrate levels (BHB). ***Materials and Methods:*** There were 156 participants (83 male) who underwent whole body [^{18}F]-fluorodeoxyglucose (FDG) PET/CT-scan for the indication of inflammatory cardiovascular diseases. Standardized uptake value (SUV) ratio was calculated with average SUV_{MAX} values of left ventricle myocardium divided by the SUV_{MAX} of the left ventricular blood pool background. SUV-ratio≤1 was defined as adequate suppression. Blood glucose and BHB were measured with a point-of-care device. Two observers independently evaluated visual ordinal coronary artery calcification (CAC)-score from non-gated CT-scans by giving each coronary artery a score ranging from 0 (no calcification) to 3 (severe calcification) and summing up the score. The arithmetic mean of the two CAC-scores was rounded to the closest integer. Inter-rater reliability for ordinal CAC-score was calculated with two-way mixed intraclass correlation coefficient (ICC) on absolute agreement. Ejection fraction of the heart was obtained from medical records of 136 patients who had undergone a transthoracic echocardiogram (TTE) within 365 days of the FDG-PET/CT-scan. Heart failure with reduced ejection fraction (HFrEF) was classified as ejection fraction <40%. The ECGs of the patients were assessed for possible left or right bundle branch block (LBBB or RBBB) or ventricular paced rhythm. The QRS-times of the patients were measured. Continuous variables were tested using Mann-Whitney U test and categorical variables using Pearson Chi-squared test. ***Results:*** Median (min-max) age was 58 (19-79) years, BMI 28.3 (17.0-54.4) kg/m^2, SUV-ratio 0.80 (0.45-12.94), BHB 0.4 (0.1-5.8) mmol/l, blood glucose 5.0 (2.8-10.4) mmol/l, visual ordinal CAC-score 2 (0-12), QRS-time 104 (75-186) ms. There were 16 patients with LBBB, 20 with RBBB and 16 with ventricular paced rhythm. ICC of ordinal CAC-score was 0.905 (0.770-0.951, p<0.001). Of the 144 patients who had undergone TTE, 13 had HFrEF. There was significant difference in BHB between those with adequate and inadequate suppression (0.3 (0.1-2.6) mmol/l vs 0.4 (0.1-5.8) mmol/l, p<0.001). There were no significant differences in blood glucose, ordinal CAC-score, intraventricular conduction, nor prevalence of HFrEF between groups with adequate and inadequate suppression. ***Conclusion:*** Only BHB predicts suppression of myocardial glucose metabolism. It seems

that neither blood glucose, ordinal CAC-score, intraventricular conduction nor HFrEF give valuable information predicting the suppression of myocardial glucose metabolism.

EP-0601

Prognostic Value of ^{18}F-FDG PET Myocardial Ischemic Memory Imaging in Patients with Non-Obstructive Coronary Artery Disease

F. Zhang, *X. Yang, Y. Wang;*
the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: ^{18}F-FDG PET myocardial ischemic memory imaging has been used to diagnose myocardial ischemia. However, its prognostic value in patients with non-obstructive coronary artery disease (NOCAD) remains unclear. This study aimed to investigate the predictive value of ^{18}F-FDG PET myocardial ischemic memory imaging for major adverse cardiovascular events (MACE) during follow-up in patients with NOCAD. ***Materials and Methods:*** This prospective, observational cohort study enrolled 106 patients with unstable angina who showed <50% stenosis in major epicardial coronary arteries on coronary angiography. All patients underwent ^{18}F-FDG PET myocardial ischemic memory imaging. A positive ^{18}F-FDG scan was defined as focal or focal on diffuse uptake. All patients received optimized medical therapy. Clinical follow-up was conducted, and the primary endpoint was the occurrence of MACE, defined as cardiovascular death, re-hospitalization for UA, heart failure, acute myocardial infarction, or stroke. ***Results:*** Among the 106 patients, 54 (50.9%) were male, with a mean age of 65.5 ± 8.5 years. The median follow-up period was 26 months (IQR: 17-42 months), during which 15 patients (14.2%) experienced MACE. Univariate Cox regression analysis identified positive ^{18}F-FDG imaging, ^{18}F-FDG standardized uptake ratio (SUR), and the extent of abnormal ^{18}F-FDG uptake as a percentage of the left ventricle (Extent) as significant predictors of MACE. After adjusting for age, sex, hypertension, hyperlipidemia, and diabetes, multivariate Cox regression analysis confirmed that positive ^{18}F-FDG imaging (HR = 7.638; 95% CI: 2.474~23.584; P = 0.0004), ^{18}F-FDG SUR (HR = 2.246; 95% CI: 1.549~3.257; P < 0.0001), and ^{18}F-FDG Extent (HR = 1.061; 95% CI: 1.034~1.088; P < 0.0001) were all independent predictors of MACE. Kaplan-Meier survival analysis further demonstrated that patients with positive ^{18}F-FDG imaging had significantly lower MACE-free survival compared to those with negative imaging results (P = 0.0001). Additionally, the incidence of MACE was significantly higher in the ^{18}F-FDG-positive group (37.5%) compared to the ^{18}F-FDG-negative group (10.0%) (χ^2 = 8.457, P = 0.010). ***Conclusion:*** Myocardial ischemia detected by ^{18}F-FDG PET ischemic memory imaging is an independent risk factor for MACE in patients with NOCAD. Patients with positive ^{18}F-FDG imaging had a 7.6-fold increased risk of MACE compared to those with negative imaging. These findings highlight ^{18}F-FDG PET ischemic memory imaging as a promising biomarker for risk stratification in NOCAD patients, with potential to accurately predict cardiovascular events and support precision-guided clinical management.

EP-0602

Myocardial [^{18}F]FDG uptake suppression after six hours fasting predicts 3-year overall survival in men

S. Hartikainen[1], *S. Sillanmäki*[2], *M. Hedman*[2], *T. Tompuri*[3], *T. M. Laitinen*[1], *T. P. Laitinen*[1];
[1]*Kuopio University Hospital, Kuopio, FINLAND,* [2]*University of Eastern Finland, Kuopio, FINLAND,* [3]*North Karelia Central Hospital, Joensuu, FINLAND.*

Aim/Introduction: Reduced myocardial uptake [^{18}F]FDG-PET/CT after 6h fasting is linked with metabolic disorders, including diabetes and fatty liver. We assessed whether 6h fasting-indused myocardial FDG suppression (FDG_{sup}) predicts overall survival (OS). ***Materials and Methods:*** We recruited adults with clinical indication for FDG-PET/CT after 6h fasting and measured glucose and β-hydroxybutyrate (BHB) with a point-of-care device. Patients who had followed a ketogenic diet before imaging were excluded. Myocardial FDG uptake was categorized visually as FDG_{sup} or non-suppressed. Two-centimeter diameter regions of interest were placed in the liver and spleen to assess for fatty liver. Liver-to-spleen attenuation ratio (LSR) <1 was defined as fatty liver. Age-adjusted survival analysis was performed using Cox regression. ***Results:*** A total of 131 patients (69 male) participated. In men, median age was 68 (25-87) years, body mass index (BMI) 26 (19-38) kg/m^2, fasting glucose 5.5 (4.5-9.4) mmol/l, BHB 0.2 (0.0-0.8) mmol/l, and LSR 1.18 (0.52-1.60). There were 17 men (25%) with diabetes, 39 (57%) with hypertension, and 15 (22%) with fatty liver. In women, median age was 67 (26-83), BMI 29 (17-55) kg/m^2, glucose 5.4 (4.2-8.2) mmol/l, BHB 0.2 (0.0-0.7) mmol/l, and LSR 1.23 (0.83-1.88). There were 7 women (11%) with diabetes, 31 (50%) with hypertension, and 6 (10%) with fatty liver. BMI was higher in women (p=0.035), while the rate of diabetes was higher in men (p=0.049). No other sex-related differences were found. During the median follow-up of 1157 days (IQR: 1083-1219 days), 35 patients (22 male) died. In men, the rate of FDG_{sup} was higher among patients who died compared to those who survived (45% vs. 21%, p=0.039). There were no other statistically significant differences between the survival groups. The OS was 50% in men with FDG_{sup}, and 76% in men without suppression (p=0.038), with an annual event rate of 19% in men with FDG_{sup} and 9% in men without suppression. The age-adjusted survival was lower in men with FDG_{sup} (p=0.052), hazard ratio 2.37 (95% CI 1.02-5.50). There was no difference regarding OS in women with or without FDG_{sup} (80% vs. 79%, p=0.974). Women had an annual event rate of 8%. ***Conclusion:*** Over a 3-year follow-up period, men with myocardial FDG suppression after 6h fasting had worse prognosis compared to those without suppression - a pattern not observed in women. This sex-specific difference may reflect metabolic disorders and suggest potential as a prognostic biomarker in men. However, further research with extended follow-up is needed.

EP-0603

A Prospective Clinical Study on the Diagnostic Value of ^{18}F-FDG PET Ischemic Memory Imaging for Unstable Angina in Diabetic and Non-Diabetic Patients

f. Zhang, *X. Yang, Y. Wang;*
the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To evaluate the diagnostic value of ^{18}F-FDG PET ischemic memory imaging for unstable angina (UA) in patients with and without diabetes mellitus. ***Materials and Methods:*** This prospective cohort study consecutively enrolled patients presenting with chest pain or discomfort to the Chest Pain Center or Department of Cardiology at The Third Affiliated Hospital of Soochow University between March 17, 2020 and May 11, 2024. All patients had an initial negative evaluation but were still clinically suspected of having UA. Each patient underwent ^{18}F-FDG PET ischemic memory imaging and coronary angiography. Based on final clinical diagnoses, patients were classified into a UA group and a non-UA group. ***Results:*** A total of 272 patients with suspected UA were enrolled in the study (mean age: 64.8 ± 9.6 years; 62.9% male; 33.2% with diabetes). UA was confirmed in 139 patients (51.1%). The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy of ^{18}F-FDG PET ischemic memory imaging for diagnosing UA were 63.3%, 92.5%, 90.7%, 70.3%, and 77.6%, respectively, in the overall cohort. In the diabetic subgroup, the corresponding values were 51.0%, 90.5%, 86.2%, 61.3%, and 69.2%, while in the non-diabetic subgroup, they were 70.0%, 93.4%, 92.6%, 75.2%, and 81.8%, respectively. Receiver operating characteristic (ROC) curve analysis yielded an area under the curve (AUC) of 0.761 for the entire cohort,

0.707 for diabetic patients, and 0.789 for non-diabetic patients (all P < 0.001). Compared with diabetic patients, non-diabetic patients demonstrated significantly higher sensitivity (70.0% vs. 51.0%) and accuracy (81.8% vs. 69.2%) (P < 0.05). The NPV was also higher in non-diabetic patients, with a trend toward significance (75.2% vs. 61.3%, P = 0.059). ***Conclusion:*** ^{18}F-FDG PET ischemic memory imaging demonstrates good diagnostic performance in patients with suspected UA. Its sensitivity is lower in diabetic patients compared to non-diabetic patients, although both groups exhibit high positive predictive values. This imaging technique shows promise as a novel adjunctive diagnostic tool for UA.

EP-0604

Evaluation of Oral Versus Intravenous Glucose Loading Protocols on Image Quality in Cardiac FDG PET: A Comparative Qualitative and Quantitative Study

M. Calderon Tobar, *A. Gümüş, K. Çağlar, F. Yılmaz, H. Önner; Selcuk University Faculty of Medicine Department of Nuclear Medicine, Konya, TÜRKIYE.*

Aim/Introduction: To compare the effects of intravenous (IV) and oral glucose loading protocols on image quality in cardiac FDG PET, utilizing both qualitative and quantitative parameters. ***Materials and Methods:*** This retrospective study included 74 patients (mean age: 65.5±10.2 years; 9 females) undergoing cardiac FDG PET. All patients required glucose loading protocols based on TSNM guidelines. Patients received an IV (n=28) or oral (n=46) glucose loading protocol before imaging. Visual image quality was scored as uninterpretable, suboptimal, or optimal. A Chi-square test was used to compare visual image quality between the two glucose loading protocols. Quantitative parameters included left ventricular (LV) myocardial SUVmax, LV blood pool SUVmax, and their ratio. Comparisons between groups were performed using the Mann-Whitney U test. ***Results:*** Optimal imaging was achieved in 71.4% (20/28) of patients in the IV group and 69.6% (32/46) in the oral group. Among the 28 patients who underwent the IV glucose loading protocol, 20 (71.4%) demonstrated optimal image quality, while 2 (7.1%) were classified as suboptimal and 6 (21.4%) as uninterpretable. In the oral glucose loading group (n=46), optimal imaging was achieved in 32 patients (69.6%), with 6 (13.0%) rated as suboptimal and 8 (17.4%) as uninterpretable. The difference in visual image quality between the IV and oral glucose loading protocols is not statistically significant (p=0.87). Among 28 patients with diabetes mellitus (DM), optimal imaging was achieved in 50% (14/28). In insulin users (n=5), optimal imaging was observed in only one patient. Quantitatively, the LV blood pool SUVmax was significantly higher in the IV glucose loading protocol group (median 2.00) than the oral glucose loading protocol group (median 1.36, p=0.002). No significant differences were observed in LV myocardial SUVmax (p=0.469) or the myocardial-to-blood pool SUVmax ratio (p=0.196). ***Conclusion:*** IV and oral glucose loading protocols yielded acceptable rates of optimal imaging in cardiac FDG PET studies, with no significant differences in myocardial SUVmax or myocardial-to-blood pool SUVmax ratios. However, the IV protocol resulted in a significantly higher LV blood pool SUVmax. These findings suggest that the choice of protocol may influence blood pool activity and, consequently, interpretation, particularly in diabetic and insulin-using patients.

EP-0605

The Impact of Preoperative Phase Analysis, Hibernating Myocardium Percentage, and Inflammatory Parameters Derived from gMPS, F-18 FDG PET/CT, and Biochemistry on Postoperative Ejection Fraction and Wall Motion Abnormalities in Patients Undergoing Coronary Artery Bypass Grafting

H. Kalkan, *A. Kılıçaslan, Ö. Bayrakcı, M. Serdengeçti, H. Şan; Ankara Bilkent City Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: F-18 FDG PET/CT myocardial viability imaging is a routine modality used to assess viable tissue in patients with fixed perfusion defects on gated myocardial perfusion SPECT(gMPS) prior to revascularization. This study aims to investigate the association between postoperative changes in ejection fraction(EF), left ventricle wall motion abnormalities, preoperative parameters obtained from gMPS phase analysis, PET/CT, and biochemical inflammatory markers in patients undergoing coronary artery bypass grafting(CABG). ***Materials and Methods:*** Thirty-eight patients who underwent both gMPS and PET/CT viability studies prior to CABG were retrospectively included. From gMPS, phase analysis parameters (histogram bandwidth and standard deviation) were extracted, while hibernating myocardial segments and their percentage were obtained from FDG PET/CT. Pre- and postoperative EF and wall motion findings were recorded from echocardiographic reports. Inflammatory markers were calculated from preoperative CBC and standard biochemistry tests performed within one month of viability imaging, using various ratio-based indices. Statistical analysis was performed using SPSS version 27. Spearman's correlation test was applied to assess associations between postoperative EF, EF improvement, wall motion recovery, and the imaging and laboratory parameters. A p-value < 0.05 was considered statistically significant. ***Results:*** Of the patients, 15.8% were female (n=6), with a mean age of 63.9±28.27 years. The mean percentage of hibernating myocardium was 16.87±11.77%. The mean preoperative EF was 36.77±11.1%, postoperative EF was 31.81±10.4%, and mean EF improvement was calculated as 4.13±3.9%. Early postoperative mortality occurred in 28.9% (n=11) of the cohort. No statistically significant correlations were found between hibernating myocardium percentage or phase analysis parameters and postoperative EF, EF improvement, or wall motion recovery (p>0.05). However, EF improvement and wall motion recovery demonstrated statistically significant negative correlations with the following inflammatory markers: neutrophil-to-lymphocyte ratio(-0.485), monocyte-to-lymphocyte ratio(-0.491), systemic immune-inflammation index(-0.363), systemic inflammatory response index(-0.490), total systemic inflammation index(-0.411), neutrophil/HDL(-0.353), neutrophil/LDL(-0.353), neutrophil/albumin(-0.394) (p<0.05). ***Conclusion:*** Preoperative gMPS-derived phase analysis and PET viability findings did not show a statistically significant relationship with postoperative EF improvement or recovery of wall motion. This may be attributed to factors such as multivessel revascularization, reliance on early postoperative (within 6 months) echocardiographic data, early mortality, lack of classification based on preoperative risk stratification, and variability in test standardization. In contrast, inflammatory indices calculated from preoperative blood and biochemistry tests were significantly correlated with both EF improvement and wall motion recovery. The inverse relationship suggests that elevated subclinical inflammation may negatively affect myocardial recovery, consistent with its known detrimental role in atherosclerotic cardiovascular disease.

EP-0606

Optimized Fast Track Protocol: Enhancing ^{18}F-FDG PET Myocardial Viability Imaging Quality While Minimizing Patient Preparation Time in Diabetic CAD Patients

A. Mandal, *S. Taywade, A. K Majeed, R. Kumar; AIIMS Jodhpur, Jodhpur, INDIA.*

Aim/Introduction: The standard ASNC protocol often leads to suboptimal image quality in ^{18}F-FDG PET myocardial viability studies for diabetic patients. In this study, we aimed to assess the impact of an alternate optimized fast track (OFT) protocol on the image quality of ^{18}F-FDG PET cardiac viability study in diabetic patients with CAD. ***Materials and Methods:*** We enrolled total 50 patients. Based on certain characteristics (duration of

diabetes, HbA1C level and FBS level), we stratified the patients into six subgroups. Then we allocated them into two groups using stratified randomization technique. In one group standard ASNC protocol was followed and in the other group OFT protocol was applied for patient preparation. Images were analysed qualitatively with visual grading scale as well as semi-quantitatively with myocardium to blood pool (M/B) ratio. Patient preparation time (PPT) was determined from the time of oral glucose administration to the time of ^{18}F-FDG injection. We compared the image quality and PPT between the two groups. ***Results:*** Demographic details in the standard protocol group were as follows: 6-females, 19-males; mean age was 58.56±8.21 years. In the OFT group, there were 7-females and 18-males; mean age was 61.20±10.05 years. There was larger proportion of interpretable images in the OFT group (92% vs. 64%) and larger proportion of un-interpretable images in the standard protocol group (36% vs. 8%). The mean±SD of M/B Ratio in the OFT group (12.44±5.37) was higher than the standard protocol group (7.23±3.42) with a p value of <0.001. PPT was lesser in the OFT group (median time = 82 minutes) as compared to standard protocol group (median time = 95 minutes). ***Conclusion:*** The proposed OFT protocol for patient preparation in ^{18}F-FDG PET myocardial viability studies delivers superior image quality and shortens preparation time for diabetic patients compared to the standard ASNC protocol. This novel OFT protocol can be readily adopted into the routine clinical practice for ^{18}F-FDG PET myocardial viability studies particularly among diabetic patients.

EP-0607

The heart-to-mediastinum ratio of [^{123}I]I-mIBG myocardial scintigraphy: planar versus reprojected planar images

J. Hagerman*, S. Akil Engblom, F. Hedeer;*
Clinical Physiology, Department of Clinical Sciences Lund, Lund University, Skåne University Hospital, Lund, SWEDEN.

Aim/Introduction: Myocardial sympathetic innervation can be assessed by determining the heart-to-mediastinum ratio (HMR) on planar iodine-123-metaiodobenzylguanidine ([^{123}I]I-mIBG) myocardial scintigraphy images, with a standardized methodology. Acquisition of single-photon emission computed tomography (SPECT) is also advised for regional assessment. Software enables SPECT-data to be reprojected to planar images, thus facilitating determining HMR on three-dimensional data and a SPECT-only acquisition. This study aimed to evaluate the agreement between HMR determined on planar and reprojected planar [^{123}I]I-mIBG myocardial scintigraphy images, acquired on two technological different gamma cameras, for the assessment of myocardial sympathetic innervation. ***Materials and Methods:*** [^{123}I]I-mIBG myocardial scintigraphy images from nineteen patients, clinically referred for assessment of myocardial sympathetic innervation due to suspected neurodegenerative disorder, were included. Planar and SPECT images, with low-dose computed tomography (CT), were acquired on an Anger camera (Discovery NM/CT 670), followed by SPECT-CT on a ring-configured CZT camera (StarGuide), four hours post-injection of 252±6 MBq [^{123}I]I-mIBG. SPECT images were reconstructed with ordered subset expectation maximization (4 iterations, 10 subsets, Butterworth 0.5/5), corrected for collimator detector response and attenuation, with and without correction for scatter (SC and NSC), and converted to reprojected planar images (RP), in a software provided by Hermes and GE HealthCare, respectively. HMR was determined on anterior projections of planar$_{Anger}$, RP$_{Anger_SC}$, RP$_{Anger_NSC}$, RP$_{CZT_SC}$, and RP$_{CZT_NSC}$ images by manually drawing regions-of-interest over the heart and the mediastinum. The planar$_{Anger}$ images were used as a reference and differences in HMR between planar and RP images were analyzed with the Wilcoxon matched-pairs signed-rank test (significance level p<0.05). The agreement was analyzed with Bland-Altman (mean difference, 95% limits of agreement). ***Results:*** The median (interquartile range) HMR was 1.44 (1.15-1.86), 1.42 (1.11-2.24) and 1.41 (1.11-1.92) from the Anger camera (planar$_{Anger}$, RP$_{Anger_SC}$ and RP$_{Anger_NSC}$), and 1.45 (1.08-1.89) and 1.32 (1.12-1.69) from the CZT gamma (RP$_{CZT_SC}$ and RP$_{CZT_NSC}$). A significant difference in HMR was found between planar$_{Anger}$ and RP$_{CZT_NSC}$ images (p=0.001). The agreement between planar and RP images was good (RP$_{Anger_SC}$:-0.077, -0.50 to 0.34, RP$_{Anger_NSC}$:-0.011, -0.19 to 0.16, RP$_{CZT_SC}$:0.023, -0.19 to 0.23, and RP$_{CZT_NSC}$:0.13, -0.13 to 0.39). ***Conclusion:*** HMRs from reprojected planar [^{123}I]I-mIBG myocardial scintigraphy images, derived from SPECT images, show good agreement with HMR determined from planar images, for both a traditional Anger and a novel ring-configured CZT gamma camera. A clinical implementation of reprojected planar images seems promising, but validation is needed in a larger cohort, especially for conclusions regarding the use of scatter or non-scatter corrected images.

EP-0608

Myocardial [18F]FDG Uptake in Lymphoma Patients Undergoing Anthracycline-Based Chemotherapy: Association with Cumulative Doxorubicin Dose and Patient Characteristics

M. Kalnina*[1,2], A. Nikolajevs[3,4], A. Vikentjeva[3,4], E. Vagalis[3,4], J. Perevozcikova[4];*
[1]ARS Nuclear Medicine Clinic, Riga, LATVIA, [2]University of Latvia, Riga, LATVIA, [3]Riga East University Hospital, Riga, Latvia, [4]Riga Stradins University, Riga, LATVIA.

Aim/Introduction: Anthracycline-based chemotherapy regimens, commonly used in Hodgkin and non-Hodgkin lymphoma (HL and NHL), are known to induce cardiotoxic effects. The identification of early, subclinical myocardial metabolic changes may support timely intervention to mitigate long-term cardiac dysfunction. This study aimed to assess changes in myocardial [18F]FDG uptake during the course of chemotherapy and to investigate their association with cumulative doxorubicin dose, sex, and lymphoma subtype. ***Materials and Methods:*** A retrospective analysis was conducted on 125 patients with HL or NHL who underwent [^{18}F]FDG PET/CT imaging at three time points: baseline (pre-treatment), interim (post two chemotherapy cycles), and end-of-treatment. Inclusion criteria included absence of myocardial uptake on baseline imaging and documented cumulative anthracycline exposure. Standardized myocardial suppression protocols were applied prior to imaging. Myocardial FDG uptake was quantified in the left ventricle using SUVmax and SUVmean. Statistical analysis included Related-Samples Friedman's Two-Way Analysis of Variance by Ranks, pairwise comparisons, Spearman's correlation, and Independent-Samples Mann-Whitney U Tests. ***Results:*** Left ventricular SUVmax and SUVmean increased significantly from baseline to interim and from baseline to end-of-treatment ($p < 0.05$), while no significant change was observed between interim and end-of-treatment scans (SUVmax: $p = 0.5$; SUVmean: $p = 0.3$). ΔSUVmax demonstrated a moderate positive correlation with cumulative doxorubicin dose ($r = 0.48$, $p = 0.003$). Mann-Whitney U analysis revealed significantly greater ΔSUVmax % in male patients compared to females ($p < 0.01$). Patients with NHL exhibited higher post-treatment SUVmax values and more pronounced metabolic changes compared to those with HL ($p < 0.05$). The mean cumulative doxorubicin dose was significantly greater ($p < 0.05$). in the NHL group (444.2 mg) compared to the HL group (386.7 mg). ***Conclusion:*** [^{18}F]FDG PET/CT detects early myocardial metabolic alterations after just two cycles of anthracycline chemotherapy, with these changes persisting through treatment completion. Increased myocardial metabolic activity is more pronounced in male patients and those with NHL, both of whom receive higher anthracycline doses. These findings support the potential role of [^{18}F]FDG PET/CT in early detection of subclinical cardiotoxicity and in the identification of at-risk patient subgroups. Further prospective studies are warranted to validate

[18F]FDG PET/CT as a routine tool in cardio-oncology monitoring protocols. ***References:*** Becker, M.M.C., Arruda, G.F.A., Berenguer, D.R.F. et al. Aim/Introduction: Cardiac amyloidosis (CA) is a rare and severe condition that can be diagnosed non-invasively with [99mTc]Tc-bisphosphonate imaging. However, the subjective nature of visual assessment may lead to misdiagnosis. This study aims to develop and validate a stacking machine learning (ML) model based on the radiomics of [99mTc]Tc-bisphosphonate SPECT/CT and clinical parameters for accurate CA detection. ***Materials and Methods:*** We conducted a retrospective multicenter analysis of 290 patients referred for CA evaluation across two Chinese hospitals using [99mTc]Tc-PYP SPECT/CT and one Austrian center using [99mTc]Tc-DPD. CA diagnosis was based on standard criteria. Radiomics features from SPECT/CT were extracted and selected using statistical methods and LASSO logistic regression. A stacking ensemble framework integrated four base ML classifiers with a meta-learner. The clinical model was constructed based on clinical features. Radiomics and clinical features were utilized to develop the combined model. Performance was evaluated on an internal dataset (n=178) and two external testing sets (n=54 and n=58) using discrimination (AUC), calibration curves, and decision curve analysis (DCA). ***Results:*** Among 290 patients, 117 were diagnosed with CA (40.3%). The stacking radiomics model showed good performance for predicting CA, with AUCs of 0.871 in the internal testing set, and AUCs of 0.824 and 0.839 in the external testing sets. The combined model achieved the highest AUC (0.841-0.946, with a mean AUC of 0.888±0.047) among all the study sets, significantly outperforming the clinical model (AUC = 0.546-0.820, with a mean AUC of 0.728±0.125,P = 0.0001-0.379, Delong test). DCA confirmed greater clinical utility of the combined model across probability thresholds. ***Conclusion:*** A stacking ML model with SPECT/CT radiomics and clinical parameters improves CA diagnosis, showing strong generalizability across imaging protocols and populations and highlighting its potential as a decision-support tool.

Application of Gated Myocardial Perfusion Imaging in Evaluating Coronary Heart Disease-Related Heart Failure with Preserved Ejection Fraction

X. Shen[1], *Z. Wang*[1], *H. Pang*[1], *C. Chen*[2], *X. Li*[2], *Z. Yao*[2];
[1]*The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA,* [2]*Beijing Hospital, Beijing, CHINA.*

Aim/Introduction: This study aimed to evaluate the utility of single-photon emission computed tomography (SPECT) gated myocardial perfusion imaging (GMPI) in assessing heart failure with preserved ejection fraction (HFpEF) among patients with confirmed or suspected coronary artery disease (CAD). ***Materials and Methods:*** In accordance with the 2021 European Society of Cardiology Guidelines, this retrospective study included a cohort of patients with confirmed or suspected CAD who underwent SPECT GMPI. These patients were stratified into an HFpEF group (n = 83) and a control group (n = 43). Furthermore, HFpEF patients were categorized according to the New York Heart Association (NYHA) functional class into Class I, II, and III–IV. GMPI parameters analyzed included left ventricular ejection fraction (LVEF), end-diastolic volume (EDV), peak filling rate (PFR), mean filling rate during the first third of diastole (MFR/3), second peak filling rate (PFR2), time to peak filling (TTPF), summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS). ***Results:*** Multivariate logistic regression analysis showed that adenosine triphosphate (ATP) stress-induced PFR (PFR_{-ATP}; OR = 0.1, P = 0.02) and SSS (OR = 1.6, P = 0.03) were independent predictors of HFpEF. Compared with SSS alone (AUC: 0.79) or PFR_{-ATP} alone (AUC: 0.84), the combined model of PFR_{-ATP} and SSS had superior predictive performance (AUC: 0.90), with statistically significant differences (P = 0.002 for comparison with SSS alone; P = 0.04 for comparison with PFR_{-ATP} alone). Notably, both PFR_{-ATP} and SSS were able to differentiate different NYHA functional classes (I, II, III–IV). Specifically, PFR_{-ATP} decreased (P = 0.004) and SSS increased (P = 0.001) with the worsening of NYHA functional class. SSS was found to be negatively correlated with $LVEF_{-ATP}$ (r = −0.48, P ≤ 0.001), PFR_{-ATP} (r = −0.36, P ≤ 0.001), and $MFR/3_{-ATP}$ (r = −0.35, P ≤ 0.001), and positively correlated with EDV_{-ATP} (r = 0.30, P = 0.005). ***Conclusion:*** SPECT GMPI can predict HFpEF in patients with confirmed or suspected CAD and effectively assess cardiac function. It has the potential to serve as a non-invasive tool for identifying the etiology of myocardial ischemia and guiding personalized management in patients with HFpEF.

EP-0611

Establishment of optimal quantitative thresholds using [99mTc]Tc-DPD SPECT/CT for the diagnosis of ATTR cardiac amyloidosis.

M. Diez[1], *A. Palomar-Muñoz*[1], *M. Marusso Fizzani*[1], *O. Hernández Cristancho*[1], *M. Pizzi*[2], *A. Roque Pérez*[3], *D. Sánchez-Artuñedo*[4], *S. Aguadé-Bruix*[1], *C. Gámez-Cenzano*[1];

Aim/Introduction: Transthyretin cardiac amyloidosis (cATTR) is an infiltrative pathology that requires early diagnosis to improve prognosis. The present prospective study aims to quantify myocardial deposit uptake using SPECT/CT in patients with suspected cATTR in our center, and to determine the diagnostic efficacy of different absolute quantitative parameters compared to standard visual assessment (Perugini score). ***Materials and Methods:*** We analyzed 81 consecutive patients studied between

2024 and 2025 with clinical suspicion of ATTR. All underwent [99mTc]Tc-DPD scintigraphy, acquiring whole-body scan and thoracic SPECT/CT at 3 hours post-injection. The Perugini score (0-3) was visually evaluated on the planar image. Absolute quantification of myocardial deposit was performed on SPECT/CT images using Q.Volumetrix software (GE Healthcare®), obtaining SUVmean, SUVmax, % injected dose, Cardiac Amyloid Activity (CAA), and retention index values. Patients were grouped as „Negative" (Perugini ≤1) and „Positive" (Perugini ≥2). Receiver Operating Characteristic (ROC) curve analysis was used to determine the ability of each of these quantitative parameters to differentiate between the two groups. The area under the curve (AUC) was calculated, and the optimal cut-off point that maximizes the sum of sensitivity and specificity was determined for each parameter. ***Results:*** Of the 81 patients included (66.6% men) with a mean age of 77.4 years (47-94), 42 were classified as negative (40 score 0; 2 score 1) and 39 as positive (5 score 2; 34 score 3). The values found excellent diagnostic capacity (AUC>0.98) to differentiate Perugini ≤1 vs ≥2 with the following parameters and their optimal cut-offs: Cardiac SUVmean: 2.66 gr/ml (AUC 0.997) Cardiac SUVmax: 4.66 gr/ml (AUC 0.988) Cardiac % Injected Dose: 0.4% (AUC 0.996) Cardiac Amyloid Activity (CAA): 761.5 (AUC 0.990) Retention Index: 0.23% (AUC 0.982). ***Conclusion:*** Absolute quantification of cardiac amyloid deposit using [99mTc]Tc-DPD SPECT/CT provides objective parameters that demonstrate a high capacity to discriminate between patients with and without significant cardiac uptake according to the visual Perugini score. These quantitative parameters and their optimal cut-off points could be useful tools to complement visual evaluation, increasing objectivity in the diagnosis, stratification, and follow-up of patients with cATTR.

EP-0612

Relationship between cardiac innervation and heart failure in patients with TTR amyloidosis: Evidence from gated SPECT with ^{123}I-MIBG and ^{99m}Tc-DPD

F. Sebastián Palacid*, N. Álvarez Mena, M. García Aragón, R. C. Zambrano Infantino, B. M. Jaramillo López, Á. R. Suazo Montero, M. Alonso Rodríguez, B. Pérez López, R. Ruano Pérez;*
Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To determine the relationship between cardiac innervation and heart failure in patients with TTR amyloidosis by joint evaluation of gated SPECT (gSPECT) images obtained with ^{123}I-MIBG and ^{99m}Tc-DPD. ***Materials and Methods:*** 51 patients with TTR cardiac amyloidosis confirmed by scintigraphy and ^{99m}Tc-DPD gSPECT were studied, divided according to the presence or absence of heart failure (HF). ^{123}I-MIBG Planar and gSPECT studies were performed and early (HMRe) and late (HMRl) myocardial uptake and washout index (WI) were calculated.Uptake scores were assigned to the polar maps obtained in both gSPECT: 0 = normal and 4 = pathological for ^{99m}Tc-DPD; 0 = pathological and 4 = normal for ^{123}I-MIBG.The data were analysed taking into account sex, age, Perugini uptake grade and HMRI, and the polar maps were compared to identify significant differences. ***Results:*** The male:female ratio was 80.4:19.6 and 82.3% of the subjects were classified as grade 3 on the Perugini scale. HF was present in 35 patients (LVEF 50.7 ± 12.3%), while 16 did not (LVEF 55.5 ± 11.6%). Cardiac innervation disturbances were observed in 96.1% (49/51) of cases. The regions exhibiting the most significant cardiac denervation were the inferior region and the basal inferolateral region in both groups (p<0.05). However, the apex region exhibited the only significant disparities between patients with and without HF (p=0.017). ***Conclusion:*** The study demonstrates a relationship between cardiac innervation and heart failure in patients with TTR cardiac amyloidosis, highlighting significant differences in myocardial denervation. The results underline the complementary value of ^{123}I-MIBG and ^{99m}Tc-DPD studies in characterising the cardiac involvement of this disease, its clinical management and prognosis.

EP-0613

P(ATTR)ONUS: Validation of a new classification system for cardiac TTR amyloidosis using ^{99m}Tc-DPD gated SPECT.

F. Sebastián Palacid*, N. Álvarez Mena, B. M. Jaramillo López, R. C. Zambrano Infantino, M. García Aragón, Á. R. Suazo Montero, C. Gamazo Laherrán, M. J. González Soto, R. Ruano Pérez;*
Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To validate a ^{99m}Tc-DPD gated SPECT (gSPECT)-based classification system for cardiac TTR amyloidosis. The study will also analyse whether the identified uptake patterns show significant differences in terms of clinical and cardiac involvement parameters. ***Materials and Methods:*** A total of 116 patients (90 males, mean age 85 years) with positive ^{99m}Tc-DPD scintigraphy for cardiac TTR amyloidosis were included in the study and underwent a gSPECT study in which the myocardial distribution of the radiopharmaceutical was assessed.Depending on the regions affected, six uptake patterns were established: Septal, waning moon, dome, crescent moon, diffuse and donut. The relationship between various clinical parameters (HF, aortic stenosis, arrhythmia, neurological alterations), the percentage of affected myocardium, LVEF and the uptake patterns obtained in gSPECT was analysed. ***Results:*** 80% of patients were classified as grade 3 on the Perugini visual scale. The mean percentage of affected myocardium was 70.5 ± 18.3% and the mean LVEF was 52.7 ± 14.7%.On the polar map, the "donut" pattern was the most common (29.3%), while the "dome" pattern was the least common (6.9%).The "diffuse" pattern had the highest proportion of patients with heart failure (p = 0.0038).The "dome" pattern was significantly associated with arrhythmias (p = 0.0034) and neurological alterations (p = 0.0098).The highest proportion of preserved LVEF was associated with the crescent pattern (p = 0.0315). ***Conclusion:*** ^{99m}Tc-DPD gSPECT allows the identification of cardiac involvement patterns and the assessment of ventricular dysfunction in patients with TTR cardiac amyloidosis. The uptake patterns are associated with clinical parameters and ventricular function, with the "diffuse" pattern standing out due to its relationship with heart failure.

EP-0614

Prognostic Value of [^{99m}Tc]Tc-DPD Quantitative SPECT/CT in Patients with suspected Amyloid Transthyretin-Related Cardiomyopathy

F. Aghapour Zangeneh[1]*, N. Gözlügöl*[1]*, A. Rominger*[1]*, C. Gräni*[2]*, F. Caobelli*[1]*;*
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Department of Cardiology, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: Quantitative Single Photon Emission Computed Tomography (SPECT) using ^{99m}Tc-3,3-diphosphono-1,2-propanodicarboxylic acid ([^{99m}Tc]Tc-DPD) may serve as a valuable tool for risk stratification in patients with amyloid transthyretin-related cardiomyopathy (ATTR-CM). This study aimed to assess the prognostic significance of different quantitative [^{99m}Tc]Tc-DPD SPECT/CT in patients with suspected ATTR-CM. ***Materials and Methods:*** Consecutive patients with suspected transthyretin cardiac amyloidosis (ATTR-CM) referred to a single tertiary care center underwent quantitative [99mTc]Tc-DPD SPECT/CT (700 MBq). Standardized Uptake Values (SUVmax and SUVpeak), Activity Total Volume (ATV), defined as the sum of voxel volumes where SUV ≥ 40% of SUVmax and Total DPD Activity (TDA), calculated as SUVmean × ATV, were automatically derived using a 40% isocontour threshold VOI. Clinical, laboratory, and echocardiographic data were collected during a follow-up period of 46.1 ± 13.4 months, along with major adverse cardiac

events (MACEs), defined as the occurrence of any of the following: all-cause mortality, sustained ventricular tachyarrhythmia, hospitalization for heart failure, or implantation of a cardioverter-defibrillator. Receiver operating characteristic (ROC) analysis was used to identify optimal thresholds of quantitative imaging parameters for predicting MACEs. Their prognostic value was further evaluated using Cox regression and Kaplan-Meier survival analysis. ***Results:*** A total of 144 patients were included (127 males, 88.2%), of whom 99 (68.8%) were eventually diagnosed with ATTR-CM. The optimal thresholds identified were 7 for SUVmax, 100 for ATV, and 640 for TDA. An SUVmax ≥7 was significantly associated with an increased incidence of MACEs (HR 3.68; 95% CI: 1.40-9.65; p = 0.008). Similarly, an ATV value ≥100 was linked to a higher risk (HR 3.31; 95% CI: 1.34-8.14; p = 0.009), as was a TDA value ≥640 (HR 2.82; 95% CI: 1.24-6.36; p = 0.013). ***Conclusion:*** In patients with suspected ATTR-CM, quantitative DPD SPECT/CT imaging effectively predicts the risk of major adverse cardiac events (MACEs). Unlike previous studies, our research demonstrates the strong prognostic value of two novel parameters, i.e. ATV and TDA, which may assist in assessing the risk of disease progression.

EP-0616

A Prospective Pilot Study for Prognosis of CRT Super Response Using Electro-Mechanical Dyssynchrony Assessment in Patients with Strauss Left Bundle Branch Block Criteria

T. Atabekov, *A. Smorgon, A. Mishkina, S. Krivolapov, S. Sazonova, M. Khlynin, R. Batalov, S. Popov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The electro-mechanical dyssynchrony underlies left ventricular (LV) contractile dysfunction in patients with left bundle branch block (LBBB). In some cases cardiac resynchronization therapy (CRT) almost completely reverses LV contractile dysfunction. The LBBB electrocardiographic Strauss criteria and mechanical dyssynchrony (MD) assessment were proposed to improve CRT response. However, using these techniques separately does not improve LV contraction in 20-40% of patients after CRT device implantation. We have evaluated whether a combined using of electrocardiography (ECG), speckle-tracking echocardiography (STE) and cardiac scintigraphy can improve the prognosis of CRT super response in patients with Strauss LBBB criteria during 6 month follow-up. ***Materials and Methods:*** The study prospectively included patients with New York Heart Association (NYHA) II-III functional class (FC) of heart failure (HF) in sinus rhythm with Strauss LBBB criteria and reduced left ventricular ejection fraction (LVEF). Before and 6 month after CRT device implantation ECG, STE and cardiac scintigraphy were performed. The study's primary endpoint was the NYHA class improvement ≥ 1 and left ventricle end systolic volume decrease > 30% or LVEF improvement > 15% after 6 month CRT. Based on collected data, we developed a prognostic model regarding CRT super response. ***Results:*** Out of 54 (100.0%) patients, 39 (72.2%) had CRT super response. Patients with CRT super response were likelier to have a greater S wave amplitude in V2 lead (p=0.004), higher rates of global longitudinal strain (GLS) (p=0.001) and interventricular delay (IVD) (p=0.005). Only 3 indicators (S wave amplitude in V2 lead, GLS and IVD) were independently associated with CRT super response in univariable and multivariable logistic regression. We created a prognostic model based on the logistic equation and calculated a cut-off value (>0.73). The resulting ROC curve revealed a discriminative ability with AUC of 0.957 (sensitivity 87.2%; specificity 100.0%). ***Conclusion:*** The electro-mechanical dyssynchrony assessment using ECG, STE and cardiac scintigraphy is useful in prediction of CRT super response in patients with Strauss LBBB criteria during 6 month follow-up. Our prognostic model is able to distinguish patients with CRT super response.

EP-0617

A Study on Risk Stratification of Heart Failure Severity Through the Evaluation of Mitochondrial Dysfunction in Patients with Cardiac Resynchronization Therapy Indications

T. Atabekov, *V. Korepanov, A. Mishkina, S. Sazonova, S. Afanasiev, R. Batalov, S. Popov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Accurate risk stratification of heart failure (HF) severity is crucial for optimizing treatment strategies and improving patient outcomes. Recent research has highlighted the role of mitochondrial dysfunction (MD) as a potential biomarker for HF severity assessment. This study aims to investigate the relationship between HF severity and MD in patients with indications for cardiac resynchronization therapy (CRT). ***Materials and Methods:*** In this prospective clinical study patients with HF classified as New York Heart Association (NYHA) functional classes (FC) II and III, who were indicated for CRT, underwent transthoracic echocardiography (TTE) alongside an assessment of MD. This assessment utilized both laboratory techniques, specifically evaluating the respiratory function of mitochondria in peripheral blood mononuclear cells (PBMC), and radionuclide imaging through myocardial perfusion scintigraphy (MPS) using the ^{99m}Tc-methoxy-isobutyl-isonitrile (^{99m}Tc-MIBI). We calculated mitochondrial respiration rates (MRR) based on various substrates (pyruvate + malate - adenosine diphosphate [$V_{4,1}$]) and determined ^{99m}Tc-MIBI washout rate (WR) indicators. The study evaluated the correlations between the NYHA FC of HF, TTE results, MRR and WR indicators. Utilizing our findings, we developed a risk model to assess the HF severity. ***Results:*** Among the 26 (100.0%) HF patients included in the study, 11 (42.3%) were classified as having mild HF, corresponding to NYHA FC II (Group 1), while 15 (57.7%) were categorized as having moderate-to-severe HF, classified as NYHA FC III (Group 2). Those with moderate-to-severe HF exhibited significantly lower $V_{4,1}$ values (33.4 [18.1; 37.8] nMol O_2/min/mg mitochondrial protein [MP]) compared to those with mild HF (65.2 [54.6; 142.4] nMol O_2/min/mg MP, p<0.001). This measurement was found to be independently associated with moderate-to-severe HF in both univariate and multivariate logistic regression analyses (odds ratio 0.87; 95% confidence interval 0.77-0.98; p<0.001). The HF risk model demonstrated strong discriminative power (area under the curve of 0.933; cutoff value > 0.7; sensitivity 80.0%; specificity 100.0%) in identifying HF severity. The risk model successfully predicted moderate-to-severe HF with an accuracy of 84.6%. ***Conclusion:*** In patients with moderate-to-severe HF MRR is markedly reduced compared to that in patients with mild HF. The HF severity is associated with PBMC mitochondrial respiratory dysfunction in patients with CRT indications. The MD indicator assessed by MPS with ^{99m}Tc-MIBI is not associated with HF severity and does not correlate with PBMC mitochondrial respiratory dysfunction. We have developed HF severity risk model including $V_{4,1}$ parameters is able to distinguish mild and moderate-to-severe HF patients.

[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, Barcelona, SPAIN, [2]Cardiology Department, Bellvitge University Hospital-IDIBELL, Barcelona, SPAIN, [3]Internal Medicine Department, Bellvitge University Hospital-IDIBELL, Barcelona, SPAIN, [4]Radiopharmacy Department, Bellvitge University Hospital-IDIBELL, Barcelona, SPAIN.

Aim/Introduction: Cardiac amyloidosis (CA) is an infiltrative disease characterized by the deposition of amyloid fibrils in myocardial tissue, leading to progressive cardiac dysfunction. Cardiac scintigraphy (CS) using [^{99m}Tc]Tc-DPD is a key noninvasive imaging technique, particularly effective in the diagnosis of transthyretin-related cardiac amyloidosis (ATTR-CA). The Perugini Visual Score (PVS) is widely used for qualitative assessment, however, it is susceptible to interobserver variability. The aim of this study was to assess the correlation between PVS and quantitative scintigraphic indices in relation to cardiac magnetic resonance (CMR) findings and amyloid subtype, and evaluate inter-observer agreement in PVS grading. ***Materials and Methods:*** We performed a retrospective analysis of 70 patients (43 males, mean age 71 years) with suspected CA who underwent both CS and CMR. Myocardial uptake was quantified by defining a circular region of interest (ROI) over the heart and mirroring it over the contralateral chest to derive CMC/HCL and CMC/HCL with background correction ratios (CMC-Bkg/HCL-Bkg). Four independent observers graded the CS images using the PVS. Interobserver agreement was assessed using Fleiss' kappa statistic. ***Results:*** CA was diagnosed in 23 of the 70 patients, with 17 cases of ATTR-CA, 5 cases of AL-CA and 1 case of AA. CS with [^{99m}Tc]Tc-DPD showed a sensitivity of over 99% and a specificity of 94%, confirming its robust diagnostic performance. A significant correlation was observed between the CMC/HCL and CMC/HCL-Bkg indices and the highest PVS values ($p<0.05$), supporting the utility of quantitative scintigraphy in the assessment of myocardial amyloid deposition. No significant correlations were found between PVS and echocardiographic parameters such as interventricular septal thickness or left ventricular ejection fraction. The inter-observer agreement for PVS was substantial with a Fleiss' kappa value of 0.75. More concordance was observed at the extreme ends of the Perugini scale (scores of 0 and 3). ***Conclusion:*** CS with [^{99m}Tc]Tc-DPD is a highly sensitive and specific modality for the detection of CA. The significant correlation between myocardial uptake quantification and PVS underlines its diagnostic value. However, the incorporation of quantitative tools to improve reproducibility and diagnostic accuracy in clinical practice is highlighted by the observed inter-observer variability in intermediate PVS.

^{18}F-FAPI PET/CT in Chronic Liver Disease: Myocardial Fibroblast Activation and Its Correlates

Y. Wang*, Y. Wang;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: This study investigates the relationship between cardiac fibroblast activation and clinical parameters, electrophysiological findings, serum fibrosis markers, and hepatic fibroblast activation in patients with chronic liver disease. ***Materials and Methods:*** In this prospective study conducted from December 2021 to April 2022, 46 patients with chronic liver disease underwent fluorine-18 (^{18}F)-labeled FAPI PET/CT imaging and 12-lead electrocardiogram (ECG). Abnormal cardiac ^{18}F-FAPI uptake was defined as uptake greater than that of the blood pool. PET/CT parameters included standardized uptake value (SUV) and target-to-background ratio (TBR). ***Results:*** Significant differences were observed between positive and negative myocardial ^{18}F-FAPI PET/CT imaging groups in terms of age (54 ± 7 years vs. 45 ± 10 years; P = 0.006), epicardial fat volume (EFV) (169.71 ± 70.78 cm^3 vs. 115.16 ± 46.76 cm^3; P = 0.004), Cornell voltage QRS amplitude (1.26 ± 0.62 mV vs. 0.88 ± 0.34 mV; P = 0.022), and QRS duration (94.64 ± 8.60 ms vs. 89.91 ± 7.48 ms; P = 0.032. The multivariable logistic regression analysis demonstrated a significant association between EFV (OR = 1.019, P = 0.024) and age (OR = 1.162, P = 0.019) and myocardial FAPI uptake positive. Myocardial TBRmax was positively correlated with hepatic TBRmax (r = 0.405, P = 0.005), hepatic TBRmean (r = 0.412, P = 0.004), and negatively correlated with the T wave amplitude in lead V6 (TV6) of the ECG (r = –0.295, P = 0.047). Moreover, myocardial SUVmax was positively correlated with serum laminin (LN) levels (r = 0.367, P = 0.042). ***Conclusion:*** In patients with chronic liver disease, fibroblast activation protein inhibitor (FAPI) PET/CT imaging demonstrated cardiac fibroblast activation, which was associated with electrophysiological parameters, hepatic FAPI uptake, and serum liver fibrosis markers. These findings highlight the potential of ^{18}F-FAPI PET/CT imaging in assessing the relationship between cardiac and hepatic fibrosis.

EP-0621

^{99m}Tc-FAPI SPECT/CT for Evaluation of Myocardial Fibrosis and Cardiac Function in Valvular Heart Disease

Y. Zhang*, W. Chen;*
Department of Nuclear Medicine, Fuzhou University Affiliated Provincial Hospital, Fuzhou, CHINA.

Aim/Introduction: Active myocardial fibrosis plays a pivotal role in valvular heart disease (VHD) progression. While conventional imaging modalities primarily detect established fibrosis, the detection of active fibroblast activation remains challenging. ^{99m}Tc-FAPI SPECT/CT, offering advantages of wider availability and lower cost compared to PET imaging, represents a promising tool for evaluating active myocardial fibrosis. ***Materials and Methods:*** We conducted a prospective study (Trial registration: ChiCTR2400094867) of 30 VHD patients who underwent ^{99m}Tc-FAPI SPECT/CT imaging with comprehensive clinical evaluation. Patients were categorized into FAPI-positive (n=24) and FAPI-negative (n=6) groups based on myocardial tracer uptake patterns. Thirteen FAPI-positive patients completed a three-month follow-up to assess therapeutic response. ***Results:*** FAPI uptake parameters showed robust correlations with established myocardial injury markers (Hs-cTnI vs. SUVmax: r=0.831, p<0.001; Hs-cTnI vs. SUVmean: r=0.795, p<0.001) and disease severity indices (VHD staging: r=0.812, p<0.001). FAPI-positive patients demonstrated significantly higher atrial fibrillation prevalence (54.2% vs. 0%, P=0.024). Post-treatment follow-up revealed significant improvements in FAPI parameters (SUVmax: 2.8±0.4 to 1.9±0.3, p<0.0001; SUVmean: 2.3±0.3 to 1.6±0.2, p<0.0001), accompanied by enhanced left ventricular ejection fraction (45.3±5.2% to 52.1±4.8%, p=0.0176) and NYHA functional status (p=0.0011), despite unchanged structural parameters. ***Conclusion:*** This study demonstrates that ^{99m}Tc-FAPI SPECT/CT enables non-invasive visualization and quantification of active myocardial fibrosis in VHD patients. The strong associations between FAPI parameters and clinical indices, coupled with its ability to monitor therapeutic response, suggest its potential as a valuable tool for risk stratification and treatment optimization in VHD management.

Aim/Introduction: Patients with a prior myocardial infarction (MI) are at a higher risk of adverse outcomes following coronary artery bypass grafting (CABG). The prediction value of preoperative multidisciplinary assessment for perioperative MI in patients undergoing CABG remains elusive. The purpose this of study was to explore the efficacy of multimodality cardiac imaging in predicting perioperative MI in patients with prior MI and triple coronary artery disease (CAD). ***Materials and Methods:*** A total of 26 patients (age 60.5 years [IQR: 54-66 years], 80.8% men) with prior MI and triple CAD were prospectively rerolled, all patients underwent cardiac sodium ^{18}F-fluoride (^{18}F-NaF) positron emission tomography/computed tomography (PET/CT), coronary angiography, and CT-based coronary artery calcium scoring before CABG. The maximum coronary ^{18}F-NaF activity (target-to-background ratio (TBR_{max}) and the global coronary ^{18}F-NaF activity (TBR_{global}) were determined. The endpoint was perioperative myocardial infarction (PMI) within 7 days after CABG. ***Results:*** Overall, 8 (30.8%) patients experienced PMI. Compared to those without PMI, those with PMI had a higher TBR_{max}(4.66 [3.17-9.44] vs. 2.53 [1.74-3.10], P = 0.017)and TBR_{global} (3.25 [2.79-5.39] vs. 2.17 [1.52-2.58], P = 0.012). No significant difference of SYNTAX and CAC scores was observed between patients with and without PMI (P > 0.05). Multivariate analysis showed that TBR_{max} (as a continuous and categorical variable) was an independent predictor of PMI(P = 0.043 and 0.017), while TBR_{global} of 2.7 had predictive value as a categorical variable (P = 0.013). Both TBR_{max} and TBR_{global} delivered substantial incremental improvement in the prognostic value for PMI. ***Conclusion:*** Among patients with prior MI and triple CAD, quantification of coronary microcalcification activity through ^{18}F-NaF PET revealed a robust predictive power for early post-CABG cardiovascular outcomes.

EP-0623

Stratification of Non-Thromboembolic Pulmonary Hypertension by V/Q SPECT/CT Patterns: Hemodynamic and Radiologic Correlates

Z. Zhang*, Z. Wang, H. Pang;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: This study aimed to investigate the hemodynamic and computed tomography (CT) characteristics associated with three distinct V/Q patterns in non-thromboembolic pulmonary hypertension (NTEPH): matched defects (VQ1), focal patchy perfusion defects (VQ2), and global perfusion defects (VQ3). ***Materials and Methods:*** We retrospectively analyzed 226 consecutive patients with NTEPH who underwent V/Q SPECT/CT. Patients were stratified into four groups based on perfusion patterns: VQ1 (n=56), VQ2 (n=16), VQ3 (n=16), and a control group without perfusion defects (VQ0, n=138). Comparative analyses included hemodynamic parameters (mPAP, PVR, among others), imaging markers of pulmonary hypertension (including MPA diameter, P/A ratio, etc.), right ventricular function (RV free wall thickness, etc.), and CT features of pulmonary vasculature (vascular morphology, mosaic perfusion, ground-glass nodules, and other parenchymal characteristics). ***Results:*** The VQ3 group demonstrated significantly worse hemodynamic profiles, with higher mPAP and PVR values compared to other groups , Conversely, the VQ1 group exhibited more favorable hemodynamics with lower mPAP, RAP, PCWP, and RVP. CT imaging revealed marked differences: the VQ3 group showed significantly larger MPA diameter (44.3±8.7 mm vs 34.5±7.1 mm in VQ0, 37.2±8.4 mm in VQ1, and 35.3±6.9 mm in VQ2; p<0.001), higher P/A ratio (1.8±0.4 vs 1.3±0.3 in VQ0, 1.2±0.4 in VQ1, and 1.2±0.4 VQ2; p<0.001), and greater RV wall thickness (8.5±3.7 mm vs 7.1±3.4 mm in VQ0; p=0.001). Notably, the VQ3 group demonstrated characteristic pulmonary vascular remodeling features, including vine-like arterial dilatation (75%), peripheral vascular tortuosity (50%), diffuse mosaic perfusion (56.2%), and centrilobular ground-glass nodules (56.2%). No specific parenchymal abnormalities were identified in VQ1 or VQ2 groups. ***Conclusion:*** V/Q scintigraphy patterns effectively stratify NTEPH phenotypes: global perfusion defects (VQ3) correlate with advanced vascular remodeling and right ventricular dysfunction, while matched defects (VQ1) may represent early disease manifestations. These distinct imaging phenotypes provide valuable insights into underlying pathophysiology and may guide clinical management. ***References:*** Chan K, Ioannidis S, Coghlan JG, Hall M, Schreiber BE. Pulmonary Arterial Hypertension With Abnormal V/Q Single-Photon Emission Computed Tomography. JACC Cardiovasc Imaging. 2018;11(10):1487-93.

Validating Rubidium-82 for LVEF Quantification: A Comparative Study with 3D Echocardiography

M. Nielsen[1,2], *J. E. Larsson*[1], *N. Tietgen*[1], *L. L. Duchstein*[1], *P. G. Joergensen*[3], *B. Kristensen*[1], *B. Zerahn*[1], *L. T. Jensen*[2,1];
[1]*Dept. of Nuclear Medicine, Copenhagen University Hospital – Herlev and Gentofte, Herlev, DENMARK,* [2]*Dept. of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK,* [3]*Dept. of Cardiology, Copenhagen University Hospital – Herlev and Gentofte, Herlev, DENMARK.*

Aim/Introduction: Accurate assessment of left ventricular ejection fraction (LVEF) remains essential for detecting cardiotoxicity during cancer treatment. Current guidelines recommend three-dimensional echocardiography (3DE) as the first-line modality due to its broad availability and no use of ionizing radiation. However, 3DE is not always feasible. While cardiac MRI is the preferred second-line method, it is often unavailable in daily clinical settings. The recommended third-line option is equilibrium radionuclide angiography (ERNA), which, despite its historical role, has limitations related to radiation dose and declining availability. Rubidium-82 PET (Rb-PET), primarily used for myocardial perfusion imaging (MPI), also provides automated LVEF estimation as part of routine workflows. Compared to ERNA, Rb-PET offers lower radiation exposure, faster acquisitions, and greater cost-effectiveness in sites with a rubidium-82 generator. This study aims to compare Rb-PET and 3DE to evaluate whether Rb-PET is a suitable alternative for LVEF quantification. ***Materials and Methods:*** In this prospective study, patients undergoing rest Rb-PET MPI were recruited for same-day 3DE. LVEF was determined independently using vendor-provided semi-automated analysis software for both modalities. We assessed agreement between the two modalities using the intraclass correlation coefficient (ICC), concordance correlation coefficient (CCC), total deviation index (TDI), and Bland-Altman analysis. Pearson correlation was used to evaluate association. Subgroup analysis evaluated classification agreement above and below a 50% LVEF threshold, a preferred cutoff for considering cardioprotective strategies. ***Results:*** LVEF was successfully measured in 45 patients (90%) with 3DE and in 49 patients (98%) with Rb-PET, out of 50 enrolled. Mean LVEF by Rb-PET was 59.4 ± 9.8%, compared to 58.3 ± 7.9% by 3DE. Agreement between methods was good (ICC = 0.86, 95% CI: 0.76-0.92; CCC = 0.85, lower 95% CI: 0.77). The 90%-TDI was 7.73%, with an upper 95% confidence limit of 9.21%, indicating that 90% of paired differences fell within ±9.21%. Association between

methods was also strong (Pearson's r = 0.87). Bland-Altman analysis revealed a mean difference of -0.9% (LoA: -10.0 to 8.3%). No patients were misclassified across the 50% LVEF threshold by either method, and most disagreement occurred in patients with LVEF well above 50%. ***Conclusion:*** Rb-PET provides a feasible and reasonably accurate estimation of LVEF compared to 3DE. The two methods showed good agreement, with consistent classification across clinically relevant thresholds. Rb-PET may well serve as a valuable alternative for monitoring LVEF when 3DE is inconclusive or not feasible. These findings are based on preliminary data from the first 50 patients in an ongoing study targeting 100 participants.

EP-0625

Combined PET and multiparametric MRI Radiomics with Machine Learning for Differentiating Symptomatic from Asymptomatic Carotid Plaques

C. Zheng[1], *R. Qin*[1], *Z. Liu*[2], *Y. Yang*[3], *J. Lu*[1];
[1]*Xuanwu Hospital, Capital Medical University, Beijing, CHINA,* [2]*Central Research Institute, United Imaging Healthcare, Shanghai, CHINA,* [3]*Beijing United Imaging Healthcare, Beijing, CHINA.*

Aim/Introduction: Identification of symptomatic carotid plaques is essential for the treatment and prevention of ischemic stroke. The aim of this study is to evaluate the performance of radiomics derived from the combination of PET and multiparametric MRI for the non-invasive differentiation of symptomatic from asymptomatic carotid plaques. ***Materials and Methods:*** A total of 103 patients with carotid plaques who underwent ^{18}F-FDG PET/MRI were enrolled in this study. The MRI protocol included T1-weighted imaging (T1WI), contrast-enhanced T1WI (T1C), T2-weighted imaging (T2WI), and 3D time-of-flight (TOF) sequences. All sequences were co-registered to the native T1WI space, intensity-normalized, and resampled to an isotropic voxel size of 1 mm. The cohort was randomly partitioned into training (70%) and testing (30%) sets. The Least Absolute Shrinkage and Selection Operator (LASSO) algorithm was employed for optimal feature selection. Four machine learning algorithms were employed to construct the classification model, including Support Vector Machine (SVM), Logistic Regression (LR), K-Nearest Neighbor (KNN), and Multi-Layer Perceptron (MLP). Model performance was evaluated on the test set using the area under the receiver operating characteristic curve (AUC), sensitivity, and specificity. ***Results:*** LASSO regression selected ten salient radiomic features for model construction: three originating from T1WI, two from T1C, three from T2WI, and two from PET images. The four machine learning models yielded largely comparable classification performance. The LR model achieved the highest discriminative ability (AUC = 0.750, sensitivity = 0.818, specificity = 0.650). The KNN model yielded an AUC of 0.742 (sensitivity = 0.727, specificity = 0.750). The SVM model demonstrated an AUC of 0.705 (sensitivity = 0.727, specificity = 0.650). Lastly, the MLP model attained an AUC of 0.732 (sensitivity = 0.818, specificity = 0.700). ***Conclusion:*** Integrated radiomic analysis combining ^{18}F-FDG PET with multiparametric MRI demonstrates considerable potential for differentiating symptomatic from asymptomatic carotid plaques. This approach may offer a valuable non-invasive tool to potentially enhance clinical stroke risk stratification.

EP-0626

Visualization of the inflammation-fibrosis communication mechanism of cardiovascular remodeling in pulmonary hypertension

B. Chen*, M. Yang;*
Beijing Chao-Yang Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: Fibroblast activation protein inhibitor (FAPI) imaging provides a new method for monitoring inflammation-fibrosis communication in pulmonary hypertension (PH). The value of FAPI imaging in disease assessment and prognosis significance in PH needs to be further explored. The goal of this study was to investigate the characteristics of FAPI activity in subtype PH and clinical significance of FAPI imaging. ***Materials and Methods:*** Consecutive patients with PH who underwent right heart catheterization, clinical assessment and FAPI imaging within 1 week were identified. Cardiovascular FAPI uptake higher than that in the blood pool was defined as abnormal. The maximum standardized uptake values (SUV_{max}) of the right ventricle (RV) and pulmonary artery (PA) were measured and further expressed as target-to-background ratio (TBR) with blood pool activity as background. In chronic thromboembolic pulmonary hypertension (CTEPH) patients undergoing balloon pulmonary angioplasty (BPA) treatment, clinical evaluation and FAPI imaging were performed after 2 BPA sessions. ***Results:*** Fifty-four CTEPH patients, 12 idiopathic pulmonary arterial hypertension (IPAH) patients and 11 connective tissue disease-associated PAH (CTD-PAH) patients were enrolled. Patients with CTEPH and IPAH had more abnormal FAPI uptake and higher FAPI activity in RV than CTD-PAH. While, patients with CTD-PAH had more abnormal FAPI uptake but lower FAPI activity in PA. Patients in intermediate- and high- risk had higher proportion of abnormal FAPI uptake in RV and PA than patients in low-risk. At follow-up, 27 patients CTEPH patients underwent 2 session of BPA and 11 patients underwent second FAPI imaging. The area under the curve (AUC) revealed the ability of RV FAPI activity to predict satisfactory BPA outcomes [RV free wall (RVFW), sensitivity: 94.0%, specificity: 50%; insert point, sensitivity: 88.0%, specificity: 67%]. There had a significantly positive correlation between ΔTBR of RVFW and ΔWHO functional class (WHO-Fc) (r = 0.695, P = 0.012), and negative correlation between ΔTBR of main PA and Δ6-minute walking distance (6WMD) (r = -0.740, P = 0.006). ***Conclusion:*** ^{18}F-FAPI PET/CT could provide insights to inflammation-fibrosis communication in subtype PAH, and serve as a vital role in prognosis of disease and efficacy prediction/monitoring.

EP-0627

Atherosclerosis Detection in the Abdominal Aorta and Iliac Arteries Using AI Segmentation of 18F-NaF and ^{18}F-FDG PET/CT Scans

O. Fanta[1,2], *W. Lee*[1,3], *S. Patil*[1], *D. Patel*[1], *T. Werner*[1], *P. F. Høilund-Carlsen*[4], *A. Alavi*[1];
[1]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA,* [2]*Charles University, Prague, CZECH REPUBLIC,* [3]*Drexel University College of Medicine, Philadelphia, PA, UNITED STATES OF AMERICA,* [4]*Odense University Hospital, Odense, DENMARK.*

Aim/Introduction: Atherosclerosis of the abdominal aorta (AA) and iliac arteries is a major form of cardiovascular disease (CVD) and significant cause of mortality. 18F-NaF and ^{18}F-FDG are two PET radiotracers that can detect vascular calcification and inflammation, respectively, which may serve as early-stage biomarkers of disease. This study aimed to evaluate AI-based segmentation of radiotracer uptake in the AA and iliac arteries and to assess correlations of these derived values with various atherosclerotic risk factors. ***Materials and Methods:*** 99 subjects from the CAMONA trial (63 healthy volunteers, 36 at-risk for CVD, mean age of 48.4±14.1 years, 53.5% female) underwent 18F-NaF and ^{18}F-FDG PET/CT imaging. AI-based segmentation was used to define ROIs around the AA and the iliac arteries using the TotalSegmentator model (Wasserthal et al. 2023). The SUVmean was used to quantify radiotracer uptake which was correlated with age, C-reactive protein (CRP) levels, and gender. ***Results:*** In the at-risk subject group, aortic and bilateral iliac 18F-NaF SUVmean correlated strongly with age (R=0.513, p<0.01 in the AA; R=0.447, p=0.01 in the left iliac; R=0.506, p<0.01 in the right iliac). Left and right iliac 18F-NaF SUVmean correlated with CRP (R=0.0407, p=0.02 and R=0.358, p=0.04, respectively). In the healthy group, aortic 18F-NaF SUVmean correlated with age (R=0.276, p=0.04). There were no significant differences in aortic or iliac 18F-NaF SUVmean between the two patient groups, but aortic, right iliac SUVmean was higher in females than males (1.00 vs. 0.890,

p=0.01 and 1.14 vs. 1.01, p=0.03 respectively). ^{18}F-FDG SUVmean correlated with age in the left and right iliac arteries in the healthy group only (R=0.358, p <0.01 and R=0.348, p<0.01, respectively). Relative to the healthy group, the at-risk group had greater average bilateral iliac ^{18}F-FDG SUVmean (1.11 vs 0.915, p<0.01 and 1.15 vs 0.98, p=0.01 in the left and right iliac arteries, respectively). ***Conclusion:*** 18F-NaF uptake showed a strong correlation with known atherosclerotic risk factors and was, on average, higher in females than in males. 18F-FDG, thought to visualize inflammation pertinent to the pathogenesis of plaque formation, had limited correlations with atherosclerotic risk factors, possibly due to the proximity of the measured structures to other organs with high ^{18}F-FDG uptake in the abdomen and pelvis. Further studies with subjects specifically selected for PAD and improved AI segmentation methods are needed to assess the clinical utility of 18F-NaF PET/CT in determining PAD risk.

EP-0628

Imaging of Acute Aortic Dissection and Intramural Hematoma by 18F-AIR-NOTA-FAPI PET/CT

Y. Lu, *X. Zhang;*
Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: Objective: The significance of the fibrotic response of acute aortic dissection (AAD) and acute intramural hematoma (AIMH) is unknown. The aim was to characterize fibrosis of AAD and AIMH respectively at acute phase using ^{18}F-AIR-NOTA-FAPI PET/CT (FAPI PET/CT). ***Materials and Methods:*** 33 patients (age 56.7±1.8y, 25 male) within two weeks (acute phase) after acute aortic syndrome, were prospectively recruited from a study population referred to the Anzhen Hospital of Capital Medical University from June 2024 to December 2024 underwent FAPI PET/CT pre-operation. The maximum standardized uptake value (SUVmax) was measured in the ascending aorta, aortic arch, thoracic aorta, and abdominal aorta. ***Results:*** In contrast to AAD, AIMH showed accentuated FAPI uptake at the injured aortic wall [(6.74±1.89) vs. (5.17±1.65), P=0.016]. Compared with the AAD, there was increased FAPI uptake (SUVmax) in the aortic arch [(5.70±2.14) vs.(4.41±1.35), P=0.045], thoracic aorta [(6.24±1.84) vs.(4.78±1.30), P=0.013], and the abdominal aorta [(4.48±1.30) vs.(3.46±1.42), P=0.05]. Besides, there was a significant positive correlation between the uptake of the abdominal aorta and its diameter (r=0.492, P=0.004). ***Conclusion:*** AIMH and AAD was associated with increased FAPI uptake, while there was higher FAPI uptake of AIMH, indicating an inflammatory-fibrotic response in the whole aorta.Additionally, FAPI uptake in the aortic wall was associated with aortic growth. This finding warrants further prospective investigations.Acknowledgements: This project was sponsored by the National Natural Science Foundation of (82171994).

EP-0629

Predicting Reverse Remodeling Following Valve Replacement in Patients with Valvular Heart Disease: A Longitudinal ^{99m}Tc-FAPISPECT/CT Imaging Study

K. Wang, *Y. Gu, K. Han, C. Yan, W. Fang, L. Wang;*
Chinese Academy of Medical Sciences & Peking Union Medical College, Fuwai Hospital, Beijing, CHINA.

Aim/Introduction: In patients with valvular heart disease (VHD), fibroblast activation induced by pressure or volume overload can be identified by molecular imaging with fibroblast activation protein inhibitor (FAPI). The study sought to explore the potential of serial FAPI imaging for monitoring the reverse myocardial remodeling triggered by valve replacement. ***Materials and Methods:*** A cohort of 31 VHD patients scheduled for transcatheter or surgical valve replacement underwent ^{99m}Tc-FAPI SPECT/CT imaging and echocardiography. All patients underwent repeated echocardiography, and 22 completed repeat FAPI scans at 3-month follow-up. Cardiac FAPI uptake was quantified as maximum standardized uptake value (SUV_{max}), maximum of myocardial-to-blood ratio (TBR_{max}), and fibroblast activation volume (FAV). Myocardial remodeling patterns were evaluated through a comprehensive analysis of left ventricular geometric parameters derived from echocardiography. ***Results:*** Myocardial FAPI uptake showed heterogeneity among VHD patients (range: SUV_{max} 0.67-8.33; TBR_{max} 1.13-7.50; FAV 0-597 mL). FAPI uptake significantly correlated with levels of circulating N-terminal prohormone of brain natriuretic peptide and left ventricle mass index before valve replacement. Following relief of overload, 22 patients who underwent repeat FAPI imaging demonstrated significant reductions in TBR_{max} (3.31 [1.73-4.87] vs. 2.43 [1.63-4.23], p = 0.029) and FAV (31.5 [0-227] vs. 12.0 [0-144] mL, p = 0.004). Follow-up echocardiography revealed that 9 out of 31 patients transitioned to normal geometry from concentric or eccentric hypertrophy, achieving complete reverse remodeling. Multivariable regression suggested that baseline FAPI uptake intensity TBR_{max} was significantly associated with complete reverse remodeling post-intervention after adjustment (OR: 0.288 [0.097-0.852], p = 0.024). ***Conclusion:*** ^{99m}Tc-FAPI SPECT/CT imaging is feasible to quantitatively track dynamics of fibroblast activation following valve replacement. Patients with lower preprocedural fibrotic activity identified by FAPI imaging mayhave greater potential for complete reverse remodeling.

EP-0630

The enhancement of the sensitivity of ^{18}F-FAPI-74 PET visualization for atherosclerosis based on Q.Clear image reconstruction.

J. Song, *Y. Hong, W. Liu, L. Li, Q. Wu;*
First Hospital of Shanxi Medical University, Shanxi, CHINA.

Aim/Introduction: To investigate whether Q.Clear reconstruction can enhance the sensitivity of ^{18}F-FAPI-74 PET/CT in visualizing atherosclerotic plaques. ***Materials and Methods:*** A retrospective analysis was conducted on 85 patients with coronary heart disease who completed ^{18}F-FAPI-74 PET/CT examination from June 2023 to September 2024. The original ^{18}F-FAPI-74 PET/CT image data were reconstructed using OSEM+TOF, OSEM+TOF+PSF and Q.Clear (TOF+PSF + BPL) (noise penalty factor β=200, 400, 600, 800), respectively. The atherosclerotic lesion sites with calcification of the arterial wall and uptake of ^{18}F-FAPI-74 as shown by CT were taken as the region of interest (ROI) for quantitative analysis. Measure the SUVmax, SUVmean and standard deviation (SD) of the blood background at the Lesion site and in the arterial lumen at the same level under different reconstruction algorithms, and calculate the lesion signal-to-noise ratio. L-SNR, Boold pool-SNR (Bp-SNR), and Lesion maximum tissue-to-blood (L-TBRmax). The 4-point Likert scale was used to evaluate the visual saliency of the lesion after image reconstruction for each patient (from 1 to 4), and the results of each observer were recorded to compare the differences in the visual saliency of the lesion among different image reconstruction algorithms. ***Results:*** In this retrospective study involving 85 patients with coronary artery disease, we analyzed 206 atherosclerotic plaques. Based on ^{18}F-FAPI-74 PET/CT images, different β values of Q.Clear reconstruction were compared with various combinations of OSEM, TOF, and PSF. We found that Q.Clear reconstruction with β = 200 yielded the highest quantitative performance (L-SUVmax: 3.33±0.89 and L-TBRmax: 2.11±0.97), as well as the highest lesion signal-to-noise ratio (L-SNR: 7.19±4.52). However, this setting resulted in relatively lower background signal-to-noise ratio (Bp-SNR: 7.41±3.07), indicating suboptimal overall image quality. Increasing the β value of Q.Clear reconstruction or using OSEM+TOF+PSF can significantly enhance image quality, but comes at the cost of reduced quantitative accuracy. Q.Clear reconstruction with β = 200 achieved the highest proportion of conspicuous lesions with 74.27% rated as Likert score 3, and demonstrated the best observer consistency evaluation. ***Conclusion:*** Utilizing Q.Clear reconstruction with a low β value in ^{18}F-FAPI-74 PET/CT imaging can enhance the sensitivity for visualizing atherosclerotic plaques, yet this refinement comes at the cost of diminished image quality.

EP-0631

^{18}F-FDG-PET/CT for Diagnosing Infective Endocarditis Within the First Few Months Following Cardiac Prosthesis Implantation

D. Ferraro[1,2], *B. G. Padilha*[1], *R. A. de Camargo*[3,4], *C. F. Togni*[1], *L. F. T. Gonçalves*[1], *T. B. Teixeira*[1], *I. R. Brigo*[1], *D. A. M. Santos*[5], *M. C. P. Giorgi*[1], *R. A. Kitamikado*[1], *L. T. Hyppolito*[1], *M. R. Paixão*[1], *T. M. V. Strabelli*[1], *A. J. Mansur*[1], *F. Tarasoutchi*[1], *R. F. Souza*[6], *D. M. Gualandro*[1], *J. Soares Jr*[1], *R. F. Siciliano*[1];
[1]*Heart Institute of the Clinics Hospital of the Medical Faculty of the University of Sao Paulo, Sao Paulo, BRAZIL,* [2]*Hospital Israelita Albert Einstein, Sao Paulo, BRAZIL,* [3]*Hospital Aliança Star - Rede D'Or São Luiz, Salvador, BRAZIL,* [4]*Heart Institute of the Clinics Hospital of the Medical Faculty of the University of Sao Paulo, São Paulo, BRAZIL,* [5]*Cancer Institute of the Clinics Hospital of the Medical Faculty of the University of Sao Paulo, Sao Paulo, BRAZIL,* [6]*School of Economics, Business Administration and Accounting at Ribeirão Preto, Ribeirao Preto, BRAZIL.*

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) with 18F-fluordeoxiglicose (FDG) has become an important additional tool for detecting infections in cardiac prostheses. However, its use within the first months after cardiac prosthesis implantation is controversial and there is a concern regarding the potential risk of imaging misinterpretation caused by inflammation from recent surgical trauma. This study aims to evaluate the accuracy of PET-CT in diagnosing endocarditis in patients with cardiac prostheses within the first few months after implantation. ***Materials and Methods:*** Between 2013 and 2024, we investigated 111 episodes of suspected infective endocarditis (IE) in patients who had prostheses implanted within the previous six months (85 prosthetic valves and 26 ascending aortic prosthesis). The accuracy of 18F-FDG-PET/CT was determined based on the consensus of two specialists in cardiac PET imaging. Reference standard was the final diagnosis by a specialist board team which was based on clinical, imaging and laboratorial information, follow up and histopathology when available. A logistic regression model using visual uptake patterns (no uptake, diffuse, heterogeneous or focal/multifocal) and SUVmax was developed and compared to the consensus of the two nuclear physicians. ***Results:*** IE was confirmed in 28 cases (25%). Most patients had prosthesis implantation within 3 months before PET/CT (76%, 85/111). Accuracy, sensitivity, specificity, and positive and negative predictive values of 18F-FDG-PET/CT were 89,2%, 75%, 94%, 81%, and 92%, respectively. The logistic regression model identified optimal accuracy for prosthetic valves with an SUVmax cutoff of ≥ 3.0, and for ascending aorta prosthesis with an SUVmax cutoff of ≥ 5.0, combined with heterogeneous and focal/multifocal uptake patterns. The accuracy based on specialist consensus was similar to that based on objective parameters for valves (89.4% vs 87.1%), but higher for ascending aortic prostheses (88.5% vs 76.9%). ***Conclusion:*** The accuracy of FDG-PET/CT for diagnosing IE was high in early prosthetic IE. Assessment of visual uptake patterns and SUVmax yields a similar accuracy to the consensus of cardiac PET specialists for prosthetic valves, but not for ascending aortic prostheses.

Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

Aim/Introduction: The role of positron emission tomography (PET)/computed tomography (CT) in the determination of inflammation in arterial disease is challenging. This technique can provide information about arterial wall inflammation and plaque stability in atherosclerotic disease. The aim of this study was to compare localization of maximum inflammatory arterial activity assessed by PET/CT with ^{18}F-FDG (fluorodeoxyglucose) and the topographic localization of atheroma plaque using morphological methods. ***Materials and Methods:*** We conducted a prospective cohort study of patients diagnosed with significant carotid artery (CA) stenosis ≥50% and no prior history of stroke, from 2023 to 2024. Carotid stenosis was graded using hemodynamic criteria on ultrasound and classified as moderate (50-69%) or severe (70-99%). Patients with complete carotid occlusion were excluded. All patients underwent PET/CT imaging. SUVmax was measured within a 4 cm segment proximal and distal to the carotid bifurcation using sequential ROIs. The location of maximal activity was categorized as: (1) common carotid artery, (2) carotid bifurcation, or (3) internal carotid artery. We assessed whether the site of highest SUVmax overlapped with the site of maximal stenosis. Concordance was evaluated using Cohen's kappa coefficient, and correlation was assessed with Spearman's rho. ***Results:*** A total of 44 patients were included, with a mean age of 72.6 years; 30% were women. Thirty-three patients (75%) had CA stenosis ≥70%. In 18 patients (40.9%), the point of maximal inflammation was located in the common carotid artery. Concordance between the site of maximal inflammation (PET/CT) and the site of maximal stenosis was observed in 14 patients (31.8%), while in 30 patients (68.2%) there was a mismatch. The kappa coefficient was 0.23, indicating low concordance. Correlation was also weak (Spearman's rho = 0.07, p = 0.673). ***Conclusion:*** In our population of patients with asymptomatic significant carotid stenosis, the location of maximal inflammatory activity on PET/CT does not correlate with the site of maximal morphological stenosis.

EP-0633

Diagnostic Value of ^{18}F-FDG PET/CT in Infective Endocarditis

F. Gur[1], *Ö. V. Topuz*[2], *B. E. Akkaş*[2];
[1]*Başakşehir Çam ve Sakura City Hospital, İstanbul, TÜRKIYE,* [2]*Sağlık Bilimleri Üniversitesi, Başakşehir Çam ve Sakura Şehir Hastanesi, Nükleer Tıp Kliniği, İstanbul, TÜRKIYE.*

Aim/Introduction: Infective endocarditis (IE) is a life-threatening condition characterized by microbial infection of the endocardial surface, most commonly affecting heart valves. Structural heart disease, prosthetic valves, and implantable cardiac devices are known risk factors. ^{18}F-FDG PET/CT is now considered a major imaging criterion for diagnosing infective endocarditis, as defined by the Modified Duke-ISCVID criteria. This study aims to evaluate the diagnostic accuracy of ^{18}F-FDG PET/CT in patients with suspected IE. ***Materials and Methods:*** We retrospectively reviewed patients who underwent ^{18}F-FDG PET/CT between January 2021 and February 2024 due to suspected IE. Patients were classified according to the Modified Duke-ISCVID criteria as definite or excluded IE. All patients were prepared with a low-carbohydrate, high-fat/protein diet prior to imaging. Visual assessment of FDG uptake was performed; lesions showing focal myocardial uptake greater than mediastinal blood pool were considered positive. Bone marrow activation was assessed by calculating the marrow-to-liver SUV ratio using the average SUVmax of three non-lesional lumbar vertebrae divided by liver SUVmean. A ratio >1.4 was deemed positive. Anemia was ruled out based on hemoglobin levels. In patients with LVADs, infected components were recorded. ***Results:*** A total of 62 patients (22 female, 40 male; age range 1-83, mean age 51) were included. Cardiac devices included prosthetic valves (n=22), native valves (n=19), pacemakers (n=12), LVADs (n=10), and vascular grafts (n=9). PET/CT revealed

findings consistent with IE in 41 patients. Among LVAD patients, FDG uptake indicating infection was observed in the pump and outflow tract in 6 cases, and in the driveline in 4. No pathological findings were noted in 21 patients. Compared with final clinical diagnoses, PET/CT yielded 37 true positives, 4 false positives, 16 true negatives, and 5 false negatives (all in native-valve IE). Marrow/liver SUV ratio was significantly higher in IE-positive versus IE-negative patients (1.6 vs. 1.2, p=0.008). Sensitivity, specificity, PPV, NPV, and overall accuracy were 86%, 84%, 92%, 73%, and 85%, respectively. ***Conclusion:*** Focal myocardial FDG uptake above mediastinal activity shows high diagnostic performance for IE. In LVAD patients, PET/CT can guide surgical planning by localizing infected components. Although its specificity is lower in native-valve IE, increased bone marrow metabolic activity may serve as a warning sign in cases with negative PET/CT findings. ***References:*** Şimşek-Yavuz S, Akar AR, Aydoğdu S, et al. The evaluation of splenic switch-off on Ammonia PET in patients with hemodialysis and renal transplantation

A. Yamamoto, *M. Nagao, A. Inoue, R. Imakado, R. Nakao, Y. Maekawa, Y. Matsuo, A. Sakai, M. Momose, J. Yamaguchi, S. Sakai; Tokyo Women's Medical University Hospital, Tokyo, JAPAN.*

Aim/Introduction: Hemodialysis is a cause of arteriosclerosis, resulted in major adverse cardiac events (MACEs). Approximately half of the deaths of patients with hemodialysis are due to cardiovascular disease. Myocardial flow reserve (MFR) derived from ^{13}N-ammonia positron emission tomography (NH_3-PET) can predict the prognosis of patients with ischemic heart disease (IHD). In NH_3-PET imaging, the splenic switch-off (SSO) sign, which visually assesses the decline in splenic ^{13}N-ammonia uptake during adenosine administration, is a hemodynamic indicator of a favorable response to adenosine. This phenomenon is assumed to be due to the fact that adenosine receptor stimulation produces coronary artery dilation while producing vasoconstriction in the splenic circulation. Previous study reported that SSO was a predictor of cardiovascular event after heart transplantation. It was speculated that patients with hemodialysis had arteriosclerosis of the systemic blood vessels, and splenic reactivity to adenosine was reduced. The aim of this study was to compare the splenic blood flow measured by NH_3-PET among patients with hemodialysis, non-hemodialysis and renal transplantation, and investigate its predictive value for MACE. ***Materials and Methods:*** 100 patients (hemodialysis:40, non-hemodialysis:50, renal transplantation:10) who underwent NH_3-PET were enrolled. We placed an ROI on the spleen and measured the mean standardized uptake value (SUV) using NH_3-PET projection images. The spleen ratio (SR) was defined as the mean SUV of the spleen at stress divided by that at rest, and compared among the three groups. The endpoint was MACEs comprising acute coronary syndrome, heart failure hospitalization, and all-cause mortality. SSO was determined by a cutoff obtained using receiver operating characteristic (ROC) analysis for the SR. The patients were divided into two groups with and without SSO, and the MACE rate was compared by Kaplan-Meier and log-rank test. ***Results:*** The hemodialysis group had reduced MFR compared to non-hemodialysis group (1.7±0.6 vs. 2.1±0.6, p=0.0012). The SR was significantly higher in patients with hemodialysis than without hemodialysis (0.92±0.16 vs. 0.78±0.21, p=0.014). The ROC curve analysis of the SR for MACE showed a cutoff value of 0.96 (sensitivity: 55%, specificity: 72%, AUC: 0.67). Patients without SSO had higher MACE rate than those with SSO (p=0.0074) (Figure). ***Conclusion:*** Reaction of splenic blood flow to adenosine in patients with hemodialysis was reduced compared to those with non-hemodialysis. SSO might be related with the endothelial function of systemic blood vessels and was a predictor for MACE.

EP-0635

Abnormal cardiac accumulation on FDG PET due to chemotherapy for breast cancer

Y. Izoe[1], *M. Nagao*[2], *H. Tsukada*[2], *S. Watanabe*[2], *Y. Maekawa*[2], *A. Yamamoto*[2], *Y. Satoh*[3], *H. Saya*[1], *S. Akashi-Tanaka*[2], *S. Sakai*[2]; [1]*Fujita Health University, Toyoake, JAPAN,* [2]*Tokyo Women's Medical University, Shinjuku-ku, JAPAN,* [3]*Fujita Medical Innovation Center Tokyo, Ota-ku, JAPAN.*

Aim/Introduction: Cancer therapy-related cardiac dysfunction (CTRCD) is an important factor in determining treatment strategy and prognosis, but effective methods for its detection have not yet been established. Myocardial accumulation on FDG PET is known to be controlled by insulin activity and is poorly reproducible even between individuals. Therefore, it has not been used to diagnose CTRCD. We focused on the distribution pattern of cardiac FDG accumulation different from physiological accumulation and myocardial SUV, and attempted to determine whether chemotherapy-induced changes in these findings could be linked to detection of myocardial damage. ***Materials and Methods:*** The presence of abnormal right ventricular and atrial accumulation (RV/atrium), diffuse homogeneous accumulation in the left ventricle (homogeneous pattern), and myocardial SUVmax on FDG PET for the diagnosis and treatment of breast cancer between November 2013 and February 2025 were evaluated by two nuclear medicine physicians. FDG PET data were classified into two groups: 79 patients (mean age, 58 years) who had never received chemotherapy and 121 patients (mean age, 60 years) who had received chemotherapy. Chemotherapy regimens consisted mainly of anthracyclines (n=15), human epidermal growth factor receptor 2 (HER2) inhibitors (n=50), immune check inhibitors (ICI) (n=7), and others (eribulin, paclitaxel, and docetaxel, etc)(n=49). Multiple FDG PETs performed after chemotherapy in the same patient were included in the analysis. Patients with other cancers, cardiac and pericardial metastases or diabetes were excluded. ***Results:*** The mean observation period for FDG PET in the chemotherapy group was 38 months with a mean number of tests of 4.4. RV/atrium positivity was found in 37% (45/121) of the chemotherapy group and 13% (10/79) of the no chemotherapy group, with a significantly higher rate in the chemotherapy group (p=0.0002, Fisher's exact test). Homogeneous pattern was found in 38% (46/121) of the chemotherapy group and 23% (18/79) of the no chemotherapy group, with a significantly higher rate in the chemotherapy group (p=0.024). Myocardial SUVmax tended to be higher in the chemotherapy group than in the no chemotherapy group, but the difference was not significant (5.32±3.71 vs. 4.93±4.17). ***Conclusion:*** After chemotherapy, the positivity rate of RV/atrium and the frequency of homogeneous pattern on FDG PET increase. This may be a sign of potential myocardial injury. Cardiac accumulation patterns on FDG PET have been conventionally overlooked in oncology, but its evaluation is expected to be useful in detecting CTRCD.

[^{18}F]FDG PET Outperforms MRI in Detecting Early Neurodegenerative Changes Linked to Neurofibrillary Tangle Pathology: An Imaging-Pathology Correlation Study

O. Vourkas, *L. Zhang, A. Rabano, P. Sanchez-Juan, M. Grothe, J. Silva Rodriguez;*
CIEN Foundation, Reina Sofia Alzheimer Center, ISCIII, Madrid, SPAIN.

Aim/Introduction: Neurofibrillary tangle pathology (NFTp) in Alzheimer's disease (AD) is closely related to neurodegeneration, which can be measured in vivo using structural MRI or [^{18}F]FDG PET. While several studies have assessed this correlation using in-vivo markers of NFTp (i.e. tau PET), these are limited by the restricted sensitivity of tau PET for early NFTp stages [1]. Here, we aimed to assess the relative sensitivities of [^{18}F]FDG PET-measured hypometabolism and MRI-measured gray matter (GM) atrophy, to early and advanced stages of NFTp, as assessed by gold-standard post-mortem neuropathological examination. ***Materials and Methods:*** We studied 88 individuals from the Alzheimer's Disease Neuroimaging Initiative (ADNI) autopsy cohort who had Braak NFTp staging performed at autopsy and had [^{18}F]FDG PET and structural T1-MRI scans acquired before death (imaging-to-death interval: 3.4±2.3 years). Associations of Braak stages with regional [^{18}F]FDG PET SUVRs and GM volumes on MRI were assessed in exploratory brain-wide Spearman correlation analyses across 52 cortical and subcortical brain regions defined by the Harvard-Oxford neuroanatomical atlas. For regions showing a significant association ($p<0.05$, FDR-corrected), we then performed pair-wise comparisons between grouped Braak stages 0/I (N=8), II-IV (N=24), and V/VI (N=56). ***Results:*** Higher Braak stages were significantly associated with lower [^{18}F]FDG PET SUVR in several temporo-parietal cortical regions typically affected by AD. Compared to the Braak 0/I reference group, most of these regions showed significant and pronounced (Cohen's $d>0.9$) hypometabolism in early Braak stages II-IV, and severity of hypometabolism further increased in Braak stages V/VI. Although GM volume on MRI showed a similar regional association with Braak stages, effect sizes were considerably lower and differences to the Braak 0/I reference group were only significant for advanced Braak stages V/VI. ***Conclusion:*** Glucose hypometabolism as measured by [^{18}F]FDG PET is a sensitive neuroimaging marker of the neurodegenerative changes that accompany progressive stages of neurofibrillary tangle pathology in AD. Earliest NFTp-related neurodegenerative changes captured by [^{18}F]FDG PET hypometabolism appear to precede macrostructural gray matter atrophy as measured by MRI. ***References:*** [1]. Mattay VS, Fotenos AF, Ganley CJ, Marzella L. Brain Tau imaging: food and drug administration approval of 18F-flortaucipir injection. Journal of Nuclear Medicine. 2020 Oct 1;61(10):1411-2.

EP-0638

Predicting Amyloid PET Positivity in Alzheimer's Disease using 18F-Fluorodeoxyglucose PET and Explainable Artificial Intelligence

Ü. Akdemir[1], *A. Öter*[2], *E. Balcı*[1], *S. Sağıroğlu*[3], *L. Ö. Atay*[1];
[1]*Gazi University Medical Faculty, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Gazi University Faculty of Technology, Department of Energy Systems Engineering, Ankara, TÜRKIYE,* [3]*Gazi University Faculty of Engineering, Department Of Computer Engineering, Ankara, TÜRKIYE.*

Aim/Introduction: Amyloid PET imaging is a core component of Alzheimer's disease (AD) diagnostic criteria, but its high cost and limited availability pose significant challenges. This study aimed to determine if brain 18F-fluorodeoxyglucose (FDG) PET scans, a more widely accessible marker of neurodegeneration, can effectively predict amyloid PET status using machine learning (ML). Furthermore, we sought to evaluate the predictive model's performance and enhance its transparency using explainable artificial intelligence (XAI) techniques. ***Materials and Methods:*** We analyzed FDG PET data from a combined cohort of 292 Mild Cognitive Impairment (MCI) patients after data cleaning, comprising 54 patients from our center and 238 subjects derived from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. Brain FDG PET images were spatially normalized using the statistical parametric mapping (SPM) software. Regional glucose metabolism was quantified for 116 anatomical regions of interest (ROIs) defined by the automated anatomic labelling (AAL) atlas, with uptake values normalized using the pons as a reference region. A Gradient Boosting (GB) ML model was developed to classify subjects based on their amyloid PET status (positive/negative). The dataset was split into training (80%, n=233) and testing (20%, n=59) sets. Model hyperparameters (including learning rate=0.01, number of estimators=200, maximum depth=3) were optimized using 10-fold cross-validation and the GridSearchCV method on the training data. Performance was assessed on the independent test set using accuracy, precision, recall, and F1-score. SHAP (SHapley Additive exPlanations) and LIME (Local Interpretable Model-agnostic Explanations) were applied for model explainability. ***Results:*** The optimized GB model, utilizing the 116 regional FDG PET features, achieved promising results in predicting amyloid PET positivity on the unseen test set. The performance metrics were calculated as: Accuracy = 71.2%, Precision = 75.9%, Recall = 91.1%, and F1-score = 82.8%. XAI analyses successfully identified the specific brain regions that most significantly contributed to the model's predictions, providing insights into the neurobiological patterns associated with amyloid positivity as captured by FDG PET. ***Conclusion:*** Our study demonstrates that quantitative regional information derived from standard FDG PET scans, when analyzed with Gradient Boosting machine learning, can predict amyloid PET status with reasonable accuracy. This approach, enhanced by XAI for interpretability, shows potential as a more accessible and cost-effective method for identifying individuals likely to have AD-related amyloid pathology, potentially aiding in patient screening and selection for further diagnostic workup or clinical trials.

EP-0639

Quantitative assessment of the evolution stages of Alzheimer's disease in amyloid PET using an anatomical brain phantom

M. Pirozzi[1], *E. Di Giorgio*[2], *A. Prinster*[3], *A. Negro*[4], *V. D'Agostino*[4], *F. Squame*[2], *L. Mansi5*[5,6], *B. Alfano*[7], *M. Spadafora*[6], *M. Quarantelli*[3];
[1]*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, ITALY,* [2]*Nuclear Medicine Unit, Ospedale del Mare, Naples, ITALY,* [3]*Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY,* [4]*Neuroradiology Unit, Ospedale del Mare, Naples, ITALY,* [5]*CIRPS, Interuniversity Research Center for Sustainability, Rome, ITALY,* [6]*Medicina Futura, Acerra, Naples, ITALY,* [7]*Human Shape Technologies s.r.l, Naples, ITALY.*

Aim/Introduction: Visual interpretation of Amyloid-PET (A-PET) is based on the assessment of the presence of high local gray/white matter (GM/WM) ratios in disease-related target regions(1). However, the low-resolution of PET decreases the difference between positive and negative studies(2) and limits the possibility to measure the actual GM/WM tracer ratios. Furthermore, procedures for correction of partial volume effects (PVE), developed and validated for FDG-PET studies, lack proper validation on A-PET. Aims of the present study were:

to validate PVE-correction of A-PET studies using a 3D-printed multicompartmental anatomical brain phantom based on brain tissue maps obtained by MRI segmentation(3); to PVE-correct ROI data from a small set of clinical A-PET studies, carried out on the same PET scanner, providing estimates of actual GM/WM tracer uptake ratios associated to increasing disease stages. ***Materials and Methods:*** All studies were acquired on the same PET/CT scanner (Biograph mCT, OSEM3D+TOF, 4 iterations, 21 subsets, 3mm Gaussian smoothing, 5.76mm in-plane and 6.11mm axial FWHM).Two PET/CT studies of the phantom were acquired, respectively, without any activity in the GM compartments, and with a GM/WM ratio of 125%, with count statistics comparable to actual clinical human studies. Weighted sums of these two studies were then obtained, simulating six GM/WM concentration ratios equally spaced from 0 to 120%.10 A-PET studies (7 Flutemetamol, 3 Florbetapir; 5 females, age range 53-77, 5 positive studies) for which MRI studies suitable for segmentation were available, were also processed.For each study, ROI values were obtained by using the corresponding segmented T1-weighted MRI volume (for human studies(4)) or segmented high resolution CT scan (for the phantom(3)), co-registered to the PET(5), and labelled by applying the Automated Anatomical Labeling atlas(6). ROI values were then corrected for PVE(7) using PVELab(8). ***Results:*** Phantom uncorrected GM/WM ROI mean value inaccuracies ranged from +16.1% (for the 0% GM/WM phantom) to 18.8% (for the 120% GM/WM phantom), while PVE correction decreased ROI value errors to +0.5 and -5.6%, respectively.The optimal GM/WM ratio cutoff for PET positivity was 70% when using uncorrected values and 75% when using PVE-corrected values. ***Conclusion:*** The analysis of the phantom studies confirmed the accuracy of the A-PET PVE-correction based on segmented brain tissue compartment. A progressive GM/WM ratio increase above 70% corresponds to the transition from negative to positive studies. ***References:*** (1)Eur J Nucl Med Mol Imaging.2021;48:2169-2182 (2) Journal of Nuclear Medicine.2024;65:781-787 (3)Journal of Nuclear Medicine.2024;65:1489 (4)NeuroImage.2005;26:839-851 (5)Medical Image Analysis.1996;1:35-51.6 (6)Neuroimage.2002;15:273-289 (7) Journal of Nuclear Medicine.1998;39:904-911 (8)Journal of Nuclear Medicine.2004;45:192-201.

EP-0640

Quantification in the 18F fluorodeoxyglucose (FDG) Positron Emission Tomography/Computed Tomography (PET/CT) in prodromal dementia

Z. Koç[1], *M. Arslan*[1], *P. Ozcan*[1], *A. Özge*[2], *H. Yanık*[3];
[1]*Mersin University Hospital Nuclear Medicine Dpt., Mersin, TÜRKIYE,* [2]*Mersin University Neurology Dpt., Mersin, TÜRKIYE,* [3]*Mersin University School of Applied Technology and Management, Information Systems and Technologies., Mersin, TÜRKIYE.*

Aim/Introduction: In our study, we aimed to examine the contribution of digitization techniques and artificial intelligence to the diagnosis of ^{18}F-FDG PET/CT imaging in the differential diagnosis of prodromal Alzheimer's dementia. ***Materials and Methods:*** In this study, we retrospectively evaluated the data of 72 patients with a preliminary diagnosis of prodromal Alzheimer's dementia attended between November 2018 and December 2023, who were found suitable for F18-FDG PET/CT brain imaging in our Nuclear Medicine Clinic. The age, gender, mini mental assessment test (MMSE) score and prediagnoses of the 72 patients were obtained from patient files and clinicians and recorded. PET/CT imaging results, MATLAB-based SPM12 (Statistical Parametric Mapping) analysis results, artificial intelligence (TensorFlow and PyTorch (Deep Learning) in the PYTHON programming language) analysis results and the final diagnoses made clinically by neurologists were recorded. Statistical Pack age for Social Sciences (SPSS) 22.0 program was used to analyze the data obtained from the study. ***Results:*** According to clinical findings, 23 (31.9%) of the patients were diagnosed as mild cognitive impairment (MCI), 46 (63.9%) as Alzheimer's disease/other neurodegenerative disease, and 4 (4.2%) as normal. The mean age was 61.26±7.61 (min:51-max:77) years and the mean MMSE score was 21.40±7.37 (min:7-max:30) in patients clinically diagnosed with HBB. Twelve (52.2%) of the patients with HBB were male and 11 (47.8%) were female. Family history was present in 2 (8.7%) of the patients with HBB. The sensitivity, specificity, accuracy, positive predictive value, negative predictive value and positive predictive value of PET/CT were 91.3%, 100%, 92%, 100% and 50%, respectively. Of the 23 patients with clinical diagnosis of HBB, 19 patients had concordance with SMP12, while 4 patients had discordance. Of the 14 patients with normal SPM12, 4 were diagnosed as mild cognitive impairment and 7 as other neurodegenerative diseases. The performance of the SPM12 analysis method in the diagnosis of prodromal Alzheimer's disease was calculated as follows: Sensitivity 82.6%, specificity 100%, accuracy 95.7%, positive predictive value 100% and negative predictive value 42.8%. In addition, the performance of the artificial intelligence (AI) method in the diagnosis of mild cognitive impairment was evaluated as follows: Sensitivity 97.69%, specificity 98.88%, accuracy 98.29%, positive predictive value 98.83% and negative predictive value 97.79%. ***Conclusion:*** In conclusion, the sensitivity and specificity of both SPM12 analysis and visual interpretation results were similar however artificial intelligence analysis in FDG PET/CT imaging in the prodromal dementia stage significantly contribute to the diagnosis.

EP-0641

DaT-scanning on a CZT: distance is the enemy

V. Nuttens[1], *D. Ooms*[1], *S. Vermeulen*[2], *M. Koole*[1];
[1]*AZORG, Aalst, BELGIUM,* [2]*AZORG Aalst, Aalst, BELGIUM.*

Aim/Introduction: DaT-scanning with ^{123}I-ioflupane takes around 35 minutes for a conventional dual-head SPECT/CT according to EANM Guidelines [1], comprising 60 25-second projection views. A 3D-CZT-SPECT/CT can significantly reduce the scanning time to as low as 15 minutes. [2] However, the observed 3D-CZT-SPECT image quality was highly variable between scans. We aimed to demonstrate that 3D-CZT-SPECT/CT systems are more susceptible to resolution degradation with increasing detector-to-subject distance compared to conventional dual-head SPECT/CT systems. ***Materials and Methods:*** The background of a striatal phantom embedded in a human skull with resin was filled with 5 kBq/mL. The cavities representing the striata were filled with a ratio of 8:1 (right striatum) and 4:1 (left striatum). The phantom was scanned both on a conventional and 3D-CZT-SPECT/CT with a radial orbit of the detector heads at increasingly larger distances relative to the center of the phantom. The SPECT resolution of the phantom scans was assessed by calculating the Peak signal-to-noise ratio (PSNR) with an increasingly smoothed template. Image quality was assessed by a nuclear medicine physician using a 5-point Likert scale. All scans were done with an ultra-low-dose CT for attenuation correction. ***Results:*** 3D-CZT-SPECT/CT resolution degraded three times faster as a function of the distance of the detector compared to a conventional system. 3D-CZT data showed a spatial resolution of 14.7mm FWHM for 13.7 cm distance (closest possible position), while this was 17mm FWHM for the conventional SPECT/CT. The fitted curves for the spatial SPECT resolution as a function of distance intersect at 27 cm, corresponding to 17.8mm FWHM resolution. Visual assessment of image quality was even more convincing, with a 3D-CZT-SPECT/CT scan at the closest position resulting in a score of 5/5. This was reduced to a score of 3/5 for only a 3 cm increase in the distance of the object to the detector. For the conventional system, the closest position resulted in a 4/5. This reduced to a score of 3/5 for a 15 cm increase in the distance. ***Conclusion:*** Our study shows that optimal positioning of patients for 3D CZT DaT-SPECT

scanning is crucial, as the SPECT resolution is heavily influenced by the distance of the detector heads to the head of the patient. If the optimal scanning position is used, 3D-CZT-SPECT/CT systems show high potential to achieve better spatial resolution and scan twice as fast as conventional SPECT/CT. ***References:*** [1] 10.1007/s00259-020-04817-8 [2] 10.1097/RLU.0000000000003969.

EP-0642

Quantitative Study of Dopaminergic Neuron Integrity and MRI Relaxation Value Changes in Early-Onset versus Late-Onset Parkinson's Disease Using PET/MR Imaging

J. Liu, *R. Wang;*
Department of Nuclear Medicine, The First Medical Center of Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: Parkinson's disease (PD) results from dopaminergic neuron degeneration in the substantia nigra-striatal pathway, showcasing clinical and genetic variations. This study explores differences in dopaminergic neuron integrity and MRI relaxation times between early-onset PD (EOPD) and late-onset PD (LOPD) using ^{11}C-β-CFT PET/MR imaging with advanced SyMRI sequences. The objective is to enhance understanding of their distinct pathophysiological mechanisms. ***Materials and Methods:*** In a prospective study, 12 EOPD and 8 LOPD patients underwent ^{11}C-β-CFT PET/MR imaging, while 15 healthy controls (HC) only received MRI scans, which included T1 BRAVO and SyMRI sequences. Quantitative T1- and T2- maps were reconstructed from SyMRI raw data using AW workstation. Subsequently, the maps and PET images were coregistered to T1 images, normalized to MNI152 template and segmented to 116 AAL brain regions. PET standard uptake value ratios (SUVR) data were calculated by normalizing to whole-brain average value. Spearman's correlation was employed to explore the relationships among SUVR, T1, and T2 values across different brain regions. Additionally, one-way ANOVA analysis was conducted to evaluate differences among the EOPD, LOPD, and HC groups. ***Results:*** The EOPD group exhibited significantly higher SUVR values in the bilateral caudate nuclei compared to the PD group ($P < 0.05$). Variations in T1 and T2 values were observed among the EOPD, PD, and HC groups in the left caudate nucleus, left olfactory cortex, and left parahippocampal gyrus ($P < 0.05$), with the HC group consistently showing the lowest T1 and T2 values. Positive correlations were observed between T1 and T2 values in the EOPD, PD, and HC groups (EOPD: $r = 0.81$, $P < 0.05$; PD: $r = 0.91$, $P < 0.05$; HC: $r = 0.83$, $P < 0.05$). Additionally, negative correlations were found between T1 values and SUVR, as well as between T2 values and SUVR across all groups (EOPD: T1 $r = -0.46$, T2 $r = -0.5$; PD: T1 $r = -0.59$, T2 $r = -0.6$, all $P < 0.05$). ***Conclusion:*** Elevated SUVR values in EOPD patients suggest milder early-stage dopaminergic neuron impairment, with lower T1 and T2 relaxation values seen in the HC group, underscoring a close link between dopaminergic dysfunction and MRI changes for personalized treatment strategies in Parkinson's disease.

EP-0643

Performance of ^{18}F-SynVesT-1 versus ^{18}F-FDG brain PET in differentiation of patients with cognitive decline

C. Carron[1], *L. Degryse*[1], *L. Boeckxstaens*[1], *G. Vanderlinden*[1], *K. Nikkita*[2], *R. Vandenberghe*[1], *M. Vandenbulcke*[1], *K. Van Laere*[1];
[1]KU Leuven, Leuven, BELGIUM, [2]Yale PET center, Yale, CT, UNITED STATES OF AMERICA.

Aim/Introduction: ^{18}F-FDG brain PET is routinely used in the clinical workup of patients with cognitive dysfunction. SV2A PET quantifies synaptic loss and may be a more precise marker of neurodegeneration as it is less influenced by e.g. acquisition context and neuroinflammation. We prospectively investigated the diagnostic performance of ^{18}F-SynVesT-1 versus ^{18}F-FDG in patients referred for imaging to a tertiary memory clinic. ***Materials and Methods:*** A pilot analysis included 70 patients that underwent ^{18}F-FDG (30-45 minutes p.i.) and ^{18}F-SynVesT-1 (60-90 minutes p.i.) PET/MR within three months. Three nuclear medicine readers with variable experience (3-28 years) evaluated randomized orthogonal and surface rendered emission and Z-score images with a short clinical summary to assess the most likely diagnosis. A consensus diagnosis was defined if at least two readers agreed. If there was no agreement, the diagnosis of the most experienced reader was considered (6% of cases). Clinical follow-up provided the gold standard diagnosis. VOI-based SUVR quantification (pons for ^{18}F-FDG and centrum semiovale for ^{18}F-SynVesT-1 as reference region) was also investigated. ***Results:*** After median follow-up of 7 months, final clinical diagnoses were 34 AD, 9 FTD, 2 DLB, 1 amnesia due to epilepsy and 24 without evidence of neurodegeneration (NoND). Consensus ^{18}F-FDG PET reads differentiated NoND from others with 83% balanced accuracy (78-84%), with correspondence to the final diagnosis in 73% (63-80%). For ^{18}F-SynVesT-1, consensus read accuracy was 75% (74-76%), with corresponding final diagnosis in 64% (59-61%). Inter-observer agreement was equal for both tracers (Fleiss Kappa 0.49). Comparing AD to NoND, quantitative SUVR evaluation showed largest differences in the precuneus, lateral parietal and lateral temporal cortex for both tracers. For these VOI's, the Cohen's d values were 1.65, 1.52, and 1.46 for ^{18}F-FDG (all $p < 0.0001$), and 0.72, 0.73, and 0.93 for ^{18}F-SynVesT-1, respectively (all $p < 0.01$). This corresponded with the visual analysis, with lateral temporal and parietal regions as most affected for both tracers, and reductions more pronounced for ^{18}F-FDG. ***Conclusion:*** ^{18}F-SynVesT-1 PET shows promise as a clinical tool for differentiating patients with cognitive decline of uncertain origin. Although semiquantitative analysis at the group level showed SV2A binding reductions had lower effect sizes compared to hypometabolism, readers were still able to differentiate neurodegenerative disorders effectively and with good correspondence, despite having differences in overall experience and with SV2A PET reading.

EP-0644

A biological model combined individual tau-PET and FDG-PET molecular connectivity to predict disease progression for AD

L. Fu[1], *Z. Zhou*[2], *T. Lu*[3], *J. Gao*[1], *Y. Cheng*[3];
[1]Department of Nuclear Medicine,China-Japan Friendship Hospital, Beijing, CHINA, [2]Department of Neurology,China-Japan Friendship Hospital, Beijing, CHINA, [3]School of information science, Beijing university of chemical technology, Beijing, CHINA.

Aim/Introduction: Alzheimer's disease (AD) exhibits significant clinical heterogeneity, with patients demonstrating either rapid cognitive decline or typical progression patterns. The association between tau pathology, glucose metabolism, and the clinical heterogeneity remains unclear. We aimed to identify a biological model of individual molecular connectivity, incorporating tau pathology and cerebral glucose metabolism network, to predict AD progression using machine learning methods. ***Materials and Methods:*** We included participants from the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset who had baseline 3D-T1WI, ^{18}F-fluoro-deoxy-glucose (FDG-PET) and ^{18}F-AV1451 PET scans, along with longitudinal Mini-Mental State Examination (MMSE) and Clinical Dementia Rating (CDR) assessments spanning at least 2 years of follow-up. Participants were categorized into rapid progressive AD (rpAD; ≥4-point annual MMSE decline) and typical AD (tAD; ≤3-point annual MMSE decline) group. Individual brain networks were constructed for each subject using Kullback-Leibler divergence similarity estimation, and four types of features were extracted through graph theory analysis: connectivity strength, global/local topological features, and their combinations. After feature selection with t-tests and LASSO to address the curse of dimensionality, we classified rpAD and cAD using five machine learning models: Support Vector Machine

(SVM), Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), and K-Nearest Neighbors (KNN), with nested cross-validation to enhance generalization. ***Results:*** A total of 58 rpAD and 70 tAD patients were recruited. Compared to tAD patients, LR with combined features achieved the best classification performance on FDG-PET networks (AUC=0.936), while RF with connectivity and combined features showed optimal performance on tau-PET networks (AUC=0.855). The top identified regions for FDG-PET network included the bilateral temporal cortex, angular cortex, precuneus and caudate. As for tau-PET network, regions included bilateral orbitofrontal cortex, and right anterior cingulate cortex, precuneus, and angular gyrus. These results aligned with voxel-wise analysis results, showing significant AD-related decreased metabolism and increased tau deposition. ***Conclusion:*** This study suggests that machine learning technique combining network features of glucose metabolism and tau pathology can provide a promising classification of rpAD and tAD.

EP-0645

Regional Centiloid Quantification of ^{18}F-Florbetaben PET in a Multicenter Study Using Publicly Available Datasets.

C. Lin[1], *L. Tang*[2], *C. Ko*[2];
[1]*Department of Nuclear Medicine, National Taiwan University Hospital Yunlin Branch, Yunlin County, TAIWAN,* [2]*Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, TAIWAN.*

Aim/Introduction: The standardized interpretation of ^{18}F-florbetaben (^{18}F-FBB) image was based on expert scoring of regional cortical tracer uptake (RCTU) to calculate brain amyloid plaque load, judging from four different regions. However, visual scoring relies on readers' experience. And the inter-reader agreements become worse in complex clinical scenario. In this multicenter study involving four independent institutions, we propose a method for deriving regional Centiloid scale (RCL) values from ^{18}F-FBB PET using publicly available Centiloid calibration data, enabling standardized transformation of SUVRs to assist in RCTU interpretation. ***Materials and Methods:*** We recruited 71 subjects of suspected mild cognitive impairment or Alzheimer's disease (AD) referred for ^{18}F-FBB imaging. The RCTU scores read by qualified experts were served as reference standard. We used MI Neurology software to automatically quantify SUVR of the four specific cortical regions with whole cerebellum as reference region. RCL transformation was performed using paired PiB and FBB scans from the Centiloid calibration dataset (10 young controls and 25 elderly subjects). Regional SUVRs of controls and AD patients were anchored at RCL=0 and 100, respectively, and region-specific conversion equations were derived. The quantified SUVR and RCL values were compared to RCTU scores. Receiver operating characteristic (ROC) analysis was performed to identify optimal RCL cutoffs predictive of positive visual reads, and relationships with Mini-Mental State Examination (MMSE) scores were assessed. ***Results:*** RCL showed strong correlations with visual RCTU scores across all cortical regions (Spearman $\rho = 0.776$-0.827, $p < 0.001$). ROC analysis identified optimal RCL cutoffs of 0 (frontal), 25 (parietal), 70 (posterior cingulate), and 45 (temporal) for predicting positive visual reads, with area under curve (AUC) ranging from 0.928 to 0.970. MMSE scores significantly differed among groups stratified by the number of RCL-positive regions ($p=0.018$), with the group showing four positive regions having lower cognitive scores than those with none (adjusted $p = 0.022$). Additionally, we found that pooling regional RCL values into a single composite score and applying a unified cutoff provided stronger discrimination of MMSE scores ($p = 0.006$) than counting region-wise positivity, suggesting that pooled amyloid burden better reflects cognitive status. ***Conclusion:*** In this pilot study, we proposed a method for regional Centiloid quantification using open-access calibration data, which showed strong agreement with visual reads. Additionally, pooled analysis correlated well with cognitive status. Importantly, these quantitative thresholds may assist in the interpretation of ^{18}F-FBB PET, particularly in borderline or equivocal cases.

EP-0646

The Revealing of Aberrant Brain Metabolic Network Based on ^{18}F-FDG PET in Patients with DLBCL

J. Wang, *Q. Zhao, X. Ma, Y. Liu;*
General Hospital of Ningxia Medical University, Ningxia Yinchuan, CHINA.

Aim/Introduction: Diffuse Large B-cell Lymphoma (DLBCL) has been associated with aberrant cerebral metabolic patterns detected via ^{18}F-FDG PET. However, systemiclevel insights into how DLBCL affects functional brain integration through metabolic networks remain limited.This study aimed to investigate global and nodal topological alterations in brain metabolic networks of DLBCL patients, comparing baseline and post-chemotherapy states to healthy controls, to identify functional connectivity changes linked to the disease. ***Materials and Methods:*** Eighty DLBCL patients and 80 age- and sex-matched healthycontrols underwent ^{18}F-FDG PET/CT scans. Patients were scanned at baseline and post-chemotherapy. The Anatomical Automatic Labeling Template (AAL) was used to construct metabolic networks, analyzed via GRETNA software for global and nodal metrics. Inter-group differences were assessed using non-parametric permutation tests. ***Results:*** Both DLBCL patients (baseline/post-chemotherapy) and controls exhibited small-world network properties. However, baseline and post-treatment DLBCL patients showed abnormal transmission efficiency in the hippocampus, amygdala-cingulate pathway, and prefrontal cortex. Reduced connectivity in specific regions and compensatory increases in others were observed, particularly within the default mode and central executive networks. ***Conclusion:*** Our findings highlight the potential of ^{18}F-FDG PET combined with graph theory as a tool for early detection of cognitive impairment in DLBCL. This work bridges a critical gap in understanding how non-CNS malignancies and their treatments influence brain function, offering implications for personalized therapeutic strategies.

EP-0647

The Impact of APOE ε4 on Amyloid Deposition and Cerebral Blood Flow in Cognitively Normal Subjects using Dual-Phase ^{18}F-Florbetaben PET Study

J. Kim[1], *D. Kim*[2], *G. Kim*[1], *H. Yoon*[1];
[1]*Ewha Womans University Mokdong Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*Research Institute, Neurophet Incorporation, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Apolipoprotein E (APOE) genotype is important information in Alzheimer's disease (AD). This study aimed to demonstrate the impact of APOE ε4 on cerebreal blood flow (CBF) and amyloid deposition in cognitively normal subjects using dual-phase ^{18}F-florbetaben (FBB) PET. ***Materials and Methods:*** A total of 133 cognitively normal subjects who completed dual-phase ^{18}F-FBB PET and APOE genotyping were enrolled in the study. Participants possessing at least one APOE ε4 allele were designated as carriers. We assessed standardized uptake value ratios (SUVRs) for cerebral blood flow (CBF) using early-phase ^{18}F-FBB (eFBB) and for amyloid deposition using delayed-phase ^{18}F-FBB (dFBB) in both the composite region and specific target subregions, including the frontal cortex, parietal cortex, temporal cortex, occipital cortex, and precuneus. Additionally, we investigated correlations between eFBB and dFBB SUVRs across these regions. ***Results:*** APOE ε4 carriers exhibited significantly increased CBF in the composite region ($p = 0.0042$) and target subregions, including the frontal cortex ($p = 0.0054$) and parietal cortex ($p = 0.0056$) (Figure 1). They also showed greater amyloid deposition in the composite region ($p = 0.0065$) and target subregions, such as the frontal cortex ($p = 0.0028$) and precuneus ($p = 0.0071$).

Significant positive correlations between eFBB and dFBB SUVRs were shown in the temporal cortex (p = 0.0007) and precuneus (p = 0.0080). ***Conclusion:*** APOE ε4 showed significant higher amyloid deposition and CBF in specific brain regions of cognitively normal subjects. Dual-phase PET could be valuable for demonstrating AD-related changes in APOE ε4 carriers during the preclinical stage.

EP-0648

Statistical FDG PET Mapping and Quantitative MRI Volumetry of Limbic Age-Related TDP-43 Encephalopathy and Alzheimer Co-pathology

P. Ngam[1], *Y. Anzai*[2], *S. Minoshima*[2];
[1]*National University Hospital Singapore, Singapore, SINGAPORE,* [2]*University of Utah Hospital, Salt Lake City, UT, UNITED STATES OF AMERICA.*

Aim/Introduction: Limbic Age-Related TDP-43 Encephalopathy (LATE) is emerging as the prevalent neurodegenerative disorder in aging populations, mimicking the clinical presentations of Alzheimer's Disease (AD). This study investigates in vivo FDG PET and MRI biomarkers in detecting probable LATE neuropathologic changes (NC). ***Materials and Methods:*** We retrospectively analyzed 944 FDG PET cases referred from cognitive disorder clinics. To characterise the LATE and AD findings objectively and quantitatively, we created 3D-SSP PET templates for LATE-NC (n=6) and ADNC (n=32) from autopsy-confirmed datasets. All 3D-SSP Z-score FDG maps were created in comparison to normal PET scans from 20 control cases whose amyloid PET scans were negative. Using the autopsy-derived Z-score maps, Z-score product indices (individual Z-score map x Z-score of autopsy-confirmed cohorts) were generated for each subject, stratifying participants into probable LATE, probable LATE+AD, and probable AD. Quantitative MRI volumetry data (NeuroQuant) were analyzed between the groups. ***Results:*** Out of the 944 clinical cases, 13.0% were characterized as probable LATE (2.4% pure LATE and 10.6% LATE+AD) and 23.7% probable AD without LATE. MRI volumetry revealed that the medial temporal lobe was most affected in pure LATE cases (p<0.001), while the orbitofrontal gyrus and lateral temporal lobe were most vulnerable in mixed LATE+AD cases (p=0.001; p<0.001). Post-hoc analysis identified the entorhinal cortex and amygdala as key regions for distinguishing mixed LATE+AD cases from pure LATE and pure AD cases, respectively (p=0.05; p<0.001). Subgroup analysis of the probable LATE+AD group demonstrated additive/synergistic effects of both pathologies, with three-quarters of cases exhibiting concordant lateralized metabolic brain changes, predominantly left-sided, based on LATE and AD Z-score products (p<0.001). A similar pattern of left-dominant brain atrophy was observed in MRI volumetry. ***Conclusion:*** Substantial numbers of our patients exhibited LATE features that were characterised objectively using scans from autopsy-proven cases. These LATE cases were associated with specific regional atrophy measured by quantitative MRI. Cases with LATE+AD co-pathologies demonstrated synergistic hemispheric involvement. Further investigations of such synergistic changes between LATE and AD are warranted.

EP-0649

MRI-Informed Graph Learning on Amyloid PET Enhances Diagnosis and Staging of Alzheimer's Disease

T. Sun[1], *X. Chen*[1], *L. Chen*[2], *S. Wang*[1], *M. Wang*[2];
[1]*Chinese Academy of Sciences, Shenzhen, CHINA,* [2]*Henan Provincial People's Hospital, Zhengzhou, CHINA.*

Aim/Introduction: Early detection and accurate staging of Alzheimer's disease (AD) remain challenging due to subtle structural and molecular brain changes. Non-invasive methods that combine imaging modalities could improve diagnostic performance. This study proposes a novel graph-based learning framework that integrates amyloid-β PET and MRI structural features to enhance early detection and staging of AD. ***Materials and Methods:*** A total of 323 ^{18}F-florbetapir PET scans from 196 patients were retrospectively collected from the Alzheimer's Disease Neuroimaging Initiative (ADNI) as the training dataset. Two additional independent cohorts (99 scans from 85 patients) were used for external testing. For each PET scan, individual brain graphs were constructed to capture topological and spatial information. A graph learning model was developed to extract functional PET features while incorporating structural information from MRI. The model was trained to distinguish between normal control (NC), mild cognitive impairment (MCI), and AD subjects. Diagnostic performance was assessed using receiver operating characteristic (ROC) curve analysis, with cortical SUVR as a baseline. A new biomarker, the GCN_score, was derived from salient graph nodes and assessed using the Kruskal-Wallis test and Cohen's effect size. ***Results:*** The graph-based model achieved an AUC of 89.8% (specificity 83.6%, sensitivity 81.6%) for distinguishing MCI from NC, and 88.3% (specificity 81.6%, sensitivity 80.6%) for distinguishing MCI from AD within the ADNI dataset. Comparable diagnostic performance was observed on the external testing cohorts. In all scenarios, the proposed model significantly outperformed cortical SUVR-based classification (DeLong test, p < 0.001). The derived GCN_score exhibited stronger differentiation between disease stages, with Cohen's effect sizes of 1.744 (MCI vs. NC) and 1.32 (MCI vs. AD), compared to 0.309 and 0.641 for cortical SUVR, respectively. ***Conclusion:*** This graph-based learning framework combining PET and MRI features demonstrates superior performance for early detection and staging of Alzheimer's disease. The interpretable GCN_score provides an effective biomarker for distinguishing clinical stages, outperforming conventional SUVR analysis. These findings support the use of graph-based multimodal analysis as a promising tool for facilitating timely intervention in AD progression.

Multimodal topographic impairment in Parkinson's disease

M. Wang[1], *W. Han*[1], *Y. Jiao*[1], *Z. Lv*[1], *Y. Su*[1], *Y. Hu*[2], *Y. Yang*[3], *C. Zhao*[1], *P. Fu*[1];
[1]*Department of Nuclear Medicine, 1st Hospital of Harbin Medical University, Harbin, CHINA,* [2]*Central Research Institute, United Imaging Healthcare, Shanghai, CHINA,* [3]*Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.*

Aim/Introduction: Parkinson's disease (PD) is a common neurodegenerative disorder characterized by progressive cognitive decline. Although previous studies have reported abnormalities in both metabolic and structural connectivity networks in PD patients, changes in brain network topological properties across different disease stages remain insufficiently understood. This study aims to investigate the alterations in topological features of metabolic and structural brain networks at

different stages of PD using multimodal ^{18}F-FDG PET/MR imaging, in order to provide imaging-based evidence for the underlying mechanisms of network disruption in PD. ***Materials and Methods:*** A total of 68 subjects were included in this study, including 24 patients with late PD, 19 patients with early PD and 25 age- and sex-matched healthy individuals. Basic clinical information and clinical cognitive scale assessments were collected, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA), Hoehn and Yahr Scale (H-Y Stage), Unified Parkinson's Disease Rating Scale Part III (UPDRS-III) and Non-Motor Symptom Assessment Scale for Parkinson's Disease (NMSS). All subjects underwent an integrated 18F-fluorodeoxyglucose (^{18}F-FDG) PET/MR scan, acquiring high-resolution T1-weighted structural images, diffusion-tensor images and ^{18}F-FDG images. Anatomical Automatic Labeling (AAL) atlas was utilized for further brain parcellation. Normalized PET standardized uptake value ratio (SUVR) images were obtained and extracted using FSL. Brain region without significant SUVr difference between PD and HC subjects was set to be reference region. Tractography with brain parcellation was performed with MRtrix3. Group covariance matrix was generated by Pearson's correlation/tractography to get both metabolic/structural network. Topographic properties including clustering coefficient, characteristic path length and global efficiency were calculated. ***Results:*** All PD patients showed significant cognitive impairment, showing reduced MMSE/MoCA and higher UPDRS-III/NMSS compared with HC group (all $p < 0.001$). In metabolic network, higher characteristic path length and lower global efficiency was found in PD patients, comparing HC groups (both $p < 0.05$). Furthermore, topographic impairment was even worse in lPD patients compared with ePD and HC group (all $p < 0.05$). No significant difference of topographic properties in structural network was found among three groups. ***Conclusion:*** We observed cognitive impairment in PD patients when comparing with HC group. Significant impairment of topographic properties was found in PD patients. Further result showed that the impairment may become worse along with the course of PD. These results may provide imaging evidence for investigating the pathology of PD.

EP-0651

Head-to-head comparison of the associations between imaging and plasma A-T-N biomarkers with synaptic density in Alzheimer's disease

J. Wang;
Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: To compare the associations between imaging and plasma A-T-N biomarkers with synaptic density assessed by ^{18}F-SynVesT-1 PET/MRI in Alzheimer's disease (AD). ***Materials and Methods:*** This study enrolled 193 participants: 62 with AD, 56 with mild cognitive impairment (MCI), and 75 normal controls (NC). All underwent ^{18}F-SynVesT-1 PET/MRI scans to assess synaptic density and T1-weighted imaging for hippocampal volume. ^{18}F-Florbetapir PET/CT and ^{18}F-MK6240 PET/CT scans were used to evaluate amyloid-β and tau pathology, respectively. Cognitive function was assessed using neuropsychological tests. Plasma Aβ42, Aβ40, p-Tau181, and neurofilament light chain (NfL) levels were measured. Correlations between synaptic density and "A-T-N" biomarkers from imaging and plasma were analyzed at the volume of interest (VOI)and voxel-wise levels, with comparisons made between the strengths of these correlations. ***Results:*** For "A", synaptic density in the medial temporal lobe was negatively correlated with global Aβ deposition ($r = -0.272$, $p < 0.001$) and positively correlated with plasma Aβ42/40 levels ($r = 0.307$, $p < 0.001$). In the AD group, only global Aβ deposition showed a negative correlation with medial temporal synaptic density ($r = -0.284$, $p = 0.028$). For "T", tau burden was negatively associated with synaptic density in the medial temporal lobe and widespread neocortex across the whole population, as well as within the AD and MCI groups. Plasma p-Tau181 levels were also negatively correlated with synaptic density in the medial temporal lobe and widespread neocortex in both the whole population and the NC group. For "N", hippocampal volume was positively correlated with synaptic density in the medial temporal lobe and widespread neocortex in the whole population and NC group, and showed positive correlations with synaptic density in both the lateral and medial temporal lobes in the AD and MCI groups. Plasma NfL levels were negatively correlated with synaptic density in the lateral temporal lobe across the whole population, and with medial temporal synaptic density as well. Notably, the correlation between synaptic density and hippocampal volume was stronger than that between synaptic density and plasma NfL levels. ***Conclusion:*** Synaptic density showed varying degrees of correlation with imaging and plasma A-T-N biomarkers, with stronger associations observed for imaging biomarkers. Among the A-T-N components, T-related biomarkers exhibited the strongest correlation with synaptic density. Given their accessibility, plasma biomarkers may serve as convenient surrogate indicators of synaptic density changes throughout the course of Alzheimer's disease in the future.

EP-0652

DTI-ALPS Index-assessed Glymphatic Dysfunction Mediates Alzheimer's Cognitive Decline via Amyloid-β-dependent Pathways: Multimodal PET/MRI Study

Y. Zhang[1], *G. Huang*[1], *J. Hao*[2], *L. Qi*[2], *J. Geng*[3], *X. Li*[4], *M. Xin*[1], *P. Yuan*[1], *Y. Wang*[1], *Q. Xu*[3], *G. Wang*[3], *G. Huang*[1], *J. Liu*[1], *C. Zhang*[1];
[1]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*United Imaging Healthcare, Shanghai, CHINA,* [3]*Department of Neurology, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [4]*Shanghai Mental Health Center, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: To determine whether DTI-ALPS index mediates AD-related cognitive decline through Aβ/tau-dependent pathways using concurrent tri-biomarker PET/MRI. ***Materials and Methods:*** This retrospective study (2020-2024) enrolled 140 participants (median age 69.00 [61.00, 74.00] years; 84 women): 99 AD (37 early-onset [EOAD], 62 late-onset [LOAD]), 35 mild cognitive impairment (MCI), and 6 subjective cognitive decline (SCD). All underwent simultaneous ^{18}F-Florbetapir (Aβ), ^{18}F-PI2620 (tau), and ^{18}F-FDG (neurodegeneration) PET/MRI with DTI-ALPS quantification. Causal mediation analyses assessed biomarker relationships ($P < 0.05$). ***Results:*** The ALPS index decreased progressively across clinical stages (SCD: 1.51 ± 0.08 vs MCI: 1.37 ± 0.13 vs AD: 1.32 ± 0.14; $P<0.001$), correlating with higher Aβ-PET ($r=-0.31$, $P=0.001$), tau-PET ($\rho=-0.18$, $P=0.035$), and FDG-PET Z-Score ($\rho= -0.22$, $P=0.008$) and positively with MoCA ($r = 0.28$, $P = 0.002$) and MMSE ($\rho = 0.27$, $P = 0.001$). Aβ-PET fully mediated ALPS effects on FDG PET ($\beta = -0.14$, $P = 0.002$) and cognition (MoCA: $\beta = 0.14$, $P < 0.001$; MMSE: $\beta = 0.12$, $P = 0.002$) with non-significant direct pathways ($P > 0.10$); independent of tau ($P > 0.05$). In Aβ-positive subgroups, ALPS correlated with Aβ-PET ($\beta = 0.05$, $P = 0.032$), and strengthened significantly with cognition after adjusting for age and education (MMSE: $\rho = 0.28$, $P = 0.009$). EOAD showed inverse ALPS-MMSE correlations ($r = 0.39$, $P = 0.016$ vs LOAD $\rho = -0.06$, $P = 0.620$). ***Conclusion:*** DTI-ALPS quantifies glymphatic dysfunction that drives AD progression predominantly through Aβ-dependent pathways, with early-onset AD exhibiting distinct neuroimaging-cognition relationships compared to late-onset disease.

EP-0653

Utility of the Centiloid Scale in [18F]Flutemetamol PET/MRI: Correlation with Visual Assessment, Brain Morphology and Clinical Variables

L. Blanco-Verdejo[1], *L. Rodríguez-Bel*[2], *M. Pudis*[2], *M. Suárez-Piñera*[2], *A. Jareno-Badenas*[3], *F. Camba-Capitan*[4], *M. Cos-Domingo*[3], *G. Reynés-Llompart*[4], *J. Díaz-Moreno*[2], *B. Hervás-Sanz*[2], *J. Gascón-Bayarri*[5], *M. Cortés-Romera*[2];
[1]*Nuclear Medicine Department. Hospital Clínico Universitario de Valencia, Valencia, SPAIN,* [2]*Nuclear Medicine Department. Hospital Universitario de Bellvitge, Barcelona, SPAIN,* [3]*Neuroradiologist Department. Hospital Universitario de Bellvitge, Barcelona, SPAIN,* [4]*Physics Department. Hospital Universitario de Bellvitge, Barcelona, SPAIN,* [5]*Neurology Department. Hospital Universitario de Bellvitge, Barcelona, SPAIN.*

Aim/Introduction: This study aimed to assess the value of the Centiloid scale in positron emission tomography/magnetic resonance imaging (PET/MRI) brain studies with [18F]flutemetamol, by analyzing its agreement with visual reads, correlation with brain atrophy and Mini-Mental State Examination (MMSE), and its utility in uncertain cases. ***Materials and Methods:*** A retrospective study was conducted on patients with cognitive impairment who underwent brain PET/MRI with [18F]flutemetamol. PET images were assessed visually (positive, negative, or uncertain) and quantitatively (SUVr referenced to the pons and Centiloid scale). Brain atrophy was evaluated on MRI using visual rating scales, and clinical data (MMSE scores) were collected. Statistical analysis included Spearman correlation tests, the Wilcoxon-Mann-Whitney test, and ROC curve analysis to assess the diagnostic performance of the Centiloid scale in relation to visual interpretation and clinical variables. ***Results:*** The cohort included 42 patients with cognitive impairment, with a median age of 73 years (49-82). A strong correlation was observed between Centiloid and SUVr values ($\rho = 0.94$, $p < 0.0001$; Spearman coefficient), confirming consistency between the two measures. ROC curve analysis yielded an AUC of 0.98 with respect to visual reads, identifying a threshold of 30.6CL as the optimal cutoff, achieving 96% sensitivity and 92% specificity. Visually uncertain cases (n=5) showed Centiloid values ranging from 13 to 25CL, within the "gray zone" described in the literature (25-35CL), where Centiloid quantification may enhance diagnostic objectivity. A significant positive correlation was found between Centiloid values and global cortical atrophy (GCA) ($\rho = 0.35$, $p = 0.033$). No significant correlations were observed with medial temporal lobe atrophy (MTA) ($\rho = 0.21$, $p = 0.217$) or posterior cortical atrophy (PCA, Koedam) ($\rho = 0.045$, $p = 0.790$). There was a non-significant negative correlation between Centiloid values and MMSE scores. However, when patients were categorized by MMSE (<24 vs. ≥24), those with MMSE<24 had significantly higher Centiloid values (mean = 66.5 vs. 25.6, $p = 0.026$; Wilcoxon-Mann-Whitney test). ***Conclusion:*** The Centiloid scale proves useful as a quantitative method, showing good agreement with visual assessment. In visually uncertain cases, it enables a more objective classification of amyloid burden, which may impact patient management and follow-up. Regarding morphologic correlation, only global cortical atrophy was significantly associated with Centiloid values. Additionally, higher amyloid burden was consistently associated with worse cognitive performance, supporting the potential clinical utility of the Centiloid scale. Nevertheless, prospective studies with larger sample are needed to confirm these findings.

EP-0654

Multimodal topographic properties of white matter functional segregation in Alzheimer's disease: a simultaneous PET/MR study

Y. Jiao[1], *M. Wang*[1], *Y. Hu*[2], *Y. Yang*[3], *P. Fu*[1];
[1]*Department of Nuclear Medicine, 1st Hospital of Harbin Medical University, Harbin, CHINA,* [2]*Central Research Institute, United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA,* [3]*Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.*

Aim/Introduction: White Matter (WM) functional networks offer insight into network processes underlying progression AD continuum. Amyloid (Aβ) retention in WM regions, as measured by Aβ-PET, reflects WM integrity and relates to cognition. This study utilized simultaneous PET/MR imaging to investigate multimodal topographic alterations in WM functional networks and Aβ-burden networks, with the aim of providing objective neuroimaging evidence for white matter-related pathology in Alzheimer's disease. ***Materials and Methods:*** A total of 85 subjects were included in this study, including 42 patients with AD, 24 patients with PAD, and 19 age- and sex-matched healthy individuals. Cognitive assessments were collected along with clinical information, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). Every enrolled subject underwent an integrated ^{18}F-Florbetapir (^{18}F-AV45) PET/MR scan. High-resolution T1-weighted structural images, blood oxygen level dependent fMRI (BOLD-fMRI) and ^{18}F-AV45 images were acquired for all subjects. K-means clustering was utilized to obtain white matter functional networks (BWM) from BOLD-fMRI. Normalized Aβ standardized uptake value ratio (SUVR) images, with whole cerebellum as the reference region, was calculated within each BWM. Group covariance matrix was generated by Pearson's correlation to get both functional and metabolic network. Topographic properties including clustering coefficient, characteristic path length and global efficiency were calculated. ***Results:*** AD patients showed reduced mean MMSE and MoCA scores compared to HC and PAD subjects ($p < 0.001$). In functional network, higher characteristic path length and lower global efficiency was found in AD patients, comparing with pAD and HC groups (both $p < 0.05$). In metabolic network, similar results were observed as higher characteristic path length and lower global efficiency in AD group (all $p < 0.01$). Furthermore, clustering coefficient was also found lower in AD patients (both $p < 0.01$). ***Conclusion:*** We observed cognitive impairment in AD patients as compared with participants of HC or pAD group. Topographic properties of AD patients also showed mega difference in both functional and Aβ-burden networks. These results may show importance of multimodal topographic properties for the early diagnosis and personalized management of AD.

EP-0655

Evaluation of Amyloid PET Centiloid Scale by APOE4 Zygosity: Comparison among Non-Carriers, Heterozygotes, and Homozygotes

B. Choi[1], *H.-C. Song*[2];
[1]*Department of Nuclear Medicine, Daegu Catholic University Hospital and Medical School, Daegu, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Chonnam National University Hospital and Medical School, Gwangju, KOREA, REPUBLIC OF.*

Aim/Introduction: It is well known that APOE4 is the strongest genetic risk factor for sporadic Alzheimer's disease, affecting both the degree and regional pattern of amyloid deposition in the brain as measured by amyloid PET. Although the Centiloid scale (CenS) is commonly used, there is a paucity of studies evaluating the relationship between APOE4 zygosity and amyloid burden quantified using the CenS. The purpose of this study is to investigate the impact of APOE4 zygosity on CenS, thereby contributing to the understanding of its genetic and clinical implications. ***Materials and Methods:*** We included a total of 203 subjects who underwent both APOE genotyping and ^{18}F-flutemetamol brain PET/CT. Based on APOE4 allele status, participants were classified as non-carriers, heterozygotes (one APOE4 allele), or homozygotes (two APOE4 alleles). Differences in CenS and SUVR were then compared according to APOE4 zygosity. ***Results:*** Of the 203 participants, 78 were male, and the mean age was 69.8 ± 8.7 years. Based on APOE4 allele status, 133 were non-carriers, 62 were heterozygotes, and 8 were homozygotes. When a Centiloid scale (CenS) value

≥30 was used as the positivity threshold, the APOE4 carrier group (n = 70) showed a significantly higher number of positive cases compared to the non-carrier group ($p < 0.001$). The mean CenS value was also significantly higher in the carrier group (57.39 ± 37.20) than in the non-carrier group (21.10 ± 37.44; $p < 0.001$). In a subgroup analysis of CenS-positive individuals (n = 91), there was no significant difference in CenS between carriers (n = 54, 73.99 ± 23.69) and non-carriers (n = 37, 75.10 ± 27.92). Furthermore, among the carriers, there was no significant difference in CenS between heterozygotes (n = 47, 76.08 ± 24.47) and homozygotes (n = 7, 59.90 ± 10.15). ***Conclusion:*** The presence of APOE4 alleles was significantly associated with CenS positivity. However, among subjects with positive CenS, APOE4 zygosity did not have a significant effect on the CenS. Further studies including a larger number of APOE4 homozygotes are warranted.

EP-0656

Dynamic ^{11}C-PIB PET evaluation of Cerebrospinal Fluid Flow in a population without cognitive impairment. Correlation with amyloid pathology in cerebrospinal fluid

J. Jiménez-Bonilla[1], *S. López-García*[2], *M. De Arcocha-Torres*[1], *F. Gómez-De la Fuente*[1], *V. Mendi-Barcina*[1], *C. Lage*[2], *F. Martínez-Dubarbie*[2], *I. Martínez-Rodriguez*[1], *N. Martínez-Amador*[1], *A. Sánchez-Salmón*[1], *A. García-Ruiz*[1], *N. Carvalho-Duarte*[1], *M. Botanch-Domingo*[1], *L. Cabrera-Portillo*[1], *A. Clavilo-Umbarila*[1], *P. Andrade-Mejía*[1], *M. Fernández-Matarrubia*[2], *E. Rodríguez-Rodríguez*[2], *R. Quirce*[1];
[1]*Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Research Group-IDIVAL. University of Cantabria, Santander, SPAIN,* [2]*Neurology Service. Marqués de Valdecilla University Hospital, Santander, SPAIN.*

Aim/Introduction: Cerebrospinal fluid (CSF) clearance is crucial for brain homeostasis. ^{11}C-PIB PET detects clearance deficits in Alzheimer's disease. This study evaluates ventricular CSF clearance in cognitively unimpaired subjects with and without amyloid pathology, using previously described methods to explore early changes before clinical symptoms. ***Materials and Methods:*** Thirteen cognitively healthy volunteers participated in this study to assess cerebrospinal fluid (CSF) clearance using dynamic ^{11}C-PIB-PET imaging. Each participant underwent PET scans from 45 to 85 minutes post-injection of 555 MBq of ^{11}C-PIB. Neuropsychological testing and CSF analysis were performed to classify subjects based on the amyloid beta 1-42/1-40 ratio, using a threshold of 0.07 to define amyloid pathology. Standardized uptake value ratios (SUVr) were calculated at 45, 60, 75, and 85 minutes, using the cerebellar cortex as a reference. Regions of interest (ROIs) were manually placed on fused PET/CT images to include lateral ventricles and cortical gray matter (frontal, parietal, temporal, and occipital lobes). A global cortical amyloid index was obtained for each participant. ***Results:*** Of the 13 participants, six showed CSF amyloid pathology and seven did not. Visual analysis of PIB PET was positive for cortical amyloid deposition in five of the six CSF amyloid-positive cases and negative in all CSF amyloid-negative subjects. Global cortical amyloid load was significantly higher in the CSF amyloid pathology group across all time points ($p < 0.001$). While SUVr measurements in the lateral ventricles did not differ significantly between groups based on CSF amyloid status, there was a noticeable trend toward reduced CSF clearance in the pathology group over time. Moreover, when patients visually PIB-PET positive and negative were compared, statistically significant differences were found along time: SUVr at 45' (0,634 + 0,126 vs 0,722 + 0,181) ($p= 0,364$); SUVr at 60' (0,76 + 0,144 vs 0,916 + 0,261) ($p< 0,001$); SUVr at 75' (0,84 + 0,148 vs 0,993 + 0,23) ($p< 0,001$) and SUVr 85' (0,856 + 0,22 vs 1,07 + 0,261) ($p< 0,001$), indicating minor ventricular CSF clearance in the PIB-PET positive group. ***Conclusion:*** Dynamic ^{11}C-PIB PET reveals reduced ventricular CSF clearance in cognitively unimpaired individuals with brain amyloid pathology, suggesting early CSF dysfunction. These findings highlight its potential in Alzheimer's research, though larger studies are needed to clarify its role in disease pathogenesis.

Tau deposition is associated with white matter changes and mediates the effects of Aβ on white matter injury in Alzheimer's disease

F. Jiao*, Z. Wang, F. Tian, Z. Zhang, W. Li, K. Liao, H. Pang;*
Department of Nuclear Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: Alzheimer's disease (AD) is pathologically characterized by the deposition of amyloid-β (Aβ) plaques, the formation of tau neurofibrillary tangles, and abnormalities in white matter (WM). This study aimed to evaluate the relationships between WM microstructure and AD molecular pathologies. ***Materials and Methods:*** Forty-six patients with AD underwent ^{18}F-MK6240 and ^{18}F-AV45 positron emission tomography (PET) scanning, as well as T1 weighted imaging and diffusion tensor imaging (DTI) on hybrid PET/MR. Eighteen normal controls (NC) who underwent DTI were included. The standardized uptake value ratio (SUVR) was employed to measure tau burden and Aβ plaques in grey matter (GM) and WM. In this study, we assessed mean diffusivity alterations in the white matter in AD compared to NC. We examined the associations between metrics derived from DTI-fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AxD), radial diffusivity (RD), and PET SUVR in GM and WM, as well as the relationships between DTI/PET metrics and clinical scores. In addition, mediation analysis was conducted to explore the interrelationships among tau, Aβ, and white matter injury. ***Results:*** Compared to the NC group, AD patients exhibited lower FA and AxD, and higher MD and RD values. Both the DTI metrics and tau deposition were significantly correlated with clinical scores (all $P < 0.05$). Additionally, FA and MD were associated with tau deposition, and elevated Aβ PET SUVR correlated with higher MD values, while no significant associations were found between Aβ PET SUVR and clinical scores. Mediation analysis revealed that Aβ exerted indirect effects on white matter injury through tau. ***Conclusion:*** AD exhibited widespread white matter abnormalities. Tau deposition is associated with white matter changes and plays a role in partially mediating the effects of amyloid deposition on white matter injury.

Novel insights into cognitive network alterations in temporal lobe epilepsy: A [^{18}F]SynVesT-1 PET study

L. Xiao[1], *L. Feng*[1], *Y. Tang*[1], *S. Hu*[1], *K. Shi*[2];
[1]*Xiangya Hospital Central South University, Changsha, CHINA,* [2]*University Hospital Bern, Bern, SWITZERLAND.*

Aim/Introduction: Cognitive deficits in temporal lobe epilepsy (TLE) frequently impair quality of life more severely than seizures themselves. Despite their clinical significance, treatment options are limited due to poorly understood pathophysiological mechanisms. Synapse loss has emerged as a key neuropathological feature underlying cognitive dysfunction, but its role in large-

scale network reorganization remains unexplored. This study investigates epileptic cognitive network alterations from a synaptic perspective to identify novel biomarkers for cognitive deficits in TLE. ***Materials and Methods:*** We combined [^{18}F] SynVesT-1 PET for in vivo synaptic density quantification with Kullback-Leibler Divergence Similarity Estimation (KLSE) for individual-level network characterization in TLE patients. Neuropsychological assessments evaluated intelligence and memory domains. Spearman correlation analysis was employed to examine relationships between synaptic connectivity strength and cognitive performance. ***Results:*** Distinct patterns of synaptic connectome reorganization were identified in TLE patients. Significant negative correlations were observed between reduced synaptic connectivity strength and impaired neuropsychological performance in both intelligence ($\rho = -0.62$, $p < 0.01$) and memory domains ($\rho = -0.58$, $p < 0.01$). The most pronounced synaptic loss occurred in hippocampal-temporal and frontoparietal networks. ***Conclusion:*** These findings suggest that synaptic connectivity attenuation may serve as a novel biomarker for cognitive deficits in temporal lobe epilepsy, providing an innovative perspective for targeted clinical interventions.

EP-0659

Spatiotemporal Cerebral Glucose Hypometabolism Progression Pattern in Alzheimer's Disease

D. Seo[1], *M. So*[1], *S. Seo*[1], *D. Kim*[2], *S. Lee*[3], *M. Yun*[3];
[1]*Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Artificial Intelligence, Yonsei University, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Nuclear Medicine, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Despite the implementation of promising pathology-targeted therapies for Alzheimer's disease (AD) in clinical practice, disease severity evaluation still largely relies on subjective cognitive assessments. To enable objective staging based on metabolic imaging, which strongly correlates with cognitive function, we investigated the spatial and temporal patterns of hypometabolism progression in AD. ***Materials and Methods:*** We analyzed 96 cognitively normal controls and 164 amyloid-positive patients with cognitive impairment who underwent ^{18}F-fluorodeoxyglucose (FDG)-PET imaging between January 2017 and December 2022. Standardized uptake value ratios (SUVRs) were extracted from FreeSurfer-segmented regions. Regions of interest (ROIs) were selected based on effect sizes (Cohen's d) calculated from SUVR comparisons between groups. Hypometabolic progression patterns were modeled using a kernel density estimation-fitted event-based model (EBM). Metabolic staging was defined according to progression patterns within AD-specific lobes, and clinical correlations with SNSB domain Z-scores were assessed with linear regression. ***Results:*** Normal controls had a mean age of 73.2 ± 8.0 years, with 40.7% female, while patients had a mean age of 70.6 ± 8.5 years, with 28.7% female. After comparing SUVR values between groups, 34 regions across the temporal, parietal, and cingulate lobes were selected. Hypometabolism first emerged in limbic regions, including the isthmus, posterior cingulate, entorhinal cortex, and hippocampus. It subsequently involved the precuneus and rostral anterior cingulate before spreading across the neocortex. In later stages, the caudal anterior cingulate, transverse temporal, supramarginal, and postcentral gyri were affected. Based on EBM modeling, four metabolic stages were defined according to the presence of hypometabolism across these regions (Stage 0, n=113, 43.5%; Stage 1, n=47, 18.1%; Stage 2, n=52, 20.0%; Stage 3, n=48, 18.5%). Metabolic stage was significantly associated with all cognitive domains except attention (language, $\beta = -0.34$, $P < 0.001$; visuospatial, $\beta = -0.61$, $P < 0.001$; verbal memory, $\beta = -0.27$, $P < 0.001$; visual memory, $\beta = -0.34$, $P < 0.001$; frontal/executive, $\beta = -0.27$, $P = 0.003$). ***Conclusion:*** This study characterized the spatiotemporal progression pattern of hypometabolism in AD, paralleling the spread of pathological tau, and demonstrated its correlation with cognitive impairment severity. Metabolic imaging may enable objective clinical staging, as FDG-PET scans are more accessible and cost-effective than other PET modalities.

EP-0660

Coupling patterns of brain gray matter volume and FDG metabolism inpatients with impaired cognitive function: a multimodal imaging study

F. Tian*, R. Wu, Z. Wang;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: The relationship between AV45 PET imaging findings and cerebral glucose metabolism or structural abnormalities remains inconclusive. Therefore, this study focuses on patients with clinically significant cognitive decline highly suspected of Alzheimer's disease (AD) who underwent multimodal PET imaging. Through multimodal coupled analysis, we aim to explore differences in glucose metabolism and brain atrophy between AV45 PET-positive and AV45 PET-negative cases. ***Materials and Methods:*** In this retrospective study, 54 patients with confirmed cognitive impairment underwent [18F] AV45 PET/MR, [18F] FDG PET/MR. Clinical data, such as age, sex, cognitive scales, and hematological AD markers, were collected. Subjects were stratified into Aβ-positive and Aβ-negative groups based on visual analysis of AV45 PET images. The correlation analysis of regional FDG metabolism and gray matter volume were performed among the two groups adjusted for age and sex. and the correlation of the two group were compaired and correlated with MMSE and hematological AD markers. ***Results:*** Of the 54 patients, 40 were Aβ-positive and 14 were Aβ- negative. There was no significant difference in gender (p=0.09) and age (p=0.084). MMSE scores (p=0.016) and P-tau181 (p=0.002) were significantly lower in the Aβ-positive group, and with comparable ADL scores (p=0.674) between two groups. In the Aβ-positive group, a significant positive correlation between metabolism and volume was observed in the posterior cingulate cortex (r=0.62, p< 0.001), indicating concurrent structure and function degradation. No such coupling was found in the Aβ-negative group. Additionally, the hippocampus showed stronger metabolism-volume coupling in the Aβ-positive group compared to Aβ-negative individuals (Z=2.4, p=0.03). In addition, the strength of metabolism-volume in the posterior cingulate coupling strength correlated with MMSE score (r=0.52, p=0.02) and plasma p-tau181 level (r= -0.41, p=0.032) in the Aβ-positive group. ***Conclusion:*** This study identifies distinct patterns of brain metabolism-gray matter volume coupling in Aβ-positive patients, especially in the posterior cingulate cortex and hippocampus. This coupling relationship is associated with cognitive impairment and plasma p-tau181 level, confirmed that A β -positive patients have more obvious brain structure and metabolic abnormalities. ***References:*** Chen K et al.,"Improved power for characterizing longitudinal amyloid-β PET changes and evaluating amyloid-modifying treatments with a cerebral white matter reference region",2015,J Nucl Med,56,4,560-6.Camus V et al.,"Using PET with 18F-AV-45 (florbetapir) to quantify brain amyloid load in a clinical environment",2012,Eur J Nucl Med Mol Imaging,39,4,621-31.Jung-Lung Hsu et al.,"Magnetic resonance images implicate that glymphatic alterations mediate cognitive dysfunction in Alzheimer disease",2023,Ann. EP-0661

Predictive Value of Serum Biomarkers for Brain Amyloid Pathology in Patients with Mild Cognitive Impairment

Ü. Akdemir[1], *Ö. Gülbahar*[2], *N. Canpunar*[2], *E. Balcı*[1], *E. Erkoç Ataoğlu*[3], *E. Saka*[4], *L. Ö. Atay*[1];
[1]*Gazi University Medical Faculty, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Gazi University Medical Faculty, Department of Medical Biochemistry, Ankara, TÜRKIYE,* [3]*Gazi University Medical Faculty, Department of Neurology, Ankara, TÜRKIYE,* [4]*Hacettepe University Medical Faculty, Department of Neurology, Ankara, TÜRKIYE.*

Aim/Introduction: While established cerebrospinal fluid biomarkers and PET imaging indicate Alzheimer's Disease (AD) pathology, less invasive serum biomarkers are emerging alternatives. This study aimed to evaluate the predictive power of these serum biomarkers for brain amyloid pathology, as determined by amyloid PET, in individuals with Mild Cognitive Impairment (MCI). ***Materials and Methods:*** Thirty-six MCI patients (17 Male, 19 Female; Age: 67.4 ± 6.9 years) underwent brain amyloid PET imaging with F-18 Flutemetamol. The consensus visual classification of PET scans as amyloid-positive or amyloid-negative by two nuclear medicine physicians was used as the reference standard for evaluating the predictive power of biomarkers. Centiloid scores were calculated to quantify amyloid burden. Concurrently, serum samples were collected and analyzed for concentrations (pg/mL) of Aβ 1-40, Aβ 1-42, and p-tau181 via enzyme-linked immunosorbent assay (ELISA). The ratios Aβ 1-42/Aβ 1-40 and p-tau-181/Aβ 1-42 were calculated. Spearman correlation analysis assessed the relationship between serum biomarkers and Centiloid scores. Receiver Operating Characteristic (ROC) curve analysis was performed to evaluate the ability of serum markers to discriminate amyloid PET status. For the best performing biomarker, the optimal cut-off (Youden's index), sensitivity, and specificity were calculated. A Chi-square test assessed the association between biomarker classification and PET status. ***Results:*** Of the 36 MCI patients, visual assessment classified 24 (66.7%) as amyloid PET-positive and 12 (33.3%) as amyloid PET-negative. No statistically significant correlations were observed between any of the serum biomarkers (Aβ 1-40, Aβ 1-42, p-tau-181, Aβ 1-42/Aβ 1-40 ratio, p-tau-181/Aβ 1-42 ratio) and the Centiloid scores (all p> 0.20). ROC analysis for predicting visual amyloid PET status yielded the following AUCs: Aβ 1-40: 0.455 (p=0.639); Aβ 1-42: 0.359 (p=0.166); p-tau-181: 0.589 (p=0.389); Aβ 1-42/Aβ 1-40 ratio: 0.316 (p=0.045). Only the serum p-tau-181/Aβ 1-42 ratio showed statistically significant predictive power for visual PET status, with an AUC of 0.694 (95% CI: 0.511-0.878, p=0.038). The optimal cut-off for this ratio was 2.9175, yielding a sensitivity of 75.0% and a specificity of 66.7%. Classification based on this cutoff was significantly associated with visual amyloid PET status (Fisher's Exact Test, p=0.029). ***Conclusion:*** In this MCI cohort, the serum p-tau-181/Aβ 1-42 ratio showed modest but statistically significant predictive value for the brain amyloid pathology status (positive/negative) derived from amyloid PET scan. While its accuracy suggests limitations for standalone diagnostic use, this serum ratio may hold potential as an accessible initial screening tool. Further validation in larger cohorts is needed.

EP-0662

^{18}F-FDG PET Imaging Reveals GPR162-Mediated Hippocampal Glucose Metabolic Dysregulation in Aging and the Therapeutic Potential of BMMSCs

P. Li, *T. Wang, Z. Yang, Z. Zhu, J. Quan, Y. Zhang, Y. Jiang, R. He, G. Zhu;*
Department of Nuclear Medicine, The First Affiliated Hospital of Kunming Medical University, Kunming, CHINA.

Aim/Introduction: Cognitive impairment associated with aging is a growing global health concern, yet effective therapeutic targets remain elusive[1]. Our team's clinical observations have revealed that glucose metabolism in the hippocampal region of aging individuals is elevated compared to younger individuals, which contrasts with the metabolic trends observed in other brain regions. This suggests that increased hippocampal metabolism may contribute to the onset and progression of cognitive dysfunction. This study aimed to identify key molecular targets involved in age-related cognitive decline and evaluate the therapeutic potential of bone marrow mesenchymal stem cells (BMMSCs)[2] by modulating GPR162, a G protein-coupled receptor implicated in hippocampal glucose metabolism. ***Materials and Methods:*** Hippocampal tissues from young and aged macaques underwent proteomic analysis, revealing 123 differentially expressed proteins. After evaluation through the PubMed database, genes lacking research significance were excluded. GPR162 was identified as one of the core genes. Cell and rat models were established by silencing GPR162 using siRNA and AAV-mediated shRNA. BMMSCs were administered via hippocampal (HIP), intracerebroventricular (ICV), or tail vein (TV) injections. Behavioral tests (Morris water maze, open field), ^{18}F-FDG PET imaging, and molecular assays (RT-PCR, Western blot, immunofluorescence) were performed to assess cognitive function, glucose metabolism, and protein expression (GAP43, SYN, P53, P16). ***Results:*** Aged macaques exhibited elevated hippocampal glucose metabolism and reduced GPR162 expression. Silencing GPR162 in rats impaired spatial memory and increased anxiety-like behaviors, accompanied by decreased synaptic proteins (GAP43, SYN) and elevated senescence markers (P53, P16). BMMSCs treatment via HIP and ICV routes significantly restored GPR162 expression, improved cognitive performance, and normalized glucose metabolism, while TV injection showed no effect. ***Conclusion:*** GPR162 downregulation contributes to age-related cognitive impairment and metabolic dysregulation. BMMSCs therapy, particularly via ICV injection, effectively upregulates GPR162, mitigates cognitive deficits, and restores hippocampal function. These findings highlight BMMSCs as a promising intervention for aging-related cognitive decline, with implications for future clinical applications. Identifying the bioactive compounds secreted by BMMSCs will be a key focus of our future research. ***References:*** 1. Sun Z, Ping P, Li Y, Feng L, Liu F, Zhao Y, et al. Neurometabolic correlates of cognitive impairments in patients with meningioma

S. Goffinet, *X. De Tiège, J. Bertels, F. Lefranc, O. De Witte, N. Sadeghi-Meibodi, H. Slama, P. Fery, A. Rovai, V. Wens, N. Trotta, G. Leurquin-Sterk;*
Université Libre de Bruxelles, Brussels, BELGIUM.

Aim/Introduction: Meningiomas are associated with cognitive impairments, but the underlying pathophysiological mechanisms remain unclear. This study aims at elucidating the neurometabolic correlates of cognitive impairments in patients with meningioma. ***Materials and Methods:*** Forty-two patients (35 women, 7 men) with a meningioma and 42 sex- and age- matched (Mann-Whitney U-test, U=736; p=0.193) healthy controls underwent a neuropsychological assessment and a hybrid positron emission tomography-magnetic resonance acquisition (PET/MR) using [^{18}F]-fluorodeoxyglucose (FDG). Neuropsychological assessment evaluated attentional and executive functions, memory, language, visuospatial abilities, and reasoning. Mann-Whitney U-tests were employed to compare cognitive performance between groups (results were considered as significant at $p \leq 0.003$ after application of Bonferroni corrections). Group-level subtractive FDG-PET comparison analyses were performed between patients and controls using Statistical Parametric Mapping

(SPM12). Pathophysiological interaction (PPI) analyses identified meningioma-related changes in the contribution of the hypo/hypermetabolic areas to the level of metabolic activity in other brain areas. Correlation analyses were conducted in patients to link neuropsychological scores and regional glucose metabolism. All FDG-PET results were considered significant at p<0.05 FEW-rate. ***Results:*** Compared to controls, patients exhibited significant decrease in processing speed and in performance in tasks assessing verbal short-term memory, verbal episodic memory retrieval, inhibition, and flexibility. Compared to controls, regional hypometabolism was found in patients in bilateral mesial and right lateral prefrontal cortex. Regional hypermetabolism was also found in bilateral cerebellum, with a right predominance, and mesial temporal structures. PPI analyses revealed significant differences in crossed cerebello-prefrontal interactions in patients compared with controls. In patients, lower cognitive performance in verbal episodic memory, flexibility, inhibition and processing speed correlated with reduced regional glucose metabolism in a right prefrontal (all tasks), fronto-parietal (processing speed) network, and in a cortico-basal ganglia loop (flexibility). Higher performance in inhibition and flexibility correlated with enhanced occipito-parietal metabolism. ***Conclusion:*** This study demonstrated significant changes in regional glucose metabolism in patients with meningioma, associated with altered crossed cerebello-prefrontal interactions. Our findings also reveal distinct neurometabolic correlates of specific cognitive impairments and therefore contribute to a better understanding of pathophysiological mechanisms underlying cognitive impairments in patients with meningioma.

Periventricular White Matter Hyperintensities and Brain Metabolism Contribute to Cognitive Dysfunction in Amyloid-Negative Patients

M. So[1], *S. Seo*[1], *S. Lee*[2], *H. Lim*[2], *Y. Yoon*[1], *D. Kim*[3], *H. Han*[3], *D. Seo*[1], *K. Choo*[4], *Y. Jun*[3], *S. Kang*[2], *D. Kim*[5], *Y. Lee*[6], *M. Yun*[2];
[1]*Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Artificial Intelligence, Yonsei University, Seoul, KOREA, REPUBLIC OF,* [4]*Department of Computer Science, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [5]*Department of Nuclear Medicine, Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Anyang, KOREA, REPUBLIC OF,* [6]*Department of Neurology, Ilsan Paik Hospital, Inje University College of Medicine, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: The association of periventricular white matter hyperintensities (PWMH) and brain glucose metabolism with cognitive decline in patients without amyloid-β (Aβ) has not been clearly defined. In this study, we investigated the relationship between PWMH and glucose hypometabolism and their effect on domain-specific cognitive performance. ***Materials and Methods:*** We enrolled 151 cognitively impaired Aβ-negative individuals (mean age: 70.5 ± 8.0 years; 56 females) and 83 cognitively normal controls (mean age: 71.1 ± 6.2 years; 34 females), who underwent ^{18}F-fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET), ^{18}F-florbetaben (^{18}F-FBB) PET, magnetic resonance imaging (MRI), and comprehensive neuropsychological evaluation using the standardized 2nd edition of the Seoul Neuropsychological Screening Battery (SNSB-II). General linear models evaluated associations between PWMH, regional glucose metabolism, and domain-specific cognition. Path analyses were performed to test both directions of mediation between PWMH and glucose metabolism across cognitive domains, with models adjusted for age, sex, education, and vascular risk compound scores (VRCS). ***Results:*** The cognitively impaired group exhibited significantly higher PWMH volumes than normal controls ($p < 0.001$). Increased PWMH burden correlated with reduced glucose metabolism in the frontal, parietal, medial and lateral temporal, insular, and limbic regions, structures including the anterior cingulate cortex (ACC), posterior cingulate cortex (PCC), hippocampus and amygdala. Domain-specific mediation analyses revealed that PWMH effects on executive scores were significantly mediated by regional glucose metabolism in the frontal cortex ($\beta = -0.058$, $p = 0.011$), parietal cortex ($\beta = -0.055$, $p = 0.013$), ACC ($\beta = -0.077$, $p = 0.008$), and PCC ($\beta = -0.118$, $p = 0.001$). Language scores were mediated by hippocampal ($\beta = -0.063$, $p = 0.008$) and ACC metabolism ($\beta = -0.060$, $p = 0.007$). In contrast to other domains, where PWMH exerted effects via regional glucose metabolism, memory domain followed an inverse pathway: glucose metabolism in the PCC predicted increased PWMH burden, which in turn mediated its impact on verbal and visual memory scores ($\beta = 0.066$, $p = 0.028$; $\beta = 0.051$, $p = 0.049$, respectively). ***Conclusion:*** Our findings suggest that in Aβ-negative individuals, PWMH and brain glucose hypometabolism are interrelated, and that their contributions to cognitive impairment follow domain-specific pathways: PWMH influenced executive and language function through regional hypometabolism, whereas PCC hypometabolism influenced verbal and visual memory dysfunction through increased PWMH burden. These findings highlight the importance of considering both vascular and metabolic factors as interconnected contributors to cognitive dysfunction in the absence of amyloid pathology.

Aim/Introduction: Primary Progressive Aphasia (PPA) is a neurodegenerative disorder characterized primarily by progressive language impairment. It is typically classified into three main variants: semantic (svPPA), nonfluent/agrammatic (nfvPPA), and logopenic (lvPPA). Although PET imaging with Pittsburgh Compound B (PiB) is widely used to detect amyloid plaques in Alzheimer's disease, its diagnostic application in PPA remains limited. This preliminary study aims to assess whether quantitative or semi-quantitative measures of PiB uptake can serve as reliable diagnostic markers in PPA. ***Materials and Methods:*** In this preliminary study, thirteen patients diagnosed with PPA underwent a 90-minute dynamic PET/CT scan following administration of ^{11}C-PiB. Brain segmentation was performed using MIM Software (MIM Software Inc., Cleveland, OH), and kinetic analysis of PiB uptake was conducted with PMOD (PMOD Technologies LLC, Zurich, Switzerland). PiB uptake kinetic was analyzed using the Logan plot method, with the cerebellum as the reference tissue. Standardized uptake values (SUV) from PET/CT were also calculated and compared. ***Results:*** Quantitative analysis revealed elevated PiB uptake in several brain regions involved in language and cognition across all patients, including the anterior, posterior, and inferior cingulate gyri; the middle and superior frontal gyri; the precuneus; the putamen and the striatum. These clinically relevant areas showed a median binding potential (BPnd) of 0.68 (interquartile range IQR = 0.40), compared to a median BPnd of 0.16 (IQR = 0.27) in other regions. A strong correlation was observed between BPnd and SUV values across all regions (median $R^2 = 0.94$). ***Conclusion:*** These results support the potential diagnostic value of PiB PET imaging in PPA, showing both quantitative and semi-quantitative data related to amyloid pathology. Further studies should be conducted to confirm

and identify the specific brain regions affected, providing a more targeted approach to understanding the progression and treatment of aphasia.

A Deep Learning Model for Detecting Alzheimer's Disease Using Structural MRI

Y. Zhang[1], *F. Huang*[1], *J. Hao*[2], *L. Qi*[2], *J. Liu*[1], *C. Zhang*[1];
[1]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA,* [2]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: To develop a deep learning model based on structural MRI data to differentiate AD from a spectrum of non-AD conditions and identify key neuroanatomical regions contributing to the classification. ***Materials and Methods:*** We utilized a DenseNet-based CNN architecture trained on structural MRI scans from a cohort of 230 participants, including 117 AD patients and 113 non-AD cases (e.g., VD, FTD, DLB). Performance metrics, including AUC, PR-AUC, F1-score, accuracy, balanced accuracy, sensitivity, specificity, PPV, and NPV, were calculated to assess the model's diagnostic efficacy. Grad-CAM was employed to generate heatmaps for visualizing the model's decision-making process. ***Results:*** The model achieved robust performance, with an AUC of 0.79 ± 0.05 and a PR-AUC of 0.82 ± 0.04. Notably, the model exhibited excellent specificity (1.00 [0.89, 1.00]) and PPV (1.00 [0.80, 1.00]). Heatmap analysis highlighted critical regions such as the inferior parietal lobule, corpus callosum, and caudate nucleus. ***Conclusion:*** This study highlights the potential of deep learning models to accurately differentiate AD from a spectrum of non-AD conditions using structural MRI data.

EP-0667

Predictive value of ^{18}F-FDG PET/CT deep learning in radiomics for cancer-related cognitive impairment in patients with non-CNS DLBCL

J. Wang, *Q. Zhao, Y. Dong, P. Ma, R. Wang;*
General Hospital of Ningxia Medical University, Ningxia Yinchuan, CHINA.

Aim/Introduction: Cancer-related cognitive impairment (CRCI) is a common and debilitating sequela of cancer treatment, which impairing memory, attention and executive function, thereby reducing quality of life, weakening daily activities and affecting treatment adherence. Effective detection and prediction methods are still lacking. This study focuses on non-Central Nervous System Diffuse Large B-cell Lymphoma (non-CNS DLBCL) patients, using cognitive scales as standards. By integrating radiomics features extracted from PET/CT neuroimaging and clinical data into structured datasets via deep learning, we evaluate the predictive value of different models and modalities for CRCI, aiming to provide a basis for precise assessment. ***Materials and Methods:*** We retrospectively analyzed 112 non-CNS DLBCL patients who underwent brain ^{18}F-FDG PET/CT at Ningxia Medical University General Hospital from October 2020 to January 2025, recording demographics (sex, age, years of education) and the results of neurological scales (MoCA and FACT-Cog). Based on cognitive scale results, patients were classified into CRCI and normal cognition groups. Cases were randomly assigned to training and testing groups at an 8:2 ratio. The open-source MOOSE120 software was used to automatically divide brain regions and extract radiomics histological features. After integrating clinical features, we constructed structured data and selected features using correlation coefficients. Seven deep learning models were built: Gated Additive Tree Ensemble, AutoInt, Categorical Embedding, FT Transformer, TabNet, NODE, and Tab Transformer. We evaluated the diagnostic performance of these models using Receiver Operating Characteristic (ROC) curves. Decision curves were employed for further assessment of their clinical applicability and different multimodal imaging data were also compared. ***Results:*** Based on MoCA and FACT-Cog results, 73 patients were included in the CRCI and 39 in the cognitively normal groups, randomly assigned to training (n=89) and testing (n=23) groups. Seven deep learning models were applied. Among them, the Category Embedding model performed the best, with AUC values of 0.923 and 0.767 in the training and validation sets, respectively, showing high diagnostic efficacy. Decision curve analysis further confirmed its robust performance. Additionally, when comparing models with different modalities, the triple modality model (clinical data + PET + CT) showed a higher AUC value with AUC values of 0.838 and 0.923 in the training sets, respectively. ***Conclusion:*** Combination of deep learning with structured data from PET/CT image showed effectively predictive value in detection of CRCI. The Category Embedding model and triple modality model (clinical data + PET + CT) demonstrated excellent performance and exhibited substantial clinical application value.

Can [18F-FDG] PET imaging patterns determine the neuropathological substrate of Corticobasal Syndrome?

S. Alvarez, *A. Mari, M. Casallas, S. Salcedo, G. Mera, E. Ardila, J. E. Orcajo, J. J. Ardila, I. Gomez, J. Alonso;*
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: To describe the different metabolic patterns assessed by [18F-FDG] PET study in patients with clinical suspicion of Corticobasal Syndrome (CBS) and variable neuropathological substrate, considering Corticobasal Degeneration (CBD) as the most common one, followed by Alzheimer's Disease (AD) and Progressive Supranuclear Palsy (PSP). ***Materials and Methods:*** 19 patients diagnosed with CBS based on clinical criteria, who also had an [18F-FDG] PET imaging study, were included. Of these, 4 patients with a history of vascular pathology were excluded. 15 [F18-FDG] PET studies were analyzed using the AW Server 3.2 software (GE HealthCare). A visual and semiquantitative assessment was performed, focusing on the main affected regions of the brain, and classifying them into three characteristic patterns described in the literature:1. CBS-CBD, 2. CBS-AD, 3. CBS-PSP. All of them, regardless of the subgroup classification assigned, showed what was called a general CBS pattern that was analyzed separately. DatScan imaging results were also evaluated in those patients for whom this study was available. ***Results:*** The mean age of those 15 patients was 64,6%with a slight female predominance (6 males and 9 females). The brain regions commonly affected across all CBS subtypes (general CBS pattern) were the superior parietal lobe (60%), thalamus (60%), perirolandic area (67%), and insula (47%), with findings usually being contralateral to the symptomatic side.On visual assessment, 10 patients (67%) exhibited a classic pattern compatible with CBS-CBD, 2 patients (13%) showed a CBS-AD pattern, and 3 patients (20%) presented a CBS-PSP pattern.In the 10 CBS-CBD patients, predominant involvement was identified in the frontal and parietal lobes, caudate nuclei, and medial cingulate. The 2 CBS-AD patients showed involvement of the inferior parietal lobe, angular gyrus, inferior temporal lobe, and posterior cingulate, with less anterior involvement and partial preservation of primary sensorimotor areas. In the 2 CBS-PSP cases, hypometabolism was observed in the medial and dorsolateral frontal regions, temporal pole, anterior

cingulate, and supplementary motor cortex. All patients who underwent DaT-Scan imaging (60%) showed impairment of the nigrostriatal pathway. ***Conclusion:*** Different cortico-subcortical patterns observed in [18F-FDG] PET studies suggest the existence of different pathological substrates. The characterization of those patterns is essential for appropriate diagnostic and therapeutic approaches in CBS patients. These findings show that PET imaging with amyloid and tau biomarkers could be highly valuable for the pathological classification of CBS.

EP-0669

An Advanced Quantitative Analysis Approach in Dopaminergic SPECT Imaging: GÜDaTSPECT

E. Tuncay Ibis, *E. Balcı, Ü. Ö. Akdemir, L. Ö. Atay;*
Gazi University Faculty of Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Idiopathic Parkinson's disease, the most common neurodegenerative cause of Parkinsonism,and loss of dopaminergic neurons in Parkinson's disease can be detected early by DaTscan imaging, aiding differentiation from other conditions. Quantitative analysis enhances diagnostic accuracy. Our aim is a fast, free, user-friendly program with machine learning and extensive benchmarking for all centers. ***Materials and Methods:*** DATquan[1], a free and reproducible software, was modified and integrated into GÜDaTSPECT. In this way, SBR(Spesific Binding Ratio), AI(Asymmetry Index) and putamen/caudate ratios were calculated from DAT binding SPECT data in caudate, putamen and striatum.To compare the calculated values, DaTscan images from the Gazi University Faculty of Medicine, Department of Nuclear Medicine(GAZI), and the Parkinson's Progression Markers Initiative(PPMI)[2][3] were analyzed, creating age-dependent normal databases for GAZI and PPMI.The quantitative analysis is influenced by multiple factors.The GAZI and PPMI datasets were harmonized using the ComBat method to create a combined GAZI+PPMI age-dependent normal database. Support vector machine(SVM) functionality was added to the GÜDaTSPECT software to enhance result reliability.Based on the SVM binary classification output, GÜDaTSPECT provides a final report indicating "dopaminergic deficiency present/absent." GÜDaTSPECT is a fully automated, open-source software. ***Results:*** Two nuclear medicine specialists visually classified the GAZI group into 72 controls(CG) and 97 Parkinson's disease(PD) cases. Combined with 235 CG and 1042 PD DaTscan images from the PPMI database, three study groups(GAZI,PPMI,GAZI+PPMI) were formed. Age and SBR comparisons revealed significant inter- and intra-group differences, highlighting the need for harmonization, as GAZI CG SBR values were higher than PPMI CG. ComBat harmonization aligned SBR averages in the combined GAZI+PPMI group, eliminating significant differences. GÜDaTSPECT assigns new patients to appropriate groups and allows harmonized visual comparison with these databases, displaying age-dependent fitted SBR values and prediction bounds graphically. SVM models, trained with SBR, asymmetry indices, age, and sex, achieved 100% accuracy in GAZI, 97.49% in PPMI, and 98.90% in the harmonized GAZI+PPMI dataset. AI and striatal/putamen SBR were key variables in the SVM classification across all groups. ***Conclusion:*** GÜDaTSPECT is a free,fully automated software uniquely combining advanced DaTscan image processing, database comparison and SVM learning to improve diagnostic accuracy and interpretation. ***References:*** [1]DOI: 10.2967/jnmt.111.090324[2]Data used in the preparation of this article was obtained on [2023-08-24] from the PPMI database(www.ppmi-info.org/access-dataspecimens/download-data),For up-to-date information on the study, visit www.ppmi-info.org.[3]PPMI-a public-private partnership-is funded by the Michael J.Fox Foundation for Parkinson's Research and funding partners. Diagnosis of Parkinson Disease using ^{123}I-FP-CIT - how confident are we?

K. Ferreira[1,2,3], *A. P. Robinson*[1], *K. M. Bradley*[4], *D. R. McGowan*[2,3];
[1]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [2]*University of Oxford, Oxford, UNITED KINGDOM,* [3]*Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM,* [4]*Wales Research and Diagnostic PET Imaging Centre, Cardiff, Wales, UNITED KINGDOM.*

Aim/Introduction: ^{123}I-FP-CIT is used for the diagnosis of Parkinson disease. Volumes of Interest (VOIs) are defined for the right and left striatum, and a background (BG) region, and the mean counts per voxel is estimated for each region. Specific Binding Ratios (SBR) are calculated for the striatum and compared to healthy controls database. The estimation of uncertainties is not common for this clinical application; however, the benefits of estimating uncertainties have been recognised for other clinical applications[1,2]. In this work, a method to evaluate the uncertainty associated with the SBR values is developed using phantom data and then applied to estimate uncertainties for patient data. ***Materials and Methods:*** Repeated SPECT/CT data for a realistic striatum phantom filled with ^{123}I was acquired on a GE Discovery 670 without moving the phantom. The data was acquired and reconstructed using the clinical protocol. A single set of VOIs were defined on the SPECT data for the left and right striatum and a background region. The uncertainty on the VOI was estimated with each point in the VOI modelled as a rectangular distribution. For each VOI, 1000 perturbed VOIs were generated to estimate the probability density function. The SBR values were estimated using the Brass method[3] and a comprehensive uncertainty analysis is presented. ***Results:*** For phantom data the mean SBR values were 2.39±18.8% for the right striatum and 2.85±11.6% for the left striatum, the uncertainties are at the 95% confidence level. More activity was dispensed to the left striatum, hence the higher ratio. The uncertainty associated with the mean counts per voxel was 4.6% (right striatum), 4.8% (left striatum) and 3.2% (BG) when considering a single scan. The larger uncertainty associated with the striatum was expected due to the smaller VOI compared to the BG. When considering all the scans, the uncertainty associated with the mean counts per voxel was 6.8% (left striatum), 12.1% (right striatum) and 5.3% (BG). The larger statistical uncertainty for the right striatum is possibly due to the phantom filling, where the right striatum is less homogeneous. A full uncertainty budget for ^{123}I-FP-CIT will be presented ***Conclusion:*** In this work, a methodology is presented to assess the uncertainty for SBR values for the diagnosis of Parkinson disease. The methodology presented here will be applied to patient data to understand the potential impact on patient classification. ***References:*** [1]Gear et al, 2018;45(13) [2]Partarrieu et al 2022;36(2):123-132 [3]Koch et al 2005; 38:1095-1103.

EP-0671

The Mickey Mouse sign in 18F-FDOPA PET: significance and clinical usefulness in idiopathic Parkinson disease

J. Darcourt, *M. Koulibaly, V. Comte, A. Schiazza, C. Maurel, N. Sapin, O. Humbert;*
Centre Antoine Lacassagne, Nice, FRANCE.

Aim/Introduction: Visualization of midbrain "Mickey mouse" shape uptake (MM) is one of the visual landmarks of 18F-FDOPA in current static PET imaging of Parkinson Disease (PD) patients[1]. The ears correspond to the visualisation of the Substantia Nigra (SN), the nose to the human periaqueductal grey matter (PAG)[2]. PAG is located around the mesencephalic aqueduct and mainly composed of serotoninergic neurons. Dynamic studies have shown an increased 18F-FDOPA PAG uptake in PD compared to controls[3]. We investigated the feasibility of semi-quantitative analysis of 18F-FDOPA PAG uptake on routine static 18F-FDOPA

SiPM camera PET imaging to explain this uptake and its role in visual analysis. ***Materials and Methods:*** 50 PD patients (mean age 70±10; H&Y 1 and 2) and 42 patients with essential tremor (ET) (mean age 70±13) were retrospectively analysed. One hour after Carbidopa premedication, patients were injected with 3 MBq/kg of 18F-FDOPA and scanned 90 minutes later. A SiPM PET/CT camera was used. Static acquisition lasted 6 minutes; images were reconstructed without and with PSF correction for visual and quantitative analysis respectively. The scans were visually analysed by 3 independent readers for normal versus PD aspect and MM uptake scoring. For quantitative analysis, a PAG and SN isocontour was iteratively eroded until a targeted volume (1.5 and 0.5 cm^3) was reached and meanSUV over occipital ratios calculated. ***Results:*** Visual MM scoring showed a good interobserver agreement (kappa = 0.46). Using a score cut off value superior to 3 (above 60% of the striatal maximum), the sensitivity and specificity and accuracy of the MM sign for the diagnosis of PD were 95%, 100% and 97% respectively. Quantitative analysis showed higher PAG uptake in PD compared to ET patients (2.09 ± 0.13 vs 1.96 ± 0.20; p = 0.0003). No difference was found for SN uptake. However, within the PD group, SN uptake was significantly lower on the side contralateral to the predominant clinical side (2.06 ± 0.47 vs 2.13 ± 0.47; p>0.001). ***Conclusion:*** When dopaminergic innervation of the striatum is low in PD: (i) SN uptake remains unchanged (becomes asymmetric) but is more visually detectable; (ii) furthermore, PAG uptake increases due to upregulation of the aminoacid decarboxylase activity in serotoninergic neurons. These results explain the MM landmark of PD visual analysis, confirm its diagnostic usefulness and opens the way to PAG serotoninergic evaluation with 18F-FDOPA PET. ***References:*** 1-Morbelli, S., et al. EJNMMI(2020).2-Benarroch, E. E. Neurology(2012). 3-Kumakura, Y., et al. Neuroimage (2010).

EP-0672

Automated Quantitative [^{18}F]FP-CIT PET/CT Analysis Without MRI for Distinguishing Parkinsonian Disorders

K. Park[1], *J. Kim*[1], *H.-C. Song*[1], *B. Choi*[2];
[1]*Chonnam National University Medical School and Hospital, Gwangju, KOREA, REPUBLIC OF,* [2]*Daegu Catholic University Medical Center, Daegu Catholic University School of Medicine, Daegu, KOREA, REPUBLIC OF.*

Aim/Introduction: The differential diagnosis of parkinsonian syndromes remains challenging despite its importance for treatment planning and outcome prediction. While [^{18}F]FP-CIT PET/CT visualizes dopamine transporter density, standard interpretation relies on subjective assessment, leading to reader variability. Current quantitative methods require MRI co-registration, increasing complexity, costs, and patient inconvenience. This study investigated whether an MRI-independent quantitative analysis could identify distinct uptake patterns across parkinsonian disorders. ***Materials and Methods:*** We retrospectively included 634 patients with confirmed diagnoses of idiopathic Parkinson's disease (IPD; n=418), parkinsonian-type multiple system atrophy (MSA-P; n=29), cerebellar-type multiple system atrophy (MSA-C; n=14), progressive supranuclear palsy (PSP; n=35), essential tremor (ET; n=78), and drug-induced parkinsonism (DIP; n=60). Using a specialized deep learning-based automated analysis software, we performed automated measurements of tracer uptake in striatal subregions, calculated asymmetry indices, and derived uptake ratios without requiring MRI. Statistical analyses compared uptake patterns across diagnostic groups. ***Results:*** Significant differences in uptake patterns emerged: Non-neurodegenerative conditions (ET and DIP) showed normal uptake throughout the striatum (ventral posterior putamen: 4.29±0.96 and 4.37±0.97). Parkinson's disease displayed characteristic posterior putaminal reduction (ventral posterior putamen: 1.06±0.67) with relative preservation of anterior regions. MSA-P showed similar posterior putaminal decrease (ventral posterior putamen: 1.12±0.57) but with significantly more uniform anterior-posterior involvement than Parkinson's disease (anterior-posterior ratio: 1.96±0.56 vs. 2.44±0.71, p=0.03). PSP demonstrated the most severe uptake reduction, especially in the caudate, with marked asymmetry (caudate asymmetry index: 10.53±14.64). MSA-C maintained relatively preserved striatal uptake (ventral posterior putamen: 3.56±1.55). ***Conclusion:*** This MRI-independent quantification approach successfully identifies measurable differences in dopaminergic degeneration patterns that align with clinical diagnoses of parkinsonian disorders. The method offers practical advantages by eliminating MRI requirements while providing objective measures to supplement visual interpretation. This approach may particularly benefit patients unable to undergo MRI and facilities with limited imaging capabilities. Further validation studies are needed to confirm these findings and establish diagnostic thresholds.

EP-0673

Long-term ^{123}I-Ioflupane SPECT Follow-up in Asymptomatic Carriers of LRRK2-G2019S Mutation as Predictor of Parkinson Disease

I. Martínez-Rodríguez[1], *A. Clavijo-Umbarila*[1], *P. Andrade-Mejía*[1], *A. García-Ruiz*[1], *N. Carvalho-Duarte*[1], *L. Cabrera-Portillo*[1], *M. Botanch-Domingo*[1], *N. Martínez-Amador*[1], *F. Gómez-de la Fuente*[1], *A. Sánchez-Salmón*[1], *J. Jiménez-Bonilla*[1], *M. De Arcocha-Torres*[1], *V. Mendi-Barcina*[1], *M. Rivera-Sanchez*[2], *M. Sánchez-Pelaez*[2], *A. Sánchez Rodríguez*[3], *J. Infante*[2], *R. Quirce*[1];
[1]*Nuclear Medicine Department. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN,* [2]*Neurology Department. Marqués de Valdecilla University Hospital. Neurodegeneratives Diseases Group (IDIVAL), Santander, SPAIN,* [3]*Neurology Department. Hospital de Cabueñes, Gijón, SPAIN.*

Aim/Introduction: LRRK2-G2019S mutation is one of the identified causes of Parkinson's disease (PD). Asymptomatic carriers of this mutation offer a valuable opportunity to explore the premotor stages of PD. Our aim was to evaluate ^{123}I-ioflupane SPECT findings in asymptomatic carriers of this mutation in a 12-year long-term study. ***Materials and Methods:*** This prospective study included 42 asymptomatic carriers of the LRRK2-G2019S mutation (26 women/16 men; 57.3 ± 9.4 years, from 2011 to 2024). Subjects underwent ^{123}I-ioflupane SPECT as follows: 42 subjects had 1 scan, 29 had 2 scans, 17 had 3 scans, and 12 had 4 scans, performed at 4-year intervals. Based on visual analysis, studies were categorized as normal or abnormal, and a severity score of the decrease of uptake at the caudate and putaminal nuclei individually was assigned (1: mild; 2: moderate; 3: severe), with a maximum combined severity score of 12. Findings were correlated with clinical outcome. ***Results:*** Globally, both baseline and follow-up ^{123}I-ioflupane scans were abnormal in 24/42 subjects (57.1%). Baseline scan was normal in 18/42 subjects (42.9%), showing 11 of them (61.1%) an abnormal scan during follow-up. Considering the subgroup of 12 subjects with a longer follow-up of 4 scans, baseline ^{123}I-ioflupane scan was normal in 10 (83.3%) and abnormal in 2 (16.7%), and follow-up scans became abnormal in 8 subjects (66.7%) and remained normal in 4 (33.3%). During the follow-up period, 8 out of 42 subjects (19.1%) developed PD. Seven of them (87.5%) had abnormal baseline and follow-up ^{123}I-ioflupane scans, while the remaining subject had a normal baseline scan and abnormal scan at 4, 8 and 12 years. These 8 subjects who developed PD showed significantly higher ^{123}I-ioflupane combined severity scores at baseline (4.38 ± 2.83 vs. 1.71 ± 2.17; p = 0.0052), as well as at 4-year (5.71 ± 3.30 vs. 2.27 ± 2.55; p = 0.0073) and 8-year follow-up scans (5.33 ± 3.51 vs. 1.79 ± 1.85; p = 0.0201), compared to those who did not develop the disease. The most intense involvement was observed in the putaminal nuclei, particularly in the left putamen. ***Conclusion:***

Visual analysis of ^{123}I-Ioflupane scan revealed a significant decline in striatal dopamine transporter binding in a high percentage of LRRK2-G2019S mutation asymptomatic carriers during a 12-year long-term follow-up, significantly higher in subjects who developed PD, suggesting the potential role of ^{123}I-Ioflupane SPECT as a valuable predictive tool for PD development in these individuals. The contribution of a more detailed semi-quantitative analysis should be evaluated in the future.

EP-0674

Distribution Patterns of ^{18}FFlorzolotau PET and Midbrain Magnetic Resonance Parkinsonism Index in Patients with Progressive Supranuclear Palsy

M. Wang[1], *X. Wei*[1], *J. Lu*[2], *R. Ling*[1,3], *J. Jiang*[3], *L. Dong*[1], *X. Yang*[1], *L. Wang*[1], *C. Zuo*[2], *J. Jiang*[1];
[1]*Shanghai University, Shanghai, CHINA,* [2]*PET center, Fudan University, Shanghai, CHINA,* [3]*School of Medical Imaging, Shanghai University of Medicine & Health Science, Shanghai, CHINA.*

Aim/Introduction: Progressive supranuclear palsy (PSP) is a neurodegenerative disorder characterized by pathological tau protein aggregation, severe dopaminergic neuronal loss, and atrophy of cerebellar nuclei. However, the relationship between regional tau accumulation and midbrain-based atrophy in PSP remains poorly understood. This study aims to investigate the spatial distribution of tau pathology, as assessed by ^{18}FFlorzolotau positron emission tomography (PET), and subcortical atrophy across healthy controls (HC) and individuals within the PSP phenotypic spectrum. ***Materials and Methods:*** T1-weighted magnetic resonance imaging (MRI) and ^{18}FFlorzolotau PET scans were acquired from 36 HCs (age = 58.8±9.2 years, 11 male [M]/25 female [F]) and 156 patients with PSP (age = 66.1±6.8 years, 83 M/73 F) from the Movement Disorders Clinic, Department of Neurology, Huashan Hospital, Fudan University. The midbrain-based magnetic resonance Parkinsonism index (MRPI) was calculated based on manual morphometric measurements independently performed by three clinicians. Regional tau burden was quantified using the standardized uptake value ratio (SUVR). Correlation analyses were conducted to assess the relationship between regional Florzolotau SUVR values and MRPI in both HC and PSP groups. ***Results:*** Compared to the HC group, PSP patients exhibited significant midbrain atrophy and elevated MRPI values ($P < 0.0001$). Concurrently, Florzolotau tau accumulation was significantly increased in PSP, particularly in the red nucleus, subthalamic nucleus, raphe nuclei, and globus pallidus. Correlation analyses revealed a significant positive association between MRPI and regional tau accumulation across the whole cohort. Notably, tau SUVR in regions corresponding to PSP pathological stage I showed significant correlations with all MRPI parameters (MRPI: $r = 0.58$, $P < 0.001$; MRPI version 2: $r = 0.51$, $P < 0.001$). In the HC group, MRPI parameters were significantly correlated with age (r range: 0.30-0.45, $P < 0.001$), reflecting normal age-related brain atrophy. In contrast, in the PSP group, MRPI parameters were not correlated with age, suggesting that the observed atrophy likely reflects PSP-specific pathological mechanisms rather than normal aging. ***Conclusion:*** ^{18}F-Florzolotau tau accumulation may reflect the severity of subcortical atrophy in PSP and serve as a potential hallmark of disease progression, potentially contributing to subsequent cortical degeneration.

EP-0675

Evaluation Of Executive Functions In Patients with Parkinsonism. Comparison Of Modified-Wisconsin Card Sorting Test With 123I-Ioflupane Basal Ganglia SPECT Findings

D. Chattigkezou[1], *K. Sakellariou*[2], *I. Sofianidis*[3], *A. Diakakis*[1], *V. Siokas*[4], *A. Provatas*[5], *Z. Tsouris*[5], *G. Angelidis*[2], *D. Psimadas*[2], *C. Ziangas*[2], *I. Tsougos*[6], *P. Georgoulias*[7], *E. Dardiotis*[4], *V. Valotassiou*[7];
[1]*Faculty of Medicine, University of Thessaly, Larissa, GREECE,* [2]*Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, Greece,* [3]*Aristotle University of Thessaloniki, Thessaloniki, GREECE,* [4]*Neurology Dpt, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE,* [5]*Neurology Dpt, University Hospital of Larissa, Larissa, GREECE,* [6]*Dpt of Medical Physics, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE,* [7]*Dpt of Nuclear Medicine, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE.*

Aim/Introduction: The modified-Wisconsin Card Sorting Test (m-WCST) is a digital adaptation of the original WCST, and was designed to assess core executive functions, particularly cognitive flexibility, which refers to the ability to shift attention, inhibit automatic responses, update working memory, and monitor relevant stimuli (salience). Cognitive flexibility is often affected in neurodegenerative Parkinsonism and its impairment is most clearly reflected through perseverative errors—failures to abandon outdated rules and adopt new ones. The aim of this study was the comparison of m-WCST scores with presynaptic dopamine transporter (DaT) SPECT findings in patients with parkinsonism for the evaluation of executive functions. ***Materials and Methods:*** We studied 59 subjects with parkinsonism (37 males and 22 females, age±SD=68,64±9,62 years). All patients underwent m-WCST and DaT SPECT imaging 3-4 hours after the i.v. administration of 185 MBq 123I-Ioflupane. Medication known to interfere with dopamine transporter binding was discontinued. Oral Lugol's solution was given prior to tracer administration for thyroid protection. DaT SPECT images were evaluated visually and semi-quantitatively, selecting the three transverse slices with the most intense tracer uptake and drawing ROIs over the right and left striatum. We also performed automated semi-quantification using a software for the comparison with an age-matched control population, based on the Parkinson's Progression Markers Initiative (PPMI). ***Results:*** A statistically significant difference in m-WCST performance scores was found between the subjects with abnormal-group A and normal-group B DaT SPECT findings ($U=283.000$, $Z=-2.268$, $p=0.023$). Specifically, group A showed significantly lower mean ranks (Mean Rank=24.48) compared to group B (Mean Rank=34.66), suggesting reduced cognitive performance in subjects with neurodegenerative parkinsonism. Additionally, a statistically significant difference in the number of perseverative errors in the m-WCST was found between the two groups ($U = 287.5$, $Z = -2.201$, $p = 0.028$). Group A showed higher rates of perseverative errors, indicating a possible link between dopaminergic depletion and reduced cognitive flexibility. ***Conclusion:*** The combination of nuclear DaT SPECT molecular imaging of basal ganglia with a neuropsychological tool, such as m-WCST, may be useful for both, the accurate diagnosis of neurodegenerative parkinsonism and the evaluation of executive functions impairment.

Aim/Introduction: Synaptic phenotypes in living patients with psychiatric disorders are poorly characterized. Excitatory glutamate α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid receptor (AMPAR) is a fundamental component for neurotransmission. We recently developed a positron emission tomography (PET) tracer for AMPAR, [^{11}C]K-2, the first technology to visualize and quantify AMPAR density in the living human brain[1]. In this study, we examined appropriate quantification methods and elucidated key characteristics of major psychiatric disorders, including schizophrenia (SCZ), major depressive disorder (MDD), bipolar disorder (BD), and autism spectrum disorder (ASD). ***Materials and Methods:*** We conducted [^{11}C]K-2 PET imaging in 143 healthy subjects aged 20 to 70 years and 149 patients with psychiatric disorders (SCZ, n = 42; BD, n = 37; MDD, n = 35; ASD, n = 35). We assessed the effects of age on standardized uptake value ratio (SUVR) in healthy subjects, comparing white matter and whole brain as reference regions. We performed regression analysis between AMPAR density and symptomatology scores of each disease, and comparison of differences in AMPAR density between patients and healthy participants using a voxel-wise analysis. ***Results:*** In healthy subjects, white matter-referenced SUVR showed widespread age-dependent declines in AMPAR density. Whole brain normalization attenuated these effects, offering more stable estimates across the adult lifespan. When we compared SUVR using white matter and whole-brain references, the coefficient of variation among healthy participants was lower with whole-brain normalization, indicating reduced inter-individual variability and minimized influence of individual factors. Based on these results, we used whole brain as the reference region for analyzing psychiatric disorders. In psychiatric disorders, we detected brain regions where AMPAR density was associated with symptom severity within each disorder. We also identified significant differences in AMPAR density between each disorder and healthy subjects. Some of these alterations were shared across disorders, indicating that certain brain areas may be commonly affected in psychiatric disorders. ***Conclusion:*** Our approach to psychiatric disorders using [^{11}C]K-2 PET imaging can elucidate the biological mechanisms across diseases and pave the way to develop novel diagnostics and therapeutics based on synaptic physiology. ***References:*** Miyazaki T, Nakajima W, Hatano M, Shibata Y, Kuroki Y, Arisawa T et al. Brain Connectivity Networks of Quantitative Kinetic Parameters from Dynamic ^{18}F-FDG PET/CT Reveals Network-Level Differences in Surgical and Non-Surgical Epilepsy

Y. Duan[1], *Y. Ng*[2];
[1]*The First Affiliated Hospital of Shandong First Medical University and Shandong Provincial Qianfoshan Hospital, Jinan, Shandong, CHINA,* [2]*United Imaging Healthcare Group Co., Ltd., Shanghai, CHINA.*

Aim/Introduction: Epilepsy is a neurological disorder involving disrupted brain networks. Accurate localization of the epileptogenic zone is essential for surgical planning and achieving optimal therapeutic outcomes, but this task remains challenging due to the complexity of seizure networks. Dynamic ^{18}F-FDG-PET has shown superior sensitivity in detecting epileptogenic foci using kinetic over semi-quantitative SUV parameters. However, brain network analysis using dynamic PET-derived kinetic parameters remains largely underexplored. This study explores brain connectivity patterns using both semi-quantitative and kinetic parameters from dynamic ^{18}F-FDG-PET in epilepsy patients, comparing connectome features between surgical and non-surgical groups. ***Materials and Methods:*** A retrospective study of 15 patients with epilepsy (10 males, 5 females; mean age: 19.53 ± 8.55 years) was conducted at The First Affiliated Hospital of Shandong First Medical University. Patients were classified into surgical and non-surgical groups based on standardized presurgical evaluation protocol. All underwent 60-min dynamic total-body PET/CT scanning, T1-weighted MRI, and video-electroencephalography. Parametric images including relative blood volume (V_b), perfusion rate (K_1) and net influx rate (K_i) were generated using an irreversible two-tissue compartment model. Motion-corrected brain PET images were processed with PNEURO module (PMOD), coregistered to T1-weighted MR images, and segmented using the AAL atlas. Statistical differences in semi quantitative (SUV) and kinetic parameters (K_i, K_1 and V_b) between groups were assessed using the Wilcoxon signed-rank test. Cross-correlation among brain regions were performed to construct brain connectivity matrices, and global network properties were assessed using GRETNA to examine inter-group network-level differences. ***Results:*** We found that SUV, K_i, K_1 and V_b all showed statistically significant differences between surgical and non-surgical groups (all $P<0.0001$). Specifically, SUV, K_i, and V_b were significantly higher in non-surgical group, whereas K_1 was significantly higher in the surgical group. Brain connectivity network analysis revealed a more complex and interconnected network in the surgical group compared to non-surgical group when the correlation threshold was set to 0.95. Brain network analysis demonstrated that global efficiency, assortativity and synchronization of K_i, K_1 and V_b were higher in non-surgical group compared to surgical group. Whereas, clustering coefficient of SUV, K_1 and V_b and characteristic path length across all parameters

were higher in surgical group relative to non-surgical group. ***Conclusion:*** Brain connectivity showed distinguished features among surgical and non-surgical groups. This may potentially improve surgical candidate selection, enhancing precision in surgical decision-making, as well as providing deeper insight into the mechanism of epilepsy.

Altered Glucose Metabolism inDefault Mode Network and Prefrontal Circuit In Patients withKallmann Syndrome

C. Zhou[1], *X. Wang*[2], *M. Men*[2], *X. Yi*[2], *K. Cao*[1], *W. Pu*[1], *M. Hacker*[3], *X. Li*[3], *M. Zhao*[1];
[1]*The Third Xiangya Hospital, Central South University, Changsha, CHINA,* [2]*Xiangya Hospital, Central South University, Changsha, CHINA,* [3]*Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: To characterize the neuro-metabolic signature of Kallmann Syndrome (KS) and elucidate their neuroendocrine-psychosocial interactions. ***Materials and Methods:*** In this prospective case-control study, 30 KS patients and 30 matched healthy controls underwent brain [^{18}F]F-FDG PET scans, sex hormone assays, and standardized neuropsychological assessments. A voxel-wise group comparison analysis was conducted to identify clusters of brain metabolic patterns between KS patients and HCs. Subsequently, correlation and mediation analyses were performed to investigate the interrelationships among brain metabolic patterns, sex hormone levels, and psychosocial factors. ***Results:*** We identified six hypermetabolic clusters in KS patients, predominantly located in the fronto-limbic system and the default mode network (DMN) in KS patients. These clusters of hypermetabolism were significantly associated fertility anxiety scale (FAS), health information avoidance scale (HIAS) and health information overload scale(HIOS). In addition, mediation analysis indicated that double basal ganglia hypermetabolism acted as a significant mediator between HIAS and FAS (β= 0.274, P =0.031). ***Conclusion:*** Patients with KS exhibited a distinct hypermetabolism pattern in the DMN-prefrontal circuit, which functionally bridges neuroendocrine dysfunction and reproductive health anxiety.

EP-0679

Microglial Activation and Glucose Hypometabolism in the Thalamus Following Traumatic Brain Injury

Y. Zhang*, X. Zhang;*
The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, CHINA.

Aim/Introduction: Neuroinflammation is a recognized consequence of traumatic brain injury (TBI). However, the long-term effects on microglial activation and associated metabolic changes in specific brain pathways require further investigation. This study aimed to evaluate microglial activation using ^{18}F-DPA-714 PET/MR and glucose metabolism using ^{18}F-FDG PET/MR in distant and subcortical brain regions of patients more than one year post-TBI compared to healthy controls (HC). ***Materials and Methods:*** Patients at least one year after TBI and healthy controls underwent ^{18}F-DPA-714 and ^{18}F-FDG PET/MR imaging. Standardized uptake value means (SUV_{mean}) and maximums (SUV_{max}) were measured in bilateral thalamus, midbrain, brainstem, cerebellar white matter, and cerebellar cortex using 5 mm diameter regions of interest. An Asymmetry Index (AI%) was calculated [200 × (ipsilateral/right - contralateral/left) / (ipsilateral/right + contralateral/left)]. Paired Wilcoxon tests compared ipsilateral and contralateral SUVs within patients, and Wilcoxon rank-sum tests compared AI% between patients and controls. Spearman correlation assessed the relationship between ^{18}F-DPA-714 and ^{18}F-FDG AI% in patients. ***Results:*** Eight patients (mean age 29.0 ± 13.4 years; 8 male) with TBI (median duration from TBI to PET 114.5 [IQR: 47.0, 307.5] months) and seven HC (mean age 28.7 ± 5.9 years; 4 male/3 female) were included. Patients with TBI showed significantly increased ^{18}F-DPA-714 SUV_{max} (1.1 [0.9, 1.3] vs. 0.6 [0.5, 0.9], p=0.016) and SUV_{mean} (1.0 [0.8, 1.2] vs. 0.6 [0.5, 0.8], p=0.008) and significantly decreased ^{18}F-FDG SUV_{max} (6.5 [4.9, 9.4] vs. 9.8 [8.2, 11.6], p=0.016) and SUV_{mean} (6.1 [4.0, 8.4] vs. 8.9 [7.6, 10.5], p=0.023) in the ipsilateral thalamus compared to the contralateral side. Thalamic AI% for ^{18}F-DPA-714 SUV_{max} (37.9 [14.8, 68.7] vs. 2.2 [-6.7, 6.9], p=0.009) and SUV_{mean} (35.6 [13.3, 67.6] vs. 4.9 [-7.3, 7.7], p=0.021) was significantly higher in patients than in HC. Thalamic AI% for ^{18}F-FDG SUV_{max} (-23.8 [-53.6, -14.4] vs. -4.4 [-13.5, 3.4], p=0.021) and SUV_{mean} (-29.8 [-61.3, -15.1] vs. -2.3 [-4.5, 0.2], p=0.014) was significantly lower in patients than in HC. No significant AI% differences were found in other measured regions. Within the patient group, thalamic ^{18}F-DPA-714 AI% (SUV_{max} and SUV_{mean}) negatively correlated with ^{18}F-FDG AI% (SUV_{max}: r=-0.71, p=0.047; SUV_{mean}: r=-0.86, p=0.007). No significant correlations were observed in other regions. ***Conclusion:*** Long-term TBI survivors demonstrate persistent ipsilateral thalamic microglial activation coupled with impaired glucose metabolism. The negative correlation between these PET markers suggests a potential link between chronic neuroinflammation and neuronal dysfunction in the thalamus following TBI.

EP-0680

^{18}F-DPA714 PET/MR Reveals Neuroinflammation-Peripheral Immune Crosstalk in Depression

L. Xu[1], *K. Liao*[1], *X. Song*[2], *P. Zheng*[2], *H. Pang*[1];
[1]*Department of Nuclear Medicine, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA,* [2]*Department of Neurology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.*

Aim/Introduction: Neuroinflammation, a major injurious mechanism in the brain, has been identified as a key trigger in the development of depression. In addition, both neuroinflammation and peripheral inflammation have been observed in patients with depression. However, the relationship between these processes remains unclear. The TSPO-targeting imaging agent ^{18}F-DPA714 PET can effectively detect the activation of microglia in the brain. This study explored the interaction between neuroinflammation and peripheral immunity by correlating ^{18}F-DPA714 PET imaging findings with peripheral blood inflammatory markers. ***Materials and Methods:*** We recruited 32 patients with depression (9 males, 23 females; mean age 41.3 years) and 24 health controls (7 males, 17 females; mean age 42.8 years). All subjects underwent ^{18}F-DPA714 PET/MR imaging. Peripheral blood samples were collected to assess blood count, C-reactive protein, and various cytokines. PMOD software was used to analyze differences in ^{18}F-DPA714 PET/MR uptake across different brain regions between the two groups. T-tests were employed to compare complete blood count, C-reactive protein, and cytokine level. Additionally, correlations among clinical assessments, including the Self-Rating Anxiety Scale (SAS), Self-Rating Depression Scale (SDS), Hamilton Anxiety Scale (HAMA)-14, Hamilton Depression Scale (HAMD)-17, and Patient Health Questionnaire (PHQ)-9, as well as peripheral inflammatory markers and ^{18}F-DPA714 PET uptake in the brain were evaluated. ***Results:*** Compared with healthy controls, patients with depression exhibited a significantly higher ^{18}F-DPA714 SUVmean in the right superior frontal gyrus, perifrontal gyrus, inferior frontal gyrus, posterior central gyrus, left superior limar gyrus, bilateral superior temporal gyrus, temporal poles, transverse temporal gyrus, hippocampus, insular lobes, anterior left cingulate gyrus, and right central sulcus (all $P < 0.05$). In patients with depression, peripheral levels of IL-4 and IL-10 were significantly elevated compared to healthy controls (all $P < 0.05$). Moreover, significant correlations were observed between brain ^{18}F-DPA714 uptake and clinical scores (HAMD-17, SAS, SDS) as well as IL-4 and IL-10 levels (all $P < 0.05$). ***Conclusion:*** In patients with depression, the uptake of ^{18}F-DPA714 was significantly elevated in multiple

brain regions—particularly in the frontal and temporal lobes—compared to healthy controls, and it showed positive correlations with peripheral inflammatory markers as well as HAMD-17, SAS, and SDS scores. These results suggest that peripheral inflammation and neuroinflammation coexist and may interact in depression, contributing to its pathogenesis.

EP-0681

Effect of ketogenic diet (KD) on brain metabolism goes beyond metabolic shifting

M. Mangia[1,2], *G. Rovera*[1,2], *M. Cioffi*[1,2], *F. Roveta*[3,4], *M. Zotta*[2], *A. Lesca*[2], *F. Giunta*[2], *E. Rubino*[3,4], *A. Cermelli*[3,4], *L. Sofia*[5,6], *S. Raffa*[5,6], *M. Bauckneht*[5,6], *D. Arnaldi*[6,7], *F. Massa*[6,7], *M. Pardini*[6,7], *I. Rainero*[3,4], *S. Morbelli*[1,2];
[1]*Department of Medical Sciences, University of Turin, Turin, ITALY,* [2]*Nuclear Medicine Unit, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [3]*Aging Brain and Memory Clinic, Department of Neuroscience "Rita Levi-Montalcini", University of Turin, Turin, ITALY,* [4]*Department of Neuroscience and Mental Health, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [5]*Nuclear Medicine Unit, Department of Medical Sciences, University of Genoa, Genoa, ITALY,* [6]*IRCCS Ospedale Policlinico San Martino, Genoa, ITALY,* [7]*Department of Neurosciences, University of Genoa, Genoa, ITALY.*

Aim/Introduction: KD has been proposed as adjuvant therapy in several neurologic disorders including epilepsy, Alzheimer's and Parkinson's disease. The mechanisms underlying its potential neuroprotective effects are not fully elucidated. The multifaceted nature of brain and body-PET imaging may be suitable for a deeper investigation of this topic; however, very few data are available in this regard. ***Materials and Methods:*** We retrospectively analyzed 74 cognitively-intact consecutive patients who underwent KD prior to whole-body [18F]FDG-PET, including brain imaging, to exclude endocarditis. Only patients with a negative scan, without a previous history of neurological and oncological diseases, were included. Patients were subgrouped according to presence/absence of myocardial metabolic shifting in terms of uptake suppression on whole-body PET. Brain-PET scan of both subgroups were processed and independently compared to an in-house database of healthy control in SPM12. Myocardial uptake was quantified in all patients by drawing a VOI on the left ventricle and normalized on blood-pool (MSUVmaxratio). SPM multiple-regression analysis was used to assess the relationship between cardiac residual metabolism and brain glucose consumption (FWE-corrected $p<0.05$ as significant). ***Results:*** 49 patients (median age 67 IQR[58-74], 49% males) showed complete cardiac metabolic shifting while 25 (median age 74 IQR[66-77], 83% males) presented only a partial shift. Both groups were characterized by a relative hypometabolism on a cluster encompassing the temporal and fronto-lateral cortex in the right hemisphere ($p<0.001$) which was, however, significantly less extended in patients with partial metabolic shifting. Notably, both groups showed a substantially overlapping pattern of relative hypermetabolism with respect to controls in a region encompassing limbic lobes (with a marked involvement of both medial-temporal lobes) and cerebellum bilaterally ($p<0.002$). In the whole-group of patients, MSUVmaxratio was directly correlated with the lateral-temporal cortex while no inverse correlations were highlighted. ***Conclusion:*** Both patterns of relative hypo and hypermetabolism hereby highlighted replicate in larger dataset the pattern emerged from the single previously available study which applied voxel-based analysis to brain FDG-PET during KD (Horowitz et al EJNMMI 2023), thus suggesting that KD might have a peculiar brain metabolic signature. Regions of cortical hypometabolism have a more direct relationship with patients' metabolic profile linked to myocardial shifting. Conversely, regions of relative hypermetabolism are independent from myocardial shifting and are located in the MTL in keeping with available preclinical findings. These regions might testify a further, more complex, interplay between KD and other factors, such as protection from oxidative stress, who deserve further investigation.

EP-0682

Neuroinflammation and Metabolism in Autoimmune Encephalitis: A Dual-Tracer PET Imaging Approach for Subgroup Differentiation

Y. Wang, *H. Shao, Y. Zhang, G. Huang, C. Zhang, J. Liu;*
Department of Nuclear medicine; Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: Autoimmune encephalitis (AE) is a heterogeneous group of neuroinflammatory disorders characterized by diverse clinical manifestations and variable responses to immunotherapy. Early and accurate diagnosis remains challenging due to the lack of specific biomarkers and the complexity of underlying pathogenic mechanisms. This study aimed to systematically investigate brain metabolic and neuroinflammatory alterations in AE patients using multimodal positron emission tomography (PET) imaging (2-deoxy-2-[^{18}F] fluoro-D-glucose [^{18}F-FDG] PET and [^{18}F]N-fluoroacetyl-N-(2,5-dimethoxybenzyl)-2-phenoxyaniline [^{18}F-PBR06] PET). By analyzing imaging patterns across different antibody subtypes (neuronal surface vs. intracellular antibodies) and etiologies (paraneoplastic, viral, and cryptogenic), we sought to evaluate the clinical utility of multimodal PET imaging in improving early diagnosis, treatment monitoring, and prognosis assessment. ***Materials and Methods:*** This prospective study enrolled 49 immunotherapy-naïve AE patients (median age 48.0 years) and matched healthy controls from Renji Hospital (2012-2024). All 49 participants underwent ^{18}F-FDG PET imaging to assess regional brain metabolism. Among these, a subset of 19 participants additionally received ^{18}F-PBR06 PET imaging to evaluate neuroinflammation through translocator protein (TSPO) expression, enabling multimodal assessment. Image analysis was performed using Statistical Parametric Mapping (SPM; voxel-level $p<0.001$, cluster-level FWE-corrected $p<0.05$) with automated quantification via NeuroQ and uWS-MI software, while excluding functionally variable regions like the visual cortex. Patients were stratified into subgroups based on antibody type (neuronal surface antigen antibodies [NSAb] and intracellular antigen antibodies [ICAb]) and etiologies (paraneoplastic [PN], viral encephalitis [VE], and cryptogenic [CG]) to investigate distinct metabolic and inflammatory patterns. ***Results:*** Multimodal PET imaging revealed distinct metabolic and neuroinflammatory profiles across AE subgroups. All 49 patients undergoing ^{18}F-FDG PET exhibited metabolic abnormalities (1-27 lesions across 47 brain regions), whereas neuroinflammation detected by ^{18}F-PBR06 PET was less frequent (42.1%, 8/19 patients) and more localized (≤6 affected regions). Antibody-specific patterns emerged, with NSAb patients showing widespread metabolic disturbances including cerebellar hypermetabolism (54.2%) and frontal hypometabolism, while ICAb patients demonstrated more focal frontal lobe neuroinflammation (T=4.50-11.19). Etiological analysis revealed cerebellar hypermetabolism in both PN and VE groups (50-55.6%), with VE cases additionally exhibiting marked limbic neuroinflammation (T=22.33-61.99). CG patients displayed a unique pattern combining pontine/cerebellar neuroinflammation (T=3.69-6.15) with frequent frontal hypometabolism (63.2%), highlighting the clinical heterogeneity of AE. ***Conclusion:*** This multimodal PET study demonstrates that distinct brain metabolic and neuroinflammatory patterns characterize different AE subgroups, with antibody type and etiology serving as key determinants of imaging phenotypes.

EP-0683

AI-based denoising to fully exploit pathophysiological meaning and clinical impact of early perfusion amyloid PET imaging

A. Coccarelli[1,2], *M. Zotta*[1,2], *S. DeKeyser*[3], *V. De Ridder*[3], *M. Cioffi*[1,2], *G. Rovera*[2], *M. Pardini*[4], *L. Sofia*[5,6], *S. Raffa*[6], *L. Roccatagliata*[6,5], *F. Massa*[6,4], *D. Arnaldi*[6], *B. Orso*[4], *M. Losa*[4], *A. Lesca*[1,2], *M. Bauckneht*[5,6], *M. Bozzali*[7], *S. D. Morbelli*[1,2,8];
[1]AOU Città della Salute e della Scienza di Torino, Nuclear Medicine Unit, Turin, ITALY, [2]Department of Medical Sciences, University of Turin, Turin, ITALY, [3]Nuclivision, Ghent, BELGIUM, [4]Department of Neuroscience, University of Genoa, Genoa, ITALY, [5]Nuclear Medicine Unit, Department of Medical Sciences, University of Genoa, Genoa, ITALY, [6]IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [7]Rita Levi Montalcini Department of Neuroscience, University of Turin, Turin, ITALY, [8]Department of Neuroscience and Mental Health, AOU Città della Salute e della Scienza di Torino, Turin, ITALY.

Aim/Introduction: Early-perfusion-amyloid PET is considered able to capture neurodegeneration, allowing same-day, same-tracer categorization of both amyloidosis and neurodegeneration. However, scanner occupancy during early-image acquisition is an unresolved issue. Moreover, while the first 3-minutes post-injection better represents cerebral blood-flow, such a short acquisition-time may result in noisy images, making pattern identification challenging. We investigated the feasibility of AI-based denoising of 3-minute early-phase-amyloid-PET and simulated its clinical use using visual and voxel-based approaches. ***Materials and Methods:*** For pathophysiological reasons, the 10-minute scan cannot serve as a gold standard due to the expected less evident hypoperfusion signals. We thus used a model trained on low-dose enhancement datasets (such as late-phase or whole-body-FDG dose-reduction data), which is designed to preserve signal, as standard count and low-count images in those cases have similar underlying signals. This was compared with a classical denoising-model using the 10-minute-scan as high-count reference. We evaluated clinical performance of enhanced-images comparing the ability expert and non-expert readers' to recognize AD patterns in original 3-, 5-, and 10-minute frames versus enhanced 3-minute images. Both readers classified scans as positive/negative and rated diagnostic confidence on a 1-to-5 scale. We evaluated 92 reconstructed scans (original and enhanced). Finally, we carried out a single-subject analysis (SPM12) comparing original and enhanced-images with a normal-subjects-dataset of early-perfusion-amyloid-PET ($p<0.05$ FWE-corrected accepted as significant and results were compared in terms of the cluster's extent). ***Results:*** The model trained on 10-minute scans erroneously removed signals present in 3-minute-scans, whereas the model trained on low-dose datasets preserved them. Enhanced 3-minute images resulted in higher diagnostic confidence for both expert and non-expert readers compared to 10 minutes images (score 5 in 75% of enhanced 3-minute scans versus 55% for 10-minute scans). The enhanced 3-minute-images showed higher interobserver-agreement (k:0.88) than original 3-minute and 10-minute scans (k:0.75) but were not inferior to 5-minute-acquisitions. In the voxel-based-analysis clusters' extent was significantly larger for both 3-min-original and 3-min-enhanced images with respect to 5-min and 10-min images (800±200 and 807±233 versus 210±160-voxels respectively). In 1 patient, bilateral hypometabolism was highlighted in the comparison involving 3-min-enhanced-images only. ***Conclusion:*** The investigation into early-phase 3-minute scans highlighted the limitations of traditional supervised learning approaches, as the high-count data (10-minute scans) lack some clinically relevant perfusion signals. The method based on low-dose-enhancement seems promising as it was able to enhance images without suppressing the hypoperfusion pattern and allowed to increase readers' agreement, diagnostic confidence and voxel-based sensitivity.

EP-0684

Head-to-Head Comparative Study of [^{18}F]FDG, [^{18}F]FMZ and [^{18}F]DPA-714 for Localizing Epileptogenic Foci in Drug-Resistant Epilepsy

G. Li[1], *H. Huang*[2], *S. Mei*[3], *W. Bao*[1], *S. Ren*[1], *S. Jiang*[3], *Q. Huang*[1], *Z. Lin*[2], *Y. Yang*[4], *Y. Guan*[1], *L. Chen*[3], *F. Xie*[1];
[1]Department of Nuclear Medicine & PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, [2]Central Research Institute, United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA, [3]Department of Neurosurgery, Huashan Hospital, Fudan University, Neurosurgical Institute of Fudan University, National Center for Neurological Disorders, Shanghai, CHINA, [4]Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.

Aim/Introduction: The localization of epileptogenic foci remains a critical challenge in the preoperative assessment of drug-resistant epilepsy (DRE). Although neuroinflammation, marked by translocator protein (TSPO) upregulation, is implicated in epileptogenesis and drug resistance, the diagnostic utility of the TSPO-specific tracer [^{18}F]DPA-714 in drug-resistant epilepsy (DRE) remains underexplored. This study aimed to systematically compare the performances of [^{18}F]FDG, [^{18}F]FMZ, and [^{18}F]DPA-714 PET in identifying epileptogenic foci, thereby optimizing preoperative multimodal imaging strategies. ***Materials and Methods:*** Fifteen surgical candidates with DRE, diagnosed according to ILAE criteria, underwent preoperative [^{18}F]FDG, [^{18}F]FMZ, and [^{18}F]DPA-714 PET scans. Analysis comprised visual assessments by three blinded nuclear medicine physicians (AAL3 atlas-defined regions) and quantitative voxel-wise analysis. The asymmetry index (AI) mapping was computed to detect cerebral regions of hypometabolism ([^{18}F]FDG and [^{18}F]FMZ) or hypermetabolism ([^{18}F]DPA-714) using the formula (ipsilateral – contralateral) / (ipsilateral + contralateral). Abnormal clusters (>40 contiguous voxels) were stratified by severity: mild ($0 < |AI| < 0.1$), moderate ($0.1 \leq |AI| < 0.2$), and severe ($|AI| \geq 0.2$). ***Results:*** Visual assessments revealed significant differences among the three tracers ($p < 0.001$), [^{18}F]FDG exhibited the highest number of abnormal brain regions, followed by [^{18}F]FMZ and [^{18}F]DPA-714($p < 0.001$ for both comparisons), and [^{18}F]FMZ exhibited moderately higher lesion counts than [^{18}F]DPA-714 ($p = 0.022$). Voxel-wise AI mapping stratification highlighted distinct tracer-specific patterns: [^{18}F]DPA-714 exhibited a broader range with higher abnormal voxel counts than [^{18}F]FDG, [^{18}F]FMZ($p < 0.001$ for both). At moderate levels, both [^{18}F]FDG and [^{18}F]DPA-714 surpassed [^{18}F]FMZ ($p < 0.001$ and $p < 0.05$), with no significant difference between [^{18}F]FDG and [^{18}F]DPA-714. At severe levels, [^{18}F]DPA-714 voxel counts were significantly lower than [^{18}F]FDG and [^{18}F]FMZ ($p < 0.001$ for both). In the quantitative analysis of combined moderate-severe abnormalities ($AI \geq 0.1$), [^{18}F]FDG demonstrated significantly larger volumes of metabolic dysfunction than both [^{18}F]FMZ ($p=0.012$) and [^{18}F]DPA-714 ($p=0.001$), with no significant difference between [^{18}F]FMZ and [^{18}F]DPA-714 ($p=0.679$). ***Conclusion:*** This first systematic comparison of [^{18}F]FDG, [^{18}F]FMZ, and [^{18}F]DPA-714 PET in drug-resistant epilepsy reveals a tracer-specific spatial hierarchy for metabolic abnormalities. [^{18}F]DPA-714 and [^{18}F]FMZ demonstrate more circumscribed abnormalities compared to [^{18}F]FDG. Future studies with expanded cohorts should 1) validate these tracer-specific efficiency gradients across epilepsy subtypes, 2) integrate surgical outcomes to establish AI thresholds for optimal tracer selection, and 3) explore hybrid PET/MRI protocols to synergize neuroinflammatory-metabolic localization.

EP-0685

Diagnostic utility and clinical impact of brain ^{18}F-FDG PET/CT in the diagnosis of autoimmune encephalitis

O. Hernandez Cristancho[1], *S. Asadurova*[1], *M. Alanís-Bernal*[2], *C. Lorenzo*[1], *H. Ariño*[3], *A. Zabalza*[3], *A. Vilaseca*[3], *E. Sáez de Gordoa*[4], *C. Auger*[4], *C. Gamez*[1];
[1]Nuclear Medicine Department, University Hospital Vall d'Hebron, Barcelona, SPAIN, [2]Neurology Department, University Hospital Vall d'Hebron, Barcelona, SPAIN, [3]CEMCat, Barcelona, SPAIN, [4]Radiology Department, University Hospital Vall d'Hebron, Barcelona, SPAIN.

Aim/Introduction: To evaluate the diagnostic utility and clinical impact of [^{18}F]-FDG PET/CT in patients with suspected autoimmune encephalitis (AE), and to identify characteristic metabolic patterns. ***Materials and Methods:*** Retrospective study of 31 patients with suspected AE who underwent brain [^{18}F]-FDG PET/CT between 05/2015 and 04/2025. Patients were classified by final diagnosis (Graus 2016 Criteria), clinical certainty (possible, probable, definitive), antibody type, and treatment with immune checkpoint inhibitors (ICIs). All PET/CT images were analyzed visually and semiquantitatively. Voxel-based group analysis was also performed. ***Results:*** 17 females, mean age 54 years [range: 33-76]. AE was definitive in 26 patients, possible in 4, and probable in 1. Fifteen patients were seronegative, including 6 treated with ICIs. Neoplasms were present in 17 patients. The most frequent antibodies were anti-NMDAR (n=4), GAD65 (n=3), LGI1 (n=2), and Hu (n=2). PET was performed at a median of 3.4 months [0.3-179 months] from symptoms' onset. PET abnormalities were detected in 27/31 patients (87%), including 19/27 (70%) with normal MRI. PET was positive in all 5 possible/probable cases, with concordance to MRI in 3/5 (showing unilateral mesial temporal involvement). Among seronegative patients, 11/15 had negative MRI with positive PET, and 4/15 had both positive MRI and PET, being the most common pattern mesial temporal and basal ganglia hypermetabolism (in 11/15 patients). Characteristic patterns included mesial temporal and basal ganglia hypermetabolism in LGI1/CASPR2 encephalitis (n=3), diffuse posterior cortical hypometabolism with subcortical hypermetabolism in anti-NMDAR encephalitis (n=3), and cerebellar or mesial temporal hypometabolism in GAD65-related cases (n=2), consistent with published data. In ICI-associated AE all patients were seronegative with a negative MRI, PET revealed basal ganglia and mesial temporal hypermetabolism alongside cortical hypometabolism (n=6) outlining its value in this subgroup. Normal PET/CT findings were seen in 4 patients (2 with anti-Ri and cerebellar degeneration, 1 anti-NMDAR, 1 anti-GAD65). Notably, all had PET performed either early (1.7-3.4 months) or very late (>70 months) after symptom onset, suggesting decreased sensitivity in late-stage disease. Thirteen patients underwent a control brain PET/CT, showing normalization of the finding in 6/13, persistence in 4/13, improvement in 2/13 and worsening (change from mesial temporal hyper to hypometabolism) in 1 patient. ***Conclusion:*** [^{18}F]-FDG PET/CT is a sensitive biomarker for AE, increases diagnostic confidence in possible/probable and seronegative cases. Specific antibody-related metabolic patterns enhance diagnostic certainty. Normal PET findings are possible in late-stage disease, underscoring the importance of timely imaging.

EP-0686

Brain [^{18}F]FDG PET identifies evolving brain metabolism patterns correlating with outcomes in autoimmune encephalitis

Aim/Introduction: Autoimmune encephalitis (AE) comprises a group of inflammatory brain disorders with highly variable clinical presentations and outcomes. While [^{18}F]FDG PET is increasingly used to support AE diagnosis, its potential as a prognostic tool remains underexplored. This study aimed to investigate whether longitudinal [^{18}F]FDG PET imaging—performed before and after immunotherapy—can identify evolving brain metabolism patterns that correlate with clinical outcomes in AE patients. ***Materials and Methods:*** In this retrospective study, 22 patients with a confirmed diagnosis, either seropositive or seronegative, of AE underwent brain [^{18}F]FDG PET scans at the acute phase (BS, baseline) and after immunotreatment (follow-up, FU). Voxel-wise paired T-test was used to identify significant metabolic changes between the two timepoints. Clusters with $p<0.05$ and ≥ 100 voxels were defined as volumes of interest (VOIs). VOI values were extracted and correlated with clinical outcomes—namely the Clinical Assessment Scale in Autoimmune Encephalitis (CASE) score, relapse, escalation of immunotherapy, and modified Rankin Scale (mRS)—using partial Spearman's correlations, adjusting for age. Prognostic value of brain metabolism at BS and FU was further assessed using general linear models. ***Results:*** Three VOIs showed significant metabolic changes between baseline (BS) and follow-up (FU) assessments. VOI-A, which was relatively hypermetabolic, included the caudate-thalamus-parahippocampal region, right amygdala, and anterior cingulate cortex. VOI-B1 and VOI-B2, relatively hypometabolic, corresponded to the right fusiform gyrus, precuneus, and temporo-parietal cortex, respectively. Lower metabolism in VOI-B1 at BS significantly predicted higher CASE scores at FU and was associated with relapse. VOI-B1 values at FU also predicted the need for escalation therapy, alongside patient age. Lower VOI-B2 metabolism at FU was associated with poor functional outcomes (mRS > 2). VOI-A did not correlate significantly with prognosis. ***Conclusion:*** Longitudinal [^{18}F]FDG PET imaging before and after immunotherapy reveals evolving regional brain metabolic patterns in AE. In particular, persistent hypometabolism in temporo-parietal areas correlates with relapse, need for intensified treatment, and long-term functional impairment. These findings support the use of [^{18}F]FDG PET as a non-invasive biomarker for prognostic stratification and treatment guidance in autoimmune encephalitis.

EP-0687

Dissociation between neurometabolic and neurovascular changes elicited by a sentence completion task: a PET-MRI study.

T. Vanbutsele[1,2], *A. Castiaux*[1,2], *N. Trotta*[1,3,2], *A. Rovai*[1,3], *V. Wens*[1,3], *S. Goldman*[1], *X. De Tiège*[1,3], *G. Leurquin-Sterk*[1,3,2];

Aim/Introduction: Functional positron emission tomography (fPET) with [18F]-fluorodeoxyglucose (FDG) is an emerging neuroimaging technique recording brain glucose metabolism over time and its modulation by experimental tasks. Simultaneous acquisition of fPET and functional magnetic resonance imaging (fMRI) using PET-MRI allows comparison of task-induced changes in neurometabolic and neurovascular couplings. Similar task-

induced increases in regional brain metabolism and perfusion have been described, but conflicting results have been reported for task-induced decreases in activity (e.g., within the default mode network (DMN)).This PET-MRI study investigates task-induced neurometabolic/neurovascular modulations elicited by a sentence completion task; a task known to recruit the left-dominant dorsal stream of the language network as well as to induce task-related decrease in fMRI signal within the DMN. ***Materials and Methods:*** Twenty right-handed, French-speaking adults performed a sentence completion task (10-min rest followed by 6 alternating 6-min rest/task blocks, task blocks: 30-second alternating task/rest blocks, total: 46 minutes) during dynamic PET-MRI data acquisition after FDG administration (bolus followed by continuous infusion). First-level general linear models were built with FDG-PET data organised into 46 frames of 1-minute duration each with task regressor modelled as a ramp function, global (mean activity across a grey matter) brain glucose uptake over time, and movements parameters as regressors of no-interest. Beta maps were used to compute ratios of regional metabolic changes over time. Second-level analyses were performed using one-sample t-tests across the whole population. fMRI data were pre-processed and analysed (block design) at the first and second levels using standard workflows. Results were considered significant at FWE-corrected p<0.05. ***Results:*** fPET and fMRI showed significant task-related increases in fPET and fMRI signals in the left-dominant dorsal stream of the language network. While fMRI showed significant decreases in blood oxygen level dependant (BOLD) signal in posterior midline DMN regions, no significant (even uncorrected) change in metabolic activity was observed using fPET. Significant increase in BOLD signal was observed in the right cerebellum, whereas fPET showed a significant decrease in metabolic activity. ***Conclusion:*** This study demonstrates that blood flow changes do not always match neural glucose demand.Neurophysiological mechanisms leading to this mismatch may involve feedforward neurovascular signalling, glia-mediated modulation, preparatory hemodynamic response, differences in neurovascular coupling and glycolytic processes during GABAergic suppression and glutamate activation. Interpretation of neuroimaging results based on fMRI should thus be done with caution.

Aim/Introduction: Chronic stress activates neurobiological pathways centred in the amygdala, a limbic structure that regulates physiological stress responses. Increased amygdala metabolic activity on [^{18}F]FDG-PET/CT may reflect chronic stress affecting tumour characteristics and aggressiveness. Given the growing recognition of amygdala uptake across cancer types, we propose the "Almond sign", a visually identifiable pattern of bilateral amygdala hypermetabolism on [^{18}F]FDG-PET/CT, to harmonise interpretation and promote consistency across studies. This study investigates the relationship between amygdala metabolic activity and pathologically confirmed lymph node (LN) metastasis in newly diagnosed breast cancer patients. ***Materials and Methods:*** This retrospective study analysed [^{18}F]FDG-PET/CT in 93 patients with newly diagnosed invasive ductal breast cancer after excluding patients with confounding stress-related factors and/or distant metastases. Six amygdala-related PET parameters were extracted, three corrected to ipsilateral temporal-lobe SUVmean, and three to cerebellar SUVmean, to improve reproducibility given temporal uptake variability. Patients were stratified into high-risk and low-risk groups based on tumour characteristics, and into premenopausal and postmenopausal subgroups. ***Results:*** All six parameters were significantly associated with LN involvement ($p < 0.01$). Among them, Amyg_amaxT, defined as the mean SUVmax of the bilateral amygdalae, each normalised to their respective temporal-lobe SUVmean, showed the strongest correlation (OR 31.6 per 0.1-unit increase, 95% CI 7.77-128.9, $p < 0.00001$) with LN metastases. ROC analysis revealed an AUC of 0.96, with an optimal cut-off of 0.84, yielding 93% sensitivity and 94% specificity. Comprehensive multivariate analysis, incorporating all six amygdala parameters, tumour characteristics (ER, PR, HER2 status, grade, Ki67), tumour stage, molecular subtypes, PET parameters, inflammatory markers, and patient characteristics, identified Amyg_amaxT as the sole independent predictor of LN metastasis across four variable selection algorithms. It also correlated significantly with MTV ($p = 0.00065$), TLG ($p = 0.00081$), and PET-detected axillary LN status (OR 5.01, $p = 0.001$). In subgroup analyses, Amyg_amaxT remained a significant predictor across both menopausal and risk groups, with the strongest performance observed in low-risk breast cancer patients. ***Conclusion:*** Increased amygdala uptake on [^{18}F]FDG PET, visually representing chronic stress, and its derived metric Amyg_amaxT, has the potential to predict axillary LN metastasis in primary staging of breast cancer. This parameter could be considered in nodal assessment when conventional imaging is equivocal, guide presurgical evaluation and clinical decision-making, and contribute to prognostic modelling in future outcome studies. Establishing a standardised term like the "Almond sign" promotes consistency across imaging research and facilitates integration of stress-related brain biomarkers into oncological PET/CT practice.

EP-0689

Association of Glymphatic Function with Glucose Metabolic Patterns in Patients with Prolonged Disorders of Consciousness

Y. Wang, *K. Guo, F. Kang, J. Wang;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: Previous studies have demonstrated that traumatic brain injury and stroke, two major etiological factors of prolonged disorders of consciousness (pDoC), can lead to dysfunction of the glymphatic system. However, it remains unclear whether patients with pDoC exhibit glymphatic system impairment and whether such dysfunction is associated with alterations in cerebral glucose metabolism. This study aimed to investigate glymphatic dysfunction in patients with pDoC and to explore its potential relationship with glucose metabolic patterns in the brain. ***Materials and Methods:*** Forty-one pDoC patients (mean age 48.4 ± 14.7 years) and 26 age-matched HCs (mean age 49.3 ± 12.8 years) were enrolled. All participants underwent diffusion tensor (DTI) imaging for in vivo assessment of glymphatic function using DTI along the perivascular space (DTI-ALPS) index, as well as ^{18}F-fluorodeoxyglucose positron emission tomography (^{18}F-FDG PET) to characterize pDoC-associated metabolic patterns, including glucose metabolic pattern (GMP) score and standardized uptake value ratio (SUVR) of ROIs relevant to the mesocircuit model. The GMP was generated using voxel-based scaled subprofile modeling combined with principal component analysis (SSM/PCA). The GMP scores were subsequently calculated. Regions of interest (ROI) for calculating SUVR were defined using

the Automated Anatomical Labeling (AAL) template, and the whole brain served as the reference region. Associations between the DTI-ALPS index and GMP score, SUVR were evaluated using Pearson's correlation analysis. ***Results:*** pDoC Patients exhibited significantly lower DTI-ALPS indices than HCs ($p < 0.001$). Partial correlation analyses revealed a significant correlation between the DTI-ALPS index and GMP score ($r = 0.654$, $p < 0.001$). Additionally, relatively strong correlations were observed between the DTI-ALPS index and the SUVR of several brain regions, including the thalamus ($r = 0.593$ and 0.564 for the left and right hemispheres, respectively, both $p < 0.001$), the globus pallidus ($r = 0.401$ and 0.362 for the left and right hemispheres, respectively, $p = 0.009$ and 0.020), the striatum ($r = 0.565$ and 0.524 for the left and right hemispheres, respectively, both $p < 0.001$), and the brainstem ($r = 0.629$, $p < 0.001$). No significant correlations were found between the DTI-ALPS index and the SUVR of the frontal or parietal cortex ($p > 0.05$). ***Conclusion:*** Our study indicates that glymphatic dysfunction is associated with the whole-brain GMP score and SUVR of regions relevant to the mesocircuit model in patients with pDoC. These findings suggest a potential mechanism underlying neurological recovery in patients with pDoC.

EP-0690

First Atlas of Resting-State Networks Based on FDG-PET Data

D. Steenken[1], *C. Eierud*[2], *A. Sala*[3], *N. Franzmeier*[1], *Y. Li*[4], *A. Zwergal*[1], *I. Yakushev*[4];
[1]*University Hospital of Munich, Munich, GERMANY,* [2]*Georgia State University, Atlanta, GA, UNITED STATES OF AMERICA,* [3]*University of Liège, Liège, BELGIUM,* [4]*Hospital of Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: Resting-state networks (RSNs) identified through functional magnetic resonance imaging (fMRI) have fundamentally transformed our understanding of intrinsic brain function. Several established fMRI-based RSN atlases have facilitated the mapping and interpretation of these intrinsic connectivity patterns. However, while fMRI primarily reflects hemodynamic changes, FDG-PET as index of glucose consumption offers a more direct assessment of neuronal function with superior signal-to-noise properties. Given the emerging evidence that RSNs can be reliably identified in FDG-PET data, we aimed to develop the first atlas of RSNs based on FDG-PET data. ***Materials and Methods:*** We analyzed data from cognitively healthy subjects derived from two independent sources: the Alzheimer's Disease Neuroimaging Initiative (ADNI) and a local institutional database. To ensure robust validation, the ADNI cohort was divided into two age- and sex-matched groups for replicability testing: Group 1 (n=61, age 67.0±3.0 years, mean±SD) and Group 2 (n=61, age 67.2±2.5 years). Group 3 (n=61, age 56.2±4.1 years) from our institutional database underwent repeated scanning to assess reproducibility. All PET data were available as one image per subject. Independent component analysis (ICA) with ICASSO stability analysis was conducted using the GIFT toolbox. The number of meaningful independent components (ICs), their replicability and reproducibility were evaluated using the Dice coefficient. RSNs with at least a fair Dice coefficient were considered to be qualified for the atlas. ***Results:*** Each of the four ICA analyses yielded 20-25 meaningful independent components. We successfully identified several well-established RSNs: cerebellar (replicability 0.86, reproducibility 0.89), primary visual (0.60, 0.81), sensorimotor (0.47, 0.54), posterior default mode (0.36, 0.84), central executive (0.58, 0.61), and basal ganglia (0.59, 0.53). Additionally, we identified several networks not previously established in the fMRI literature in their current form. They were named according to their anatomical distribution: medial prefrontal (0.74, 0.55), parieto-occipital (0.23, 0.55), and inferior temporal (0.48, 0.36). ***Conclusion:*** A number of RSNs could be identified in FDG-PET data in a replicable and reproducible manner. The spatial distribution of the canonical RSNs partially differed from those of fMRI atlases. Moreover, we found a few RSNs that have not been established by fMRI studies in this form so far, underscoring the complementary value of FDG-PET in mapping brain functional architecture. This novel atlas is being integrated into publicly available software, offering researchers and clinicians a new reference framework for brain connectivity analyses.

Aim/Introduction: Positron-emission-tomography (PET) imaging with the novel monoamine oxidase B (MAO-B) radiotracer [^{18}F] D2-Deprenyl ([^{18}F]F-DED) to detect reactive astrogliosis enables imaging of neuroinflammation/neurodegeneration in patients with autoimmune-encephalitis (AIE) and multiple system atrophy (MSA). This study investigated the use of short static time windows for [^{18}F]F-DED MAO-B-PET imaging of AIE and MSA. ***Materials and Methods:*** 20 patients with AIE and 20 patients with MSA, either Parkinsonian (MSA-P) or cerebellar subtype (MSA-C), with visual positive PET-signal and 17 controls (CTRL) were evaluated. [^{18}F]F-DED PET was performed by a dynamic 60-minute scan. Standardized uptake value ratios (SUVrs; cerebellar cortex as a reference tissue) of disease related target regions (i.e. mesial temporal lobe, posterior putamen, cerebellar deep white matter) were obtained 0-10, 10-20, 20-30, 30-40, 40-50 and 50-60 minutes p.i.. Additionally, quantification was performed with PMOD. Volume of distribution ratios (VTrs) via one-tissue-compartment model (1TC2k) with carotid image-derived input function and total distribution volume ratios (DVRs) via Logan plot were calculated using full scan durations (0-60 minutes p.i.). ***Results:*** 10 minutes intervals between 10-60 minutes p.i. indicated good image contrast and strong signal to noise ratio for [^{18}F]F-DED PET. Early imaging intervals between 0-10 and 10-20 minutes p.i. showed significantly lower SUVr compared to all later time windows for both AIE (all $p < 0.001$, Cohen's d: 0.6-2.9) and MSA lesions (all $p < 0.05$, Cohen's d: 0.5-1.8). Overall, SUVr as a function of imaging time tended to approach a plateau around 60 minutes p.i.. SUVrs of all time windows correlated significantly positive with DVRs for both AIE and MSA ($r = 0.72$-0.95, $p < 0.01$), except for SUVr 0-10 for MSA ($p = 0.09$). DVRs were significantly larger than VTrs for all groups (all $p < 0.01$) and correlated positively with each other ($r = 0.63$-0.97, $p < 0.01$). Temporomesial DVRs allowed a better discrimination between patients with AIE and controls compared

to VTrs (p = 0.017), whereas no advantage of putaminal DVRs over VTrs was detected for the comparison of MSA-P and controls (p = 0.16). ***Conclusion:*** Static images of [^{18}F]F-DED PET, even with only 10 minutes emission recording, deliver good image quality for detection of neuroinflammation in AIE and MSA. Late static scanning (30-60 minutes p.i.) offers the best balance between accuracy and economic scanning. DVR may offer an advantage over VTr for regions with low MAO-B expression (e.g. differentiation between patients and controls).

EP-0692

Individual-Level Connectivity Biomarker from Sparse Inverse Covariance Estimation in [18F]-FDG PET

M. Doyen[1], *S. Heyer*[2], *A. Verger*[3];
[1]*Nancyclotep / University of Lorraine, IADI INSERM U1254, Nancy, FRANCE,* [2]*CHRU Nancy, Nancy, FRANCE,* [3]*CHRU Nancy / University of Lorraine, IADI INSERM U1254, Nancy, FRANCE.*

Aim/Introduction: Connectivity analyses are increasingly utilized in PET imaging, though they are predominantly explored at the group level. This study aimed to develop an individual-level connectivity biomarker using Sparse Inverse Covariance Estimation (SICE) to distinguish between Alzheimer's disease (AD), mild cognitive impairment (MCI), and cognitively normal (CN) individuals as compared to classical semi-quantitative methods (Dementia Prognostic Index, DPI) or more traditional methods based on connectivity (Principal Component Analysis, PCA). ***Materials and Methods:*** A total of 763 subjects with brain [18F]-FDG PET scans were selected from the ADNI database (1): 195 AD (73.8±8.2 years), 378 MCI-AD patients (73.1±7.0 years), including 123 who converted to AD within two years and 190 CN (mean age 72.8±6.1 years). For each subject, three biomarkers were computed: i, a DPI based on the ratio of uptake in AD-hypometabolic regions to stable reference regions (2), ii, an individual metabolic covariance pattern expression derived using PCA (3), iii, an individual likelihood index of belonging to AD, MCI (± converters), or CN SICE-based connectivity matrices (4). Leave-one-out cross-validation was used for individual-level classification. Thresholds maximizing sensitivity and specificity were determined from ROC curve analyses to evaluate the diagnostic performance of the three methods. ***Results:*** Accuracy for discriminating AD from CN was 85% for both DPI and PCA, and 90% for SICE (SICE > DPI/PCA, p = 0.02). For MCI-AD vs. CN, accuracies were 67% (DPI), 64% (PCA), and 70% (SICE) (SICE > PCA, p < 0.01). For predicting MCI-AD conversion to dementia, accuracies were 66% (DPI), 57% (PCA), and 67% (SICE) (SICE and DPI > PCA, p < 0.01). Across all comparisons, diagnostic performance improved when DPI was combined with connectivity-based methods (p ≤ 0.02). ***Conclusion:*** Individual-level connectivity analysis, particularly via SICE, is feasible and provides complementary diagnostic value to conventional intensity-based metrics in [18F]-FDG PET imaging for suspected AD. Incorporating such methods into clinical practice could enhance early diagnosis and prognosis. ***References:*** 1.Data used were obtained from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database (adni.loni.usc.edu). 2.Torosyan N et al, Alzheimer'sDisease Neuroimaging Initiative. Aim/Introduction: The purpose of this study was to evaluate a novel glucose derivative SPECT imaging agent, ^{99m}Tc-CN7DG, and to compare ^{99m}Tc-CN7DG quantitative SPECT/CT with ^{18}F-FDG PET/CT in patients with intracranial space-occupying lesion. ***Materials and Methods:*** Five healthy volunteers were enrolled to assess the safety, biodistribution, dosimetry and optimal acquisition time of ^{99m}Tc-CN7DG. Subsequently, patients with pathologically confirmed intracranial space-occupying lesion were prospectively recruited. Each patient underwent ^{18}F-FDG PET/CT on the first day and ^{99m}Tc-CN7DG quantitative SPECT/CT on the second day. The number of ^{99m}Tc-CN7DG quantitative SPECT/CT versus ^{18}F-FDG PET/CT lesions detected and semi-quantitative parameters were compared using MR as the gold standard. ***Results:*** ^{99m}Tc-CN7DG was safe in humans, and the whole-body effective dose (5.24 × 10-3 mSv/MBq) was comparable to that of bone scan. Normal brain tissue did not take up the tracer and 2 hours after injection was the best time for SPECT imaging. 26 lesions from 11 patients were analysed. The number of lesions detected by ^{18}F-FDG PET/CT was significantly less than that by ^{99m}Tc-CN7DG quantitative SPECT/CT (12 vs. 23, P = 0.002), and with ^{99m}Tc-CN7DG quantitative SPECT/CT detected a comparable number of lesions as MR (23 vs. 26, P = 0.348). ^{99m}Tc-CN7DG quantitative SPECT/CT reduced the false-negative rate of ^{18}F-FDG PET/CT by 42.3% (sensitivity: 0.88 vs. 0.46, accuracy: 0.85 vs. 0.48). The max of lesion background ratio (LBRmax) and the mean of lesion background ratio (LBRmean) of ^{99m}Tc-CN7DG quantitative SPECT/CT were significantly higher than that of ^{18}F-FDG PET/CT (LBRmax: 10.87 ± 7.49 vs. 1.08 ± 0.41, LBRmean: 6.93 ± 7.44 vs. 1.0 ± 0.38, all P < 0.0001). SUVmax and LBRmax of ^{99m}Tc-CN7DG quantitative SPECT/CT and ^{18}F-FDG PET/CT were not related to lesion size (all r < 0.03 and P > 0.05). ***Conclusion:*** ^{99m}Tc-CN7DG is a safe and promising SPECT tracer for intracranial space-occupying lesion that reduces the false-negative rate due to intracranial lesions caused by ^{18}F-FDG hypermetabolism.

EP-0694

Evaluation of Structural-Functional Connectivity Coupling and Metabolism in Adolescent with Bipolar Disorder and Major Depression Disorder

S. Liu[1], *Y. Zhong*[1], *L. Liu*[2], *F. Hu*[1], *Y. Huo*[1], *J. Ma*[1], *Y. Zhang*[1], *C. Ma*[1], *E. Cong*[1];
[1]*Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA,* [2]*Central Research Institute, United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA.*

Aim/Introduction: Utilizing simultaneous PET/MR imaging to investigate the structural-functional connectivity (SC-FC) coupling and metabolic abnormalities in adolescents with bipolar disorder (BDD) and major depressive disorder (MDD). ***Materials and Methods:*** 14 participants with BDD (mean age, 14.29±1.62 years; 14 female, 0 male) and 14 with MDD (mearn age, 15±2 years; 10 female, 4 male) were enrolled. Group assignment was based on scores from the Hamilton Depression Rating Scale (HAMD) and Hypomania Checklist (HCL). The severity of the patient's suicidal thoughts and behavior were assessed using Columbia-Suicide Severity Rating Scale (C-SSRS). Simultaneous ^{18}F-FDG PET and MRI data were acquired using a hybrid 3.0-Tesla TOF-PET/MRI scanner. MRI sequences included 3D T1-weighted image, diffusion tensor imaging (DTI), and resting-state funtional MRI (fMRI). fMRI was used to construct functional connectivity (FC), and DTI was used to construct structural connectivity (SC). A multilinear regression model was used to predict FC from SC. The SC-FC coupling was

defined by the Pearson correlation coefficient between the predicted FC and the original FC. Cerebellar gray matter uptake value was used as the reference region to calculate cortex ratio standardized uptake value (SUVr) as a metabolic parameter. ***Results:*** Reduced SC-FC coupling and decreased FDG metabolism were observed in the BDD group, particularly in the thalamus ($p<0.01$). In the association analysis between SC-FC coupling and metabolism, the significantly related brain regions in the BDD group all showed a positive correlation ($p<0.05$, $r>0.58$), and in the MDD group, most significantly related brain regions showed negative correlation ($p<0.05$, $r<-0.60$). In the correlation analysis between SC-FC coupling and clinical metrics (HAMD, HCL, and C-SSRS), negative correlations for SC-FC coupling with HCL and C-SSRS were found in BDD group ($p<0.05$). In MDD group, SC-FC coupling of Hippocampus showed maximum correlation with C-SSRS ($p=0.0000$, $r=0.9582$). Receiver-operating characteristics (ROC) analysis showed SC-FC coupling features were better than metabolism features in distinguishing the BDD from MDD. ***Conclusion:*** BDD and MDD had different differential brain regions in SC-FC coupling and metabolism, with SC-FC coupling differential brain regions being more advantageous in discriminating between the groups, suggesting that the SC-FC coupling parameter has the potential to be a biomarker for differentiation. Second, the correlation analysis between SC-FC coupling and metabolism revealed divergent patterns between groups, suggesting distinct pathogenic mechanisms underlying BDD and MDD.

EP-0695

Structural-functional connectivity and metabolism analysis in adolescent depression with suicidal behavior

S. Liu[1], *Y. Zhong*[1], *L. Liu*[2], *Y. Huo*[1], *Y. Jiang*[1], *J. Ma*[1], *C. Ma*[1], *E. Cong*[1]; [1]*Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA,* [2]*Central Research Institute, United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA.*

Aim/Introduction: Current neuroimaging studies of adolescent depression predominantly focus on isolated imaging modalities, overlooking the potential role of aberrant interactions among brain structure, function, and metabolism in psychiatric disorders. This study aimed to characterize differences between suicidal and non-suicidal major depressive disorder (MDD) in adolescents by integrating structural-functional connectivity and metabolic situation. ***Materials and Methods:*** 9 participants with suicidal MDD (mean age, 14.33±1.83 years; 6 females, 3 males) and 10 with non-suicidal MDD (mean age, 14.70±1.49 years; 10 females, 0 male) were enrolled. Depressive symptoms were assessed using the Hamilton Depression Rating Scale (HAMD) and Hypomania Checklist (HCL). The suicidal behaviors were assessed using Columbia-Suicide Severity Rating Scale (C-SSRS). Simultaneous ^{18}F-FDG PET and MRI scans were performed on a hybrid 3.0-Tesla TOF-PET/MRI scanner. MRI sequences included 3D T1-weighted imaging, diffusion tensor imaging (DTI), and resting-state functional MRI (fMRI). Resting-state fMRI was used to construct functional connectivity (FC), and DTI was used to construct structural connectivity (SC). A multilinear regression model was used to predict FC from SC. The SC-FC coupling was defined by the Pearson correlation coefficient between the predicted FC and the original FC. Cerebellar gray matter uptake value was used as the reference region to calculate cortex ratio standardized uptake value (SUVr) as a metabolic parameter. ***Results:*** In suicidal MDD, SC-FC coupling was increased in superior frontal gyrus and decreased in inferior temporal gyrus compared with non-suicidal MDD ($p<0.01$). Metabolic differences were predominantly observed in the fusiform gyrus and occipital gyrus ($p<0.01$), with suicidal MDD patients exhibiting elevated metabolism in these regions. SC-FC coupling was strongly correlated with metabolic activity in the precentral gyrus, superior parietal lobule, and striatum in suicidal MDD ($p<0.01$, $|r|>0.87$) , and a similar association was observed in the superior parietal lobule in non-suicidal MDD. Suicide scores showed strong correlations with temporal lobe and thalamus SC-FC coupling values but differed sub-regional in both group ($p<0.05$,$|r|>0.72$). ***Conclusion:*** Suicidal and non-suicidal MDD had different differential brain regions in SC-FC coupling and metabolism, these differences may provide an opportunity to predict suicidal behavior in patients with MDD, support clinics in the management of patients better.

MRI-arterial spin labeling and FDG-PET reveal reduced whole brain perfusion and changes in regional glucose uptake in severe sustained hypoxia

H. Weis[1], *J. Hönemann*[2], *F. Hoffmann*[2], *L. DeBoni*[3], *L. Kessler*[4], *C. Rischpler*[5], *M. Schmitz*[6], *D. Elmenhorst*[7], *S. Beer*[7], *A. Drzezga*[1], *J. Jordan*[3], *J. Tank*[3], *U. Limper*[3]; [1]*Department of Nuclear Medicine, Faculty of Medicine and University Hospital of Cologne, Cologne, GERMANY,* [2]*Department of Internal Medicine III, Division of Cardiology, Pneumology, Angiology, and Intensive Care, University of Cologne, Cologne, GERMANY,* [3]*Institute of Aerospace Medicine, German Aerospace Center (DLR), Cologne, GERMANY,* [4]*Department of Nuclear Medicine, University Essen, Essen, GERMANY,* [5]*Department of Nuclear Medicine, Klinikum Stuttgart, Stuttgart, GERMANY,* [6]*Institute for Medical Biometry, Informatics and Epidemiology (IMBIE), University of Bonn, Bonn, GERMANY,* [7]*Institute of Neuroscience and Medicine (INM-2), Forschungszentrum Jülich, Jülich, GERMANY.*

Aim/Introduction: Previous studies suggest reduced arterial oxygen content at high altitude is compensated by increased cerebral blood flow and glucose uptake, resulting in an unchanged oxygen delivery [1]. Already in normoxia, the brain shows regional differences in oxidative metabolism which may be further intensified in hypoxia. We tested whether the adaptive mechanisms of the brain are preserved during severe sustained normobaric hypoxia. ***Materials and Methods:*** We included three men (55-64 yrs.) with fully revascularized myocardial infarction (MI) 49-126 months prior to study entry and one age-matched healthy man, each without signs or symptoms of neurological disease. After preacclimatization, we induced normobaric hypoxia in the hypoxic chamber at the DLR :envihab facility in Cologne, Germany by gradually adding nitrogen until alveolar oxygen partial pressure had reached about 35 mmHg. We maintained hypoxia for 14 consecutive days (FiO2=0.095) and nights (FiO2=0.105). We estimated cerebral perfusion by brain magnetic resonance (MRI) based arterial spin labeling (ASL), and cerebral glucose uptake by 18-FDG PET-MRI, at baseline, after 14 days of severe hypoxia, and after one months of recovery. We regularly assessed cognitive function. ***Results:*** In hypoxia, absolute whole brain perfusion decreased by 30±13% ($p=0.02$), resulting in approximately 25% reduced cerebral oxygen delivery. Values returned to baseline at recovery. Relative to the whole brain, perfusion decreased in the parietal lobes, occipital lobes, and precuneus and increased in temporal lobes, basal ganglia, insula, thalamus and hippocampus. Relative to the whole brain, glucose uptake responded concordantly but less pronounced. In contrast, in the posterior cingulum relative increased FDG uptake was accompanied by decreased perfusion. Changes were similar in MI-patients and the healthy control person. Reversible white matter hyperintensities appeared in hypoxia. Cognitive function remained unaffected. ***Conclusion:*** Severe sustained normobaric hypoxia paradoxically decreased whole brain perfusion and cerebral oxygen delivery in humans, which may have been compensated by augmented 0_2 extraction. Changes in glucose uptake and perfusion in parts of the default mode network may be a consequence of an even further reduction in oxidative metabolism. ***References:*** [1] Hoiland

RL, Bain AR, Rieger MG, Bailey DM, Ainslie PN. Hypoxemia, oxygen content, and the regulation of cerebral blood flow. Am J Physiol Regul Integr Comp Physiol. 2016 Mar 1;310(5):R398-413.

Metabolic Alterations in the Brain and Tumor Incidence of Patients with Long COVID: Insights from ^{18}F-FDG PET Imaging

Y. Wang[1], *M. Xin*[1], *H. Shao*[1], *Y. Zhang*[1], *X. Wu*[2], *J. Hao*[3], *J. Liu*[1], *C. Zhang*[1];
[1]*Department of Nuclear medicine; Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA,* [2]*Department of Respiratory medicine; Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA,* [3]*United Imaging Healthcare, Shanghai, CHINA.*

Aim/Introduction: Emerging evidence suggests neurological sequelae in COVID-19 survivors, yet comprehensive characterization of cerebral metabolic alterations remains limited. This study investigates regional glucose metabolism changes in post-COVID patients using ^{18}F-FDG PET imaging and explores their temporal dynamics. ***Materials and Methods:*** A retrospective analysis included 51 COVID-19 survivors (median age: 68 years; range: 15-93) who underwent ^{18}F-FDG PET-CT scans. Age- and sex-matched healthy controls (HCs) were used for comparison. Regional metabolic patterns were analyzed via SPM8 (cluster-level FWE-corrected, $p<0.05$) and NeuroQ software, excluding functionally susceptible regions (e.g., visual cortex, Broca's area). Subgroup analyses stratified patients into acute (≤1 month), subacute (2-3 months), and chronic (>3 months) phases. ***Results:*** Global metabolic patterns: Compared to HCs, patients exhibited widespread hypometabolism in frontal, temporal, parietal, and occipital lobes ($T = 3.17$-5.62, $p<0.001$) and hypermetabolism in cerebellum, pons, amygdala, and corpus callosum ($T = 3.17$-4.34, $p<0.001$). All patients (51/51) showed 1-31 abnormal metabolic regions across 47 brain areas. Cerebellar/vermis hypermetabolism (82.35%) and frontal hypometabolism (82.35%) predominated. The left medial frontal cortex demonstrated the highest hypometabolic sensitivity (93.33%) in chronic-phase patients. Cerebellar hypermetabolism prevalence declined from 88% (acute) to 73.33% (chronic). Frontal hypometabolism persisted across phases (acute: 80%, subacute: 90.91%, chronic: 100%). ***Conclusion:*** COVID-19 survivors display distinct spatiotemporal metabolic disturbances, marked by persistent frontal hypometabolism and dynamic cerebellar hypermetabolism. These findings suggest prolonged neuroinflammatory or neurodegenerative processes post-infection, highlighting potential biomarkers for long-term neurological monitoring and intervention.

[18F]fluorodeprenyl-D2 PET imaging as a new tool to detect disease activity in GAD65-Ab Autoimmune Encephalitis

J. S. Dorneich[1], *M. Zeinaki*[1], *L. Tagnin*[1], *L. Vogler*[1], *L. Sanzo*[1], *S. Lindner*[1], *R. A. Werner*[1], *G. N. Bischof*[2], *J. A. Gernert*[3], *T. Kümpfel*[3,4], *M. Kerschensteiner*[3,4,5], *E. Kaufmann*[6,7], *M. Brendel*[1,5], *F. Thaler*[3];
[1]*Department of Nuclear Medicine, University Hospital of Munich, Munich, GERMANY,* [2]*Life Molecular Imaging (LMI), R&D, Berlin, GERMANY,* [3]*Institute of Clinical Neuroimmunology, University Hospital, LMU Munich, Munich, GERMANY,* [4]*Biomedical Center, Faculty of Medicine, LMU Munich, Munich, GERMANY,* [5]*Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY,* [6]*Epilepsy Center, Department of Neurology, LMU University Hospital, Munich, GERMANY,* [7]*Department of Neurology, LMU University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Aim of this study is to evaluate the feasibility of [18F]fluorodeprenyl-D2 ([18F]F-DED) positron-emission-tomography (PET) imaging to detect local astrogliosis in autoimmune encephalitis (AIE) associated with antibodies (Abs) to glutamic acid decarboxylase 65 (GAD65) in a monocentric cohort. ***Materials and Methods:*** Dynamic [18F]F-DED PET scans (0-60 min) were obtained from n=22 GAD65-AIE patients, 3 of whom were re-examined during the disease course, and from n=8 healthy controls. The PET images were processed using the PET data analysis software PMOD. Volumes of distribution (VT) were determined using a one-tissue-compartment model (1TC2k) with a carotid image derived input function. Clinical phenotype and severity (mRS, cerebellar score, stiffness score), GAD65-Ab levels, levels of serum Neurofilament light chain (sNfL) as a marker for neuroaxonal damage as well as glial fibrillary acidic protein (GFAP) as a marker for astroglial reactivity were correlated with [18F]F-DED VT. ***Results:*** Patients with GAD65-AIE with different clinical phenotypes were included (temporal lobe epilepsy (TLE)/ limbic encephalitis (LE): n=14; stiff-person syndrome (SPS): n=4; cerebellar ataxia (CA): n=4; n=8 patients clinically exhibited an overlap of at least two of the above mentioned phenotypes) with a median age of 55 years and a median disease duration of 5 years at PET-imaging. 9/22 patients did not receive immunotherapy at the time of PET-imaging. [18F]F-DED VT was significantly increased in the mesiotemporal lobe ($p<0.001$), parahippocampal gyrus ($p<0.001$) and the cortex ($p=0.023$) in patients with GAD65-AIE compared to controls. The cerebellum showed a trend towards [18F]F-DED VT increase in the same contrast ($p=0.081$). Anatomical distribution of [18F]F-DED signals correlated with clinical phenotypes in patients with TLE/LE, showing predominance of [18F]F-DED VT in the mesiotemporal lobe, and patients with CA, showing increased cerebellar tracer uptake - both of which were associated with disease severity. Patients with SPS did not show increased [18F]F-DED signals. Furthermore, a tendency toward a positive correlation between the [18F]F-DED signal and the GFAP levels was observed ($r=0.392$, $p=0.119$). ***Conclusion:*** Dynamic [18F]F-DED PET imaging enables the detection of astroglial inflammatory changes in patients with GAD65-AIE. Regional [18F]F-DED uptake in patients with GAD65-AIE reflects disease phenotype and correlates with disease severity.

EP-0699

Assessment of ^{18}F-UCB-H as a biomarker in focal epilepsy

V. Pakula[1], *C. Vollmar*[2], *L. Bartos*[1], *J. S. Dorneich*[1], *N. Fearns*[2], *S. Lindner*[1], *A. Zwergal*[2], *G. Höglinger*[2], *R. Werner*[1], *J. Rémi*[2], *M. Brendel*[1], *J. Gnörich*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*Department of Neurology, LMU University Hospital, Munich, GERMANY.*

Aim/Introduction: Synaptic vesicle protein 2A (SV2A) is a universal marker of synaptic density. Recent advances in SV2A-targeted radiotracers have opened new windows into in-vivo synaptic imaging. We compared the SV2A ligand ^{18}F-UCB-H against the clinical gold standard ^{18}F-FDG-PET in patients with pharmaco-resistant, unilateral focal epilepsy to identify optimal imaging windows and post-processing filters for maximizal lesion contrast and diagnostic accuracy. ***Materials and Methods:*** Twenty-nine patients with unilateral focal epilepsy underwent both dynamic ^{18}F-UCB-H-PET (0-60 min) and static ^{18}F-FDG-PET (30-50 min). Of those twenty-nine patients, seven had had levetiracetam (LEV) or brivaracetam (BRV) and even though in some LEV and BRV were discontinued, the ^{18}F-UCB-H uptake was blocked. We extracted time-activity curves from 35 frames across cortical and subcortical regions, calculating Pearson correlation coefficients against ^{18}F-FDG uptake in each time frame. Furthermore, early (0-10 min) and late (30-60 min) ^{18}F-UCB-H images were directly compared to ^{18}F-FDG images. For lesion quantification, individual brains normalized to MNI space were flipped laterally; voxel-wise percentage differences between epileptogenic and contralateral healthy hemispheres were computed. Finally, we evaluated Gaussian smoothing kernels (0-20 mm FWHM) for minimizing background noise while preserving lesion volume and contrast. ***Results:*** In unaffected contralateral regions, late-phase ^{18}F-UCB-H-PET signals showed stronger concordance with ^{18}F-FDG-PET signals than early-phase: ($R=0.62$-0.69 vs. $R=0.49$-0.57) all $p<0.02$. Incremental smoothing up to 8-10 mm FWHM substantially reduced background noise in flipped ^{18}F-UCB-H images, with

only a modest decrease in lesion volume, yielding an optimal lesion-to-background ratio at 8 mm. Within epileptogenic foci, lesion intensity correlated significantly with both early (R=0.58, p=0.010) and late (R=0.48, p=0.036) ^{18}F-UCB-H versus FDG uptake. However, only early ^{18}F-UCB-H lesion volume correlated with FDG lesion volume (R=0.55, p=0.015), whereas late-phase volume did not (R=0.15, p=0.53). In line, ^{18}F-FDG and early ^{18}F-UCB-H-PET visually showed broad, diffuse hypometabolic areas around the epileptogenic zone, whereas late-phase ^{18}F-UCB-H-PET yields much sharper, high-contrast delineation of the lesion. In Patients taking LEV and BRV, ^{18}F-UCB-H will not give a sufficient signal, illustrating the high binding potential of LEV and BRV to the SV2A. ***Conclusion:*** ^{18}F-UCB-H-PET reliably mirrors metabolic patterns in the healthy contralateral hemisphere and, when optimally filtered, enhances lesion contrast in focal epilepsy. Early-phase ^{18}F-UCB-H captures the spatial extent of epileptogenic zones akin to perfusion deficits, while late-phase imaging more selectively reflects synaptic dysfunction. These dual-phase insights position ^{18}F-UCB-H SV2A-PET as a powerful adjunct to ^{18}F-FDG, offering broad lesion mapping and refined synaptic specificity for improved pre-surgical evaluation.

How sure can we be? - Graves' disease or Multi-nodular Goitre: Usefulness of isotope thyroid scan

A. Chamnan*, V. Pant, F. Naeem, S. Salam, L. Yeung, S. Vinjamuri;*
Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM.

Aim/Introduction: Hyperthyroidism could result from Graves' disease or multi or toxic nodular goitre which are the most common causes. The diagnosis is based on clinical, biochemical and imaging tests. With frequent diagnostic challenges to characterize the aetiology of the hyperthyroidism, a comprehensive approach is essential for accurate characterization including the use of radioactive iodine thyroid scans. ***Materials and Methods:*** A retrospective study involving 517 patients who were referred for a Tc-99m pertechnetate thyroid scan at the Royal Liverpool University Hospital between January 2022 and December 2023 (ages 16 to 92, M:F ratio 145:372). We tabulated and analyzed the initial clinical impressions at referral and the post-pertechnetate thyroid scan findings. ***Results:*** Out of the 517 patients, 194 were referred with possible Graves' disease, 171 with possible MNG, and 152 had non-specific referrals, simply indicating hyperthyroidism without specifying the cause. In 337 out of 365 cases (92.3%), the initial clinical impression aligned with the post-scan findings. This reflects a good clinical assessment based on the value of true positive cases. In 28 patients, the initial clinical assessment differed from the scan results—16 patients had Graves' disease, 6 had MNG, 2 had thyroiditis, and 4 had normal findings, contrary to the initial diagnosis. Among the 152 non-specific hyperthyroid patients, the majority were diagnosed with MNG (74), followed by Graves' disease (63), normal scan findings (10), and thyroiditis (5). ***Conclusion:*** To conclude, our study confirms the clinical value of isotope thyroid scans in the diagnostic evaluation of hyperthyroidism. Despite the fact that the initial clinical impression of the aetiology of hyperthyroidism is frequently accurate, this may need to be revised in a small proportion of patients after the scan, which can impact treatment options, including the choice of medication, surgery, or radioiodine therapy, as well as the appropriate dosage of radioiodine when applicable. We would like to encourage a larger study with different demographic population for better understanding the value of the isotope thyroid scan. ***References:***

EP-0701

Revisiting Piga's Criteria for Amiodarone-Induced Thyrotoxicosis Using ^{99m}Tc-Sestamibi Thyroid Scintigraphy: Interobserver Reproducibility and Semiquantitative Analysis

R. Sá e Silva*, J. Escaleira, L. Costa;*
Centro Hospitalar Universitário do Porto, Porto, PORTUGAL.

Aim/Introduction: Amiodarone-induced thyrotoxicosis (AIT) is a well-recognized adverse effect of amiodarone therapy. Piga's criteria classify AIT into 3 types based on the 99mTc-Sestamibi scintigraphic visual pattern: AIT Type 1, Type 2 and Indeterminate. This study aimed to assess the interobserver agreement of AIT classification using Piga's criteria and to explore the utility of semiquantitative analysis. ***Materials and Methods:*** Retrospective, observational study including 21 patients treated with amiodarone (> 3 months), who presented with thyrotoxicosis not attributable to other known causes and that underwent ^{99m}Tc-Sestamibi scintigraphy acquired 10 minutes after radiotracer injection. Two independent observers visually classified each scan according to Piga's criteria: AIT Type 1 (increased uptake), Type 2 (low uptake), or Indeterminate. Interobserver agreement was assessed using Cohen's Kappa coefficient. A semiquantitative analysis (only concordant cases) was performed using regions of interest(ROIs) in the thyroid, upper skull region, and mediastinum (Figure 1). Thyroid-to-skull (TSR) and thyroid-to-mediastinum (TMR) ratios were estimated using both mean and maximum counts. ***Results:*** Observers agreed in 16 of 21 cases (76%), indicating substantial agreement (Cohen's Kappa 0.63; Table I). Among concordant cases, significant differences were found only in the maximum count TMR(p=.026), with higher values in AIT1 compared to AIT2 (p=.020), aligning with the visual pattern (intense vs. reduced uptake). Indeterminate AIT cases didn't display intermediate ratio values; instead, their quantitative parameters often fell below those of AIT2, challenging the assumption that this category represents a visual midpoint (Table II).All observed classification discrepancies occurred between AIT1 and Indeterminate (14%) or AIT2 and Indeterminate(10%)- never between AIT1 and AIT2- highlighting the visual ambiguity and heterogeneity of the Indeterminate group. Discordant cases often showed semiquantitative values that fell between or outside the observed ranges for concordant AIT1 and AIT2 maximum count TMRs, suggesting a potential role for semiquantitative parameters in reducing classification subjectivity. ***Conclusion:*** This study supports the moderate-to-high reproducibility of Piga's visual classification for AIT and identifies maximum count TMR as a promising parameter to support subtype differentiation, especially between AIT1 and AIT2. However, the Indeterminate group remains heterogeneous and poorly defined, both visually and quantitatively. The lack of clear diagnostic resolution, compounded by the fact that clinicians often initiate empirical "cocktail" therapy (e.g., glucocorticoids, antithyroid drugs) without obtaining definitive histological or cytological confirmation, limits the ability to validate imaging-based classification. Prospective studies with larger cohorts and standardized diagnostic confirmation are needed to refine Piga's criteria and validate semi-quantitative thresholds using 99mTc-Sestamibi scintigraphy.

EP-0702

SUVmax utility in parathyroid scintigraphy

M. Kocemba, *M. Tulik, J. Kunikowska;*
Medical University of Warsaw, Warsaw, POLAND.

Aim/Introduction: Hyperparathyroidism is a disease characterized by overproduction of parathormone with clinical manifestation as osteoporosis, renal failure and kidney stones. The only effective form of therapy is surgical parathyroidectomy, which requires localization of the lesions, usually in [^{99m}Tc]Tc-MIBI dual-phase scintigraphy. The aim of this study was to evaluate the use of standardised uptake value (SUV) in parathyroid scintigraphy. ***Materials and Methods:*** This retrospective study included 19 examination performed in 5 men and 14 women (age 19-82, median 65), with clinical and biochemical signs of primary hyperparathyroidism. Serum levels of parathormone, phosphates and calcium were recorded. Dual-phase planar and early and late SPECT/CT examinations after intravenous administration of 600MBq [^{99m}Tc]Tc-MIBI scans were performed between February 2023 and March 2024 on Siemens Intevo Bold. Volumes of parathyroid lesions were measured using postoperative specimen diameters and the ellipsoid formula**.** SUVmax was calculated for each parathyroid lesion following PET/CT protocols. Thyroid SUVmax was also measure idependently for central area of each lobe. Washout percentage was calculated as (late SPECT SUVmax / early SUVmax) x 100% for each lesion and thyroid lobe. Pearson correlation assessed relationships between variables. ***Results:*** Median serum blood level of parathormone, calcium and phosphates were 167 pg/ml(range 78.1-1065), 2.77 mmol/l (range 2.14-3.09) and 0.71 mmol/l (range 0.39-1.25), respectively. Fifteen out of 19 scans were considered positive in initial visual assessment. All patients underwent surgical parathyroidectomy up to 3 months after imaging; histopathology confirmed 17 parathyroid adenomas and 2 parathyroid hyperplasia. Median lesion volume was 0.75 ml (range 0.03-2.73) for positive SPECT/CT examinations and 0.67 ml (range 0.2-1.13) for negative examination; no significant difference was found due to small sample size. Median value of SUVmax for parathyroid adenomas were 5.0 (range 2-11.4) and 2.2 (range 0.8-8.1) for early and late SPECT/CT examinations respectively. For both patients with parathyroid hyperplasia early SUVmax value was 6.3, while late SUVmax values were 4.1 and 2.9. In all patients with adenomas, difference in washout level between thyroid gland and parathyroid lesions was 15.8% (95% CI 9%-22%), statistically significant ($p<0.01$). Early and late SUVmax showed moderate positive correlation ($p<0.05$) with volume of parathyroid lesion ($r=0.42$ and $r=0.6$) and weak negative correlation with calcium serum blood level ($r=-0.35$ and $r=-0.26$). ***Conclusion:*** Parathyroid SUVmax appears to be a promising parameter for the preoperative diagnosis of parathyroid glands. The study needs to be continued and confirmed on a larger group of patients.

EP-0703

Inter-reader Agreement and additive benefit of SPECT or SPECT/CT modality with [^{99m}Tc]Tc-Pertechnetate Scintigraphy Imaging for the Assessment of incidental Thyroid Nodules in a tertiary care center

E. Novruzov, *K. Julian, K. Mattes-György, D. Schmitt, M. Muchalla, M. Schott, C. Antke, F. L. Giesel, E. Mamlins;*
University Hospital Düsseldorf, Düsseldorf, GERMANY.

Aim/Introduction: In central Europe, up to 76% of population exhibit thyroid nodules (TN). The combination of ultrasound findings and thyroid scan imaging are supposed to ensure a cost-effective and reliable prediction of malignancy risk. However, real-world impact of ultrasound findings, i.e. TI-RADS, has raised concerns due to its highly limited reliability and reproducibility. The recent advancements and increasing access of SPECT/CT scanners might contribute to thyroid management. This study aimed to elucidate additive value of SPECT(-CT) imaging in initial evaluation of complex TN cases, particularly on multinodular goiter and difficult-to-characterize solitary nodules. ***Materials and Methods:*** A total of 61 patients (19 males and 42 females with a mean age of 56 (± 17)) with incidental TN were retrospectively enrolled in this study between November 2022 and July 2023, who underwent both conventional planar thyroid scan and SPECT(-CT) imaging. 3 readers with varying experience level selected a target nodule within thyroid gland and evaluated its functionality, ACR TI-RADS categorization and additive benefit of SPECT(-/CT) imaging. Kappa-value for inter-reader agreement (IRA) was interpreted as follows: < 0.01-0.20, slight agreement; 0.21-0.40, fair agreement; 0.41-0.60, moderate agreement; 0.61-0.80, substantial agreement; and 0.81-1.00; almost perfect agreement. ***Results:*** Of the target TNs, 33 (54%) were located in the left thyroid lobe, 5 (8%) in the isthmus and the remaining target TNs (38%) in the right lobe. The median target TN size was 20 mm (10 -59). The target nodule match rate among readers was almost perfect (kappa value 0.81; 95% CI: 0.72 - 0.90). The IRA regarding ACR TI-RADS was moderate with k-value of 0.47 (95% CI: 0.40 - 0.54). The IRA regarding patient referral was substantial among readers with k-value of 0.60, while k-value was even higher at pairwise comparison of experienced readers (k-value: 0.64). IRA regarding the target TN functionality among readers was good with k-value of 0.68 (95%CI: 0.59 - 0.77). IRA involving the less experienced reader revealed only slightly lower reliability scores, i.e. a k-value of 0.61. The correlation with ground truth results revealed comparable results among experienced and less-experienced readers. ***Conclusion:*** Increasing clinical experience of physicians appeared to have a direct correlation with a higher referral rate of SPECT(-CT) imaging, although the additive clinical benefit was only evident for a minority of patients. Hence, SPECT(-CT) imaging might be more suitable for tertiary care centers, as its additive benefit at primary care level would have only negligible effect for patients.

EP-0704

From Image to Outcome: Optimizing [I-131] Therapy in Hyperthyroidism Using Scintigraphic Patterns in Our Experience

S. Alvarez, *G. Mera, E. Ardila, V. Castillo, S. Salcedo, M. Casallas, I. Gomez, J. C. Alonso;*
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: To analyze the outcome of [I-131] treatment for hyperthyroidism at our institution, taking into account the different thyroid scintigraphy patterns as well as TSH and free T4 / T3 blood levels. ***Materials and Methods:*** 102 hyperthyroid patients who underwent radioiodine [I-131] treatment after performing a thyroid scintigraphy were selected. Of those, 67 were checked through two follow-up blood tests and clinical examination, success was considered if either hypothyroidism or euthyroidism was achieved. The dose of [I-131] varied from 7 to 20 mCi, and it was calculated by an empirical fixed ranged based mainly on the goiter size and scintigraphy imaging pattern . The 1st and 2nd follow-up blood tests were taken in a mean of 2.4 months and 6.2 months respectively. ***Results:*** Mean age of 67 patients was 57.1 years old, with a female predominance of 74.6% (50 females and 17 males). The results were divided in 3 groups based on the scintigraphy imaging pattern in Graves' disease (GD), toxic adenoma (TA), and toxic multinodular goitre (TMG). For GD patients, a mean dose of 9mCi was used obtaining a success rate of 74.1% (of which 85% were hypothyroidism and 15% euthyroidism). For TA patients, the mean dose was 12mCi, with a 83.3% success rate (40% hypothyroidism and 60% euthyroidism). Lastly, mean dose used on TMG was 16.7mCi, achieving a success rate of 84.8% (39.3% hypothyroidism and 60.7% euthyroidism). 2 patients, 1TMG and 1TA, were treated with a second [I-131] dose achieving euthyroidism and hypothyroidism respectively. ***Conclusion:*** This study indicates that radioiodine [I-131] therapy

is an effective treatment for hyperthyroidism, with overall success rates of 79% .Treatment outcomes varied depending on the underlying etiology. TMG and TA showed slightly higher success rates (84.8% and 83.3%, respectively) compared to GD (74.1%). Notably, GD patients more frequently developed post-treatment hypothyroidism.The imaging pattern on thyroid scintigraphy, in combination with pre-treatment, TSH, free T4, and free T3 levels, proved to be useful in guiding empirical dosing strategies and predicting therapeutic outcomes.

EP-0705

Effectiveness of 18F-Fluorocholine PET/CT (18F-FCH PET/CT) in the Localization of Multiglandular Disease (MGD) in Patients with Hyperparathyroidism.

P. Portilla Merino[1], *C. Lancha Hernández*[2], *L. Giraldo Gonzalez*[1], *J. Otero Gonzalez*[1], *M. Coronado Poggio*[1], *S. Rizkallal Monzon*[1], *J. Cordero*[1], *L. Domínguez Gadea*[1];
[1]*Hospital La Paz, Madrid, SPAIN,* [2]*Hospital La Paz, Hospital Univeristario La Paz, SPAIN.*

Aim/Introduction: The aim of this study was to evaluate the utility of 18F-FCH PET/CT in the preoperative localization of multiglandular disease (MGD) in patients diagnosed with hyperparathyroidism. ***Materials and Methods:*** This retrospective study analyzed data from 159 patients who underwent 18F-FCH PET/CT between April 2019 and June 2024. Among them, 9 patients with MGD were selected based on surgery or 18F-FCH PET/CT results. Clinical, biochemical, and 18F-FCH PET/CT data, as well as preoperative, postoperative, and follow-up data, were collected.18F-FCH PET/CT was considered positive for MGD when two pathological glands were visualized and histologically confirmed; negative when only a single gland was involved, confirmed by pathology and/or clinical follow-up. The mean follow-up time after surgery was 29.5 ± 14.15 months. ***Results:*** The mean age of the patients was 58.55 ± 11.21 years, with 67% females and 33% males. 89% of the patients had primary hyperparathyroidism, while 11% had secondary hyperparathyroidism (due to chronic kidney disease). The average preoperative PTH value was 214.4 (range: 86.7 to 716). All patients met surgical criteria.Of the 9 patients with MGD, 15 glands were removed, all confirmed as adenomas. 3 patients (33.3%) demonstrated MGD (double adenoma) on 18F-FCH PET/CT, which was confirmed histologically (6 glands resected). These cases were considered true positives.3 patients (33.3%) initially underwent surgery for a single adenoma detected by 18F-FCH PET/CT but continued to show elevated postoperative PTH levels. This led to the resection of a second pathological gland during exploration, which ultimately normalized their PTH levels (6 glands resected). These cases were classified as false negatives for double parathyroid adenoma.3 patients (33.3%) had two suspected adenomas on PET/CT; however, after resection of one gland, PTH normalized (3 glands resected). These cases were considered false positives for double parathyroid adenoma. 18F-FCH PET/CT showed a sensitivity of 50% and specificity of 98.04% (153 negatives studies).Gland location: 40% right superior, 33% left superior, 13% left inferior, 7% right inferior, 7% intrathyroidal.Mean postoperative PTH drop: 74.4% ± 9.At follow-up, 89% (8p) had normalized PTH and calcium; 1 CKD patient (11%) showed marked PTH improvement (716 → 144), despite receiving a glandular autoimplant in the forearm. ***Conclusion:*** 18F-fluorocholine PET/CT is useful for localizing double parathyroid adenomas in patients with hyperparathyroidism, although its diagnostic performance is lower compared to single-gland disease.

EP-0706

A study on the construction of a nomogram for predicting the postoperative outcome of unilateral primary aldosteronism based on ^{68}Ga-Pentixafor PET/CT imaging targeting CXCR4

Y. Jin[1], *Y. Yang*[1], *Y. Yang*[1], *J. Yang*[1], *T. Long*[1], *S. Hu*[1,2,3];
[1]*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [2]*Department of Dermatology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [3]*Department of Oncology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA.*

Aim/Introduction: Primary aldosteronism (PA) is a clinical syndrome characterized by hypertension with or without hypokalemia. It has a large patient base and can easily cause damage to target organs such as the heart, brain, and kidneys. Unilateral PA(UPA) is primarily treated with surgery, but more than half of the patients continue to suffer from hypertension after the operation. Therefore, predicting the postoperative efficacy of UPA can help doctors and patients make treatment decisions and identify patients who need close follow-up. This study aims to construct a nomogram model based on the clinical data of UPA patients and ^{68}Ga-Pentixafor PET/CT data targeting CXCR4 to predict the postoperative efficacy of UPA, thereby providing precise guidance for treatment decisions and patient follow-up management. ***Materials and Methods:*** A retrospective analysis was conducted on patients with UPA who underwent surgery at Xiangya Hospital of Central South University from November 2021 to April 2024. Preoperative CXCR4 data, clinical indicators, and 6-month postoperative follow-up data were collected. Patients were divided into clinical cure and non-cure groups based on their postoperative blood pressure status. Univariate and multivariate logistic regression analyses were performed using R language to construct a nomogram prediction model. The predictive performance and clinical applicability of the model were evaluated using ROC curves (AUC), calibration curves, and decision curves. ***Results:*** A total of 93 patients with unilateral PA were included, of whom 53 (57%) achieved clinical cure and 39 (43%) did not. The final factors included in the nomogram were age, SULmax,creatinine,aldosterone/renin ratio (ARR), duration of hypertension, and estimated glomerular filtration rate (eGFR). The AUC of the model in the training and validation sets were 0.71 and 0.76, respectively, with a sensitivity of 0.68-0.64 and a specificity of 0.77-0.62. The calibration curve showed good consistency between predicted and actual results, and the decision curve confirmed the clinical net benefit of the model. ***Conclusion:*** The nomogram constructed based on ^{68}Ga-Pentixafor PET/CT imaging targeting CXCR4 can effectively predict the postoperative blood pressure outcome of UPA patients, providing a quantitative basis for individualized treatment decisions and postoperative management.

EP-0707

Tc99m-pertechnetate thyroid imaging on a 3D-ring CZT-based SPECT/CT system is a superior alternative to conventional thyroid scintigraphy

A. Harteveld, *A. van de Burgt, M. Segbers, F. A. Verburg;
Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: Two-dimensional (2D) planar thyroid scintigraphy using a single or dual detector-head gamma camera systems with scintillation-based detectors is the standard clinical practice. However, uptake in overlapping structures as well as attenuation of photons by overlying tissue limits interpretation. The recent introduction of 12-headed ring-shaped cadmium-zinc-telluride (CZT) based single-photon emission computed tomography/computed tomography (SPECT/CT) systems enables three-dimensional (3D) SPECT imaging with similar acquisition times to conventional planar scintigraphy due to the higher sensitivity and energy resolution [1]. This study evaluated thyroid

scintigraphy using a 3D-CZT ring system through phantom experiments and scanning the same patient on both scanners. ***Materials and Methods:*** Phantom experiments: utilized a custom thyroid phantom including hot and cold spots filled with 0.11 MBq/mL (3.6 MBq in a volume of 33 mL water; assuming ~2% uptake of 180 MBq in patients) Tc99m-pertechnetate and scanned on a 3D-CZT ring SPECT/CT scanner. A 20-minute SPECT acquisition was performed with/without Focus mode. Retrospective 5, 10, 15 minutes SPECT reconstructions were made from list-mode data. All SPECT reconstructions were performed using the manufacturer recommended protocol. Recovery coefficients (RCs) were calculated for a CT-based volume-of-interest of a cold region. Dual patient scans: involved three patients referred for Tc99m-pertechnetate thyroid exams. After informed consent, patients underwent 10-minute planar imaging on a conventional gamma camera and 10-minute SPECT/CT with Focus mode and low-dose CT for localization and attenuation correction on a 3D-CZT system. Scans were performed 20 minutes after injection of 180 MBq (range 178-197) Tc99m-pertechnetate. Two experienced nuclear medicine physicians rated the images. ***Results:*** Phantom images with 20-minute acquisitions showed good quality and clear distinction of hot and cold regions. Reducing acquisition time to 5 minutes did not significantly affect image quality. Cold spot RCs ranged from 0.816-0.819 and 0.930-0.934 between the different acquisition times with non-Focus and Focus mode, respectively. Focus mode also showed visually greatly improved recovery of the cold regions compared to non-focused acquisitions. The patient scans demonstrated that 3D-CZT images were rated equal to or better than conventional 2D planar images. Additionally, 3D imaging combined with CT-based anatomical details provided significant added diagnostic value with findings missed on planar scintigraphy. ***Conclusion:*** Preliminary results showed that thyroid Tc99m-pertechnetate imaging using the 3D-CZT ring system with Focus mode and factory SPECT reconstruction parameters achieves superior image quality compared to current 2D planar protocols and offers additional diagnostic information while maintaining similar acquisition times. ***References:*** [1] Zorz et al. EJNMMI Physics 2024.

Radioguided Occult Lesion Localization (R.O.L.L.) Technique for Minimal Invasive Parathyroidectomy (M.I.P.). Our Experience

M. Fornito[1], *G. Giordano*[2], *M. Trovato*[3], *M. Iago*[1], *S. Fiorino*[1], *F. Stracuzzi*[1];
[1]*ARNAS GARIBALDI CATANIA Nuclear Medicine - PET/TC center dep., Catania, ITALY,* [2]*ARNAS GARIBALDI CATANIA Interventional radiology, Catania, ITALY,* [3]*ARNAS GARIBALDI CATANIA Oncological Surgery, Catania, ITALY.*

Aim/Introduction: Radio-guided occult lesion localization (R.O.L.L.) is a localization technique, originally described for non-palpable breast lesions, based on the direct injection of radioactive particles such as Tc-99m-labeled albumin (MAA) into the lesion guided by monitoring methods (US/CT) to accurately identify and localize parathyroid lesions that may be difficult to detect through conventional method and during surgery. M.I.P. constitutes one of the main surgical approaches for the patient with primary hyperparathyroidism (PHPT) especially in complicated case as ectopic/atypical site of adenoma, small adenomas, recurrences or precedent neck surgery. This study assesses the efficacy of R.O.L.L. in facilitating M.I.P. and investigating the technical feasibility, effectiveness and safety as an adjuvant method in surgical excision of parathyroid adenoma. ***Materials and Methods:*** We analysed clinical outcomes from a cohort of ten patients with PHPT due to a singular adenoma documented by MIBISPET/CT, undergoing parathyroidectomy with R.O.L.L., focusing on localization success rate, operative and hospitalization time and post-operative complications. Four patients had previously undergone thyroid/parathyroid surgery; three had ectopic/atypical site parathyroid adenoma; three wanted minimal invasive surgery for aesthetic reasons. ^{99m}Tc-MAA was administered in the pathological parathyroid gland under US-guidance in eight patients and under CT-guidance in two ectopic adenoma. All of the injected lesions were located over the skin with Gamma camera imaging. During the surgery, parathyroid adenomas were searched for and identified with an intraoperative gamma probe that easily guided the surgeon to the target lesions. ***Results:*** Mean operation time (from incision to excision of the adenoma) was 29 ± 8 min. Serum intraoperative parathyroid hormone (PTH) levels measured before incision and 20 min after excision of adenoma decreased over 50%. All intraoperative histopathologic examination confirmed the presence of parathyroid tissue. ***Conclusion:*** Our findings demonstrate that ROLL-MIP significantly enhances the detection of ectopic or small parathyroid adenoma, especially in case of previous neck surgery, leading to improved surgical precision and reduced invasiveness. It also shortens operative and anaesthesia time and hospitalization time (no longer than 1 day) and hospital costs and not impair the intra- e post-operative histopathologic examination of the parathyroid glands allowing immediate verification of parathyroid adenoma removal. Additionally, patients experienced shorter recovery time and lower rates of complication compared to traditional approaches. Overall, the ROLL-MIP technique represent a valuable advancement in the surgical management of hyperparathyroidism, promoting more effective and less invasive options. ***References:*** Saizl.B. et al Radio-guided procedure in minimally invasive surgery for primary hyperparathyroidism. 2023 Cir Esp.

EP-0709

Assessment of oral [^{18}F]FDG administration for examining gastrointestinal glucose uptake, biodistribution and dynamic glucose metabolism using total-body PET/CT.

M. Brogaard[1], *P. Cramon*[1], *T. Andersen*[1], *U. Lindberg*[1], *F. Andersen*[1], *J. Brittain*[1], *M. Sørensen*[2], *C. Nguyen*[2], *H. Larsson*[1], *J. Madsen*[1], *I. Law*[1], *L. Gasbjerg*[1];
[1]*Rigshospitalet, 2100 Copenhagen, DENMARK,* [2]*Nuklearmedicin, Rigshospitalet, Copenhagen, DENMARK.*

Aim/Introduction: This study investigates oral administration of 2-[18F]fluoro-2-deoxy-D-glucose ([^{18}F]FDG) as a method for assessing gastrointestinal glucose uptake, dynamic glucose metabolism, and the biodistribution of glucose in all organs using total-body positron emission tomography (PET)/computed tomography (CT). Additionally, we evaluate the possibility of incorporating an oral glucose tolerance test (OGTT) to provide more comprehensive understanding of glucose metabolism in healthy controls. We compare the dynamics and distribution of orally versus intravenously (i.v) administered [^{18}F]FDG and examine how the OGTT may enhance the assessment of dynamic glucose metabolism. ***Materials and Methods:*** Four healthy participants (three women and one man, aged 20-27 years) underwent three separate total-body PET/CT scans (Biograph Vision Quadra, Siemens Healthineers, Erlangen, German), A-C. Another four healthy participants are enrolled with scheduled scans in May-June, 2025. Participants completed a food diary for two days leading up to the scan and consumed a minimum of 150 g of carbohydrates on the day before the scan. Scan A was preceded by intravenous administration of [^{18}F]FDG. Scans B and C were preceded by oral administration of [^{18}F]FDG, which was encapsulated in a gelatine capsule and ingested with a maximum of 100 mL of water. During scan C, the participants also underwent a 75 g-oral glucose tolerance test (250 ml). During all scans, glucose levels were monitored, and blood samples were collected at 15-minute intervals to measure glucagon, insulin, glucose-dependent insulinotropic polypeptide, and glucagon-

like peptide-1. The PET/CT scans were conducted over a 2-hour period started immediately after [18F]FDG administration, followed by a 60-minute break and finished with a 10-minute scan at 3 hours. ***Results:*** Eight oral gelatine capsules were produced with activity levels ranging from 47-56 megabecqurel. All capsules were ingested orally within few minutes after release from the radiochemistry. All scans (A-C) resulted in usable PET/CT data showing the distribution of [18F]FDG to all expected tissues of the body. Furthermore, during oral glucose ingestion (scan C), gastric [18F]FDG retention, slower uptake [18F]FDG and higher blood glucose levels were observed. ***Conclusion:*** This study demonstrated that [18F]FDG capsules ingested orally can be used to assess the biodistribution of [18F]FDG. As expected, we observed gastric [18F]FDG retention, slower [18F]FDG uptake and increased blood glucose levels following oral glucose ingestion.

EP-0710

Semiquantitative analysis of ^{18}F-FCH PET/CT in the Dual-Time-Point protocol in patients with primary hyperparathyroidism

E. Campaña Díaz[1], *P. García-Talavera San Miguel*[1], *F. Gómez-Caminero López*[1], *J. Álvarez Pérez*[1], *C. Montes Fuentes*[1], *E. Martin Gallardo*[2], *J. Badell Martínez*[1], *S. Rama Alonso*[1], *A. Peñaherrera Cepeda*[1], *J. Villanueva Curto*[1], *F. Caltagirone*[1], *B. Santos García*[1], *M. Tamayo Alonso*[1], *M. Martín Gómez*[1];
[1]*Hospital Universitario de Salamanca, Salamanca, SPAIN,*
[2]*Professor at UCIII y UPComillas, Madrid, SPAIN.*

Aim/Introduction: To evaluate the difference in parathyroid visualization on ^{18}F-FCH PET/CT images obtained at 5 and 60 min. To analyze through semi-quantitative analysis, the uptake at different time points of parathyroid glands, lymph nodes, and thyroid nodules. ***Materials and Methods:*** We included 74 patients (59 females; 60.11±12.82 years) in whom ^{18}F-FCH PET/CT was performed for pre-surgical localization of PHPT. Standard ^{18}F-FCH images were acquired 5 and 60 minutes after 185 MBq intravenous administration. Early and delayed images were assessed semiquantitatively by means of calculation of SUVmax and SUVpeak of pathological parathyroid (P-SUVmax, P-SUVpeak), thyroid gland SUVpeak (T-SUVpeak), mediastinum SUVpeak (M-SUVpeak), lymph nodes (N-SUVmax, N-SUVmean) and thyroid nodules (NT-SUVmax, NT-SUVmean). SUV ratios were calculated with thyroid and mediastinum. The diagnostic performance of the ^{18}F-FCH PET/CT to discriminate pathological parathyroid gland vs lymph node and thyroid nodule was evaluated by analysis of the receiver operating characteristic (ROC) curve analyzing P-SUVpeak/M-SUVpeak vs N-SUVpeak/M-SUVpeak, P-SUVmax/T-SUVpeak vs NT-SUVmax/T-SUVpeak. ***Results:*** The ROC curve of PET/CT quantitative parameters for the diagnosis of HPT and lesions showed that the P-SUVpeak/M-SUVpeak vs N-SUVpeak/M-SUVpeak ratios and P-SUVmax/T-SUVpeak vs NT-SUVmax/T-SUVpeak ratios for 60 min imaging has a higher accuracy compared to the 5 min imaging. The AUC for P-SUVpeak/M-SUVpeak vs N-SUVpeak/M-SUVpeak was 0.7 in the early images (sensitivity 67% and specificity 72%) and 0.8 in delayed (sensitivity 69% and specificity 85%), and for P-SUVmax/T-SUVpeak vs NT-SUVmax/T-SUVpeak 0.7 in the early images (sensitivity 65% and specificity 60%) and 0.8 in delayed (sensitivity 65% and specificity 87%). PET/CT quantitative parameters can distinguish parathyroid adenoma, lymph nodes and thyroid nodules. ***Conclusion:*** Semiquantitative parameters in PET/CT at 60 min have more advantages in assisting the pathological diagnosis and clinical treatment of HPT.

EP-0711

Early-phase [^{18}F]Fluorethyltyrosine positron emission tomography for localisation of corticotroph pituitary adenomas in Cushing's disease

F. Völter, *J. R. O. L. Schweizer, I. Stüfchen, A. Bollenbacher, E. Nowak, K. Ritzel, J. Thorsteinsdottir, M. Theodoropoulou, M. Reincke, N. L. Albert;*
Ludwig-Maximilian-Universität, Munich, GERMANY.

Aim/Introduction: The preoperative localisation of ACTH-producing pituitary adenomas remains challenging. Magnetic resonance imaging and inferior petrosal sinus sampling correctly localise up to three of four ACTH-producing adenomas. Unclear preoperative findings of ACTH-producing pituitary adenomas often result in extended resection areas and postoperative pituitary insufficiency. We therefore aimed to evaluate the potential of [^{18}F]Fluorethyltyrosine positron emission tomography ([^{18}F]FET PET) in localising ACTH-producing pituitary adenomas in patients with first diagnosis and with recurrent Cushing's disease. ***Materials and Methods:*** [18F]FET PET/CT was conducted in 24 patients with Cushing's disease, 14 patients with a primary diagnosis, 9 patients with recurrent disease and 1 patient with Cyclic Cushing's syndrome. Dynamic PET images were acquired 0-40 min after injection with a mean injected dose of 166 MBq. Maximal tumor-to-background ratios (TBRmax) were determined comparing maximum standardized uptake values of pituitary adenomas to mean standardized uptake values of the right frontal and temporal lobe. Numeric values were reported with median (interquartile range). ***Results:*** In all 24 patients, a focal radioligand uptake was noted in the intrasellar region (median TBRmax 6.8 (6.0-8.2)) with a mean maximum uptake during the first minute post injection. At the time of imaging, the median ACTH was 59.0 pg/mL (40.0-112), the median cortisol was 14.4 µg/dL (7.7-26.9). Eleven of the 24 patients were receiving adrenostatic therapy at the time of imaging. 10/14 patients with a first diagnosis of Cushing's disease underwent transsphenoidal surgery until April 2025. 3 patients are still awaiting surgery, 1 patient refused surgery. In all operated patients, the focal intrasellar hotspot was consistent with the histopathologically proven ACTH-producing adenoma. All operated patients showed a postoperative remission with a median basal ACTH of 7.0 pg/mL (4.0 - 10.5) and cortisol of 1.1 µg/dL (0.6 - 2.8). No patient experienced a postoperative anterior pituitary insufficiency. ***Conclusion:*** Functional imaging with [^{18}F]FET PET can be effective in localising ACTH-producing pituitary adenomas and can add valuable information to MRI and inferior petrosal sinus sampling.

EP-0712

Metabolic imaging of brown adipose tissue in female patients treated for obesity with tirzepatide

L. Lezaic[1], *R. Herman*[2], *U. Begus*[1], *S. Rep*[1], *I. Slodnjak*[1], *B. Trebec Lukman*[1], *M. Jensterle Sever*[2], *A. Janez*[2];
[1]*University Medical Centre Ljubljana, Division of Nuclear Medicine, Ljubljana, SLOVENIA,* [2]*University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, SLOVENIA.*

Aim/Introduction: Obesity is a common, chronic and relapsing disease with multifactorial etiology. Recently, potent incretin-based therapies have been successfully introduced into the pharmacological treatment of the condition. Pharmacodynamic mechanisms of action include reduced hunger and delayed gastric emptying, while there is no solid evidence for the purported mechanisms of increase in energy expenditure. In this context, emerging data suggest that brown adipose tissue (BAT) may represent a promising therapeutic target. The aim of the study is to assess BAT changes during obesity treatment with the dual GIP/GLP-1 agonist tirzepatide, to identify factors influencing these changes and to develop optimal BAT imaging protocol for obesity

research. ***Materials and Methods:*** Forty female patients with an indication for pharmacological treatment of obesity per EASO guidelines underwent controlled 1-hour hypothermia according to previously determined appropriate threshold for BAT activation (cooling vest, controlled vest and room temperature), after which 0,8 MBq/kg of [^{18}F]FDG was injected. Cooling was continued for further 1-hour period and during PET/CT acquisition (skull base - upper mediastinum). Metabolic activity (SUVmax, SUV mean), volume and total glycolitic activity (TGA) of the BAT was assessed per CT-based segmentation. Patient body mass index (BMI), age, blood glucose and vest temperature were compared according to presence or absence of activated BAT by a non-parametric test (p<0,05 considered for statistical significance). ***Results:*** At the time of analysis, 30 patients completed enrollment. In 10 patients, BAT was detected on PET/CT imaging (SUVmax 5,4±1,5; SUVmean 2,2±0,3; volume 51,8±34,9 ml; TGA 122±87,4 g). No significant difference (p=NS) was found for patient age (38,3±5,6 vs 41±8,0 years), BMI (35,5±3,7 vs 37,6±3,8), blood glucose (5,6±0,3 vs 5,4±0,6 mmol/L) and vest temperature (10,2±2,0 vs 9,9±1,9°C) between activated and non-activated BAT. ***Conclusion:*** BAT was activated in one third of patients; at the time of analysis no included physiological parameters were found to predict the BAT activation. After completed enrollment, patients will undergo randomization and reevaluation (including repeated imaging) for a placebo-controlled study to determine the role of BAT in treatment of obesity with tirzepatide.

EP-0713

Diagnostic value of [^{18}F]FET PET/CT in patients with negative or inconclusive MR imaging for pituitary neuroendocrine tumours

L. Lezaic[1], *A. Kunst*[1], *K. Surlan Popovic*[2], *T. Kocjan*[3], *R. Bosnjak*[4], *S. Rep*[1];
[1]*University Medical Centre Ljubljana, Division of Nuclear Medicine, Ljubljana, SLOVENIA,* [2]*University Medical Centre Ljubljana, Institute of Radiology, Ljubljana, SLOVENIA,* [3]*University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, SLOVENIA,* [4]*University Medical Centre Ljubljana, Department of Neurosurgery, Ljubljana, SLOVENIA.*

Aim/Introduction: Accurate localization of pituitary neuroendocrine tumours (pitNET) aids significantly in surgery planning and adds to diagnostic certainty, in particular when MRI as an imaging modality of choice is negative or inconclusive. Recently, PET imaging with [^{18}F]fluoroethylthyrosine (FET) was introduced for molecular imaging of pitNET in this setting, but is performed typically on PET/MR equipment to enable optimal fusion of molecular and structural imaging modality of choice with the additional benefit of improved spatial resolution of modern PET detectors. The aim of this study was to evaluate diagnostic performance of conventional PET/CT imaging in this setting. ***Materials and Methods:*** Patients with known or suspected de novo or residual pitNET and negative or inconclusive MRI examination were referred for [^{18}F]FET PET/CT by the multidisciplinary team. After a 4-hour fast, patients were injected with [^{18}F]FET (2 MBq/kg body weight); after 20 minutes, a 20-minute acquisition of the head was performed. PET reconstruction was optimized for small lesion imaging using an appropriate in-line pixel size matrix, time-of-flight and point-spread-function optimization per vendor-specific algorithm; low-dose CT parameters were not altered (120 kEv, 35 mAs, vendor-specific dose reduction algorithm). Results of [^{18}F]FET PET/CT were correlated to MRI findings, postoperative histology and biochemistry 6-month follow-up. ***Results:*** Twelve patients (10 female) were enrolled: 4 with de novo pitNET (2 ACTH-, 2 GH-secreting), 8 after prior surgery for pitNET (4 ACTH-, 4 GH-secreting). [^{18}F]FET PET/CT was positive in 7/12 patients (6 ACTH-, 1 GH-secreting). Six patients with positive findings underwent surgery (5 ACTH-, 1 GH-secreting); histology was positive in 4 (all ACTH-secreting). On follow-up, 3 patients were considered cured (2 still completing follow-up) and persistence of hormone oversecretion was found in the remaining 3 patients. ***Conclusion:*** [^{18}F]FET PET/CT is a useful molecular imaging method in patients with de novo or residual pitNET and negative or inconclusive MRI findings. Diagnostic performance is comparable to one performed on dedicated PET/MR equipment.

EP-0714

Assessing the value of [^{99m}Tc]Tc-MIBI/ Na[^{99m}Tc]TcO4 SPECT/CT in parathyroid imaging - a new approach on the dual-tracer method

A. Dyczka*, A. Aulich, Z. Adamczewski;*
Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: The current standard method in hyperfunctioning parathyroid glands imaging is the combination of [^{99m}Tc]Tc-MIBI SPECT/CT and cervical ultrasonography (cUS). However, [^{99m}Tc]Tc-MIBI scintigraphy has certain limitations, particularly in the presence of thyroid nodules, whereas cUS is strongly dependent on physician's experience. Alternative imaging techniques may be beneficial. These include dual-tracer subtraction scintigraphy with [^{99m}Tc]Tc-MIBI and Na[^{123}I]I performed in one-day protocol. Though, this technique adds additional radiation exposure to the thyroid and is more expensive. The aim of this study is to evaluate the usefulness of performing additional Na[^{99m}Tc]TcO4 SPECT/CT after standard combination of [^{99m}Tc]Tc-MIBI SPECT/CT and cUS in order to improve the efficiency of detecting parathyroid adenomas and/or hyperplasia in inconclusive cases. ***Materials and Methods:*** We retrospectively analysed 52 patients (44 female, 8 male) who underwent parathyroid scintigraphy at the Nuclear Medicine Department Medical University of Lodz between 2022 and 2024. The study consists of patients, in whose cases [^{99m}Tc]Tc-MIBI SPECT/CT in combination with cUS did not provide a clear outcome confirming or excluding the presence of hyperactive parathyroid glands. The patients underwent additional 111MBq Na[^{99m}Tc]TcO4 SPECT/CT imaging at least 24 hours after [^{99m}Tc]Tc-MIBI SPECT/CT. Radiotracer accumulation in both studies was then compared visually, using localization CT to correctly superimpose the scintigraphic images. ***Results:*** Out of 52 patients included in the study, 38 had positive scintigraphy results: 28 patients had a confirmed diagnosis of singular adenoma or multiglandular disease and in one case parathyroid cancer, 5 patients did not qualify for surgery due to comorbidities. At present, it has not been possible to determine the further course of action for the 5 remaining patients 14 out of 52 patients had negative scintigraphy results: 7 patients had either biopsy or further imaging confirming our results, 4 patients had cUS suggesting hyperfunctioning parathyroid glands, which did not appear in SPECT/CT probably due to limited spatial resolution, 3 patients underwent surgery with post-operative diagnosis of hyperfunctioning parathyroid glands. ***Conclusion:*** This study demonstrates that additional Na[^{99m}Tc]TcO4 SPECT/CT can be valuable in patients with inconclusive results in [^{99m}Tc]Tc-MIBI SPECT/CT (evaluated in combination with cUS) both to confirm and exclude the presence of hyperfunctioning parathyroid glands. It offers lower radiation exposure compared with Na[^{123}I]I scintigraphy and is more cost-effective. This method not only allows for determining the exact location of the parathyroid glands, which can lead to minimally invasive parathyroidectomy but also reduces the risk of false-positive results.

EP-0715

Concordance Between I-123/Tc-99m Sestamibi Subtraction SPECT/CT and Histopathology in Localizing Single Parathyroid Adenomas

A. Hassan, *A. W. Alessi, E. Wahab, S. J. Hughes;*
Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: Accurate preoperative localization of parathyroid adenomas has shifted the surgical paradigm from conventional four-gland exploration to focused, minimally invasive parathyroidectomy. Functional imaging plays a critical role in enabling this transition by guiding targeted surgical approaches.[1, 2] I-123/Tc-99m sestamibi subtraction SPECT/CT is among the most widely adopted modalities for this purpose, offering improved spatial resolution and anatomical correlation over traditional planar scintigraphy.[3] This study evaluates the diagnostic accuracy of I-123/Tc-99m sestamibi subtraction SPECT/CT in localizing single parathyroid adenomas, using histopathological confirmation and surgical findings. ***Materials and Methods:*** This single-institution retrospective cohort study reviewed 72 consecutive patients who underwent preoperative I-123/Tc-99m sestamibi subtraction SPECT/CT and parathyroidectomy between January 2012 and October 2024. Only patients with histopathologically confirmed parathyroid adenomas were included. Imaging results were compared to intraoperative findings and histology to assess concordance. Sensitivity, positive predictive value (PPV), and overall diagnostic accuracy were calculated. Preoperative and postoperative serum calcium and parathyroid hormone (PTH) levels were compared to evaluate surgical efficacy. The true positive group was defined as patients with positive imaging and histologically confirmed adenomas; the false negative group was defined as patients with negative imaging but positive histology. ***Results:*** Of 72 patients, 59 were true positives and 13 were false negatives. The sensitivity of SPECT/CT in localizing parathyroid adenomas was 82%, with a PPV of 92% and an diagnostic accuracy of 77%. The median weight of resected glands in the true positive group was 0.5 g (range, 0.2-1.6 g), while the false negative group had a mean weight of 0.7 g (range, 0.2-1.7 g). Surgical efficacy was achieved in 97% of patients. Median serum calcium levels decreased from 2.8 mmol/L preoperatively to 2.4 mmol/L postoperatively ($p < 0.0001$), and median PTH levels declined from 13.8 to 4.0 pmol/L ($p < 0.0001$), confirming surgical efficacy. ***Conclusion:*** I-123/Tc-99m sestamibi subtraction SPECT/CT demonstrates high sensitivity and positive predictive value in preoperative localization of single parathyroid adenomas, even for low-weight lesions. The observed improvement in biochemical markers further supports its clinical utility in managing primary hyperparathyroidism through targeted surgery. ***References:*** [1] Cheung et al. A meta-analysis of preoperative localization techniques for patients with primary hyperparathyroidism. Ann Surg Oncol. 2012;19(2):577-83. https://doi.org/10.1245/s10434-011-2009-1 [2] Rodgers et al. EP-0716

New insights into malignancy risk in trapping-only versus hypofunctioning nodules

L. Sobral Torres, *R. Nunes, J. Maria Veloso Trevisan, R. Albergueiro, A. Oliveira, P. Soeiro;*
Unidade Local de Saúde São João, Porto, PORTUGAL.

Aim/Introduction: Thyroid scintigraphy with Na[^{131}I]I and Na[^{99m}Tc]TcO_4 remains fundamental for evaluating the functional status of thyroid nodules. Hypofunctioning nodules—demonstrating reduced uptake of both tracers—are associated with a higher malignancy risk. Trapping-only nodules, characterized by increased Na[^{99m}Tc]TcO_4 uptake but reduced Na[^{131}I]I uptake, have also been proposed to carry malignant potential, although likely lower than that of hypofunctioning nodules. This study aims to compare malignancy rates between trapping-only and hypofunctioning nodules. ***Materials and Methods:*** A single-center retrospective observational study was conducted, including adult patients who underwent thyroid scintigraphy between January 2020 and June 2024. Patients were included if there was evidence on scintigraphy of trapping-only or hypofunctioning nodules corresponding to a nodule on ultrasound. Patients were excluded if cytological or histopathological analysis was not available. Demographic, biochemical and clinical data were collected, including thyroid medication use, ultrasound findings and results of fine-needle aspiration cytology (FNAC) and/or histopathological analysis following surgery. A descriptive analysis was performed using boxplots for numerical variables and contingency tables for categorical variables. ***Results:*** Eighty patients were included: 36 with trapping-only nodules and 44 with hypofunctioning nodules. In the trapping-only group, 64% were female (mean age: 59±13 years) and 75% had subclinical hyperthyroidism. The main cause was multinodular toxic goiter (70%), followed by Graves' disease (19%). The average nodule size was 22±10 mm. Using ACR-TIRADS, 50% were classified as TIRADS 3, 39% TIRADS 4, and 11% TIRADS 2. Radioiodine uptake average was 41±16%. Most nodules (97%) were benign and one nodule (3%) was suspicious and confirmed as a hyalinizing trabecular tumor, a low-risk follicular cell-derived neoplasm. In the hypofunctioning group, 86% were female (mean age: 61±13 years) and 95% had subclinical hyperthyroidism. Multinodular toxic goiter accounted for 89% and Graves' disease for 9%. The average nodule size was 29±10 mm. Using ACR-TIRADS, 70% were classified as TIRADS 3, 28% TIRADS 4, and 2% TIRADS 5. Radioiodine uptake average was 44±15%. Benign pathology was found in 91%, borderline lesions (NIFTP) in 7%, and malignancy (papillary carcinoma) in 2%. ***Conclusion:*** Our analysis shows similar malignancy risk for trapping-only nodules and hypofunctioning ones, thereby justifying an equivalent clinical approach.

EP-0717

Preoperative localisation of hyperfunctioning parathyroids: Scintigraphy or 4D Computed Tomography?

O. Silva, *I. Ferreira, S. Carmona, A. I. Santos;*
Hospital Garcia de Orta, Almada, PORTUGAL.

Aim/Introduction: Accurate identification of hyperfunctioning parathyroid glands is essential before surgical treatment. The most widely used imaging modality is parathyroid scintigraphy (combined with cervical ultrasonography), but four-dimensional computed tomography (4D CT) has emerged. We aimed to compare the results of parathyroid scintigraphy and 4D CT in our institution. ***Materials and Methods:*** A retrospective study was conducted on patients with a diagnosis of hyperparathyroidism. Between January 2019 and April 2025, all patients underwent dual-phase parathyroid scintigraphy with [^{99m}Tc]Tc-Sestamibi (and when necessary, additional thyroid scintigraphy with Na[^{99m}Tc]TcO_4 was performed) and 4D CT. Patients who underwent the two imaging tests more than one year apart and had a variation in PTH levels equal to or greater than 10% were excluded. For each exam, the number of hyperfunction parathyroid glands and their localisation were analysed, as well as the outcome of surgery (when applicable). Statistical analysis was performed using IBM SPSS Statistics, Version 30.0. ***Results:*** A total of 26 patients were included, of whom 21(80.8%) were women. The mean age at the time of parathyroid scintigraphy was 62(±13.5)years. The time interval between the two imaging exams had a median of 174[P25:52;P75:330]days, and the difference in PTH levels showed a median of 3.5%[P25:0.0;P75:14.85%].Ten(38.5%) of the

parathyroid scintigraphies performed were negative, 10 identified one hyperfunctioning gland (one in an ectopic location), and 6(23%) identified two or more hyperfunctioning glands. Regarding the 4D CT scans, 5(19.2%) were negative, 14(53.9%) identified only one parathyroid gland (including one ectopic gland), and 7(26.9%) identified two or more hyperfunctioning glands. Concordance between scintigraphy and 4D CT findings was observed in 17(65.4%) patients. A significant correlation was found between the results of parathyroid scintigraphy and 4D CT (Pearson Chi-Square: p<0.001).Among the 10(38.5%) patients who underwent surgery, parathyroid scintigraphy findings were concordant with histopathological results in 6 cases (60%), while 4D CT findings showed concordance in 7(70%) cases. ***Conclusion:*** Although 4D CT identified more hyperfunction parathyroid glands, parathyroid scintigraphy with [^{99m}Tc]Tc-MIBI demonstrated a significant correlation with 4D CT results in the preoperative localisation of hyperfunctioning parathyroid glands and has the added value of allowing radioguided minimally invasive surgery. It also provides a lower radiation dose (on average, 5-8 mSv for scintigraphy and 10-20 mSv for 4D CT, according to literature).Further prospective studies with larger cohorts and comparison with PET/CT with [^{18}F]fluorocholine are warranted, to better define the role of each modality in preoperative imaging and surgical outcomes.

EP-0718

Incidence of Hypothyroidism Following Radioactive Iodine Therapy in Patients with Single Toxic Thyroid Nodules and evaluation of possible predictive factors.

H. Al-JNABI, *T. Ball, I. Mitra, J. Philips, E. Sanverdi, A. Wren, A. DEDE, A. Meanhout;*
Chelsea and Westminster NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: This study aimed to evaluate the incidence of hypothyroidism in patients who received radioactive iodine (RAI) therapy for single toxic (hot) thyroid nodule and to investigate the impact of a series of factors on the likelihood of development of post-treatment hypothyroidism at 6 months. ***Materials and Methods:*** A retrospective cohort analysis was conducted using patient data collected at Chelsea and Westminster Hospital NHS Foundation Trust. Data were obtained from 43 eligible patients for the period between 2011 and 2024. Each patient had a thyroid uptake scan and TSH measurement performed within the 6 months prior to RAI treatment.Patients diagnosed with a single toxic thyroid nodule were included; patients with thyroid cancer or >1 hot nodules were excluded. I-131 administered for therapy was in the range 400 - 835 MBq, with mean dose 485 MBq.Factors evaluated for correlation to the likelihood of hypothyroidism at 6 months post-therapy were: gender, age, TSH level prior to treatment, I-131 activity administered, largest nodule diameter, uptake of radiotracer in the thyroid gland, and ratio of uptake of radiotracer in the hot nodule to the uptake in the remaining thyroid. Uptake rates were derived from Tc-99m thyroid uptake scans with scanning 20 minutes post injection. ***Results:*** Of 43 patients, 15 developed hypothyroidism at 6 months, of whom 3 exhibited transient hypothyroidism. 27 of the patients were euthyroid at 6 months; one of these later developed hypothyroidism more than 12 months after RAI therapy. 1 patient remained hyperthyroid therefore was excluded from statistical analysis as an outlier.No statistical correlation was found between the incidence of hypothyroidism at 6 months and age, gender, TSH level, administered RAI dose, largest nodule diameter, or overall thyroid uptake.A significant difference was found in the hot nodule to remaining thyroid uptake ratio in patients with hypothyroidism at 6 months compared to the euthyroid subgroup ($p < 0.05$, with means of 81.2% and 68.1% respectively). ***Conclusion:*** 15/43 (34%) of patients developed hypothyroidism at 6 months post RAI treatment for toxic nodule. Those patients had an overall higher ratio of tracer uptake in the hot nodule to the uptake in the remaining thyroid when compared to the euthyroid subgroup, which may serve as a potential predictor for the RAI therapy outcomes in the patient group with single toxic nodule.

EP-0719

Parathyroid multitracer CZT SPECT/CT with Tc-99m MIBI and I-123 NaI for simultaneous imaging of parathyroid adenomas and thyroid tissue

D. Heute, *J. D. Heute, A. J. Heute;*
Nuklearmedizin Telfs GmbH, Telfs, AUSTRIA.

Aim/Introduction: CZT SPECT/CT offers high spatial resolution, which may be crucial in detecting parathyroid adenomas. Furthermore these new systems make simultaneous multitracer aquisitions possible. We combinded Tc99m-MIBI, a wellknown tracer to image parathyroid adenomas, with I-123 NaI to localize thyroid tissue. The purpose of our study was to evaluate the use of a novel solid state SPECT/CT general purpose gamma camera (VeritonCT) in the diagnostic workup for patients with suspected parathyroid adenomas. ***Materials and Methods:*** We investigated 19 patients (15 female and 4 male) with elevated or borderline high PTH and Calcium showing a mean PTH of 113 pg/ml (57 to 225, SD 40 pg/ml) and mean calcium of 2,69 mmol/l (2.35 to 3.09, SD 0.18 mmol/l). The patients had been referred to our institution for routine parathyroid investigations. After giving consent each of them receivend an intraveneous injection of a mean dose of 9 MBq I-123 NaI and 237 MBq 99m-Tc-MIBI. Images were taken with a solid state 360° SPECT/CT scanner (VeritonCT 200) 15 and 120 minutes after tracerinjection. Focal uptake of iodine and MIBI was compared and a mismatch was regarded to be suspicious for parathyroid adenoma.The SPECT/CT findings were compared with high resolution ultrasound images being acquired on GE LOGIQ Fortis. Sonographically the maximal diameter of the suspected nodules ranged from 6 to 32 mm with a mean of 15.2 mm (SD 6.2 mm). Based on these results patients were referred to endocrine specialists for further treatment, four of them have undergone surgery, already. ***Results:*** Multitracer SPECT/CT with Tc-99m MIBI and I-123 is feasible in routine workup of patients suspected of parathyroid adenoma. In our group 16 of the 19 nodules showing a typical mismatch between MIBI and iodine uptake correlating with a typical features for parathyroid adenoma in ultrasound. In all of the four patients having undergone surgery, already, parathyroid adenomas were histologically proven. Three nodules positive in SPECT/CT could not be visualized by ultrasound because of unfavourable position: one small retrotracheal and two retroclavicular nodules, still one retroclavicular nodule was positive in histology. SPECT/CT with I-123 NaI and Tc-99m MIBI using a CZT full ring camera has shown to be helpful in localizing even small parathyroid adenomas. ***Conclusion:*** Doubletracer CZT SPECT/CT seems to be a valuable tool in localizing parathyroid adenomas. This new technique may become a reasonable alternative in routine nuclear medicine, especially if choline PET/CT is not available.

EP-0721

Correlation between biochemical parameters and quantitative indices on Ga68 DOTANOC PET/CT for localising the source of Cushing's Syndrome- A Retrospective SingleCentre Analysis

N. Kundu, *D. Khan, S. Sagar, A. Mahalik, A. Roy, R. Kumar;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Functional imaging with Ga68-labelled somatostatin analogue (SSA) PET/CT complements anatomical modalities when the source of adrenocorticotropichormone (ACTH) excess is unclear. Semiquantitative PET indices may mirror hormonal activity and help discriminate a pituitary from an ectopic origin. We analysed our centre'sexperience

to relate basal ACTH levels to lesion and pituitary metabolic metrics derived from Ga68 DOTANOC PET/CT. ***Materials and Methods:*** The departmental database was screened for patients with biochemically proven Cushing's syndrome who had undergone baseline Ga68 DOTANOC PET/CT and had ACTH documented prior to imaging. Thirtythree children and adults (19 males,14 females) fulfilled these criteria. Regions of interest were drawn around the dominantlesion and normal pituitary to obtain maximum SUV (SUVmax), SSTR expressing tumour volume (STV) and totallesion SSTR expression (TLS). Patients were dichotomised as pituitary (n = 6) or ectopic (n = 27) according to final multidisciplinary consensus. Groupcomparisons used the MannWhitney Utest; associations were explored with Spearman ρ. ***Results:*** Source distribution: Of the 27 ectopic cases, lung primaries were most frequent (hilar/lobar/bronchial = 10), followed by thyroid medullary carcinoma (n = 4), bulky adrenal disease (n = 2), duodenal and omental neuroendocrine tumours (n = 2 each) and other thoracic or abdominal masses (n ≤ 2 each). ACTH concentrations were more than twice as high in ectopic than in pituitary Cushing's (median 184.5 vs 85.0 pg mL^{-1}; p =0.01). Ectopic lesions showed significantly higher STV (median 2.30 vs 1.09 cm^3; p = 0.01) but modestly lower SUVmax compared withpituitary adenomas. Within the whole cohort, ACTH correlated moderately with lesion SUVmax (ρ = +0.47). Pituitary metabolic indices were consistently lower in ectopic Cushing's than in pituitary disease (median SUVmax 3.65 vs 6.45). ***Conclusion:*** Ga68 DOTANOC PET/CT semiquantitative parameters echo underlying endocrinology. Elevated ACTH paired with suppressed pituitary uptake and comparatively lowtomoderate lesion SUV favours an ectopic source, whereas high pituitary SUVmax with smaller STV supports a pituitary adenoma. These objective metrics, drawn solely from the present dataset, may expedite localisation and streamlinemanagement algorithms for Cushing's syndrome. Prospective validation in larger cohorts is warranted to establish clinically actionable cutoff values.

EP-0722

Dual-isotope subtraction scintigraphy and SPECT-CT for preoperative localization of parathyroid adenomas: A diagnostic study

P. Udholm, *C. Eriksen, S. d'Este, P. Bach-Mortensen, S. Møller;*
Hvidovre Hospital, Region Hovedstaden, Hvidovre, DENMARK.

Aim/Introduction: Primary hyperparathyroidism (PHPT) is often caused by a parathyroid adenoma (PTA). Subtraction scintigraphy with ^{123}I and ^{99m}Tc -MIBI SPECT-CT, and neck ultrasound examination as a hybrid scan (HS) can be used to localize the PTA in order to promote minimally invasive surgery. This study evaluated patients referred for HS, the ability of the HS to correctly localize PTA(s), as well as the diagnostic performance of HS. ***Materials and Methods:*** Data was retrieved for 300 patients referred for HS from 2019-2023. We used Begg and Greenes' correction method to calculate diagnostic accuracy as well as calculated percentage of adenoma(s) correctly localized per patient who underwent PTX or bilateral neck exploration (BNE). ***Results:*** In 282 patients with PHPT undergoing HS for PTA localization, the HS was positive in 71 %. Only 65 % of these patients were referred to PTX. Using correction methods, we found a sensitivity and specificity of the HS of 73 % and 78 %, respectively. The positive predictive value was 99 %, while the negative predictive value was 9 %. The HS correctly localized PTA in 90% of the patients. Scintigraphy correctly localized 86 % of the PTAs, SPECT-CT 85 %, and ultrasound 76 %. ***Conclusion:*** A positive HS was very likely to localize the PTA correctly, whereas a negative HS had limited diagnostic value. Surprisingly, a large proportion of patients undergoing HS were never considered for surgery, resulting in partial reference bias in the evaluation of the diagnostic accuracy.

EP-0723

The Role of Ga-68 DOTA-Pentixafor PET/CT Imaging in the Diagnosis of Benign Functional Adrenal Cortical Masses: Preliminary Results

Ö. Sahin[1], *Z. Tosunoğlu*[1], *A. E. Öztürk*[1], *E. Akgün*[1], *G. Alçın*[1], *T. F. Çermik*[2], *E. Arslan*[1];
[1]*Istanbul Training and Research Hospital, Nuclear Medicine Clinic, Istanbul, TÜRKIYE,* [2]*Acibadem Maslak Hospital, Nuclear Medicine Department, Istanbul, TÜRKIYE.*

Aim/Introduction: Conventional imaging modalities and ^{18}F-FDG PET/CT often lack sufficient specificity in evaluating the functional characteristics of benign adrenal lesions. CT and MRI provide structural evaluation but lack functional information. Adrenal venous sampling (AVS) is gold standard for distinguishing unilateral aldosterone-producing adenomas (APA) from bilateral hyperplasia. Ga-68 DOTA-Pentixafor binds specifically to CXCR4, allowing for high-sensitivity imaging of adrenal cortical lesions. Study evaluates the efficacy of Ga-68 DOTA-Pentixafor PET/CT determining functional status lesion lateralization. ***Materials and Methods:*** Included patients suspected of benign functional adrenal masses; 6 aldosterone-secreting,18 cortisol-secreting, 1 suspected ectopic ACTH syndrome Patients underwent ^{18}F-FDG PET/CT, Ga-68 DOTA-Pentixafor PET/CT in same week. SUVmax, lesion-contralateral adrenal (LKR), lesion-liver SUVmax ratio (LKCR) measured. Correlations aldosterone and cortisol levels, lesion size, and Hounsfield Unit (HU) analyzed. ***Results:*** 6 Primary Aldosteronism (PA)SUVmax showed a strong positive correlation with aldosterone levels (r:1, p:0.003), moderate positive correlation with lesion size (r:0.759, p:0.080), and weak negative correlation with HU (r:-0.067, p:1).LKR showed a strong positive correlation with aldosterone (r:0.828, p:0.022) and moderate correlation with lesion size (r:0.643, p:0.080), but no significant correlation with HU.LKCR showed a strong positive correlation with aldosterone (r:0.733, p:0.056), moderate positive correlation with lesion size (r:0.690, p:0.056), and a negative correlation with HU (r:-0.333, p:0.469). 5 Cushing SyndromeSUVmax showed weak negative correlations with cortisol levels (r:-0.400, p:0.483) and lesion size (r:-0.200, p:0.817), with no relationship to HU.LKR showed a moderate negative correlation with cortisol (r:-0.600, p:0.233) and lesion size (r:-0.400, p:0.483), with a weak positive correlation with HU (r:0.200, p:0.817).LKCR showed a weak positive correlation with cortisol (r:0.200, p:0.817), no significant correlation with lesion size (r=0, p=1), and a weak positive correlation with HU (r:0.200, p:0.817)**.** Imaging Findings: Ga-68 DOTA-Pentixafor PET/CT identified a unilateral focal uptake in all 6 PAAmong 18 CS, 3 unilateral, while 2 distinct bilateral uptake.Two CS underwent surgery, pathology confirming Ga-68 DOTA-Pentixafor PET/CT findings.One suspected EAS underwent adenectomy and bilateral adrenalectomy, negative CT/MRI results. Ga-68 DOTA-Pentixafor PET/CT and ^{18}F-FDG PET/CT revealed a suspicious focal uptake in the left adrenal region.Follow-up ongoing. ***Conclusion:*** Preliminary results suggest that Ga-68 DOTA-Pentixafor PET/CT successfully localized lesions in PA, CS, and EAS that were not identified with conventional imaging or ^{18}F-FDG PET/CT. This technique may contribute significantly to surgical decision-making. For PA and CS without definitive functional assessment, SUVmax, LKR, and LKCR may serve diagnostic criteria. However, postoperative tissue diagnosis and clinical follow-up are necessary for definitive conclusions. The study is ongoing.

EP-0724

The effect of thyroid hormone medication on radioiodine-131 bio-kinetics in solitary toxic thyroid nodules

C. Happel, *B. Bockisch, D. Groener;*
University Medical Center Frankfurt; Clinic for Radiology and Nuclear Medicine; Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Radioiodine-131 treatment (RIT) is a well-established therapeutic option in solitary toxic thyroid nodules (STN). The required therapeutic activity depends on individual intra-therapeutic effective half-life (EHL) and has to

be determined in a radioiodine uptake test (RIUT). In order to suppress radioiodine-131 uptake in healthy thyroid tissue an additional suppressive medication with triiodthyronine (T3) or tetraiodthyronine (T4) may be required. Aim of this retrospective analysis was to quantify the influence of suppressive medication on intra-therapeutic effective half-life (EHL). ***Materials and Methods:*** A total of 928 patients with STN undergoing RIUT and RIT was subdivided into three groups and analysed retrospectively. Group A: T3 medication (n=274), group B: T4 medication (n=184) and group C: no additional medication (n=470). The subgroups A and B were further subdivided depending on the dose of hormone medication. The influence of hormone medication on EHL was evaluated by calculation of the variance of the determined individual EHL between RIUT and RIT within the single groups and within the subgroups. ***Results:*** Intra-therapeutic EHL was significantly reduced in subgroups A and B when compared to EHL in RIUT. Group A: 5.9 ± 1.1 d in RIUT and 3.3 ± 1.4 d in RIT (-43 %) (p<0,05); Group B: 5.9 ± 1.2 d in RIUT and 3.4 ±1.5 d in RIT (-42 %) (p<0,05). The reduction of EHL between the subgroups A and B did not differ statistically. Both subgroups A and B showed a highly significant difference compared to subgroup C (p<<0.05). The dose of hormone medication was found to be a significant influencing factor on the decrease in EHL (35 - 58 % (T3) and 15 - 67 % (T4)) (p<0.05). ***Conclusion:*** The significantly reduced intra-therapeutic EHL in patients with additional thyroid hormone medication may be caused by stunning effects or a stimulation of the cell metabolism in the follicle cells by this medication. However, the effect should be considered when calculating the required therapeutic RIT activity for patients with STN.

EP-0725

Alternation of Organic Metabolic Profiling in Obese Patients Following Bariatric Surgery Assessed by ^{18}F-FDG PET/CT

Z. Wang, *S. Xue, O. Kulterer, X. Li, M. Hacker;*
Medical University of Vienna Department of Biomedical Imaging and Image-guided Therapy, Vienna, AUSTRIA.

Aim/Introduction: Bariatric surgery is a powerful intervention for obesity, leading to marked improvements in metabolic dysfunction across multiple organs. However, the complexity of systemic metabolic adaptation and inter-organ communication following surgery remains poorly characterized. This study aimed to comprehensively evaluate organ-specific metabolic changes and inter-organ network remodeling in obese patients before and after bariatric surgery, using AI-assisted whole-body ^{18}F-FDG PET/CT and extensive biochemical profiling. ***Materials and Methods:*** A total of 28 obese patients who underwent laparoscopic sleeve gastrectomy (LSG) or one-anastomosis gastric bypass (OAGB) were enrolled. All patients received whole-body ^{18}F-FDG PET/CT imaging and comprehensive biochemical testing preoperatively and at 12 months postoperatively. Organ segmentation was conducted using TotalSegmentator, an AI-based tool, to extract SUVmean values. Changes in organ volume, tissue-specific glucose uptake, and systemic biochemical markers were assessed. Metabolic connectivity networks were constructed using Pearson correlation matrices and evaluated pre- and postoperatively to characterize inter-organ communication patterns. ***Results:*** After surgery, most organ SUVmean values significantly declined, while SAT, VAT, and adrenal gland SUVmean increased. Organ volumes were markedly reduced across multiple systems, including adipose tissue (SAT, VAT), hepatopancreatic system (liver, pancreas), cardiovascular system (heart, pulmonary vein), and digestive tract (stomach, small bowel). Correlation network analysis revealed strengthened inter-organ metabolic coordination after surgery. Several organ pairs that were negatively correlated before surgery, such as subcutaneous adipose tissue (SAT) with the duodenum, spinal cord, and liver, shifted to positive correlations postoperatively. In addition, certain organ interactions that were already positively correlated—such as VAT with the pancreas, SAT, liver, and spleen—became more tightly coordinated after surgery, indicating an overall enhancement of systemic metabolic integration. PET-derived SUVmean changes showed significant correlations with improvements in lipid profiles, insulin resistance (HOMA-IR), and liver histological scores (NA and SAF score). Additionally, skeletal muscle SUVmean negatively correlated with changes in C-peptide, insulin, HOMA-IR, and GH, while cardiovascular and skeletal system metabolic changes were associated with hormone and inflammatory markers. ***Conclusion:*** This study demonstrates that bariatric surgery induces robust systemic metabolic reorganization, including reduced organ volumes, altered glucose uptake, and reprogrammed inter-organ metabolic networks. Whole-body ^{18}F-FDG PET/CT combined with AI-based segmentation and network analysis provides a novel systems-level approach to quantify these adaptations. Our findings highlight the central roles of hepatic and adipose tissue remodeling and support the use of metabolic network features as potential biomarkers for predicting surgical outcomes and guiding personalized management of obesity.

EP-0726

^{68}Ga-Pentixafor PET/CT Imaging Characteristics in Primary Aldosteronism with Coexisting Subclinical Cushing Syndrome: A Retrospective Cohort Study

S. Liu, *H. Pang;*
The First Affiliated Hospital of Chongqing Medical University, Chongqing, CHINA.

Aim/Introduction: The coexistence of subclinical Cushing syndrome (SCS) in primary aldosteronism (PA) patients complicates diagnosis and management. This study aimed to characterize the endocrine-metabolic profiles and ^{68}Ga-pentixafor PET/CT imaging features in PA-SCS patients, and explore the discriminative value of CXCR4-targeted imaging for SCS identification. ***Materials and Methods:*** Retrospective analysis of 52 PA patients (25 PA-SCS vs. 27 PA) undergoing ^{68}Ga-pentixafor PET/CT at The First Affiliated Hospital of Chongqing Medical University from 2022 to 2024. Clinical parameters (cortisol, ACTH, 24hUFC, renin-aldosterone ratio) and PET-derived metrics (SUVmax, lesion-to-contralateral ratio [LCR], lesion-to-liver ratio [LLR]) were compared. Statistical analyses included Mann-Whitney U tests, ROC curve analysis, and Spearman correlation. ***Results:*** PA-SCS group showed significantly larger adrenal lesions (median 2.8 vs. 1.5 cm, P<0.0001).Elevated 10min-LCR (3.2 vs. 1.7, P=0.003) and 40min-LCR (4.1 vs. 2.3, P=0.012) distinguished PA-SCS from PA.10min-LCR demonstrated optimal diagnostic performance (AUC=0.737, cutoff=1.935, sensitivity 76%, specificity 68%).Weak correlations existed between PET parameters and cortisol-related indices (|r|=0.3-0.5, P<0.05). ***Conclusion:*** ^{68}Ga-pentixafor PET/CT provides functional insights into adrenal CXCR4 expression patterns in PA-SCS. Early-phase LCR enhancement may serve as a potential biomarker for SCS identification, complementing conventional endocrine testing.

EP-0727

First-in-Human Evaluation of [^{18}F]AldoView: A Highly Selective PET Tracer for Aldosterone Synthase Imaging in Primary Aldosteronism

T. Long[1], *G. Liu*[2], *M. Zhou*[1], *X. Xie*[3], *Y. Jin*[1], *L. Liu*[4], *X. Luo*[2], *T. Jiang*[2], *S. Hu*[1];
[1]*Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [2]*Department of Endocrinology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA,* [3]*Hunan University of Information Technology, Changsha, Hunan, CHINA,* [4]*Department of Urology, Xiangya Hospital, Central South University, Changsha, Hunan, CHINA.*

Aim/Introduction: Aldosterone synthase (CYP11B2) is overexpressed in primary aldosteronism (PA), making it a promising target for imaging. This first-in-human study evaluates the safety and feasibility of [^{18}F]AldoView, a highly selective PET tracer targeting CYP11B2, for PA subtyping. ***Materials and Methods:*** Biodistribution and dosimetry of [^{18}F]AldoView were assessed in three healthy volunteers using whole-body PET/CT. Fifteen patients with adrenal lesions (13 with PA, 1 with Cushing's syndrome, 1 with a nonfunctional adenoma) were enrolled. PET/CT scans were performed 60 minutes post-injection. Lesions were considered positive if tracer uptake exceeded normal adrenal tissue. Semi-quantitative analyses included maximum standardized uptake value (SUVmax), lesion-to-liver ratio (LLR), and lesion-to-adrenal ratio (LAR). Ten PA patients with positive imaging findings and one with Cushing's syndrome underwent adrenalectomy, and resected specimens were analyzed for CYP11B2 expression. This ongoing study is registered with the Chinese Clinical Trial Registry (ChiCTR2400093214). ***Results:*** [^{18}F]AldoView was well-tolerated, with no adverse events. The effective dose was 0.012 ± 0.0022 mSv/MBq. PET/CT identified positive lesions in all 10 PA patients, with mean SUVmax of 15.73 ± 8.57, LAR of 8.02 ± 4.06, and LLR of 10.24 ± 1.48. No positive lesions were observed in patients with idiopathic hyperaldosteronism, Cushing's syndrome, or nonfunctional adenomas. Positive lesions showed strong CYP11B2 staining on pathology, confirming aldosterone-producing adenomas (APA) or nodules (APN). ***Conclusion:*** [^{18}F]AldoView PET/CT is safe and feasible for the imaging of APAs and APNs in PA patients. These results highlight its potential for non-invasive in-vivo detection of CYP11B2, supporting its use in PA subtyping. ***References:*** Sander K, Gendron T, Cybulska KA, et al. Development of [(18)F]AldoView as the First Highly Selective Aldosterone Synthase PET Tracer for Imaging of Primary Hyperaldosteronism. J Med Chem. 2021;64:9321-9329.

EP-0728

^{18}F-FDG PET/CT in the Assessment of Indeterminate Adrenal Lesions

W. Schlötelburg[1], *T. Jedamzik*[1], *S. Hahner*[2], *A. K. Buck*[1], *M. Fassnacht*[2], *P. E. Hartrampf*[1];
[1]*University Hospital, Department of Nuclear Medicine, Würzburg, GERMANY,* [2]*University Hospital, Medicine I, Division of Endocrinology and Diabetes, Würzburg, GERMANY.*

Aim/Introduction: The objective of this analysis is to evaluate and compare PET parameters obtained from ^{18}F-FDG PET/CT for the characterisation of adrenal lesions indeterminate by conventional imaging methods, especially lesions with densities >10 HU on unenhanced CT-scans. ***Materials and Methods:*** A total of 414 patients with adrenal masses and ^{18}F-FDG PET/CT were classified according to either histopathological confirmation or clinical/imaging follow-up. The final diagnoses included 218 adrenal adenomas, 52 other benign adrenal tumours, 22 phaeochromocytomas, 62 adrenocortical carcinomas, seven adrenal lymphomas, and 53 metastases. Receiver operating characteristic (ROC) curves were used to assess the performance of standardized uptake values (SUVmax, SUVpeak, SUVmean), as well as adrenal tumour-to-liver ratio (SUVmax lesion/SUVmean liver, ALR) and adrenal tumour-to-bloodpool ratio (SUVmaxlesion/SUVmean aorta, ABR) for the discrimination of benign from malignant findings. Segmentation of the lesions was conducted with a threshold of 40%. ***Results:*** All adrenal masses with unenhanced HU <10 (n=198) were classified as benign lesions. In these cases, FDG PET/CT did not offer any advantages in terms of classification. In the more challenging group, characterised by densities >10 HU (n=216) on unenhanced CT-scans, malignant tumours exhibited higher SUVmax, SUVpeak and SUVmean values in comparison to benign lesions (13.6, 10.3 and 8.4 vs. 4.1, 3.2 and 2.7; P<0.0001). The area under the curve (AUC) was 0.92 for SUVmax and ALR, 0.88 for SUVpeak, 0.90 for SUVmean and 0.91 for ALR. The optimal cut-off for differentiating malignant from benign lesions was determined as follows: SUVmax: 6.5 (sensitivity 85%, specificity 84%), SUVpeak: 5.1 (sensitivity 84%, specificity 86%), SUVmean: 4.4 (sensitivity 83%, specificity 93%), ALR: 2.6 (sensitivity 86%, specificity 84%), ABR: 4.5 (sensitivity 76%, specificity 91%). To achieve a required clinical sensitivity for malignancy of >90%, a SUVmax of 5.8 or an ALR of 2.2 would be necessary, which consequently results in a decrease in specificity to 77%for SUVmax and 73% for ALR. ***Conclusion:*** 18F-FDG-PET/CT is a valuable diagnostic tool that may help to differentiate between benign and malignant adrenal lesions of indeterminate aetiology. Nevertheless, the specificity is reduced if a clinical relevant sensitivity of 90% or more is desired.

EP-0729

^{18}F-choline long-axial-field of view PET-CT accurately localises intrathyroid parathyroid adenoma in 5-month pregnant patient

T. Wagner[1], *T. Willson*[2], *B. Ferreira*[2], *J. Edwards*[3], *P. Wijewickrama*[4], *B. Holman*[2];
[1]*Nuclear Medicine, London, UNITED KINGDOM,* [2]*Nuclear Medicine department, Royal Free London NHS Trust, London, UNITED KINGDOM,* [3]*Radiology department, Royal Free London NHS Trust, London, UNITED KINGDOM,* [4]*University Hospital Sussex, Department of Endocrinology, Brighton, UNITED KINGDOM.*

Aim/Introduction: A 44-year old pregnant patient with severe hypercalcaemia caused by primary hyperparathyroidism was referred for ^{18}F-choline long-axial-field of view (LAFOV) PET-CT for pre-surgical localisation of parathyroid adenoma. The patient had needed multiple hospitalisations to treat the hypercalcaemia and was at risk of severe complications for herself and the foetus. Exploratory neck surgery had been attempted and did not localise a parathyroid adenoma. ***Materials and Methods:*** We performed an ultra-low-dose PET and CT acquisition to minimise radiation exposure to the foetus. The patient was injected with 17 MBq (0.2 MBq/kg) and scanned for 30 mins from vertex to diaphragm, 62 mins after injection on a Vision Quadra PET-CT (Siemens Healthineers, Erlangen, Germany). CT parameters were ref mAs 7mAs, CAREDose on, CAREkV off, ref kV 100. Following the PET-CT acquisition, we performed a PET only uncorrected acquisition of vertex to thighs to evaluate ^{18}F-choline uptake within the foetus to estimate foetal radiation exposure. ***Results:*** ^{18}F-choline LAFOV PET-CT demonstrated focal intense choline uptake in a low density intrathyroid nodule in the left lower pole, consistent with an intrathyroid parathyroid adenoma. No other focus of abnormal uptake was identified. The uncorrected images demonstrated only mild uptake in the region of the foetus, likely in the liver. Despite choline being an essential nutrient for foetal brain development, there was no uptake in the brain of the foetus. The estimated foetal dose was 0.5 mSv from the PET and 0.1 mGy from the CT. The patient had surgery the following week, which identified and removed the parathyroid adenoma. Pathological analysis confirmed the presence of an intrathyroid parathyroid adenoma. The patient was discharged successfully and was mildly hypocalcaemic following surgery. ***Conclusion:*** This is the first reported case of ^{18}F-choline PET-CT in a pregnant patient, which we performed on a LAFOV PET-CT while delivering very low radiation to foetus and mother and obtaining a high-quality diagnostic scan. ***References:*** 1. van Snick JH, Koopmans KP, Glaudemans AWJM, Stormezand GN, Ivashchenko OV. EP-0730

Diagnostic Value of MIBI Thyroid Washout Rate in Differentiating Types of Amiodarone-Induced Thyrotoxicosis

T. Bogovic Crncic[1,2], *L. Fischer*[1,2], *M. Ilić Tomaš*[1,2], *I. Iskra*[1,2], *N. Girotto*[3,4], *M. Mavrinac*[5];
[1]*University of Rijeka, Faculty of Medicine, Rijeka, CROATIA,* [2]*Clinical Hospital Centre Rijeka, Rijeka, CROATIA,* [3]*University of Rijeka, Faculty of Health Studies, Rijeka, CROATIA,* [4]*PET/CT Center Rijeka, Medikol Polyclinic, Rijeka, CROATIA,* [5]*Faculty of Educational Sciences, Juraj Dobrila University of Pula, Pula, CROATIA.*

Aim/Introduction: Amiodarone-induced thyrotoxicosis (AIT) is a potentially serious complication of amiodarone therapy and is categorized into three types: AIT-1, resulting from increased thyroid hormone synthesis, AIT-2, caused by destructive thyroiditis due to cytotoxic effects of amiodarone and AIT- 3, or mixed type, which presents with overlapping features. Accurate differentiation is clinically important, due to different treatment approaches. However, making this distinction remains a diagnostic challenge. This study aimed to evaluate the diagnostic utility of the 99mTc-sestamibi (MIBI) thyroid washout rate (WR) in differentiating between AIT types. ***Materials and Methods:*** This prospective study included 55 AIT patients who underwent thyroid scintigraphy with 99mTc-MIBI, 10 and 60 minutes post-injection. Based on the visual early image interpretation, patients were categorized into AIT-1 (intense uptake), AIT-2 (absent/minimal uptake) and AIT-3 (intermediate uptake) group. Semi-quantitative analysis involved calculating thyroid-to-background MIBI uptake ratios using mediastinal and supraclavicular background regions of interest (ROIs). Ratios between 66.66th and 100th percentile indicated the highest MIBI uptake and were classified as the AIT-1, between 0th and 33.33rd percentile as the AIT-2, and between the 33.33rd and 66.66th percentile as the AIT-3 type. WR was calculated as the percentage decrease in thyroid uptake between early and delayed images and compared with values from 35 euthyroid control subjects. Statistical analysis was performed using t-tests, with $P < 0.05$ considered statistically significant. ***Results:*** According to visual analysis 18 patients were classified in AIT-1, 17 in AIT-2 and 20 in AIT-3 group. Semi-quantitative analysis led to reclassification, resulting in 19 patients in AIT-1, 20 in AIT-2 and 16 in AIT-3, when using the mediastinal ROI, with similar results for the supraclavicular ROI. Using the mediastinal ROI, median WR values were 32.48% for AIT-1, 27.19% for AIT-2, and 29.31% for AIT-3 type, compared to 28.88% in controls ($P = 0.258$). With the supraclavicular ROI, WR values were similar: 32.85% for AIT-1, 26.04% for AIT-2, 29.80% for AIT-3, and 28.88% for controls ($P = 0.120$). Visual assessment also revealed no statistically significant differences in WR rate among the AIT types ($P = 0.823$). ***Conclusion:*** Thyroid MIBI washout rates did not significantly differ among AIT types or when compared to euthyroid controls, regardless method of analysis or background ROI used. While useful in evaluating thyroid nodules, MIBI WR analysis did not contribute significantly to the diagnostic differentiation of AIT types.This work has been supported in part by the University of Rijeka: project number (uniri-pr-biomed-19-141495).

EP-0731

Optimization of 3T PET/MRI Protocol with [18F] Fluorocholine in the Detection of Parathyroid Microadenomas.

V. Carrero-Vásquez*, Á. Espigares-Santiago, J. Díaz-Moreno, M. Cortés Romera, M. Suárez-Piñera, L. Gracia-Sánchez, L. Rodríguez-Bel, I. Sanchez-Rodriguez;*
Nuclear Medicine, Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: Parathyroid adenomas (PAs) are low-fat-content lesions that pose a diagnostic challenge, particularly when they are small. 3T PET/MRI has shown promise in localization, but the need for multiple MRI sequences remains a topic of debate. This study aims to optimize the PET/MRI acquisition protocol, evaluate signal characteristics by lesion size, and determine whether any sequence can be safely omitted without compromising diagnostic accuracy. We aimed to analyze MRI signal intensity and PET uptake to lesion size, assess the relationship between acquisition parameters and adenoma size, optimize the PET/MRI protocol for detecting parathyroid adenomas, and evaluate the redundancy of T2-TSE and T2-STIR sequences for protocol simplification. ***Materials and Methods:*** A retrospective study included 23 patients (2021-2024) with primary hyperparathyroidism and negative conventional imaging. MRI included axial T1-Dixon, T2-FSE (T2-TSE), and coronal T2-STIR. PET data were quantified by SUVmax. Lesions were categorized as microadenomas (<6 mm), subcentimetric (6-10 mm), or centimetric (>10 mm). Histopathological confirmation (APA) was available in a subset. Signal intensities were classified, and SUVmax values were compared using Kruskal-Wallis tests. ***Results:*** A total of 24 lesions were detected (one patient had two): microadenomas (n=5), 3 confirmed by APA. 100% detected. Isointense in T1 (60%), hyperintense in T2/STIR (80%). SUVmax moderate (3.9) or intense. Subcentimetric (n=14): 4 confirmed. 100% detected. Mixed T1 (hypo 50%, iso 43%), hyperintense in T2/STIR (90%). SUVmax 5.8 ($p<0.01$).Centimetric (n=5): 2 confirmed. 100% detected. Hypointense T1 (>70%), hyperintense T2/STIR (100%). SUVmax 11.5.Hyperintensity in T2-TSE and STIR was nearly identical across all groups. T1 showed more variability. SUVmax strongly correlated with signal intensity (Kruskal-Wallis: T1 $p=0.0011$, T2 $p=0.0014$, STIR $p=0.0035$). Among APA-confirmed lesions (n=9), all were hyperintense in T2/STIR and had SUVmax > 4. ***Conclusion:*** T2-STIR and T2-TSE provide overlapping diagnostic value. Given the similar detection rates and superior contrast properties of STIR, T2-TSE may be omitted to streamline the protocol. A simplified sequence set (T1 + STIR) appears sufficient for accurate detection across all lesion sizes, including microadenomas. These results support the optimization of PET/MRI protocols for clinical and operational efficiency. Further prospective studies are recommended to validate these findings.

EP-0732

Frequency of osteoporotic Trabecular Bone Score adjusted T-score in daily clinical practice compared to standard densitometric measurements

M. Jensen[1], *B. Zerahn*[1], *C. K. Andersen*[1], *M. K. Skjødt*[2,3];
[1]*Dept. of Nuclear Medicine, Copenhagen University Hospital – Herlev and Gentofte, Herlev, DENMARK,* [2]*Dept. of Medicine, Copenhagen University Hospital - Herlev and Gentofte, Herlev, DENMARK,* [3]*Research Unit OPEN, Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.*

Aim/Introduction: Trabecular Bone Score (TBS) can be measured by dual energy x-ray absorptiometry (DXA) in addition to Bone Mineral Density (BMD). TBS provides a quantitative assessment of bone microarchitecture in the form of either a unitless TBS or as a TBS-adjusted T-score and as such provides partly independent information on fracture risk beyond BMD. Categorization of the standalone TBS has been proposed as follows: normal (≥1.350), partially degraded (1200 < TBS < 1.350) and degraded (≤1.200). The International Society for Clinical Densitometry (ISCD) official positions from 2023 regard TBS to be appropriate in adults ≥ 40 years to assist management of pharmacological intervention. The aim of this study is to report the frequency of TBS-adjusted T-score ≤ -2.5 among individuals referred for baseline Dual X-ray Absorptiometry (DXA) with one or more risk factors associated with osteoporosis as compared to unadjusted BMD based T-score measured at the lumbar spine and bilateral hip. ***Materials and Methods:*** This is a retrospective study of 115 individuals aged ≥ 40 years and referred for DXA based baseline assessment of

osteoporosis. Eight (four men) were excluded because they were already diagnosed with osteoporosis due to low energy vertebral fractures and 5 were excluded due to a BMI > 37. Of the included 102 patients (avg. age of 66,4Y) seven patients had measurements of the forearms of which four had bilateral hip arthroplasty, two had primary hyperparathyroidism and one because of metastases in the hips. In 26 patients one or more vertebrae were excluded from analysis primarily because of spondylosis. ***Results:*** A total of 35 individuals had a T-score ≤ -2.5 of which 7 (all women) were found only with TBS-adjusted T-score. Unadjusted T-scores ≤ -2.5 was found in the lumbar spine in 17 individuals, femoral neck 18, total hip 10, radius 33% 1 while TBS-adjusted T-scores ≤ -2.5 were found in 22 individuals. 15 patients could be categorized with a degraded TBS, 42 with a partially degraded TBS and 45 with a normal TBS. ***Conclusion:*** Adding TBS to the standard procedure in our local clinical setting will increase the number of individuals with a T-score ≤ -2.5 from approximately 27 to 34%. The impact of this increased occurrence of osteoporosis on the capture of patients with subsequent fracture(s) remains to be elucidated. ***References:*** Cormier C, Lamy O, Poriau S. TBS in routine clinical practice: Proposals of use. Medimaps. 2012:1-14.

EP-0733

[^{18}F]Fluorocholine-PET Imaging at Different Time Points in Patients with Primary Hyperparathyroidism

F. Hedeer[1], *A. Stenvall*[2], *E. Mellhammar*[2], *M. Matkovic*[1], *M. Nilsson*[3], *J. Oddstig*[2], *M. Almquist*[3], *U. Bitzén*[1];
[1]*Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund University, Lund, SWEDEN,* [2]*Radiation Physics, Department of Haematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, SWEDEN,* [3]*Department of Surgery, Skåne University Hospital, Lund University, Lund, SWEDEN.*

Aim/Introduction: [^{18}F]FluorocholinePET has emerged as a powerful tool for preoperative localisation of pathological parathyroid glands in primary hyperparathyroidism (pHPT). Limited data is, however, available regarding optimal imaging time point. The aim was to explore performance of [^{18}F]FluorocholinePET at different imaging time points for localisation of pathological parathyroid glands in pHPT. ***Materials and Methods:*** In 25 consecutive patients referred for preoperative localisation of pathological parathyroid glands, static PET images at 26, 48, 610, 812 min (derived from a 12minute dynamic acquisition) and 60 min after intravenous injection of 4 MBq/kg [^{18}F]Fluorocholine were, together with low-dose CT, blinded and retrospectively read by two experienced nuclear medicine physicians. Uptakes were specified regarding localisation (side and relation to the ipsilateral thyroid lobe) and degree of suspicion (1=no focal uptake, 2=faint unspecific uptake, 3=intermediately suspicious uptake, 4=suspicious uptake and 5=strongly suspicious uptake). Results were compared to surgical and histopathological results, and ionised calcium levels in serum at postoperative follow-up. One patient declined surgery resulting in 24 patients to be analysed. ***Results:*** In the 24 patients, 27 pathological parathyroid glands with adenoma or hyperplasia (two in three patients, one in 21 patients) were surgically removed. 19 of these glands (70%) corresponded to distinct grade 45 uptakes at all time points and one (4%) to a faint grade 2 uptake reported at all time points. Four glands (15%) were better visualised 60 minutes post injection (uptake grade 45) compared to earlier time points (uptake grade 24) and one (4%) was correctly localised as a grade 4 uptake 60 minutes post injection but not clearly visualised at earlier timepoints (grade 1-2). In two of the patients with two surgically removed pathological parathyroid glands, one in each patient (7%) was not detected by [^{18}F]Fluorocholine-PET. Thus, 24 of the 27 surgically removed pathological parathyroid glands, i.e. 89%, were localised by distinct grade 4-5 uptakes 60 minutes post injection. None of the reported uptakes graded 45 were false positive. In 5 of the 24 patients, 12 additional unspecific uptakes were reported but without obvious correlation to imaging time point. All patients were normocalcemic at follow-up after surgery. ***Conclusion:*** Most of the pathological parathyroid glands were clearly and correctly localised by [^{18}F]FluorocholinePET and equally well visualised regardless of imaging time point. In some patients, however, the detection was favoured by a longer, i.e. 60-minute, accumulation time. Further studies are needed to investigate whether this is a true tendency or not.

EP-0734

Evaluation of Dynamic C-X-C motif Chemokine Receptor 4-directed PET/CT Imaging in Primary Aldosteronism

J. Enke[1], *F. Voelter*[2], *J. Baessler*[1], *K. Ritzel*[2], *R. A. Bundschuh*[3], *N. Dreher*[1], *O. Viering*[1], *J. Tran-Gia*[4], *C. H. Pfob*[1], *M. Kircher*[1], *A. Dierks*[1], *M. Reincke*[2], *C. Lapa*[1];
[1]*Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY,* [2]*Department of Medicine IV, Ludwig Maximilians University Hospital Munich, Munich, GERMANY,* [3]*Department of Nuclear Medicine, University Hospital Carl Gustav Carus at the TU Dresden, Dresden, GERMANY,* [4]*Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.*

Aim/Introduction: C-X-C motif chemokine receptor 4 (CXCR4)-directed positron emission tomography (PET) has been evaluated in the diagnostic work-up of primary aldosteronism (PA), since overexpression of CXCR4 has been described for aldosterone-producing adenomas (APA). In this retrospective evaluation of dynamic PET/CT imaging with [^{68}Ga]Ga-PentixaFor in patients with PA, we aimed at determining an optimal imaging time point for CXCR4-directed imaging in PA. ***Materials and Methods:*** After injection of 151 ± 16.5 MBq (mean ± SD) of [^{68}Ga]Ga-PentixaFor, dynamic PET imaging over the upper abdomen was performed in 24 patients at a single bed position and reconstructed into 33 time frames (1×40 s, 10×5 s, 3×10 s, 2×15 s, 5×30 s, 5×120 s, 5×300 s and 2×600 s). In a subset of 12 patients, list-mode data was reconstructed in 10-minute frames starting from minute 10. Mean, maximum and peak standardized uptake values (SUV) of adrenal glands and maximum lesion-to-contralateral ratio (LCRmax) were extracted for all time frames. Mann-Whitney U-Tests were used to compare parameters between time frames, and AUC values were calculated. Histopathology and clinical follow-up served as the reference standard and were available for 12 of 24 patients; evaluation is still pending for the remainder. ***Results:*** In 11 out of 24 patients, adrenal lateralization was successfully identified by [^{68}Ga]Ga-PentixaFor PET (mean lesion diameter: 15.0 ± 5.66 mm). APA was confirmed histopathologically in 5 of these 11 patients; 2 received mineralocorticoid receptor antagonists at their own request, and follow-up is still pending in the remaining cases. PET imaging showed rapid tracer wash-out from the blood and stable adrenal retention beginning at minute 5 post-injection. For LCRmax, the earliest time point with excellent discriminatory performance (AUC = 1) was at 9-11 minutes post-injection (lateralization 2.13 ± 0.79 vs. no lateralization: 1.10 ± 0.09; $p < 0.01$).In 10-minute frame reconstructions, an AUC of 1 for LCRmax was observed consistently from minutes 10 to 50, with a slightly lower value between minutes 50 to60 (AUC = 0.972). The optimal cut-off for LCRmax to discriminate lateralization was consistently ≥1.5 across all time points. ***Conclusion:*** This retrospective analysis of dynamic PET data revealed that adrenal lateralization can be detected as early as 10 minutes post-injection and remains stable over time. An LCRmax cut-off of 1.5 provided consistent discrimination between APA and non-lateralizing cases. Ten-minute time frames between minutes 10 and 50 demonstrated excellent discriminatory performance, suggesting that shorter and more flexible acquisition protocols may be feasible in the diagnostic work-up for PA patients.

EP-0735

Thyroid disorders in primary school children in North Macedonia: A cross-sectional study

N. Manevska[1,2], *A. Jankulovska*[1], *B. Stoilovska Rizova*[1], *N. Kolovcevska Bozinovska*[1], *N. Stojkovska*[3], *T. Makazlieva*[1], *S. Stojanoski*[1];
[1]*Institute of Pathophysiology and Nuclear medicine, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [2]*University Institute of positron emission tomography, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [3]*Institute of Histology and Embryology, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF.*

Aim/Introduction: While thyroid disorders are often associated with adults, they represent the most prevalent endocrine disorder among school-age children. Autoimmune thyroiditis, in particular, is a leading cause of hypothyroidism in this age group, leading to potential growth impairments, cognitive development and overall health if left undetected. Early detection of thyroid dysfunction and intervention are crucial mitigating these risks, ensuring normal development. ***Materials and Methods:*** A cross-sectional study was conducted involving 53 randomly selected children, from five different schools in single in North Macedonia. Participants were aged 14 to 15 years and were attending their final year of primary education. They had never been tested for thyroid function prior to this study. Informed consent was obtained from all parents or legal guardians of before participation. Each participant underwent a thorough neck ultrasonography using a linear probe to assess thyroid morphology, size and detect any structural abnormalities. Based on ultrasonography findings, selected children underwent further clinical evaluation at the thyroid unit at the Institute of Pathophysiology and nuclear medicine. Laboratory tests included measurements of free thyroxine (fT4), thyroid-stimulating hormone (TSH), and where indicated anti-thyroid peroxidase (aTPO) antibodies, and anti-thyroglobulin antibodies (aTg). A detailed family history of thyroid disease was also collected. ***Results:*** The female to male ratio was 1:1.52. Ultrasound features mainly detected benign small anechoic cysts in 47.16% (n=25) of the children, while autoimmune pattern was noted in 32.07% (n=17) of the participants. Laboratory analysis revealed that 9.43% (n=5) had subclinical hypothyroidism, defined by elevated TSH levels (4.13-6.7mIU/L), Moreover, 13.2% (n=7) had Hashimoto's thyroiditis, confirmed through elevated autoantibodies and characteristic ultrasonographic patterns. The remaining participants were found to be euthyroid. A positive family history was noted in 15.09% (n=8). ***Conclusion:*** A significant burden of early thyroid autoimmunity and dysfunction was observed in school children aged 14-15 years. These findings highlight the importance of early screening and monitoring to detect thyroid disorders in this population, enabling timely diagnosis and management.

EP-0736

Minimally invasive radioguided parathyroidectomy using a handheld gamma detector probe: First experience with primary hyperparathyroidism - A pilot study

N. Bozhinovska[1], *A. Jankulovska*[1], *B. Stoilovska Rizova*[1], *B. Antevski*[2], *S. Stojanoski*[1], *N. Manevska*[3], *T. Makazlieva*[1];
[1]*Institute of Pathophysiology and Nuclear Medicine "Isaac Tadzer", Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [2]*University clinic for thoracic and vascular surgery, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [3]*University Institute of positron emission tomography, Skopje, NORTH MACEDONIA, THE REPUBLIC OF.*

Aim/Introduction: Hyperparathyroidism (HPT) is a common endocrine disorder caused by autonomous hyperactivity of enlarged parathyroid glands, most often due to a solitary adenoma (85%), multiglandular hyperplasia (10%-15%) and carcinoma (less than 1%). Imaging techniques like ultrasonography and 99mTc-MIBI are crucial for surgical planning. Minimally invasive parathyroidectomy offers a safe, simple and cost-effective alternative to the conventional surgery. ***Materials and Methods:*** We reviewed 21 patients (18 females and 3 males) between december 2022 and march 2025, who underwent minimally invasive radioguided parathyroidectomy using a handheld gamma probe. Preoperative evaluation included dual-phase parathyroid scintigraphy with SPECT/CT and neck ultrasonography. Radioguided surgery was performed 90-120 minutes after intravenous injection of 370 MBq 99mTc-MIBI. A handheld gamma probe was used for neck scanning prior to a small (2-3cm) skin incision to localize the cutaneous projection of the hyperfunctional parathyroid tissue and its confirmation during surgery. ***Results:*** All the patients had biochemical evidence of HPT, with mean laboratory levels as follows: PTH 326.5 (range: 90.5-1005), total calcium levels 2.86 mmol/L (2.56-3.4), ionized calcium 1.54 mmol/L (range: 1.4-1.77), vitamin D 26.5ng/mL (range: 14-38), phosphate 0.78 mmol/L (range: 0.62-0.93). 52% of the parathyroid adenomas were localized below the inferior left lobe, 28% below the inferior right lobe and 20 % had an ectopic paratracheal and retrosternal localization. The gamma probe successfully identified the hyperfunctional parathyroid tissue in all patients, and minimally invasive radioguided surgery was completed without major complications. The average time of the surgery was 29 minutes. Postoperative laboratory values normalized in all cases. Histopathology confirmed parathyroid adenoma in 20 patients and a parathyroid carcinoma in one patient. ***Conclusion:*** Minimally invasive radioguided parathyroidectomy is a safe and effective technique that provides excellent surgical outcomes with less morbidity, faster recovery time, improved cosmetic results, and a lover overall cost compared to the conventional surgery.

EP-0737

Possibly coexistence of Hashimoto thyroiditis (HT) and papillary thyroid carcinoma (PTC)

K. Zaplatnikov*;*
MVZ Nuklearmedizin Mögeldorf, Nürnberg, GERMANY.

Aim/Introduction: HT is an offen autoimmune thyroid disease, known to be the most common cause of hypothyroidism in nonendemic goitrous areas. It is usually characterized by symmetric, painless, and diffused but sometimes localized swelling of the thyroid gland with features of hypothyroidism. ***Materials and Methods:*** The coexistence of the two diseases is possible but not common, in this situation is diagnostic is several, where many pseudonodul with hypoechogenic. The fine needle aspiration is not for all possible, we estimated algoorithmus for diagnosis. Patients with HT/PTC (Gr.A) and PTC without HT (Gr.B) were studied In prospective way. In algorithm of initial investigation 99mTc-scitigraphy, thyroid hormone and anti-TPO/anti-Tg antibodies levels estimation were performed along with clinical examination, thyroid sonography with Doppler DS and FNAC. Every case of PTC was confirmed by patho-histological examination. Age, sex, geographic anamnesis, tumour features (dimensions, angioinvasion, capsular infiltration, multifocality and lymphnode metastases) nuclear medicine examination data, therapy history and estimated total effective doses received by former inhabitanats of contaminated areas were analysed. ***Results:*** Statistically significant (P=0.001) difference in tumour size was found in two Groups: the average diameter was found to be 1.721+/-0.5812 and 1.145+/-0.871 cm in Gr.A and in Gr.B, respectively. Capsular infiltration was present only in Gr.A in 3 cases. The angioinvasion was found in 8 cases of Gr.A and 1 cases in Gr.B (P=0.310). Multifocality was found in 19 patients in Gr.A and in 2 in Gr.B (P=0.0009). There were no statistical differences in sex (P=0.423) and age (P=0.330). All pts in Gr.A had HT with high levels of thyroid Abs (TgAb/TPOAb). 51.5% autoantibody positive pts with US suspicious multifocal non-uniform thyroid goiter revealed scintigraphic cold lesion , in Gr.B 60% nodes were undetectable

in scans. Unfortunately, no thyroid gland and collective thyroid doses were available and estimated total effective doses were found for less than half of Gr.A with no cases of documented high over-doses. ***Conclusion:*** Statistically proven high prevalence (100%) of HT and multifocal PTC in Gr.A compared to Gr.B in our study might be related to the fact, that a majority of patients were previously residents of regions with probability of extensive radiation exposur. Our results justify a necessity of screening for PTC in population group exposed to external radiation and with concomitant HT, taking them into account and assuming more aggressiveness of tumours.

EP-0738

Added Value of MRI Multi-parameter Information for Diagnosing Subcentimeter Functional Adrenal Nodules using CXCR4-targeted PET/MRI imaging

X. Meng, *Z. Quan, F. Kang;*
Xijing Hospital of Airforce Military Medical University, Xi'an, CHINA.

Aim/Introduction: This study aims to evaluate the clinical utility of ^{68}Ga-pentixafor PET/MRI in diagnosing primary aldosteronism (PA) in functional adrenal nodules, with a particular focus on subcentimeter nodules. Additionally, the diagnostic performance of integrated PET/MRI is compared to single-modality PET imaging. ***Materials and Methods:*** A total of 62 patients with clinical suspicion of PA were prospectively enrolled from a tertiary hospital in China. Prior to adrenalectomy, all patients underwent ^{68}Ga-pentixafor PET/MRI, followed by CXCR4 and CYP11B2 immunohistochemical analysis post-surgery. Adrenal lesions were stratified into two size groups: ≥ 1 cm and < 1 cm. Quantitative PET parameters, including SUVmax, SUVmean, and lesion-to-liver uptake ratio (LLR), were evaluated alongside MRI parameters such as outphase/inphase signal ratio (OIR), relative percent washout (RPW), T2-weighted image intensity, ADC value. Receiver operating characteristic (ROC) curve analysis was performed to establish diagnostic thresholds. Comparative analyses were conducted between single-modality PET and integrated PET/MRI for diagnostic accuracy. ***Results:*** Among 62 patients, 74 adrenal lesions were confirmed pathologically, comprising 37 aldosterone-producing adenomas (APA, ≥ 1 cm), 21 aldosterone-producing micronodules (micro-APA, < 1 cm), and 16 non-functioning adenomas (NFA). Key PET/MRI parameters, including SUVmax, SUVmean, LLR, OIR, and RPW, showed significant differentiation between functional and non-functional groups (P < 0.001). For nodules ≥ 1 cm, the PET SUVmax threshold of 7.87 achieved a sensitivity of 92.3% and specificity of 95.0% for APA diagnosis. For nodules < 1 cm, the PET SUVmax threshold of 6.49 yielded a sensitivity of 68.8% and specificity of 83.3% for micro-APA diagnosis. Integrated PET/MRI notably improved the diagnostic sensitivity for nodules < 1 cm from 68.8% (PET alone) to 87.5%, with the area under the ROC curve increasing from 0.760 to 0.854. ***Conclusion:*** ^{68}Ga-Pentixafor PET/MRI demonstrated high diagnostic accuracy for functional adrenal nodules in PA, particularly enhanced sensitivity for subcentimeter nodules compared to PET alone. ***References:***

EP-0739

99mTc-Pertechnetate Scintigraphy predicts successful postoperative ablation in patients with low-risk differentiated thyroid carcinoma.

I. El Bez, *R. Tulbah, S. Alhazza, R. Alsalah, K. Ibrahim, F. Algmlas, M. Alharbi;*
AAML, Riyad, SAUDI ARABIA.

Aim/Introduction: Postoperative radioiodine treatment (RAI) is currently debated for patients with low-risk differentiated thyroid carcinoma (DTC) patients. If performed, a low ^{131}I activity is usually recommended with the aim to ablate thyroid remnant. The purpose of this study is to evaluate the relationship between postsurgical technetium-99m (^{99m}Tc)-pertechnetate scintigraphy and the rate of successful remnant ablation after low activity radioiodine ablation in patients with low-risk DTC. ***Materials and Methods:*** 72 patients with DTC who underwent total thyroidectomy followed by low-activity RAI ablation were enrolled. ^{99m}Tc pertechnetate scintigraphy scans were acquired before ablation. Response to treatment was assessed at 6 to 12 months after ablation. ***Results:*** The thyroid remnant ablation success rate was seen in 40/72 patients (55.6 %). Statistically Significant difference was noted in success rate of thyroid remnant ablation according to the presence of thyroid remnant uptake on the preablative ^{99m}Tc pertechnetate scintigraphy. The successful ablation rate in patient with negative preablative uptake on ^{99m}Tc pertechnetate scintigraphy was 74.2% (26 patients). In logistic regression analysis only the thyroid remnant uptake on preablative ^{99m}Tc pertechnetate scintigraph was significant predictive factor for ablation success (P = 0.002). ***Conclusion:*** Preablative ^{99m}Tc pertechnetate scintigraphy is a simple and feasible tool to evaluate for thyroid remnant and predict predicts successful postoperative ablation in patients with low-risk DTC.

Can We See More with Three-Phase Bone Scintigraphy in Patients with Prosthetic Infection?

J. Mendes, *P. Soeiro;*
Hospital de São João, Porto, PORTUGAL.

Aim/Introduction: The global rise in orthopaedic arthroplasty has led to a proportional increase in prosthetic complications, particularly aseptic loosening and periprosthetic joint infection (PJI). While hybrid imaging modalities such as [^{18}F]FDG PET/CT offer promise, their limited specificity and complex interpretation—especially in distinguishing infection from postoperative inflammation—restrict routine use. Moreover, in many centres without access to labelled leucocyte imaging, three-phase bone scintigraphy (TPBS) remains the only nuclear medicine tool available for prosthesis assessment. However, reliably distinguishing septic from aseptic loosening using TPBS alone remains a diagnostic challenge. This study aimed to evaluate whether specific visual or semi-quantitative TPBS patterns are predictive of prosthetic infection as opposed to aseptic loosening. ***Materials and Methods:*** We conducted a retrospective, single-centre study of patients who underwent TPBS between May 2006 and February 2020. Adult patients with hip or knee prostheses and clinical suspicion of prosthetic complications were included. Clinical records and TPBS images were analysed visually and semi-

quantitatively. Uptake patterns across vascular, blood pool, and osseous phases were evaluated. Outcomes were categorised as (1) successful prosthetic integration, (2) aseptic loosening, or (3) septic loosening/infection. Statistical analysis was performed using IBM SPSS Statistics. ***Results:*** A total of 123 TPBS studies were included, comprising hip prostheses (47.2%) and knee prostheses (44.7%). The study population was 67.5% female and 32.5% male, with a median age of 72 years. TPBS findings showed a strong correlation with clinical outcomes ($p < 0.000001$ for all phases). Focal uptake in the osseous phase was observed in both aseptic (96.7%) and septic (87.5%) loosening. Diffuse osseous uptake was seen exclusively in septic cases. Altered vascular and blood pool phases were significantly more frequent in septic loosening (87.5% and 100%, respectively) than in aseptic cases (68.3% and 70%). Normal uptake across all three phases was predominantly associated with prosthetic integration. ***Conclusion:*** Three-phase bone scintigraphy remains a valuable diagnostic tool in centres without access to more advanced nuclear imaging. While focal osseous uptake alone lacks specificity, the combination of altered vascular and blood pool phases—particularly with diffuse osseous uptake—appears to be strongly predictive of infection. These results support the development of structured visual and semi-quantitative TPBS interpretation criteria to improve diagnostic accuracy in suspected prosthetic complications.

Diagnostic Accuracy of ^{18}F-FDG-Labelled Autologous Leukocyte Positron Emission Tomography - Computed Tomography in Suspected Cardiac Infections

P. Malik, *A. Bhattacharya, R. Kumar, H. Singh, P. Panda, H. Singh, B. R. Mittal;*
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Cardiac infections are an important cause of cardiovascular morbidity and mortality with nonspecific presentations contributing to delayed diagnosis. The 2023 Duke-International Society for Cardiovascular Infectious Diseases Criteria for Infective Endocarditis (ISCVID IE) Criteria have proposed ^{18}F-FDG-PET as a major imaging criterion. ^{18}F-FDG-labelled autologous leucocyte PET/CT (^{18}F-FDG-LAL-PET/CT) circumvents the need for special dietary preparation to suppress physiological myocardial FDG uptake. This study aims to assess the diagnostic accuracy of ^{18}F-FDG-LAL-PET/CT against common imaging modalities like echocardiography (ECHO) for detection of cardiac infections. ***Materials and Methods:*** Twenty-nine patients who presented with suspected cardiovascular device infection (CVDI) or "possible IE" as per 2023 Duke-ISCVID IE criteria were prospectively recruited. ^{18}F-FDG-LAL-PET/CT was performed in all patients with total leucocyte count > 5000/mm^3 and erythrocyte sedimentation rate > 15mm in 1st hour after clinical workup, laboratory investigations and conventional imaging. Clinical follow-up / histopathology (when feasible) were used to confirm the diagnosis as a composite reference standard. Patients who had blood cultures or ECHO positive and clinical response to antibiotics/device removal were considered as true positives. ***Results:*** The study included 29 patients (5 female, 24 male), aged 49 +/- 17.9 (standard deviation) years. The commonest symptom was fever, followed by dyspnoea. Suspected diagnoses comprised native-valve IE (n=10), prosthetic-valve IE (n=7), pacemaker infection (n=5), stent/graft infection (n=4) and mycotic aneurysms (n=3). ^{18}F-FDG-LAL-PET/CT showed abnormal tracer localisation in 15 (10 IE, 5 CVDI) patients, 14 of which were diagnosed as true positive. No tracer localisation was detected in 14 patients (2 false negative). The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of ^{18}F-FDG-LAL-PET/CT was 87.5%, 92.3%, 93.3%, 85.7%, and 89.7% respectively. ECHO vegetations were reported in 11 suspected valvular IE patients, of which only 4 showed LAL localisation. Tracer localisation was detected in 2 patients with no significant ECHO findings and 3 with negative blood cultures. One patient with prosthetic mitral valve vegetation on ECHO showed LAL localisation in the prosthetic aortic valve instead. In patients who had undergone ^{18}F-FDG-PET/CT previously, some myocardial regions showed physiological tracer uptake despite adequate diet preparation, likely due to increased cardiac workload. ***Conclusion:*** ^{18}F-FDG-LAL-PET/CT can detect IE and CVDI with good specificity. It can be especially useful in the setting of possible IE and patients with negative cultures, and does not require compliance to special diets and prolonged fasting.

EP-0742

Sensitivity and Specificity of F-18 FDG PET/CT İmaging in IE; Usefulness of Dual İmaging

A. Çelik Arslan[1], *C. Engür Uyanık*[1], *A. Çınar*[1], *D. Karamanlıoğlu*[2], *N. Aydınbelge Dizdar*[1], *Ö. Özmen*[1];
[1]*Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Etlik City Hospital, Department of Clinical Microbiology and Infectious Diseases, Ankara, TÜRKIYE.*

Aim/Introduction: This study aims to investigate the correlation of F-18 FDG PET/CT with clinical and TEE findings in the diagnosis of IE and to assess its sensitivity and specificity in patients with native and prosthetic valves. ***Materials and Methods:*** Patients referred to our clinic between January 2023 and February 2025 with a suspected diagnosis of IE were included in the study. Images of 42 patients who underwent FDG PET/CT after an appropriate diet regimen were retrospectively analyzed. Patients were further divided into two subgroups based on the localization of the infection focus (native/prosthetic valve). Visual assessment of the images obtained at 60 and 90 minutes: patients with heterogeneous distribution around the valve, intense focal FDG uptake were considered as positive for IE, while those with homogeneous and diffuse F-18 FDG distribution were considered negative for IE. Patients were evaluated for accompanying septic emboli. ***Results:*** In 14 of the 42 patients included in the study, increased FDG uptake consistent with the diagnosis of IE was observed. The sensitivity of PET/CT for diagnosing IE was found to be 52.63%, specificity 84.62%, positive predictive value 83.3%, negative predictive value 55%, and accuracy 65.63%. The sensitivity of TEE was 45.45%, specificity 90.91%, positive predictive value 83.33%, negative predictive value 62.5%, and accuracy 68.18%. Among the 18 patients considered suspicious by TEE, 8 were found to be positive on PET/CT and clinically diagnosed with IE. In the evaluation of PET parameters in prosthetic valve patients, a cutoff value was determined with 86% sensitivity and 87.5% specificity; for first images, the cutoff was 3.28 and for late images, 4.47. For native valve patients, the PET parameters for detecting IE were evaluated, with first and late SUVmax cutoff values calculated as follows: 67% sensitivity and 69% specificity for first images with a cutoff of 2.59 , and 83% sensitivity and 81% specificity for late images with a cutoff of 2.95. Late images showed more significant SUVmax values. There was no statistically significant correlation between the duration of antibiotic use and valve SUVmax values. ***Conclusion:*** In suspected valve-associated IE, FDG PET/CT is a non-invasive imaging method with sensitivity and specificity similar to TEE. Late images are valuable in evaluating native valve IE, while first and late images in prosthetic valve IE show significant activity increase in diagnosing the condition. Whole-body imaging in PET/CT helps to explore supportive findings and aids in diagnosis beyond just the heart.

EP-0743

Evaluating the Role of [18F]FDG PET-CT in Infective Endocarditis: Correlations with Systemic Inflammatory Markers

A. Militaru[1], *D. F. Militaru-Minea*[2], *A. Marin*[1], *M. M. Matei*[1], *D. Craciun*[1], *C. V. Mazilu*[1], *R. M. Mititelu*[1,3];
[1]*Clinic of Nuclear Medicine - Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,* [2]*Clinic of Infectious Diseases- Central Universitary Emergency Military Hospital, Bucharest, Bucharest, ROMANIA,* [3]*Nuclear Medicine Department-University of Medicine and Pharmacy "Carol Davila" Bucharest, Bucharest, ROMANIA.*

Aim/Introduction: Infective endocarditis (IE) is a diagnostic challenge, especially in cases with equivocal echocardiographic findings. [18F]FDG-PET-CT has been shown to be a valuable imaging modality for detecting infections of the prosthetic heart valve and device-related infections. ***Materials and Methods:*** In this study, 25 patients with suspected infective endocarditis who underwent ^{18}F-FDG PET-CT were retrospectively analyzed. Among them, 10 patients had prosthetic heart valves, while 15 patients had native valves. Imaging results were correlated with clinical, microbiologic and laboratory data, including inflammatory markers such as C-reactive protein (CRP) and leukocytosis. Patients were classified based on PET-CT positivity and inflammatory markers, and statistical analysis was performed to evaluate the association between inflammatory markers and imaging results. ***Results:*** Of the 25 patients, PET-CT was positive in 10 cases (40%), with a higher detection rate in patients with prosthetic valves than in patients with native valves (7 vs. 3). PET-CT positivity was significantly associated with elevated CRP levels ($p = 0.0084$), suggesting a close association between systemic inflammation and PET-CT findings. Although leukocytosis was observed in both PET-CT-positive and PET-CT-negative cases, there was no significant association with PET-CT positivity ($p = 0.1648$), suggesting that leukocytosis alone may not be a reliable marker of infection. In addition, echocardiography did not show a significant correlation with either CRP ($p = 0.8807$) or leukocytosis ($p = 0.8350$), reinforcing its lower sensitivity in detecting inflammation-related changes. These results emphasize the superior diagnostic performance of PET-CT compared to echocardiography, especially in patients with prosthetic valves and elevated inflammatory markers such as CRP. ***Conclusion:*** ^{18}F-FDG PET-CT is a valuable tool in the diagnostic workup of infective endocarditis, particularly in patients with prosthetic valves where echocardiography is limited. The correlation between PET-CT findings and CRP levels could provide additional insights into disease activity and prognosis. Further studies with larger cohorts are needed to validate these results.

Seeing Beyond Symptoms: How FDG-PET/CT Detects Silent Myositis in Seronegative Dermatomyositis in a retrospective cohort

R. Karna*, A. S. Babu, A. Dhiman, R. Kumar;*
All India Institute Of Medical Sciences, New Delhi, New Delhi, INDIA.

Aim/Introduction: Dermatomyositis (DM) and other inflammatory myopathies can present with muscle inflammation that often goes undetected using standard blood tests, especially in seronegative DM patients. FDG-PET/CT imaging may help identify subclinical inflammation that is missed by conventional biomarkers like creatine kinase (CK). This study aims to evaluate the role of FDG-PET/CT in detecting subclinical muscle inflammation in DM and other inflammatory myositis subtypes and to correlate PET findings with serum markers, such as CK, CRP, and LDH. ***Materials and Methods:*** We conducted a retrospective analysis of 42 patients diagnosed with DM or inflammatory myositis. FDG-PET scans were scored using a three-tier system: Score 0 (uptake less than blood pool), Score 1 (uptake more than or equal to blood pool), and Score 2 (uptake more than or equal to liver). PET scores were compared with serum levels of CK, CRP, and LDH. Patients were divided into subgroups: classic DM, overlap syndromes, and inflammatory myositis. ***Results:*** Discordant Cases: 35% (6/17) of CK-negative patients had significant FDG uptake (Scores 1 or 2), indicating occult muscle inflammation that was not detected through routine blood tests. PET-Biomarker Correlations:48% of patients had a PET Score 2, with 70% showing elevated CK, 85% with raised LDH, and 60% with high CRP, suggesting active inflammation.14% of patients had a Score 1, with 83% showing elevated CK, but lower CRP levels (median 3 mg/dL), reflecting intermediate disease activity. Subtype Variations: Classic DM patients showed the highest FDG uptake (71% with Score 2), while 75% of overlap syndrome patients had Score 0, a significant difference ($p=0.04$). ***Conclusion:*** FDG-PET/CT is an effective tool for detecting subclinical muscle inflammation, particularly in CK-negative DM patients. It complements serum biomarkers in assessing disease activity and can help monitor inflammation in different myositis subtypes, especially classic DM, where biomarkers and imaging findings often do not align. FDG-PET/CT may improve early detection and monitoring of active inflammation in these patients.

EP-0745

Utility of ^{18}F-FDG PET/CT in the initial characterization of silicosis

J. Rodríguez-Rubio Corona[1], *M. Piñero Fernández-Reyes*[1], *J. Jiménez-Murillo*[2], *Y. Santaella-Guardiola*[1], *F. Cañete-Sánchez*[1], *M. Gutiérrez-Amares*[1], *A. Campos-Caro*[3], *A. León-Jiménez*[4], *M. Pajares-Vinardell*[1];
[1]*Nuclear Medicine Department, Puerta del Mar University Hospital, Cádiz, SPAIN,* [2]*Technical Advisory Subdirectorate for Information Management, Servicio Andaluz de Salud, SPAIN,* [3]*Institute of Biomedical Research and Innovation of Cádiz (INiBICA), Cádiz, SPAIN,* [4]*Pulmonology Department, Puerta del Mar University Hospital, Cádiz, SPAIN.*

Aim/Introduction: Silicosis is an occupational inflammatory lung disease caused by the inhalation of silica particles. Diagnosis is based on occupational history, radiological findings as defined by the International Classification for Occuptaional and Environmental Respiratory Diseases (ICOERD), and the exclusion of other conditions. Although the role of ^{18}F-FDG in the study of inflammatory diseases is well known, it's application in the assessment of silicosis remains limited. The aim of this study is to assess the usefulness of ^{18}F-FDG PET/CT in the initial characterization of silicosis and the correlation between metabolic parameters and the findings observed on CT. ***Materials and Methods:*** Descriptive study of 17 patients diagnosed of silicosis who underwent a chest CT at the time of diagnosis (April 2017-July 2020) where lesions were classified according to ICOERD and if they were or not calcified. The location of lymphadenopathy and pulmonary lesions was analysed. Later, a whole-body ^{18}F-FDG PET/CT scan was performed (November 2021-September 2022), recording the maximum Standardized Uptake Value (SUVmax) of the lesions. The correlation between ICOERD and SUVmax was estimated using Spearman's correlation coefficient, and a hypothesis test was conducted. ***Results:*** Five patients were classified as ICOERD A, six

as B, and six as C. The average SUVmax increased as is scaled in the ICOERD classification: 3.96 for A, 6.25 for B, and 8.88 for C, with a Spearman's coefficient of 0.70 ($p<0.01$). Calcified lesions also showed a higher average SUVmax than non-calcified ones (7.14 and 4.83, respectively). The average SUVmax of the lymph nodes was 6.22, and PET/CT detected lymphadenopathies not identified on CT in 10/17 patients (58.82%), mainly in lower thoracic and abdominal regions. ***Conclusion:*** ^{18}F-FDG PET/CT allows a better initial characterization of silicosis due to its higher sensitivity in detecting lymphadenopathies, mainly extrathoracic. Metabolic activity is higher in advanced ICOERD categories and in calcified lesions.

EP-0746

Role of 99mTc-Ethambutol Scintigraphy in Diagnosis of Pulmonary and Extra Pulmonary Tuberculosis

A. Roy, *N. A. Damle, S. Sikdar;*
AIIMS new delhi, New Delhi, INDIA.

Aim/Introduction: To determine the sensitivity, specificity, predictive values, and overall diagnostic accuracy of 99mTc-Ethambutol scintigraphy in detecting pulmonary and extrapulmonary tuberculosis. ***Materials and Methods:*** A prospective observational study was conducted at AIIMS, New Delhi, involving 28 adult patients diagnosed or clinically suspected to have TB. Patients received 10 mCi of 99mTc-Ethambutol intravenously, and serial planar and SPECT/CT scans were performed. Uptake patterns were correlated with microbiological, histopathological, and clinico-radiological findings. Diagnostic accuracy parameters were calculated using standard statistical methods. ***Results:*** Out of 28 enrolled patients, 25 had reference diagnostic standards. 99mTc-EMB scintigraphy showed an overall sensitivity of 81.25%, specificity of 66.67%, PPV of 81.25%, NPV of 66.67%, and accuracy of 76%. Subgroup analysis revealed significantly higher diagnostic accuracy in bone TB (sensitivity and NPV 100%, accuracy 92.3%). In contrast, sensitivity and PPV were lower in soft tissue EPTB (40% and 50%, respectively). False negatives were primarily due to necrotic tissue or reduced perfusion; false positives were attributed to non-specific uptake and radiochemical impurities. ***Conclusion:*** 99mTc-Ethambutol scintigraphy is a promising non-invasive imaging modality for TB, particularly in skeletal involvement, where it demonstrates high diagnostic accuracy. However, caution is advised in interpreting results for soft tissue EPTB due to lower sensitivity. This imaging technique also holds potential for guiding biopsy site selection and monitoring treatment response.

EP-0747

The use of a portable ultrasound device to control intra-articular puncture during radioisotope synovectomy of the knee joints - Is post-injection scintigraphy always necessary?

M. Wlodarczyk, *Z. Adamczewski;*
Nuclear Medicine Department, Central Clinical Hospital, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: Radioisotope synovectomy is a recognized method used in the treatment of joint effusions. It involves intra-articular administration of an isotope-labelled colloid emitting beta radiation. The condition for safely carrying out this type of procedure is to deposit the isotope in the joint cavity. The flow of synovial fluid confirms the correct position of the needle tip during injection. Additionally, ultrasound imaging is used to monitor the injection or to select the best place for the injection just before starting the procedure. Guideline for radiosynoviorthesis recommend the post-injection scintigraphy to confirm proper radiopharmaceutical distribution, which in many cases seems unnecessary. ***Materials and Methods:*** Nuclear Medicine Department of the Medical University of Lodz has extensive experience in performing radiosynovectomy of the knee joints. Over the last 12years, approximately 1,200 procedures of this type have been performed. For several months, a portable ultrasound device equipped with a linear head with 4-12MHz frequency has been used for ultrasound control during injection. Over this period, 153 radiosynovectomy procedures were performed in selected patients without popliteal cyst or synovial septa. In case of previous arthroscopy or arthroplasty, the required 2-month intervals were maintained. ***Results:*** During procedures performed under portable ultrasound guidance, synovial fluid outflow could not be obtained in only 18 cases (12%). In all 153 cases, safe isotope deposition was achieved by confirming the presence of the needle tip in the joint cavity (photographic documentation recorded). In 18 cases of so-called "dry joints" prior administration of a small amount of saline was required. Only in 1 case was it necessary to perform another puncture due to significant hypertrophy of the synovium and the inability to locate the needle tip in the joint cavity. The choice of an alternative injection site was made based on the ultrasound image, which allowed the procedure to be performed successfully. In all 153 cases subsequent scintigraphy confirmed the correct distribution of the radiopharmaceutical. ***Conclusion:*** The use of a portable ultrasound device allows for selection of the best joint puncture site and for high probability of obtaining synovial fluid outflow. The quality of the generated image is sufficient to visualize the needle tip during injection, which is particularly important in the case of so-called "dry joints". Properly performed injection under portable ultrasound guidance allows to omit additional acquisition of a scintigraphic image in selected patients, which significantly shortens the time and reduces the cost of the entire procedure.

Scintigraphic Findings of Inflammatory Pseudotumour in Long-standing Osteoarticular Arthroplasties: Experience at Our Centre

M. Rosado Hidalgo, *L. Ramos Rodríguez, S. Romero Acevedo, J. Vela León, M. Lara Martínez, F. Medina Romero, M. González Díaz, M. Gómez Rodríguez-Bethencourt;*
Hospital Universitario de Canarias HUC, Tenerife, SPAIN.

Aim/Introduction: Wear particle-induced periprosthetic osteolysis is a well-known phenomenon in total arthroplasties and the leading cause of aseptic loosening. Occasionally, it presents aggressively with soft tissue mass, or 'inflammatory pseudotumour', often requiring revision and complex reconstruction surgery. The aim of this study is to assess the scintigraphic findings on blood pool and delayed SPECT-CT in patients with long-standing total hip and knee arthroplasties complicated with loosening due to particle disease and associated pseudotumour formation. ***Materials and Methods:*** A retrospective descriptive study was conducted on eight patients seen between 2021 and 2025 with wear particle-induced periprosthetic osteolysis associated with a soft tissue mass. Bone scintigraphy with ^{99m}Tc-HDP, including blood pool (5-10 minutes) and delayed (3-4 hours) phases, along with SPECT-CT in both phases, was visually assessed. Pseudotumour dimensions were measured from CT. Demographic variables and pain presence were recorded. Infectious and neoplastic complications were excluded through clinical and laboratory evaluation. ***Results:*** The study included 8 patients, 5 women and 3 men, with a mean age of 75 years and an average interval of 17 years from prosthesis implantation to molecular imaging. All patients

reported pain, contrary to previous literature. A pseudotumour was identified on the acetabular component in 2 cases (mean size: 45×40×75 mm, AP×T×CC), on the femoral component in 1 case (20×40×40 mm), and in 4 cases affecting both components (mean size: 123×95×119 mm). One case involved a right total knee arthroplasty with pseudotumour affecting the femoral component (100×100×240 mm). The scintigraphic pattern observed in all cases was characterised by central photopenic defect in the soft tissue mass with peripheral radiotracer uptake in severe periprosthetic osteolysis with bone destruction in some cases. Blood pool presented similar behaviour as in the late phase. ***Conclusion:*** Inflammatory pseudotumours represent a rare complication of total hip and knee arthroplasties. In our series, all cases were symptomatic and demonstrated a characteristic uptake pattern on SPECT-CT. Its recognition is essential, as it may influence clinical decision-making, favouring revision surgery due to associated complications. ***References:*** 1. Fabbri N, Rustemi E, Masetti C, et al. Contribution of Renal Scintigraphy Findings to Clinical Management

B. Bozca*, A. Cinar, D. Cayir, N. Aydinbelge Dizdar, O. Ozmen;*
Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Renal scintigraphy is a highly accurate and sensitive imaging method used to evaluate organ function. Tc-99m DMSA is a reliable radiopharmaceutical for assessing differential renal function (DRF) and visualising renal parenchyma. Additionally, Tc-99m MAG-3 is another radiopharmaceutical that can be used to calculate DRF. Background activity correction is a necessary step in DRF calculation, and it may represent a potential source of error. Aim of this study is to consider DRF calculated with DMSA as gold standard and to determine which background activity region is associated with the least error when using MAG-3. ***Materials and Methods:*** A retrospective analysis was conducted on 93 patients who underwent both DMSA and MAG-3 scintigraphy within two-week period between December 2023-December 2024. In DMSA scintigraphy, DRF was calculated using geometric mean and automatic perirenal ROI for background correction. In MAG-3 images, DRF was determined by drawing three different regions of interest: inferior (group 1), superior pole (group 2), and crescentic (group 3). 21 patients with normal renal function formed the control group, while 72 patients with varying degrees of obstruction patterns were defined as patient group. DRF obtained from DMSA images were accepted as gold standard. DRF from MAG-3 images were compared with DMSA images. DFR's were compared using linear regression analysis. The Mann-Whitney U test was used to compare laboratory parameters. P-value of <0.05 was considered statistically significant. ***Results:*** In both groups with normal and pathological renal function, no statistically significant differences were found in age, sex, or renal function tests (Table 1). Among patients with normal renal function, there was no statistically significant difference between DRF values obtained from DMSA and MAG-3 scintigraphy. In patient group with pathological renal function, background correction using superior pole and crescentic regions yielded results that differed markedly from DMSA scintigraphy. When the background activity region was drawn from inferior pole, DRF values were the most consistent with DMSA scintigraphy. This background region was found to be statistically significant. ***Conclusion:*** In conclusion, DMSA is considered a reliable method for determining differential renal function. In our study, in the presence of normal renal function, similar DRF values were obtained using three different background activity regions. However, in the presence of an obstructive pattern, the background activity region drawn from the inferior renal pole in the MAG-3 study was found to be more consistent and reliable when compared with the DRF values obtained from DMSA scintigraphy.

A Simple Numeric Clue: Non-Decay Corrected 4-Hour Retention Percentage on Tc-99m LLEC Scans to Distinguish PUJO from Delayed Clearance in Equivocal Tc-99m LLEC Renograms

A. Mahalik*, N. Kundu, A. Roy, K. Jain, V. R. Singh, J. Choudhary, S. Singh, J. Krishna P., R. Kumar;*
All India Institute of Medical sciences, New Delhi, INDIA.

Aim/Introduction: Differentiating pelviureteric junction obstruction (PUJO) from delayed non-obstructive clearance (DNOC) in patients with equivocal renogram curves presents a common diagnostic dilemma. Tc-99m L,L-ethylenedicysteine (LLEC) is a preferred radiotracer for assessing renal drainage due to its favorable pharmacokinetics. This study evaluates the diagnostic value of 4-hour retention percentage using non-decay corrected counts from static images in distinguishing PUJO from DNOC. ***Materials and Methods:*** We retrospectively analyzed 61 renal units showing equivocal or uprising curves on Tc-99m LLEC dynamic scans. Retention percentage was calculated using counts from prevoid and 4-hour delayed post-void static images. Importantly, decay correction was not applied, as static image ROIs in routine clinical settings yield non-decay corrected counts, and this approach enhances reproducibility in day-to-day practice. Based on surgical or clinical follow-up, renal units were grouped into PUJO (n=29) and DNOC (n=32). ROC analysis was conducted to identify an optimal diagnostic cut-off. ***Results:*** The PUJO group showed a significantly higher mean retention percentage (58.6 ± 18.7%) compared to the DNOC group (32.5 ± 16.4%, $p < 0.001$). ROC analysis identified a cut-off value of 44.5% using non-decay corrected counts, with an AUC of 0.84, sensitivity of 86.2%, and specificity of 78.1% for diagnosing PUJO. ***Conclusion:*** Retention percentage from 4-hour static images using non-decay corrected Tc-99m LLEC counts is a simple and effective tool for differentiating PUJO from DNOC in equivocal renogram curves. This method reflects real-world imaging workflows and can serve as a reliable adjunct to curve morphology in decision-making.

EP-0751

Use of Dynamic Renal Scintigraphy as a Method to Predict Renal Outcome in Acute Kidney Injury

P. Korol*[1], O. Shcherbina[1], M. Tkachenko[2], M. Kostylev[3];*
[1]Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE, [2]Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE, [3]Shalimov National Scientific Center of Surgery and Transplantation, Kyiv, UKRAINE.

Aim/Introduction: Acute kidney injury (AKI) is characterized by a rapid loss of renal function (<48 hours). Dynamic renal scintigraphy (RS) with Tc-99m-MAG3 is routinely prescribed by physicians in our Department of Nuclear Medicine to assess renal function in patients with AKI. The aim of our study is to determine the ability

of dynamic RS to predict renal recovery after AKI. ***Materials and Methods:*** We retrospectively included 270 patients (127 men and 143 women) with a mean age of 56±9 years who suffered RS during AKI. During RS, the accumulation index (AI), defined as the percentage of input activity recovered by the kidney in one minute, was calculated, and the slope of the accumulation curve (SAC) of the most functional kidney was measured. Renal function was assessed 6 months after RS, and patients were divided into two groups: patients with recovery of renal function and patients without significant recovery, defined as recovery of less than 30% of the loss of function during AKI. ***Results:*** When RS was performed during AKI, the sum of the AI of both kidneys was significantly higher in patients with recovery of renal function 3 months after AKI than in patients without significant recovery of renal function (9.3 [6.2-11.4] versus 6.1 [3.4-7.6]; $p < 0.05$). SAC of the most functional kidney was also significantly higher in patients with renal function recovery (0.34 [0.23-0.54] than without 0.21 [0.12-0.29]; $p = 0.05$). ***Conclusion:*** Quantitative AI and SAC measured during RS are useful indices to predict renal function recovery after AKI.

EP-0752

Dynamic Renal Scintigraphy In Pediatric pelviureteric junction stenosis : Impact In Therapeutic Decision

R. Belakroum, *H. Bouzidi;*
Regional University Military hospital, Constantine, ALGERIA.

Aim/Introduction: Pelviureteric junction (PUJ) stenosis antenatally diagnosed is an urodynamic disorder responsible for renal dilation. Its imaging modalities and therapeutic choices are controversial. Non-operative postnatal treatment consistent with PUJ stenosis, has functioned well during follow-ups. However, doubts are still expressed and admittedly, the final verdict on this therapeutic approach is still debated. The purpose of this prospective study is to define the state of art and to serve as a background for future studies, which still are needed. ***Materials and Methods:*** Through a prospective study, we have followed 80 children with antenatally diagnosed, unilateral PUJ stenosis during a 9 years period (between 2016 and 2024), with a median follow up of 102 months. Repeated ultrasounds, and ^{99m}Tc-EC (ethylene-dicysteine) renograms under strict guidelines were performed in all children during the follow up. Initial differential renal function (DRF), quality of renal drainage and cortical transit were analyzed and compared to the late DRF outcome. ***Results:*** Surgical repair (Anderson-Hynes dismembered pyeloplasty) was performed in 33 (41,25 %), while 47 (58,75 %) patients did not underwent a surgical intervention. Early pyeloplasty was performed in 19 patients, and late pyeloplasty in 14 cases. During conservative approach, DRF deterioration was observed in 13% of cases. When analyzing the DRF evolution, DRF deterioration was equally distributed between the different levels of abnormal renal drainage. However, there was no DRF degradation in patients with good drainage, and only abnormal cortical transit were predictive of DRF deterioration in case of conservative approach. ***Conclusion:*** In children with antenatally diagnosed PUJ stenosis, a conservative management might be a safe attitude without routine surgery. A good renal drainage could rule out PUJ obstruction. ***References:*** [1]- Koff SA, Campbell KD. EP-0753

Assessment of 99mTc-DTPA renal scintigraphy in monitoring cisplatin nephrotoxicity in oncology patients in Saudi Arabia

M. Alqahtani[1,2];
[1]*Najran university, Najran, SAUDI ARABIA,* [2]*Najran university hospital, Najran, SAUDI ARABIA.*

Aim/Introduction: Cisplatin-based chemotherapy is a cornerstone treatment for various cancers but is associated with nephrotoxicity, which can lead to renal dysfunction. Monitoring renal function during chemotherapy is crucial for early detection and management of nephrotoxicity(1-2). This study aimed to evaluate the efficacy of 99mTc-DTPA scintigraphy in detecting cisplatin-induced nephrotoxicity among cancer patients in Saudi Arabia***. Materials and Methods:*** A total of 85 non-hypertensive, non-diabetic, or unstable patients with adequate baseline renal function were enrolled. These patients, diagnosed with various cancers including carcinoma of the head and neck, breast, testicular, and lung, received cisplatin therapy at an average dose of 867.5 mg. Radionuclide renal scans were conducted to measure glomerular filtration rate (GFR) using 99mTc-DTPA scintigraphy and creatinine clearance. ***Results:*** The technique involved meticulous preparation of 99mTc-DTPA according to manufacturer guidelines, with careful calibration to ensure dose accuracy. Patients underwent dynamic renal studies under the gamma camera, with GFR automatically calculated using the Gates method. Statistical analysis was performed using Microsoft Excel and SPSS, with paired sample t-tests demonstrating statistical significance ($p < 0.001$).The study found a significant reduction in renal function parameters, with GFR decreasing by 9.787 ml/min per chemotherapy cycle and serum creatinine clearance decreasing by 3.655 ml/min per cycle. Post-chemotherapy GFR was lower than pre-chemotherapy levels, with a reduction factor of 0.83, and creatinine clearance decreased post-chemotherapy by a factor of 0.4985. Age and BMI were identified as significant factors influencing renal function. ***Conclusion:*** Proactive monitoring and intervention are essential to mitigate nephrotoxicity-associated risks during chemotherapy. The findings underscore the importance of 99mTc-DTPA scintigraphy in detecting cisplatin-induced nephrotoxicity and optimizing patient care in oncology practice. ***References:*** 1. Approaches to Renal Function Assessment: A Comparative Perspective

T. Makazlieva[1], *A. Peshevska*[1], *I. Sazdova*[1], *Z. Markovska Shterjova*[2], *I. Rambabova-Bushljetik*[2];
[1]*Institut of pathophysiology and nuclear medicine, Medical faculty, University Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF,* [2]*University Clinic of Nephrology, Medical faculty, University Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, THE REPUBLIC OF.*

Aim/Introduction: Accurate assessment of renal function is essential in various clinical scenarios such as staging acute or chronic kidney disease, optimizing drug dosing, and evaluation of potential kidney donors. A range of techniques are available for evaluating renal function. Our study aimed to evaluate the

correlation between the measured GFR (mGFR) values obtained by the three-plasma sample (TPS) slope-intercept method with 99mTc-DTPA, as a reference method, and estimated GFR (eGFR) with different creatinine formulas. The second objective of our analysis was to evaluate the correlation between mGFR and tubular extraction rate (TER) value with 99mTc-MAG3. ***Materials and Methods:*** A total of 72 subjects (31 male, 41 female) with a mean age of (57,67±13,17) years were included. The mGFR value was obtained by the TPS slope-intercept method after i.v. application of ^{99m}Tc-DTPA and eGFR was obtained with the CKD-EPI (2009), CKD-EPI (2021) and MDRD formula. In 36 subjects, the tubular extraction rate (TER) was additionally evaluated using ^{99m}Tc-MAG3 Bubeck methodology and correlated with the mGFR value. ***Results:*** Our study revealed that the CKD-EPI (2021) formula had the highest bias and mean percentage error, while the MDRD method demonstrated the weakest correlation with the reference method. Bland-Altman plots indicated that all three creatinine-based formulas consistently overestimated GFR. Statistical analysis revealed a significant correlation between ^{99m}Tc-DTPA mGFR values obtained using TPS method and TER values measured with ^{99m}Tc-MAG3 across a broad range of GFR values in all patients. ***Conclusion:*** The study found that creatinine-based formulas tend to overestimate GFR. In clinical situations requiring better accuracy, plasma sampling nuclear medicine methods offer a more reliable alternative assessment and should be considered as a more appropriate diagnostic method. ***References:*** Itoh K. 99mTc-MAG3: review of pharmacokinetics, clinical application to renal diseases and quantification of renal function. Impact of [18F]FET PET imaging on diagnosis and prognosis in pediatric and adolescent brain tumors: a systematic review and quantitative analysis

T. Antonevskaya[1], *M. Yadgarov*[1,2], *Y. Likar*[1];
[1]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION,* [2]*Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Pediatric and adolescent brain tumors are the most prevalent neoplasms in children and contribute significantly to cancer-related morbidity and mortality in this demographic. Accurate diagnosis and characterization of brain neoplasms are crucial for clinical decision-making and treatment planning. Traditional imaging modalities, while essential, often lack the nuanced information for effective management of these tumors. This study aims to assess the diagnostic and prognostic utility of baseline and post-therapy [18F]FET (O-(2-[18F]fluoroethyl)-l-tyrosine) PET imaging parameters in pediatric and adolescent brain tumors, focusing on tumor detection, grading, recurrence assessment, residual tumor evaluation, and survival prediction. ***Materials and Methods:*** A systematic review and meta-analysis were conducted in accordance with PRISMA guidelines, incorporating data from prospective and retrospective cohort studies published up to September 9, 2024, without language restrictions. Parameters such tumor-to-brain ratio (TBRmax and TBRmean), time-to-peak (TTP), kinetic pattern (KP), maximum standardized uptake value (SUVmax), and metabolic tumor volume (MTV) were analyzed for diagnostic and prognostic value. Bayesian models for diagnostic accuracy and paired meta-analysis techniques were applied. ***Results:*** A total of 12 studies involving 352 patients, published between 2005 and 2023, were included in the analysis. Baseline TBRmax exhibited limited diagnostic accuracy in differentiating tumor grades, with an area under the summary receiver operating characteristic curve (AUSROC) of 0.639, a sensitivity of 73.8% (95% confidence interval (CI): 52.8%-88.4%), and a specificity of 53.9% (95% CI: 27.5%-75.7%). Paired meta-analysis revealed significantly higher baseline TBRmax (mean difference: 1.93, $p < 0.001$) and TBRmean (mean difference: 1.25, $p = 0.02$) values in patients diagnosed with high-grade tumors. In contrast, post-therapy TBRmax demonstrated strong diagnostic performance for identifying tumor recurrence, with an AUSROC of 0.850, sensitivity of 81.5% (95% CI: 67.8%-90.9%), and specificity of 88.5% (95% CI: 66.4%-97.8%). Due to limited available data, other parameters and clinical outcomes could not be included in the meta-analysis. ***Conclusion:*** This systematic review and meta-analysis shows the diagnostic and prognostic potential of [18F]FET PET imaging in pediatric and adolescent brain tumors. While several factors limited a comprehensive meta-analysis, the inclusion of dynamic parameters alongside established static ones revealed promising associations with clinical outcomes, suggesting their utility in baseline and post-therapy imaging. Stronger evidence and wider clinical implementation can be achieved through the implementation of standardized imaging protocols and multicenter prospective research.

EP-0756

Enhancing Pulmonary Metastasis Detection in Pediatric Bone Sarcomas: The Added Value of Thoracic SPECT-CT in Bone Scintigraphy

A. Khelifa*, F. Koudri, D. Meziane, S. Benali, H. Labiod, L. Chelghoum, M. Lamali, D. Tahmi, L. Belabas, S. Benzerdjeb, A. Amimour;*
Bab El Oued Hospital, Algiers, ALGERIA.

Aim/Introduction: To evaluate the diagnostic contribution of thoracic SPECT-CT performed during bone scintigraphy for detecting pulmonary metastases in pediatric patients with bone sarcomas. Bone scintigraphy remains a standard tool for detecting skeletal metastases in pediatric bone sarcomas. However, the intrinsic limitations of planar imaging in terms of sensitivity and spatial resolution may compromise lesion detectability. Although primarily aimed at osseous evaluation, these scans may incidentally reveal thoracic abnormalities. Considering the high prevalence of pulmonary metastases at initial diagnosis, thoracic SPECT/CT offers added anatomical detail that can enhance lesion characterization, thereby improving staging accuracy and guiding therapeutic decision. ***Materials and Methods:*** This retrospective study included 33 pediatric patients (mean age 14.0 ± 3.9 years; 58% male) with histologically confirmed bone sarcomas. Of these, 20 patients (61%) had Ewing sarcoma and 13 (39%) had osteosarcoma. All underwent bone scintigraphy with additional thoracic SPECT-CT (Pediatric Low dose protocol). Detection rates of pulmonary and skeletal metastases were assessed. Associations between skeletal and pulmonary involvement were analyzed using Fisher's exact test. ***Results:*** Thoracic SPECT-CT identified pulmonary metastases in 9 patients (27%) and skeletal metastases in 11 (33%). No significant association was found between pulmonary and skeletal metastases ($p = 0.12$). SPECT-CT also improved anatomical localization and interpretation of equivocal thoracic foci on planar imaging, leading to staging revisions in several cases. ***Conclusion:*** Thoracic SPECT-CT significantly improves the detection and characterization of pulmonary metastases during routine bone scintigraphy in pediatric bone sarcomas. Although no statistical correlation was observed between pulmonary and skeletal metastases, the added value of SPECT-CT supports its systematic use to enhance diagnostic confidence and inform therapeutic decisions in pediatric oncology.

^{18}F-FDG PET/CT in Rare Histiocytic Disorders: Insights into Metabolic Parameters and Disease Burden in Rosai-Dorfman Disease and Juvenile Xanthogranuloma: A Comparative PET/CT Case-Analysis

K. Hlongwa, *F. Smith, N. Jacobs, M. P. Rivombo, M. Hendricks, S. More;*
University of Cape Town, Cape Town, SOUTH AFRICA.

Aim/Introduction: Rosai-Dorfman disease (RDD) and Juvenile Xanthogranuloma (JXG) are rare forms of non-Langerhans cell histiocytic disease which typically present in the paediatric population. ^{18}F-FDG PET/CT has been used in staging these patients to characterize and assess disease extent, however, there has been limited reporting on the relationship between metabolic activity and disease burden of these conditions. We aimed to compare the quantitative metabolic parameters and disease burden of RDD and JXG in paediatric patients using ^{18}F-FDG PET/CT imaging for staging. ***Materials and Methods:*** We retrospectively analyzed staging ^{18}F-FDG PET/CT scans from patients with RDD and JXG. SUVmax, SUVmean, SUVpeak were measured and total lesion glycolysis (TLG), and metabolic tumor volume (MTV) were calculated for each lesion as well as cumulative measurements of wholebody SUVmax, wholebody SUVpeak and wholebody SUVmean and calculations of wholebody MTV and wholebody TLG. Histological analysis and biochemistry results were also reviewed. ***Results:*** Three patients with RDD and JXG were identified from our database respectively. Patients with RDD lesions exhibited higher median and mean values for SUVmax, SUVmean and SUV peak in comparison to JXG lesions. Median and mean TLG values were higher and mean MTV were also higher in the RDD patients compared to JXG patients. Quantitative parameters for Wholebody SUVmax, SUVmean, SUVpeak, Wholebody MTV and Wholebody TLG also demonstrated higher median and mean values for RDD in comparison to JXG. See table 1.The distribution of disease in patients with RDD typically involved lymphadenopathy that was distributed above and below the diaphragm with intense uptake in comparison to the patients with JXG that had more limited disease with less intense uptake. Histological analysis confirmed the diagnosis of RDD and JXG, with RDD demonstrating positive histiocytes for S100 and CD68 whilst JXG was S100 negative but strongly positive for CD68 and FXIIIa. Biochemistry results were unremarkable in both groups. ***Conclusion:*** Our limited case findings suggest that RDD lesions exhibit higher metabolic activity and disease burden compared to JXG lesions, potentially consistent with their cell biology. These results may have implications for treatment planning, monitoring and survival benefit of patients with these rare histiocytic disorders.

Application of Quantitative Analysis in Salivary Gland Scintigraphy with 99mTc-Pertechnetate

M. Zamorano Rivas[1], *F. Camba*[2], *A. Bagán Trejo*[1], *L. Gracia Sánchez*[1], *G. Reynés Llompart*[2], *P. Notta González*[1], *A. Dacosta Escobar*[1], *D. Tamayo Ossa*[1], *E. Ricart Paredes*[3], *M. Cortés Romera*[1];
[1]*Nuclear Medicine- PET (IDI) Department. Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN,*
[2]*Medical Physics and Radiation Protection Department. Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona, SPAIN,*
[3]*Radiopharmacy Department. Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.*

Aim/Introduction: Salivary gland scintigraphy with 99mTc-pertechnetate is routinely used to evaluate glandular function, primarily through visual interpretation, with is inherently subject to interobserver variability. This study aims to assess the utility of quantitative analysis in providing more objective and reproducible evaluations. ***Materials and Methods:*** 62 patients underwent dynamic anterior projection imaging of the cervicofacial region for 30 minutes. An acid stimulus (lemon juice) was administered 15 minutes after tracer injection. Three quantitative parameters were calculated for the major salivary glands (bilateral parotid and submandibular glands) using MIM 7 software (GE Healthcare): uptake rate at 15 minutes (UR), uptake percentage (UP) and ejection fraction (EF).Glands were classified as having normal or impaired based on visual assessment. Statistical analysis was performed to identify significant differences in quantitative parameters between the two groups, RPC analysis to differentiate normal from impaired glands, and optimal thresholds were calculated using the Youden index. ***Results:*** Significant differences ($p < 0.05$) were observed between normal and functionally impaired glands. Right parotid glands with normal function showed a UR of 8.0 ± 4.8 vs. 5.2 ± 3.2, UP of 12.7 ± 3.8 vs. 6.7 ± 2.9, and EF of 68.0 ± 6.4 vs. 50.1 ± 17.1, compared to pathological glands. Similarly, normal right submandibular glands showed a UR of 4.4 ± 2.8 vs. 3.0 ± 1.8, UP of 5.6 ± 2.7 vs. 3.1 ± 1.4, and EF of 55.8 ± 8.7 vs. 40.6 ± 13.9. Similar findings were found in the contralateral glands. The ROC analysis shows that UP of the parotid glands had the best diagnostic performance with an Area Under the Curve (AUC) of 0.904 and 0.922 for the right and left parotid gland, respectively. The optimal thresholds were, for the right parotid gland, a UP cutoff value of 9.0 with a sensitivity of 80.4% and a specificity of 93.8%, and for the left parotid gland, a UP cutoff value of 8.0 with a sensitivity of 78.3% and a specificity of 100%. ***Conclusion:*** These results suggest that quantitative analysis could improve the objectivity and diagnostic accuracy of salivary gland scintigraphy, with UP of the parotid glands emerging as the most effective parameter for distinguishing between normal and impaired glandular function.

EP-0759

Utility of [^{99m}Tc] Tc-99m-Macroaggregated Albumin (MAA) Brain Quantitation Tool for the Diagnosis of Hepatopulmonary Syndrome in Pakistani Cirrhotic Patients and Comparison with Contrast Echocardiography

S. Mardan;
Pakistan Institute of Engineering and Applied Sciences, Islamabad, PAKISTAN.

Aim/Introduction: The study aims to validate the potential use of [99mTc]Tc -MAA brain quantitation(Macro aggregated Albumin) tool for establishing a local population-based cutoff in Hepato Pulmonary Syndrome (HPS) diagnosis with a comparison to TransThoracic Contrast Echocardiography (TTCE). ***Materials and Methods:*** 32 cirrhotic patients were divided into 2 groups on the basis of dyspnea, hypoxemia and alveolar arterial gradient [P (A-a) O_2]. Group I (17 patients) includes clinically HPS positive cirrhotic while Group II (15 patients) serves as HPS-negative controls. Both groups underwent TTCE and [99mTc] Tc-MAA scans. Presence of bubbles in left heart chambers after 3 cardiac cycles and uptake in brain /kidneys were taken as positive on TTCE and [99mTc] Tc-MAA scan respectively. The shunt index was calculated by the percentage of [99mTc]Tc-MAA shunted to the brain. Local population-based cutoff of shunt index was derived using the mean ± 2SD of Group I. Sensitivity, specificity, PPV and NPV values at this cut off, the internationally established 6%, and for TTCE was calculated. ***Results:*** The cut-off value for our population was found to be > 3.81% on Tc-99m-MAA lung perfusion scan. [99mTc] Tc-MAA scan at the local cutoff (3.81%) shows increased sensitivity (47% vs. 29.41% vs. 41.17%) and diagnostic accuracy (68.75% vs. 65.62% vs. 62.5%) compared to the internationally established 6% cutoff and TTCE. Significant clinical parameter differences were found between patients with and without Intrapulmonary

Vascular Dilatation includes shunt indices (3.9±2.44vs1.6±1.10, P=0.0021), PaO_2 (65.07±13vs 92.181±10.3, P=<0.00001) & P(A-a) O_2 (50.57±16.77vs.24.93±7.99, P=<0.00001). ***Conclusion:*** [99mTc] Tc-MAA lung perfusion scan demonstrates a better diagnostic performance in the diagnosis of HPS as compared to TTCE. Local population cutoff >3.81% emerges as a more accurate cutoff than 6% established cutoff and contrast echocardiography for early screening of HPS in Pakistani cirrhotic population.

EP-0760

Old rockstars never die: Gastric emptying scintigraphy of solids in current clinical practice, results by disease and usefulness in therapeutic decision making

V. Aina Monterde, *M. Calderón Calvente, L. M. Del Barco Díez Canseco, A. M. Olmedo Chiva, C. Lorente Fonrodona, G. B. Cárdenas Apaza, M. Falgás Lacueva, M. J. Sangrós Sahún, P. Navarro Beltrán, S. Álvarez Ruiz, L. de la Cueva Barrao; Hospital Universitario Miguel Servet, Zaragoza, SPAIN.*

Aim/Introduction: To analyse the solid GE results of our patients in daily routine versus normal, to assess whether these results vary by subgroups according to the reason for the request, and to study the usefulness of GE studies in therapeutic decision-making. Gastric emptying scintigraphy (GE) is a classic technique that continues to be used because it allows the assessment of gastric dynamics in a physiological and non-invasive way. ***Materials and Methods:*** Retrospective review of consecutive solid GE scintigraphy. Quantitative results from activity/time curves, latency period (Tlag) and half-emptying time (T50) are collected for the sample and are compared with those of a historical control group (n=27) by non-parametric test. GE outcomes are analyzed by subgroups according to the clinical condition motivating are request for the study, as well as the impact of the scintigraphy result on therapeutic decisions, based on patient clinical evolution. ***Results:*** 46 patients: 14 men and 32 women; median age 54 years (range 19-79). The main indication for the study was retentionist symptoms in 39 patients, of whom 28 presented with vomiting; 3 had symptoms following bariatric surgery, 2 had scleroderma, and 2 had episodes of intestinal subocclusion. In 28 patients, gastric emptying (GE) was normal (61%), while in 18 it was abnormal (39%); 7 with rapid GE (dumping) and 11 with gastroparesis. Statistically significant differences were found in the Tlag results between patients diagnosed with rapid GE and gastroparesis compared to the control group (p=0.0002 and p=0.003, respectively); the difference in T50 was also significant in these two groups (p=0.000096 and p=0.00033, respectively). Of the 39 studies requested due to retentionist symptoms, 14 showed abnormal gastric emptying (GE) (36%), of which 11 had vomiting (11/14, 78.5%). Among the 29 patients with vomiting, 11 had abnormal GE (38%), and 8 of them were diagnosed with gastroparesis (72.2%). Both patients with subocclusive symtoms had abnormal Tlag results, while those with sclerodema and hystory of gastric surgery showed variable GE findings. In 33 cases (71.7%), the GE study contributed to therapeutic decision-making. ***Conclusion:*** Solid gastric emptying remains a useful and reliable tool in daily practise, supporting therapeutic decision-making. Among the conditions that justify its use, patiens with clinical signs of distress and vomiting benefit the most from undergoing the solid gastric emptying study.

EP-0761

Pulmonary Uptake in Patients with Suspected Primary Aldosteronism on [^{68}Ga]Ga-pentixafor PET: Incidence and Etiology

L. Yang, *P. Dong, L. Li, M. Su; Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.*

Aim/Introduction: We have incidentally noted pulmonary uptake in a cohort of our patients with suspected primary aldosteronism(PA) on [^{68}Ga]Ga-pentixafor PET/CT or PET/MR images. We aimed to assess the incidence and explore the potential etiologies of pulmonary uptake. ***Materials and Methods:*** The study comprised 217 consecutive patients with suspected PA who underwent [^{68}Ga]Ga-pentixafor PET/CT or PET/MR at our center between January 2023 and August 2024. The PET/CT and PET/MR scans were retrospectively reviewed for the presence of pulmonary uptake. Clinical and PET-related parameters were collected. In patients with pulmonary uptake, recent chest CT scans, and serum leukocyte and neutrophil counts were reviewed for further evaluation. ***Results:*** Of the 217 included patients, 101 were male and 116 were female, with a mean age of 50 years (range, 22-80 years). Pulmonary uptake was present in 37 of 217 patients (17%). Of these 37 patients, 13 were male and 24 were female, with a mean age of 52 years (range, 36-76 years). No clinical or PET-related parameters were found to be significantly associated with pulmonary uptake, including clinical (age, sex, body mass index (BMI), hypertension, duration of hypertension, highest blood pressure), laboratory (hypokalemia, serum potassium, urine potassium, plasma aldosterone (PAC), direct renin concentration (DRC), aldosterone/renin ratio (ARR), 8 AM cortisol (F), 8 AM adrenocorticotropin (ACTH), urine cortisol) and PET-related parameters (SUV_{max} of pulmonary uptake foci, SUV_{mean} of blood pool (BP), injected [^{68}Ga]Ga-Pentixafor activity, length of uptake phase) (all P>0.05). As for the patients with pulmonary uptake, the SUV_{max} of pulmonary uptake foci showed no significant difference between the left lungs (median, 3.7) and right lungs (median, 3.8) (P=0.473). Besides, no significant difference was observed between the lower lung fields (47%) and upper lung fields (49%) (P=0.846). Of these 37 patients, 20 patients had recent chest CT scans. Abnormalities in the corresponding areas were noted in two patients, one with subpleural linear opacities and the other with consolidations. The remaining 18 scans showed no abnormalities at the corresponding site and the surrounding field. Twenty-seven patients had recent leukocyte and neutrophil counts. Seven patients exhibited elevated counts, including the two patients with abnormal CT findings. The remaining 20 patients had normal counts. ***Conclusion:*** In our cohort, 17% of patients with suspected PA demonstrated pulmonary uptake on [^{68}Ga]Ga-pentixafor PET scans. Given the absence of significant associations with clinical or imaging parameters, our findings suggest the possibility of non-specific pulmonary uptake on [^{68}Ga]Ga-pentixafor imaging.

EP-0762

Interobserver and intraobserver agreement of planar, pseudoplanar, and SPECT/CT images in ventilation/perfusion (V/Q) lung scintigraphy

B. Serrallonga, *S. Castejón, G. Guzman, Y. Delisau, M. Calls-Calahorro, P. Stefaneli, M. Velasco-Nuño, A. Fernández-León, J. Duch, S. Asadurova, V. Camacho, A. Flotats; Nuclear Medicine Department, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.*

Aim/Introduction: To assess diagnostic agreement across planar, pseudoplanar, and SPECT/CT V/Q scintigraphy and evaluate whether pseudoplanar images can substitute planar images as a visual adjunct to SPECT/CT. ***Materials and Methods:*** Thirty-two patients with suspected or prior pulmonary thromboembolism (PTE) underwent V/Q scans using planar, pseudoplanar, and SPECT/CT modalities. Four nuclear medicine physicians (one in training) independently reviewed the images on separate days using modified PIOPED II criteria and EANM guidelines. Agreement in perfusion defect detection and PTE probability estimation was analyzed using intraclass correlation coefficients (ICC) and weighted kappa (κ) statistics. ***Results:*** Intraobserver agreement for

perfusion defects was moderate to good (ICC = 0.513-0.780). Planar and pseudoplanar images showed strong agreement for PTE probability (κ = 0.489-1.00). Agreement between planar-SPECT/CT and pseudoplanar-SPECT/CT was moderate (κ = 0.351-0.662). Interobserver agreement for perfusion defects was acceptable overall (ICC = 0.655, p < 0.001), and higher for pseudoplanar (ICC = 0.731) and SPECT/CT (ICC = 0.703) compared to planar images (ICC = 0.658). SPECT/CT had the highest interobserver agreement for PTE probability (κ = 0.590-0.904), followed by pseudoplanar (κ = 0.398-0.570) and planar (κ = 0.285-0.837). ***Conclusion:*** SPECT/CT demonstrated the most consistent diagnostic performance. Pseudoplanar imaging showed more stable interobserver agreement than planar and may be a viable replacement in workflows combining it with SPECT/CT, maintaining diagnostic reliability while enhancing efficiency.

EP-0763

The Impact of Metabolic Tumor Burden on the Physiological Biodistribution of ^{18}F FDG in Normal Tissues and Organs

S. A. Yilmaz*, A. Akbulut, G. Koca, K. Demirel, M. Korkmaz;*
University of Health Sciences, Ankara Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: This study investigates the relationship between metabolic tumor burden and ^{18}F FDG biodistribution in normal tissues and organs—including the cerebrum, cerebellum, liver, spleen, kidneys, and skeletal muscle—to improve cancer staging accuracy, guide treatment strategies, and enhance reporting reliability. ***Materials and Methods:*** A total of 189 patients who underwent ^{18}F FDG PET/CT for initial cancer staging or solitary pulmonary nodule (SPN) evaluation were retrospectively analyzed. Group 1 included 64 patients with advanced-stage cancer and distant metastases; Group 2 included 74 patients with localized disease and SUVmax >10; the control group consisted of 51 SPN patients without pathological FDG uptake. SUVmax values were recorded for the cerebrum, cerebellum, liver, spleen, kidneys, and psoas muscle. MTV and TLG values were calculated in tumor-bearing patients. The study population was also stratified based on primary organ/system involvement. Among the 138 patients referred for initial staging, 41 (29.7%) had gastrointestinal malignancies, 37 (26.8%) had lung cancer, 24 (17.4%) had breast cancer, 12 (8.7%) had urinary tract malignancies, 7 had gynecologic malignancies, 7 had head and neck tumors, 6 had lymph node involvement, 2 had malignant melanoma, 1 had testicular cancer, and 1 had sarcoma. Subgroup comparisons were performed for categories with sufficient patient numbers. ***Results:*** Significant differences in SUVmax values were observed between groups in the cerebrum, liver, and both kidneys ($p<0.05$), while no significant differences were found in the spleen and skeletal muscle. Subgroup analyses revealed consistent variations in cerebrum, cerebellum, liver, and renal SUVmax values in gastrointestinal and lung cancer patients compared to controls. A weak negative correlation was found between cerebrum SUVmax and MTV (ρ = -0.256; p = 0.002). ***Conclusion:*** Increased metabolic tumor burden significantly alters the physiological biodistribution of ^{18}F FDG, particularly reducing uptake in the brain, liver, and kidneys. These findings support the concept of a metabolic superscan, where high tumor glycolytic activity limits FDG availability for normal tissues. Liver SUVmax, frequently used as a reference in PET-based response criteria (e.g., Deauville), was significantly reduced in high-burden patients, potentially affecting response evaluation. In contrast, skeletal muscle uptake remained stable, indicating its potential as an alternative reference region. Recognizing these changes is essential to prevent misinterpretation and to improve the accuracy of PET-based assessment strategies in patients with extensive disease.

EP-0764

Role of Machine Learning Models in Predicting the NCCN High & Very High-Risk Group in Prostate Cancer Patients

R. Wakankar*, S. Sharma, B. Khangembam, M. Kavin, R. Kumar, C. D. Patel, A. Seth, R. K. Sahoo, S. Kaushal, C. J. Das, A. R. Chanu;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To develop machine learning (ML) models using biochemical & imaging data for predicting NCCN risk group in treatment-naïve prostate cancer patients undergoing whole-body ^{68}Ga-PSMA-11 PET-CT. ***Materials and Methods:*** Between January, 2018 to March 2025, 314 treatment-naïve prostate cancer patients with pathologically confirmed diagnoses were enrolled. The primary outcome was the presence of NCCN high-risk & very high-risk disease, determined by ^{68}Ga-PSMA-11 PET-CT imaging and pathological findings. A training set (n = 251) was generated by splitting the original dataset in a 80:20 ratio, with 63 patients reserved as an independent cohort for external validation of the ML models. After feature normalization, Gini Index was used for feature selection. 3 ML models (Logistic Regression, Random Forest and Naïve Bayes) were trained using stratified 10-fold cross-validation. Model performance was assessed using AUC, accuracy, F1 score, precision, recall, and specificity. SHAP plots and confusion matrices were used for model interpretation. ***Results:*** Gini index scoring selected the best-ranked 7 features for cross-validation. In cross-validation, 3 models exhibited >0.850 in all performance metrics, with Random Forest achieving the highest AUC of 0.947 (CA: 0.930, F1 score: 0.951, precision: 0.951, recall: 0.951, specificity: 0.875). On external validation using the test dataset, Random Forest had an AUC of 0.988 (CA: 0.906, F1 score: 0.930, precision: 1.000, recall: 0.868, specificity: 1.000). No significant overfitting was observed, and SHAP plots revealed clear patterns of interpretability. ***Conclusion:*** Machine learning models helped classify high-risk & very high-risk NCCN groups in treatment-naïve prostate cancer patients using biochemical & imaging data. These interpretable models can help aid in personalized patient management in clinical practice.

EP-0765

Decoding Hepatopulmonary Syndrome: Exploring the Relationship Between Liver Disease Severity and Pulmonary Shunt

S. Ramos Barata*[1], S. Paiva[1], I. Casimiro[1], D. Carvalho[1], J. Silva[1], A. Albuquerque[1], A. Moreira[1,2], G. Costa[1,3];*
[1]Hospitais da Universidade de Coimbra - ULS Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL, [3]Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Hepatopulmonary syndrome (HPS) is characterized by intrapulmonary vascular dilatations leading to the formation of intrapulmonary shunt and hypoxemia in patients with liver disease. Abnormal extrapulmonary uptake of [^{99m}Tc]Tc-macroaggregated albumin ([^{99m}Tc]Tc-MAA) in pulmonary perfusion scintigraphy aids diagnosis and allows shunt quantification. HPS can occur across varying stages of liver disease, however, the association between liver dysfunction severity and shunt extent remains unclear. This study aims to investigate the association between liver disease severity - assessed by MELD, PELD, and Child-Pugh scores - and shunt percentage determined by [^{99m}Tc]Tc-MAA scintigraphy in HPS patients. ***Materials and Methods:*** This retrospective study included patients that underwent [^{99m}Tc]Tc-MAA pulmonary perfusion scintigraphy between 2009 and 2025 at our institution. Two groups were analyzed: 20 patients under age 12 and 10 patients aged 12 years or older. Demographic data, shunt percentage, pulse oximetry values, and Child-Pugh, MELD and PELD parameters were collected. Liver disease severity was assessed using age-appropriate scoring systems. Statistical analysis was performed using SPSS-Statistics v.30.0. P-values<0.05

were considered significant. ***Results:*** In the cohort under the age of 12 (10 female(50%); median age 3.55y(IQR 1.61-7.46)), the mean PELD score was 0.00(IQR 0.00-10.68), with a median shunt percentage of 8.2%(IQR 7.43-12.7). In the ≥12 years-old group (3 female(30%); median age 15.31y(IQR 13.73-53.51)), 30%(n=3) were Child-class A and 70%(n=7) Child-class B, with a mean MELD score of 13.00±3.23 and median shunt percentage of 22.85%(IQR 10.95-51.85). In both age groups, PELD and MELD scores showed positive but very weak and non-significant correlation with shunt percentage (pediatric: ρ=0.053, p=0.825; ≥12 years-old: ρ=0.128, p=0.724). No significant differences in shunt percentages were found between Child-class A and B patients (p=0.425). Additionally, no significant associations were observed between shunt percentage and individual parameters of the liver disease scores (bilirubin, albumin, INR, and age) in either group. Regarding the full cohort, oximetry (median 98%(IQR 96.5-99)) showed a strong and significant negative correlation with shunt percentage (ρ=-0.671, p<0.001), as the shunt becomes more severe, oximetry levels tend to decrease. ***Conclusion:*** No significant association was found between liver disease scores and shunt percentage, suggesting that liver disease severity, as assessed by these scores, does not directly influence the extent of intrapulmonary shunt. However, the significant inverse relationship between pulse oximetry and shunt percentage highlights its clinical relevance as a non-invasive marker of shunt severity. Further research with larger cohorts is needed to better understand the relationship between liver disease severity and shunt percentage.

EP-0766

Pressure-Induced Ischemia Artefacts at Sacral and Scapular Regions During Dynamic PET/CT: Characterization and Mitigation

C. Hinge*, F. L. Andersen, F. E. Høi-Hansen, K. Korsholm;*
Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Dynamic ^{18}F-FDG PET/CT often involves prolonged patient immobilisation on the scanner table. This can lead to pressure exceeding capillary perfusion pressure at bony prominences, potentially causing ischemia and reduced ^{18}F-FDG uptake, manifesting visually as photopenic artefacts ("cold spots"). These artefacts, particularly prominent at the sacrum and scapulae, may mask pathology and affect quantification. We aimed to characterize these artefacts in 100 age- and sex-stratified healthy volunteers undergoing dynamic 70-minute PET/CT and evaluate synthetic sheepskin padding as a mitigation strategy. ***Materials and Methods:*** 100 healthy volunteers (50 male, 50 female) underwent dynamic ^{18}F-FDG PET/CT on a Long Axial Field of View Siemens Biograph Quadra as part of a separate study. Participants were positioned headfirst supine, injected with 0.4 MBq/kg 18F-FDG, and remained stationary for the 70-minute dynamic acquisition. The initial 42 participants were scanned without padding, while the subsequent 58 were scanned with synthetic sheepskin padding. Images were assessed blindly by a PhD student for photopenic artefacts at the sacrum and scapulae using a 3-point scale: None, Small, or Big. ***Results:*** Without sheepskin (N=42), artefacts were highly prevalent: None=3 (7%), Small=13 (31%), Big=26 (62%). With sheepskin (N=58), artefacts were significantly reduced: None=46 (79%), Small=12 (21%), Big=0 (0%). Sheepskin padding completely eliminated the severe ('Big') artefacts. We also observe that artefacts occur more frequently in individuals with lower BMI, potentially due to less protective fatty tissue. Visual assessment of non-attenuation-corrected (NAC) and histogram PET images for 5 patients confirmed artefacts were not attributable to reconstruction algorithms. ***Conclusion:*** Significant photopenic artefacts, consistent with pressure-induced ischemia, frequently occur at the sacrum and scapulae during dynamic ^{18}F-FDG PET/CT when patients are positioned directly on the scanner bed throughout uptake and scanning. These artefacts are markedly reduced by using synthetic sheepskin padding. For dynamic scans where pressure is applied from time zero, the ischemic effect can severely impair or nullify the tissue input function throughout the 70-minute. This effect may also impact static scans by inducing ischemia during the shorter scan duration (5-10 minutes), potentially affecting quantification methods like Patlak analysis that rely on late-scan data. Routine use of pressure-relieving padding should be considered standard practice for dynamic and other long-duration PET protocols to improve image quality and diagnostic accuracy. ***References:*** [1] https://pubmed.ncbi.nlm.nih.gov/35440473/.

EP-0767

Development and Validation of a Nomogram for Predicting Pulmonary Embolism Recurrence Using Muscle and Fat Parameters

J. Cao[1]*, S. Niu*[1]*, X. Li*[1]*, H. Liu*[2]*;*
[1]*Shanxi Medical University, Taiyuan, CHINA,* [2]*First Hospital of Shanxi Medical University, Taiyuan, CHINA.*

Aim/Introduction: This study evaluated the predictive value of muscle and fat parameters in managing and improving the prognosis of patients with PE. ***Materials and Methods:*** Data from 184 patients were retrospectively analyzed using the CT component of SPECT/CT at the axial section of the fourth thoracic vertebra. Key parameters included skeletal muscle, pectoral muscle, and subcutaneous fat, with indices such as SMI, PMAI, and SATI calculated. The primary outcome was the recurrence of pulmonary embolism. ***Results:*** The 184 patients were divided into a training cohort (n = 129) and a validation cohort (n = 55). LASSO logistic regression identified independent risk factors, and a nomogram was constructed using age, PMA, PMAI, and PMAD. Model performance was assessed via ROC curves, calibration curves, and decision curve analysis (DCA). Individual predictors such as age, PMA, PMAI, and PMAD showed AUCs of 0.825, 0.769, 0.752, and 0.759, respectively. The nomogram demonstrated robust predictive capabilities for recurrence, with AUC values of 0.902 (95% CI [0.852-0.951]) in the training cohort and 0.871 (95% CI [0.775-0.968]) in the validation cohort. DCA confirmed significant net clinical benefit, highlighting the importance of muscle-fat parameters in predicting PE recurrence. ***Conclusion:*** This study demonstrates advanced age and low chest muscle mass play a significant role in predicting PE recurrence.

EP-0768

Revisiting Pituitary and Adrenal Physiological FDG Accumulation, Using Time-of-Flight PET/CT Scanner Equipped with Semiconductor Detectors and Deep Learning Reconstruction Technology

K. Nakatani[1]*, K. Yoshino*[2]*, T. Kumazawa*[2]*, H. Tanaka*[2]*, T. Koyama*[2]*, K. K. Miyake*[1]*, Y. Nakamoto*[1]*;*
[1]*Kyoto University Graduate School of Medicine, Kyoto, JAPAN,* [2]*Kurashiki Central Hospital, Kurashiki, JAPAN.*

Aim/Introduction: Conventional PET/CT scanners underestimate physiological accumulation in small and thin organs due to sensitivity and spatial resolution limitations. This study aimed to verify the extent to which a TOF-PET/CT scanner equipped with a semiconductor detector and a noise reduction technique using deep learning reconstruction can improve the representation of pituitary and adrenal physiological FDG accumulation compared to conventional PET/CT scanners. ***Materials and Methods:*** The cases included 103 healthy individuals (female: male = 31: 72, age: 31-88) who underwent FDG-PET/CT equipped with digital silicon photomultipliers (SiPM) and Lutetium-yttrium oxyorthosilicate (LYSO) detectors as a medical check-up for cancer screening between June and December 2024 and showed no abnormalities. The controls included 90 healthy individuals

(female: male = 18: 72, age: 26-83) who underwent FDG-PET/CT equipped with conventional photomultipliers and lutetium oxyorthosilicate (LSO) detectors as the same medical check-up between June and December 2023 and showed no abnormalities. The evaluation target was the physiological accumulation of the pituitary and adrenal glands. First, SUVmax and SUVmean using Clear Adaptive Low-noise Method (CaLM) reconstruction in the case group were compared with those using ordered subsets expectation maximization (OSEM) reconstruction in the control group for each organ. We also compared measurements for each organ using CaLM reconstruction to those using Advanced intelligent Clear-IQ Engine (AiCE) reconstruction with deep learning techniques for the same patients in the case group. The relationship between pituitary physiological accumulation and age and sex was also investigated. ***Results:*** Pituitary physiological accumulation was visually recognizable in 103/103 of the cases and 48/90 of the controls. In the case group (with CaLM), SUVmax=2.4±0.9, SUVmean=1.6±0.5, while in the controls, SUVmax=2.1±0.5, SUVmean=1.8±0.3. When AiCE was used in the cases, SUVmax=5.2±2.2 and SUVmean=3.3±1.3 were significantly higher than those using CaLM (P<0.0001 for each). Adrenal physiological accumulation was visually recognizable in 83/103 of the cases and 29/90 of the controls. In the case group (with CaLM), SUVmax=2.4±0.6, SUVmean=1.7±0.3, while in the controls, SUVmax=1.8±0.4, SUVmean=1.4±0.3. When AiCE was used in the cases, SUVmax=3.1±0.9, SUVmean=2.0±0.4 (P<0.0001 for each). The pituitary physiological accumulation SUVmax (using AiCE) in the cases was 5.3±1.4 in females and 5.2±2.5 in males, with no significant difference. The correlation between SUVmax (using AiCE) and age was r=0.20, showing almost no correlation. ***Conclusion:*** Semiconductor TOF-PET/CT scanners with deep learning reconstruction can visualize pituitary and adrenal physiological accumulation in most cases. Pituitary physiological FDG accumulations appear to be considerably stronger than previously thought.

EP-0769

The Brain-White Adipose Tissue Axis May Play a Crucial Role in Diabetes Mellitus: A Metabolic Network Analysis Using Total-Body PET/CT Imaging

L. Sun*;*
Zhengzhou University People's Hospital and Henan Provincial People's Hospital, Zhengzhou, CHINA.

Aim/Introduction: Diabetes mellitus (DM) is the most prevalent metabolic disorder worldwide.The development of DM is frequently associated with inflammatory or tissue-damaging processes that disrupt the delicate equilibrium maintained by the complex interactions between various organs within the body[1]. There has been a paucity of research investigating their specific role in DM.Total-body PET imaging offers a distinctive advantage in the study of multi-organ relationships, as its extended field of view allows for the simultaneous imaging of multiple organs. allows the construction of a glucose metabolic network that reflects the dysregulation that is characteristic of DM, The objective of this study is to utilize total-body ^{18}F-FDG PET to construct an individualized glucose metabolism network, integrating insights from previous research on structural brain MRI networks[2]. ***Materials and Methods:*** In this study, we constructed covariance metabolic networks using static total-body PET images, normalized by lean body mass, from 36 patients with DM (DM group) and 36 age- and sex-matched healthy controls (HC group). Differences in network properties between the DM and HC groups were evaluated at both group and individual levels. In addition, correlation analysis was performed to explore the relationship between network properties and baseline clinical data in the DM subjects. ***Results:*** We observed that the same edges in the first three edges with the largest values were brain-subcutaneous adipose tissue (SAT) and brain-visceral adipose tissue (VAT) at both group and individual levels. There was a positive correlation between the brain-VAT and BMI(r=0.528, P < 0.001) and there was a negative correlation between the brain-SAT and age (r=-0.499, P = 0.002). The most perturbed organ was the brain at both group and individual levels, and there was a positive correlation between the strength of abnormality of brain and age(r=0.428, P = 0.009). ***Conclusion:*** This study successfully used static total-body PET imaging to construct individualized glucose metabolism networks for patients with DM, identifying the brain-VAT and brain-SAT as the most significantly altered edge and the brain as the most affected organ. These findings provide novel insights into the role of the brain-white adipose tissue axis in glucose metabolism in DM. ***References:*** 1. Knobil E. The Wisdom of the Body Revisited. PET/CT with ^{11}C-Methionine and ^{18}F-FDG in Multiple Myeloma Patients

V. Manukova*, I. Aslanidis, O. Mukhortova, M. Metelkina;*
A.N. Bakulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of Russia, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: To evaluate the impact of "a one-day two-radiopharmaceuticals Positron emission tomography in combination with computed tomography (PET/CT)" with ^{11}C-Methionine (MET) and ^{18}F-fluorodeoxyglucose (FDG) on physiological distribution of FDG in patients with multiple myeloma (MM). ***Materials and Methods:*** 40 patients with a history of MM were included in the analysis, 60 PET/CT exams were conducted: in the 1st group - 20 doubled PET/CT (MET PET/CT followed by FDG PET/CT); in the 2nd group - 20 FDG PET/CT. ***Results:*** Comparative analysis of the physiological accumulation of FDG in two groups of patients with MM - one group passed one day 11C-MET PET/CT followed by ^{18}F-FDG PET/CT and another group passed standard ^{18}F-FDG PET/CT - revealed no statistically significant difference. SUL_{max} and SUL_{mean} was calculated in the right lobe of the liver, in the ascending aorta and in the head of the pancreas. The mean values of liver SUL_{max} were: in the first group - 2.37 ± 0.36, in the second group - 2.46 ± 0.40, p = 0.1. The mean values of aortic SUL_{max} were: in the first group - 1.42 ± 0.25, in the second group - 1.51 ± 0.37, p = 0.11. The mean SUL_{max} values in the pancreatic head were: in the first group - 1.43 ± 0.26, in the second group - 1.59 ± 0.36, p = 0.08. ***Conclusion:*** A one-day MET and FDG PET/CT does not affect the pharmacokinetics of FDG and can be used in MM patients. ***References:*** 1. Correlation Analysis of Inflammatory Markers, ^{18}F-FDG PET/CT Metabolic Parameters and Skeletal Muscle Parameters in Advanced Epithelial Ovarian Cancer

Z. Zhang, *H. Liu;*
First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: Epithelial ovarian cancer (EOC) is the most common malignant ovarian tumor, often diagnosed at an advanced stage, leading to poor prognosis. Beyond conventional prognostic factors, inflammatory markers, metabolic parameters, and muscle parameters from ^{18}F-FDG PET/CT are emerging as important indicators. However, few studies have explored the interplay between inflammation, tumor metabolism, and skeletal muscle. This study examines the correlations among these factors in advanced EOC patients, aiming to provide a foundation for future research on their complex interactions. ***Materials and Methods:*** This retrospective study included 32 patients with advanced EOC who underwent baseline ^{18}F-FDG PET/CT at the First Hospital of Shanxi Medical University between February 2018 and September 2024, with complete clinical data.Collected variables included clinical information, inflammatory markers, ^{18}F-FDG PET/CT metabolic parameters, and skeletal muscle metrics. Inflammatory markers comprised platelet-to-lymphocyte ratio (PLR), neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR), platelet-to-albumin ratio (PAR), systemic immune-inflammation index (SII), systemic inflammation response index (SIRI), prognostic nutritional index (PNI), and systemic inflammation score (SIS). PET/CT parameters included whole-body maximum standardized uptake value (WBSUVmax), whole-body metabolic tumor volume (WBMTV), and whole-body total lesion glycolysis (WBTLG). Skeletal muscle metrics included skeletal muscle index at the L3 level (SMI), skeletal muscle density (SMD), percentage of low-attenuation muscle (L%), skeletal muscle gauge (SMG), and intermuscular fat area (IMFA). Inter-observer agreement for skeletal muscle measurements was assessed via intraclass correlation coefficients. Spearman correlation analysis was used to evaluate associations among variables, with $p < 0.05$ considered statistically significant. ***Results:*** Inflammatory Markers and ^{18}F-FDG PET/CT metabolic parameters: PLR, PAR, SII, and SIS were positively associated with WBMTV (all $p < 0.05$). LMR was negatively correlated with WBTLG ($p < 0.05$). Most inflammatory markers showed positive associations with WBTLG, except for lymphocyte count and PNI, which were not significantly correlated. Inflammatory Markers and Skeletal Parameters: Neutrophil count and SIRI were weakly negatively associated with SMD and weakly positively associated with L% ($p < 0.05$ for all). Age and Skeletal Muscle Parameters: Age was inversely associated with SMD and SMG, and positively associated with L% and IMFA ($p < 0.05$ for all). ***Conclusion:*** Higher systemic inflammation is associated with increased tumor burden on ^{18}F-FDG PET/CT. The negative correlation between LMR and WBTLG may reflect the anti-tumor effect of lymphocytes. Systemic inflammation was negatively correlated with muscle density, implying impaired muscle quality in inflammatory states. Advancing age is linked to increased intermuscular fat and decreased muscle density, which may precede muscle mass loss.

EP-0772

[^{99m}Tc]Tc-Besilesomab Scintigraphy in a Patient with Stuve-Wiedemann Syndrome

A. Marques[1,2], *F. Abreu*[1,2], *J. Duarte*[2], *J. Carvalho*[2], *S. Pintão*[2];
[1]*Institute of Nuclear Medicine, Faculty of Medicine, University of Lisbon, Lisbon, PORTUGAL,* [2]*Western Lisbon Hospital Centre, Lisbon, PORTUGAL.*

Aim/Introduction: Stuve-Wiedemann syndrome is a rare osteochondrodysplasia characterized by progressive bone deformities and dysautonomia[1]. This case presents a 27-year-old woman with Stuve-Wiedemann syndrome, who was evaluated for suspected left hip osteomyelitis using [^{99m}Tc]Tc-Besilesomab scintigraphy. ***Materials and Methods:*** A 27-year-old female with Stuve-Wiedemann syndrome presented to the emergency department with swelling and fluctuation in her left thigh, associated with local inflammatory signs and high fever for four days. The swelling's distal region had a scar from a previously drained abscess. Laboratory tests showed leukocytosis, and imaging (soft tissue ultrasound and CT) revealed a superficial hematoma in the left thigh and a large retroperitoneal hematoma extending from L4-L5 to the left hip joint. No communication between the hematomas was observed. The drainage of the collection revealed hemopurulent material, and Staphylococcus aureus was identified, leading to the initiation of intravenous antibiotherapy. Due to concerns of potential osteomyelitis in the adjacent bone tissue, [^{99m}Tc]Tc-Besilesomab scintigraphy was performed at 4 and 24 hours post-injection to investigate possible infection. ***Results:*** Planar whole-body images acquired at 4 and 24 hours post-injection revealed a heterogeneous and irregular distribution of the radiopharmaceutical within the bone marrow, showing focal uptake in the humeri and femora, along with enhanced uptake in the sternum and lumbar vertebrae. These findings were consistent with osseous dysmorphism and marked scoliosis, both of which are typical features of Stuve-Wiedemann syndrome. Importantly, no abnormal radiopharmaceutical uptake was seen in the bone or soft tissue of the left thigh, which excluded the presence of infection in that region and contributed to the decision to discharge the patient. ***Conclusion:*** [^{99m}Tc]Tc-Besilesomab scintigraphy was a valuable tool in this unique case of Stuve-Wiedemann syndrome. While the imaging revealed typical features of the syndrome, it did not show infection or inflammation in the left thigh, crucially excluding osteomyelitis and supporting the decision for discharge. This highlights the value of scintigraphy in rare conditions, where imaging must be carefully interpreted in light of the patient's distinctive clinical presentation. ***References:***

EP-0773

Is [^{68}Ga]Ga-FAPI-46 PET/CT Safe? A Safety Evaluation of the FAPI PET/CT Procedure with Haemodynamic Measurements and Patient-Reported Outcomes

M. Bentestuen[1], *C. Sylvest*[2], *M. Ladekarl*[3], *O. Thorlacius-Ussing*[4], *H. D. Zacho*[1];
[1]*Department of Nuclear Medicine and Clinical Cancer Research Centre, Aalborg, DENMARK,* [2]*Department of Gynaecology and Obstetrics, Aalborg University Hospital, Aalborg, DENMARK,* [3]*Department of Oncology and Clinical Cancer Research Centre, Aalborg University Hospital, Aalborg, DENMARK,* [4]*Department of Gastrointestinal Surgery and Clinical Cancer Research Centre, Aalborg University Hospital, Aalborg, DENMARK.*

Aim/Introduction: The novel PET tracer [^{68}Ga]Ga-Fibroblast Activation Protein Inhibitor-46 ([^{68}Ga]Ga-FAPI-46) has demonstrated promising diagnostic performance compared to [^{18}F] Fluorodeoxyglucose (FDG) PET/CT across multiple malignancies. Although no adverse events (AEs) related to [^{68}Ga]Ga-FAPI PET/CT have been reported to date, a formal safety evaluation is lacking. While often omitted in early-phase studies, systematic safety evaluations of promising investigational radiopharmaceutical are essential to support risk-benefit analysis required for regulatory approval and clinical implementation. This study aimed to evaluate the safety and tolerability of the [^{68}Ga]Ga-FAPI-46 PET/CT procedure, focusing on objective haemodynamic changes, AEs, and patient-reported discomfort. ***Materials and Methods:*** Participants were enrolled from two ongoing prospective diagnostic accuracy trials: (1) [^{68}Ga]Ga-FAPI PET/CT in ovarian cancer (FAPI-OC, EU CTIS no. 2023-505938-98-00) and (2) [^{68}Ga]Ga-FAPI PET/CT in gastric and

gastro-oesophageal junction cancer (FAPI-GC, EU CTIS no. 2023-505916-40-01). All scans were performed at Aalborg University Hospital, Denmark. A standard fixed dose of 150-250 MBq [^{68}Ga]Ga-FAPI-46 was administered, and the CTs performed were low dose without intravenous contrast. Haemodynamic parameters-systolic and diastolic blood pressure (BP) and heart rate (HR) - were measured in the supine position at four timepoints: Baseline (pre-injection), 1-minute post-injection, 10 minutes post-injection, and post-scan. Paired two-tailed T-tests ($p<0.05$) and a mixed-effects regression model were used for statistical analysis. Participants were actively asked about discomfort and AEs at each timepoint and instructed to report delayed AEs. AE severity was graded using Common Terminology Criteria for Adverse Events version 5.0 (CTCAE v5.0). Events attributable to pre-existing medical conditions, concomitant treatment, or unrelated incidents were not classified as [^{68}Ga]Ga-FAPI PET/CT related AEs. ***Results:*** Thirty participant were included: 16 from FAPI-GC and 14 from FAPI-OC. No significant changes were observed in systolic BP or diastolic BP across the four timepoints. A clinically insignificant, but statistically significant ($p<0.01$) decrease in HR (from 77 to 73 beats-per minute from baseline to post-scan) was observed, likely reflecting pre-scan procedural nervousness. No [^{68}Ga]Ga-FAPI PET/CT-related AEs or patient-reported discomfort were reported. ***Conclusion:*** [^{68}Ga]Ga-FAPI-46 PET/CT appears to be well tolerated, with no evidence of haemodynamic instability or scan-related AEs. Our findings support an acceptable safety profile. Larger-scale safety evaluations and continued clinical investigations are warranted to support broader clinical adoption.

EP-0774

Clinical Utility Of Platelet Kinetics Studies In Patients With Idiopathic Thrombocytopenic Purpura (ITP).

S. Faílde Balea*, E. Triviño-Ibáñez, T. Balibrea Zúñiga, A. Delgado García, L. Entrena Ureña, Á. Ramírez-Navarro, R. Sánchez-Sánchez;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To evaluate the usefulness of platelet kinetics in patients with ITP and its possible association with the therapeutic regimen and platelet count. ***Materials and Methods:*** Retrospective observational study of 41 patients with ITP who underwent autologous platelet labelling with [^{111}In]In-Oxin, studied by platelet kinetics (Jan/17-Nov/23) with splenic uptake indices compared to baseline (minute 30) (B/B30) >1.2.The current treatment line and minimum platelet count were included as variables of interest. ***Results:*** The mean age of the patients was 40.24±16.76 years (53.7% male). Follow-up without drug treatment was the most frequent therapeutic option (61%), followed by treatment with thrombopoietin receptor agonists (TPO-RA) (21.9%), corticosteroids (4.9%), rituximab or fostamatinib (4.9%), splenectomy (4.9%) and immunosuppressants combined with TPO-RA (2.4%). In platelet kinetics, the mean B/B30 index was 1.38 ± 0.20, B/B30max was 1.63 ± 0.36, and the minimum platelet count was 23609.80 ± 21231.85 platelets/µL.The untreated group showed significantly lower B/B30 (1.34 ± 0.22 vs. 1.44± 0.16; p= 0.032) and B/B30max (1.61±0.37 vs. 1.86 ± 0.35, p= 0.039) and higher minimum platelet count (29360.00 ± 22267.09 vs. 14625.13 ± 4089.46; p= 0.017). Analysis of the discriminative ability of the B/Bmax index by ROC curve showed an ABC of 0.687 (95% CI 0.501-0.873) with the cut-off point with the best sensitivity/specificity ratio being 1.67. ***Conclusion:*** Patients with lower hypersplenism indices need less frequent pharmacological treatment than those with higher B/B30.

Revealing the Unexpected: Urgent PET/CT Findings and Their Impact on Clinical Management-A Decade of Clinical Experience

M. Vaillant*[1], G. Cuesta[1], A. Ortega[1], C. Rodríguez[1], R. Cano[2], P. Daudén[1], P. Nespral[1], M. Cornide[1], M. Romero[1], M. Zapardiel[1], C. Wakfie[1], P. Bascuñana[3], M. Cabrera[1];*
[1]Nuclear Medicine Department, Hospital Clínico San Carlos, Madrid, SPAIN, [2]Cardiology Department, Hospital Infanta Sofía, Madrid, SPAIN, [3]Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, SPAIN.

Aim/Introduction: To retrospectively evaluate patients who required urgent medical care following clinically relevant or unexpected critical radiological findings identified during PET/CT examinations. ***Materials and Methods:*** This retrospective study included a total of 49,493 consecutive PET/CT scans performed between 2014 and 2024 at our institution, primarily for oncologic indications. Most scans were performed with intravenous (IV) iodinated contrast. A thoracic sequence in arterial phase during inspiration and a whole-body portal phase acquisition were acquired, followed by a whole-body PET scan. In patients with contraindications—such as allergy, impaired renal function, pump failure, or refusal—IV contrast was not administered. All studies were reviewed by an experienced nuclear medicine physician immediately post-acquisition. Only cases that resulted in referral to the Emergency Department due to incidental findings requiring immediate clinical evaluation were included in the analysis. ***Results:*** Out of the total cohort, 1,082 patients (2.19%) presented with incidental findings that prompted urgent medical referral. The leading cause of referral was pulmonary embolism, detected in 383 patients, with 20.87% of these being bilateral. This was followed by thrombosis in other anatomical regions (165 patients), and vertebral posterior wall fractures with associated spinal canal compression (83 patients). Collectively, these three categories accounted for 58.3% of all emergency referrals. Less frequently observed findings included obstructive uropathy (5%) and brain space-occupying lesions (5%). The most common underlying malignancies among referred patients were lung cancer (202 cases), breast cancer (190 cases), and colorectal cancer (122 cases). ***Conclusion:*** Systematic review of all PET/CT scans upon acquisition is essential, and nuclear medicine physicians must be proficient in recognizing urgent clinical findings. The use of IV contrast proves highly beneficial not only for oncologic assessment but also for the detection of emergent or clinically significant events.

EP-0776

Isotopic determination of Red Cell Mass to study the haematocrit increase in patients in treatment with SGLT-2 inhibitors

I. Romero-Zayas*[1,2], N. Navarro-Niño[1], J. Álvarez-Doral[1], F. Campos Añón[1,2], A. Alvarez-Larrán[3,2], H. Brillembourg Cubillan[3], M. Garrote Ordeig[3], A. Farré Melero[1,4], A. Niñerola Baizán[1,2,5], E. Cano Cumellas[1], C. Santos Montero[1], J. Cordón del Pozo[1], D. Fuster Pelfort[1,2];*
[1]Nuclear Medicine Department, Hospital Clínic, Barcelona, SPAIN, [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, SPAIN, [3]Hematology Department, Hospital Clínic, Barcelona, SPAIN, [4]Faculty of Medicine and Health Sciences - University of Barcelona, Barcelona, SPAIN, [5]Faculty of Medicine and Health Sciences - University of Barcelona,, Barcelona, SPAIN.

Aim/Introduction: Treatment with sodium-glucose cotransporter type 2 inhibitors (SGLT2i) has been associated with a decrease in cardiovascular risk and progression of chronic kidney disease. There is evidence of the drug's relationship with the increase in haematocrit. It has been attributed to haemoconcentration due to their diuretic effect and the decrease in plasma volume (PV), but also to an increase in erythropoiesis. The aim is to analyse the measured red cell mass (RCM) and PV estimation using the isotopic dilution test with autologous [^{99m}Tc]Tc-erythrocytes in

patients in treatment with SGLT2i and increased haematocrit. ***Materials and Methods:*** This is a retrospective review of 41 patients (2019-2024) in treatment with SLGT2i drugs. The haematology department ruled out polycythaemia vera by determination of serum erythropoietin and JAK2V617F mutation by digital PCR. The isotopic RCM determination was performed with the administration of approximately 3.7 MBq of autologous radiolabelled [^{99m}Tc]Tc-erythrocytes. After reaching the circulating steady state, blood samples were withdrawn, and 2 ml measured in a gammacounter. RCM was determined with samples of a known volume standard and corrected by the capillary haematocrit. Indirect estimation of PV was calculated. Polyglobulia is considered when the RCM is more than 25% respect the expected value for a person of the same age, sex and height. The percentage of deviation from the central value of the normal range (%DCVN) for RCM and PV was stablished to compare patients. It was used Mann-Whitney U test, to compare by sex and type of SLGT2i (Empagliflozin and Dapagliflozin) and the Pearson's correlation for age. ***Results:*** Patients with polyglobulia were 22.0 % (n=9) with a mean %DCVN-RCM of + 49.8 % (SD 27.5). Polyglobulia-negative patients were 78.0 % (n=32) with a %DCVN-RCM of + 5.0 (SD 11.8) and for PV -5.3 (SD 11.2). In 4 patients (12.9%) clinicians considered haemoconcentration with a %DCVN-PV of -20.9% (SD 3.0). No significant differences were found in %DCVN between males and females (p>0.05) and neither for different SLGT2i (p>0.05). It was found a negative correlation with age (r=-0.178) without significance (p=0.21). ***Conclusion:*** In 22% of patients in treatment with SLGT2i and elevated haematocrit presents a real polyglobulia. The percentage of deviation from the central value of the normal range allows us to compare groups and to assess the pattern.The isotopic measurement of the RCM with [^{99m}Tc]Tc- erythrocytes provides an excellent tool to stablish the mechanism of the haematocrit increase in patients taking SLGT2i.

EP-0777

SeHCAT Protocol Optimisation: A Single-Scan Approach to Increased Capacity

K. Tallat-Szczotka, *H. McMeekin, M. Costa, J. Hidalgo, T. Hussain, B. Riberio;*
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Bile acid malabsorption (BAM) affects an estimated 1-4% of the population and accounts for up to 30% of patients with functional diarrhoea or diarrhoea-predominant irritable bowel syndrome. Diagnosis typically involves a [^{75}Se] tauroselcholic acid (SeHCAT) scan, which provides a gold-standard quantitative assessment of BAM. To meet growing demand and improve efficiency, the Nuclear Medicine Department at St. Bartholomew's Hospital has adopted a predictive model based on patient height and weight to eliminate the need for a day-0 image and performing a day-7 scan only. This model was proposed by Smout et al., who demonstrated a single day-7 scan, combined with predictive models, can maintain diagnostic accuracy [1]. ***Materials and Methods:*** A dataset of 100 patients was used to trial the best-fitting predictive model which is based on patient height and logarithm of weight. Firstly, patient imaging data was used to derive camera sensitivity factor (CSF), followed the methodology suggested by Smout et al [1]. Secondly, patient data was used to derive new fitting parameters using least-squares regression. ***Results:*** Both methods resulted in very strong correlation between the SeHCAT results obtained using measured and predicted Day 0 counts (0.99). The absolute deviation from the standard SeHCAT result was slightly larger for the CSF method than for the second method (6.61% vs 6.08%). Residuals analysis showed a moderate positive correlation (0.31) between measured and predicted counts for the CSF method. Very weak correlation was observed for the second method (0.11). For both methods, there was no change in the BAM diagnosis for any of the patients. In total, 96% of patients had no change to severity grading (mild/moderate/severe, representing 5%/10%/15% SeHCAT retention respectively) when using the predicted baseline counts. ***Conclusion:*** The model developed by Smout et al. [1] can successfully be used to implement a day-7 only imaging protocol. However, rederivation of fitting parameters should be considered over the simpler CSF derivation, particularly for centres using different imaging protocols from that described by Smout et al [1]. The day-7 only protocol has been implemented at St. Bartholomew's Hospital resulting in significant savings of departmental resources and patient time, as well as increasing capacity. ***References:*** [1] Smout, A. et al., (2021). Single scan SeHCAT studies: A model for the investigation of bile acid malabsorption. Nuclear Medicine Communications, 42(11), 1209-1216. https://doi.org/10.1097/MNM.0000000000001450.

EP-0778

A Comparative Analysis of Qualitative and Quantitative Findings in Lymphoscintigraphy for the Grading of Lymphedema

A. Pala, *H. Pala, M. F. Bozkurt;*
Hacettepe University Faculty of Medicine, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Lymphoscintigraphy is the primary imaging technique used to assess the function of the lymphatic system and confirm a diagnosis of lymphedema. Various qualitative grading systems are utilized to diagnose lymphedema. Additionally, quantitative methods have recently been introduced to provide a more objective insight into interpretation. This study aims to compare the effectiveness of qualitative and quantitative parameters for interpreting lymphoscintigraphy. ***Materials and Methods:*** Lymphoscintigraphic imaging was conducted on both lower extremities in a large cohort of adult patients with a preliminary diagnosis of lymphedema, and the results were assessed. Qualitatively, the presence of lymphatic flow in dynamic images for each lower extremity, main lymphatic flow, the presence and number of collaterals, the presence and number of in-transit lymph nodes, and the appearance of dermal backflow were visually evaluated using images obtained at the 1st and 3rd hour after bipedal radiocolloid injection. Additionally, the regions of interest were marked at the injection site and inguinofemoral lymph nodes on the 1st-hour images for each lower extremity, and the percentages of radiotracer passing through were calculated. Furthermore, according to the Taiwan lymphoscintigraphy staging system, the findings are classified as normal lymphatic flow, partial obstruction, or total obstruction. ***Results:*** The study included 350 patients (F/M:290/60,median age:52,range:18-89). Out of a total of 450 extremities evaluated,425 exhibited normal lymphatic flow (60.7%),217 had partial obstruction (31%), and 58 experienced total obstruction (8.3%). In extremities with normal lymphatic flow, the transit rate in dynamic images was 60.7%,normal main lymphatic flow was 93.2%,collateral observation was 43.3%,in-transit lymph nodes presence was 7.1%,and dermal-backflow was 2.8%. For partial obstruction, the transit rate in dynamic images was 34.1%,normal main lymphatic flow detection was 39.6%,collateral detection was 27.2%,in-transit lymph nodes presence was 35.5%,and dermal backflow findings were 40.6%. In total obstruction,the transit rate in dynamic images was 5.2%,normal main lymphatic flow detection was 0%,collateral detection was 0%,in-transit lymph nodes presence was 4%,and dermal backflow findings were 39.6%. In quantitative analysis, the median lymphatic passage rate was 32.6% for normal lymphatic flow,8% for partial obstruction,and 0% for total obstruction. ***Conclusion:*** Quantitative and qualitative parameters should be combined to diagnose lymphedema accurately and appropriately grade lymphatic obstruction. In lymphoscintigraphy reports, it is essential to include details regarding dynamic transit, main lymphatic flow, collateral flow, in-transit lymph nodes, and

dermal backflow, along with the percentage of the quantitative radiotracer transit. This information is crucial for grading lymphatic obstruction and managing patient care.

C: Therapy Clinical Study -> C1 Oncological Therapy Clinical Study -> C11 Neuroendocrine Therapy

EP-0779

One therapy, many measures: a comparative study of response evaluation methods to Peptide Receptor Radionuclide Therapy (PRRT) in patients with neuroendocrine tumors (NET)

P. Guglielmo[1,2], *J. Jandric*[3], *C. Vallone*[4,5], *M. Rodari*[3], *C. Carnaghi*[6], *A. Bertuzzi*[7], *G. Tarullo*[3], *K. Marzo*[3], *M. Olivieri*[8], *M. Marenco*[3], *L. Evangelista*[3,1];
[1]*Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Milan, ITALY,* [2]*Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [4]*Humanitas University, Via Rita Levi Montalcini 4, Pieve Emanuele, Milan, ITALY,* [5]*Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY,* [6]*Oncology Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [7]*Medical Oncology and Hematology Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY,* [8]*Medical Physics Unit, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY.*

Aim/Introduction: The assessment of treatment response in NETs presents significant challenges. The multifactorial mechanism of action of PRRT further complicates accurate response evaluation, especially in the absence of a standardized assessment method. Therefore, the aim of our study is to compare various response assessment modalities and identify the one most predictive of clinical outcomes. ***Materials and Methods:*** In this single-centre retrospective study, we collected data from patients who received PRRT and underwent [^{68}Ga]DOTATOC PET/CT imaging both before and after treatment, with a minimum follow-up period of 12 months, between 2020 and 2022. Response to PRRT was evaluated using five different methods: (a) changes in the Krenning Score; (b) 'adapted' PERCIST criteria (MORE) [1]; (c) the ZP-normalized parameter [1]; (d) qualitative visual interpretation of PET images; and (e) RECIST-based morphological response. Each assessment modality was then correlated with clinical and follow-up data to identify the most reliable predictor of treatment outcome. Non-parametric analyses were used to compare each response criteria, by using the MedCalc® software. ***Results:*** A total of 15 patients were included in the study, with a median age of 60 years (range: 29-82); 9 were males and 6 females. All patients, except one, completed the full four cycles of PRRT; the remaining patient received three cycles. [^{68}Ga]DOTATOC PET/CT scans were performed at a median of 3 months (range: 1-8 mo.) after the completion of PRRT. Based on the different response criteria, patients were stratified into responders (including those with partial response) and non-responders (including those with stable or progressive disease). Classification of patients into responders and non-responders varied depending on the assessment method: 4 (33%) and 8 (66%) using the Krenning Score; 11 (73%) and 4 (27%) using the MORE criteria; 12 (86%) and 2 (14%) with the ZP-normalized parameter; 12 (80%) and 3 (20%) based on qualitative visual interpretation; and 5 (42%) and 7 (58%) using RECIST criteria (all $p < 0.05$). The median time to disease progression was significantly shorter in non-responders compared to responders when stratified by MORE criteria (median: 9 vs. 23 months, $p < 0.05$) and the ZP-normalized parameter (median: 7.5 vs. 23 months, $p < 0.05$). ***Conclusion:*** Based on our preliminary results, the MORE criteria and ZP parameter appear to be predictive of clinical outcomes, providing a more robust framework for response assessment. These preliminary results support the need for standardized molecular criteria to guide PRRT response evaluation. ***References:***

Improved Response of Advanced NET After Switching From ^{225}Ac-Octreotate to ^{225}Ac-LM3: A Preliminary Analysis

T. Speicher, *M. B. Bastian, A. Blickle, S. Maus, M. Bartholomä, C. Burgard, F. Rosar, S. Ezziddin;
Nuclear Medicine, Saarland University Hospital, Homburg, GERMANY.*

Aim/Introduction: Targeted alpha therapy with ^{225}Ac-labeled somatostatin analogues represents a promising approach in patients with advanced neuroendocrine tumors (NET), especially after limited effects of beta-emitting radiopeptide therapy. Somatostatin receptor antagonist LM3 exhibits higher receptor binding capacity compared to agonists with promising initial data. ***Materials and Methods:*** We retrospectively analyzed a cohort of n=8 advanced metastatic NET patients switching from [^{225}Ac]Ac-DOTA-octreotate to [^{225}Ac]Ac-DOTA-LM3 (Ac-LM3) following prior treatments. Pre- and post-switch responses according standardized PET imaging ([^{68}Ga]Ga-DOTATOC and [^{68}Ga]Ga-NODAGA-LM3 PET/CT), EORTC-based response categorization. Adverse events according CTCAE (Common Terminology Criteria for Adverse Events). ***Results:*** Before switching to Ac-LM3, most patients had stable disease (SD), with three showing partial response (PR) and one progressive disease (PD). Following Ac-LM3, four patients (50%) achieved PR and four remained stable. No progressive disease was observed. Toxicity was mostly restricted to grade 1-2 events, with no treatment discontinuations. However, one patient experienced a grade 3 renal adverse event, managed conservatively. ***Conclusion:*** Switching "standard" Alpha-PRRT to [^{225}Ac]Ac-DOTA-LM3 was well tolerated and resulted in improved molecular imaging response in half of the patients and maintained disease control in the remainder. These findings support further evaluation in larger cohorts.

EP-0781

Skeletal Muscle Uptake on [^{131}I]-Metaiodobenzylguanidine Post-Therapy Imaging

B. Lumb Morollon, *C. Brown;
Department of Clinical Physics and Bioengineering, NHS Greater Glasgow & Clyde, Glasgow, UNITED KINGDOM.*

Aim/Introduction: EANM procedural guidelines for [^{131}I]-mIBG list drugs that could interfere with the uptake, but do not state the nature of the interaction effect[1]. Dose rate measurements of retention and post-therapy imaging are used to verify distribution of [^{131}I]-mIBG and determine individualised discharge restrictions. Anecdotally, several local patients have shown varying degrees of skeletal muscle uptake. Literature has associated this with the use of tricyclic-related antidepressants suggesting blockage of alpha-2 receptors[2]. The prevalence, magnitude of muscle uptake and subsequent retention rates of these patients is unknown. This study aimed to assess the degree of skeletal muscle uptake in the local population and determine a correlation with patient medications. Additionally, the relationship between skeletal muscle uptake and whole-body retention of [^{131}I]-mIBG was investigated. ***Materials and Methods:*** 55 retrospective images (n=33, 17F/16M, age 17-84) were categorised qualitatively based on severity of skeletal muscle uptake. Images were assigned Grade 0 for no visible muscle uptake and Grade 1-3 with increasing muscle uptake. For patients with Grade2/3, listed medications were reviewed for those that could alter the biological uptake of the [^{131}I]-mIBG, e.g. tricyclic or tricyclic-related antidepressants. Patient dose rates recorded at intervals of approximately 24h during the inpatient period were used to plot the retention curves. Assuming

mono-exponential decay after the first phase post-administration of [^{131}I]-mIBG[3], the gradient of the log-linear retention curves was used to assess the correlation between degree of skeletal muscle uptake and whole-body retention. ***Results:*** Of the cases audited, 51.5% of patients demonstrated relatively high grade of skeletal muscle uptake (Grade 2/3) with 15.2% of patients showing no uptake. A subgroup of patients with visible skeletal muscle uptake were found to be on mirtazapine (tricyclic-related antidepressant). However, the data set was too small to determine a correlation. Unintuitively, results do not indicate a correlation between grade and gradient of the retention curve. ***Conclusion:*** Over half the patients audited show a notable degree of skeletal muscle uptake on post-therapy imaging, which is higher than expected for the population if drug interference alone were the main contributing factor. Ongoing investigation into the effect of skeletal muscle uptake on [^{131}I]-mIBG retention has demonstrated no correlation. ***References:*** [1]F Giammarile et al. 2008 Eur J Nucl Med Mol Imaging 35 (***5***) 1039-47; [2]SR Goel et al. 2009 Radiol Case Rep. 4(***3***) 306; [3]D Broggio et al 2023 J. Polish Registry of RLT - first report

M. Kolodziej[1], *V. Rosiek*[2], *J. Musiałkiewicz*[3], *A. Ledwon*[4], *A. Lewczuk-Myślicka*[5], *K. P. Sagan*[6], *B. Kos-Kudła*[2], *M. Ruchała*[7], *D. Handkiewicz-Junak*[4], *R. Swiatkowska-Stodulska*[5], *A. Syrenicz*[6], *G. Kaminski*[1];
[1]*Department of Endocrinology and Isotope Therapy, Military Institute of Medicine - National Research Institute, Warsaw, POLAND,* [2]*Department of Endocrinology and Neuroendocrine Tumours, Department of Pathophysiology and Endocrinology, Medical University of Silesia, Katowice, POLAND,* [3]*Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznań, POLAND,* [4]*Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie National Research Institute of Oncology, Gliwice Branch, Gliwice, POLAND,* [5]*Department of Endocrinology and Internal Medicine, Medical University of Gdansk, Gdansk, POLAND,* [6]*Department of Endocrinology, Metabolic and Internal Diseases, Pomeranian Medical University, Szczecin, POLAND,* [7]*Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznan, POLAND.*

Aim/Introduction: Radioligand therapy (RLT) with [^{177}Lu]-DOTA-TATE is approved method of second line treatment for gastroenteropancreatic neuroendocrine tumours (GEP-NETs). This treatment is available in Poland from March 1, 2023 under the NHS Drug Program. The six largest Polish centers have created the Polish Registry covering over 80% of all patients treated with RLT in Poland. We present the first report prepared after 2 years of the Registry's operation. ***Materials and Methods:*** The online platform created for the Registry records subsequent patients who received RLT at one of the participating centers - the initial duration of the project was set at 96 months, with the possibility of extension. The primary objective is to evaluate RLT effectiveness in terms of progression-free survival. Secondary objectives include safety and identification of prognostic factors. ***Results:*** Of the 180 patients yet included in the Registry, 110 completed RLT, and another 70 are undergoing RLT. The mean age was 64.7 ±10.3 years, RTL was used on average 6.8 ±3.3 years after diagnosis, mainly as second-line treatment (69%), after somatostatin analogue. The group contained midgut, pancreatic and other location NETs (42%, 37% and 21% respectively). NETs G1 and G2 were 37% and 57%, respectively. Over 95% of patients had metastatic lesions, most often to the liver (87%). 31% of patients showed hormonal activity of the tumor, and over 90% were in very good or good (ECOG 0 and 1) status performance. In a whole-body scintigraphy performed after the 4th course of RLT 97% of patients achieved an objective response. By the time of the first report 7% patients had died. ***Conclusion:*** The presented Registry is the first and largest Central-Eastern European real-world data. These are the first results showing the characteristics of patient included in the Registry and the initial effects of treatment, confirming the effectiveness and safety of RLT in this group. In the following months, the Registry will be systematically expanded to include more patients, which will allow for further implementation of the assumed project goals.

EP-0783

Initial and re-challenge Lutetium-177-DOTATATE PRRT in a Metastatic Ovarian Neuroendocrine Tumour: a case report

N. Eftychiou, *H. Ahmed, R. Fernandez, F. Hassan;
Guy's and St Thomas Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: Ovarian neuroendocrine tumours (NETs) are extremely rare, constituting less than 5% of all NETs, and only 0.1% of all ovarian cancers. Due to their rarity, there are no established therapeutic guidelines for these tumours. This case report presents the use of peptide receptor radionuclide therapy (PRRT) with Lutetium-177-DOTATATE in a patient with metastatic ovarian NET, highlighting its potential efficacy and the need for further research to develop standardised treatment protocol for this rare condition. ***Materials and Methods:*** A 58-year-old female diagnosed with a complex medical history including papillary thyroid carcinoma and endometrioid endometrial carcinoma, was diagnosed with a right ovarian tumour containing both a mature teratoma and a well differentiated NET (Ki67 5%) with distant metastases. Disease progression led to her referral to our hospital. Baseline imaging with Gallium-68-DOTATATE PET/CT revealed extensive metastatic disease affecting multiple sites, including the lymphnodes, liver, lungs, peritoneum and skeleton. Symptoms pre-treatment included diarrhoea, abdominal pain (requiring opioids) and fatigue. Patient underwent four cycles of Lutetium-177-DOTATATE over an 8 month period and two re-challenge cycles 21 months subsequently. ***Results:*** After the first two PRRT cycles, the patient experienced significant symptomatic relief, including resolution of diarrhoea and abdominal pain. Energy levels improved over time. Imaging throughout treatment showed stable disease. Gallium-68-DOTATATE-PET-CT scan at 3- and 12- months post-treatment showed mainly stable disease with partial nodal response. However, disease progression in the bone and liver was noted at 24 months after the initial cycle of PRRT. A re-challenge treatment was initiated , which has so far resulted in improved energy levels and stable disease on imaging. ***Conclusion:*** This case highlights the potential role of PRRT in managing metastatic ovarian NETs, offeing symptomatic relief and disease stability in short term. Given the rarity of these tumour's and the lack of therapeutic guidelines this case also underscores the need for further research to develop evidence-based therapeutic strategies for ovarian NETs.

EP-0784

Alpha Peptide Receptor Radionuclide Therapy (PRRT) with the somatostatin receptor (SSTR)-antagonist 225Ac-DOTA-LM3 as rescue therapy after failure of conventional treatments in neuroendocrine neoplasm G3

E. Perrone[1], *K. Ghai*[2], *T. Parkar*[2], *A. Eismant*[2], *L. Greifenstein*[2], *M. Pavel*[3], *R. P. Baum*[2];
[1]*Nuclear Medicine Unit, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, ITALY,* [2]*CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY,* [3]*Department of Medicine 1, Uniklinikum Erlangen, Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, GERMANY.*

Aim/Introduction: Patients with metastatic neuroendocrine neoplasm (NEN) progressing after standard therapies, including SSTR-agonists PRRT and systemic therapies, represent a clinical challenge. SSTR-antagonists are promising due to higher tumour uptake, tumour-to-background ratio and longer tumour retention. Safety, efficacy and survival were assessed in advanced

NEN G3 patients treated with α-emitter Actinium-225-labelled SSTR-antagonist DOTA-LM3 PRRT, in monotherapy and with Lutetium-177 (TANDEM), as rescue therapy after established treatments. ***Materials and Methods:*** Following 68Ga-DOTA-LM3 PET/CT, 14 patients with metastatic well-differentiated NEN G3 received α-PRRT with 225Ac-DOTA-LM3 (03/2022-02/2025). Hydration, antiemetics, dexamethasone and para-aminohippuric acid were provided. Acute adverse events and long-term haematological, renal and hepatic toxicity were prospectively collected and retrospectively analysed (03/2025), graded using CTCAE v.5.0. Molecular-imaging-based response was assessed following THEranostic Response Criteria In Solid Tumours (THERCIST) by 68Ga-DOTA-LM3 PET/CT and post-therapeutic SPET/CT. Survival was calculated from first α-PRRT to death. ***Results:*** We treated 14 patients (38-66 years; M:F=9:5) with metastatic NEN (n=10 pancreas, n=3 small bowel, n=1 colo-rectal), classified as well-differentiated NEN G3 at diagnosis (n=5) or upgraded to well-differentiated NEN G3 following repeated biopsy (n=9). The overall median Ki67 value was 33% (range 21-60%). Prior treatments included: SSTR analogues (100%), chemotherapy (93%), surgery (64%), 177Lu-DOTATATE (64%), Everolimus (64%), 177Lu-DOTA-LM3 (36%), 177Lu-DOTATOC (29%), 90Y-DOTATOC (21%), hepatic intra-arterial PRRT (14%), 90Y-DOTATATE (7%). 26 cycles of 225Ac-DOTA-LM3 PRRT were totally administered (9 monotherapies, 17 TANDEM). Six patients received 1 cycle, six patients 2 cycles, two patients >2 cycles. α-PRRT was overall well tolerated, with few G1 self-limiting acute adverse events, mainly nausea (n=4). Long-term toxicity included: anemia G2 (n=4), anemia G3 (n=1), absolute neutrophilic count reduction G3 (n=1), thrombocytopenia G1/G2 (n=4), thrombocytopenia G3 (n=2), creatinine increase G1 (n=2), liver impairment G2 (n=1) and G3 (n=1) in patients with hepatic metastases. No patients discontinued α-PRRT due to toxicity, but one was diagnosed with acute myeloid leukemia 12 years after first 90Y-DOTATOC-PRRT and 3 months after TANDEM-PRRT. Molecular-imaging responses included one complete remission (7%), five partial remission (36%), five disease progression (36%), two stable disease (14%); one clinical progression (7%). At time of analysis, after a median follow-up of 11 months: 50% of patients were alive, 50% had died. ***Conclusion:*** Our retrospective analysis showed that α-PRRT with SSTR-antagonist 225Ac-DOTA-LM3 (monotherapy or TANDEM) in heavily pretreated advanced well-differentiated NEN G3 patients failing standard treatments is well-tolerated, with favourable safety and encouraging efficacy results. Prospective randomized trials are warranted to confirm and optimize its clinical use.

EP-0785

IPAX-2: Phase 1 safety and dose finding study of [^{131}I]IPA plus standard of care in patients with newly diagnosed glioblastoma

J. Roetman[1], *J. Pichler*[2], *N. Singhal*[3], *H. Gan*[4], *A. Braat*[5], *W. Pullin*[6], *B. Cerqueira*[1];
[1]*Telix Pharmaceuticals, Melbourne, AUSTRALIA,* [2]*Kepler University Hospital, Linz, AUSTRIA,* [3]*Royal Adelaide, Adelaide, AUSTRALIA,* [4]*Austin Health, Heidelberg, AUSTRALIA,* [5]*UMC Utrecht, Utrecht, NETHERLANDS,* [6]*Gold Coast University Hospital, Southport, AUSTRALIA.*

Aim/Introduction: Glioblastoma (GBM) overexpresses L-type amino transporter (LAT) 1 and 2, which are the target 4-L-[^{131}I] iodo-phenylalanine ([^{131}I]IPA). Previous studies of [^{123}I]IPA as a SPECT tracer showed retention in glioma tissue, high metabolic stability, and uptake by >85% of gliomas. Results from a phase 1 trial (IPAX-1) that explored [^{131}I]IPA + radiotherapy in patients with recurrent GBM demonstrated a favourable safety profile and promising efficacy. The objective of IPAX-2 (NCT05450744) is to evaluate the safety and tolerability of [^{131}I]IPA in patients newly diagnosed with GBM. ***Materials and Methods:*** IPAX-2 is a phase 1, multicentre, open-label, single-arm, parallel-group, dose-finding study aimed to evaluate the safety of ascending radioactive dose levels of [^{131}I] IPA plus standard of care (chemoradiation) in newly diagnosed patients with GBM. Eligible patients (N=12) will be aged 18-65 years with histologically confirmed intracranial GBM following surgical resection; no prior systemic therapy or radiation for GBM; a Karnofsky Performance Status ≥70; a plan to begin chemoradiation 3-6 weeks after surgical resection with Stupp regimen; adequate organ function; and adequate tissue samples previously archived. Four cohorts (n=3 for each cohort) will encompass a 3+3 dose escalation, beginning with [^{131}I]IPA intravenously administered as 2 doses of 3 GBq each (dose escalation schedule: 2x3 GBq, 2x4 GBq, 2x5 GBq, 2x6 GBq). Dose 1 will be administered 7 days prior to chemoradiation, and dose 2 will be administered after last chemoradiation session. Chemoradiation will consist of 6 weeks of external beam radiation therapy (60 Gy/30 fractions) plus temozolomide 75 mg/m^2 daily. Following dose 2 of [^{131}I]IPA, patients will receive a 4-week treatment break before starting 6 maintenance cycles of temozolomide 150-200 mg/m^2 on days 1-5 every 28 days. ^{18}F-FET PET will be used to identify suitable candidates with LAT1 and LAT2 overexpression, establish a baseline, and provide quantitative follow-up information. The co-primary objectives are to 1) determine dose-limiting toxicity, maximum tolerated dose, and recommended phase 2 dose, and 2) determine the incidence of treatment-emergent adverse events. ***Results:*** This study is currently enrolling; no results are available at the time of abstract submission. ***Conclusion:*** The unique characteristics of [^{131}I]IPA, including its specific and sustained tumour accumulation and intrinsic cytostatic and radiosensitizing effect, make it an attractive therapeutic probe against GBM.

EP-0786

The role of quantitative analysis of Post-Therapeutic CZT SPECT/CT Imaging in the Evaluation of Tumor Response to PRRT in Neuroendocrine Tumors

H. Noamen*, Y. Cras, M. Longo, C. Garcia, J. Hadoux, L. Lamartina, S. Moog, E. Baudin, D. Deandreis;*
Gustave Roussy Cancer Campus, Villejuif, FRANCE.

Aim/Introduction: The assessment of treatment response to ^{177}Lu-DOTATATE therapy in neuroendocrine tumors (NETs) is still an issue. RECIST 1.1 criterias are limited and the lack of standardized protocols for functional imaging introduces further challenges. This study aimed to evaluate the feasibility of quantitative analysis of post-treatment ^{177}Lu-DOTATATE SPECT/CT imaging obtained by CZT gamma camera. ***Materials and Methods:*** This retrospective study includes 25 patients (12 F,13 M; mean age: 65 ± 12 years) with GEP NETs (n=20) and lung NET (n=5) treated with ^{177}Lu-DOTATATE (median activity 7192 MBq, [7113;7400]. Grades were distribued as follows : G1 (n=9), G2 (n=12), and G3 (n=4) respectively. All patients underwent whole body 3D post therapeutic images 24 hours after treatment with a CZT gamma camera after each single cycle. 19/25 patients were finally analyzed for technical reasons. For each scan, whole-body somatostatin receptor tumor volume (SSTRTV) and median SSTR SUVmean were quantified using dedicated software that applied a patient-specific semi-automatic segmentation approach, incorporating an additional 10% threshold evaluation. ΔSSTRTV and ΔSSTR SUVmean were evaluated after each cycle and compared to RECIST 1.1 response. ***Results:*** Median SSTRTV and median SSTR SUVmean were 914.01 ml ([398.125; 1252.46]) and 8.05; [2.73; 12.1] respectively, with no statistical difference between primary tumor location or pathological grade (p=0.406 and p=0.22 respectively). Metastatic lesions were located in liver (n=20), lymph nodes (n=10), bone (n=10), peritoneum (n=3), lungs (n=3), and other organs (n=5) respectively. Among the 19 patients, at the end of treatment 16 patients had stable disease (SD), 2 partial responses (PR), and 1 disease progression (PD), according to RECIST 1.1

criteria (for new lesion appearance). Median ΔSSTRTV and ΔSSTR SUVmean were respectively -17.94% and +14.7% between C1-C2, -18.28% and +1.64% between C2-C3, and -18.73% and +23.09% between C3-C4. Patients with SD in RECIST 1.1 presented median ΔSSTRTV of -16.13% [-25.84; -4.39] after C2 and -6.91% [-25.84; -4.39] after C4. Patients with PR presented a median ΔSSTRTV of -60.5% ; [-67.01; -54.12] and -44.9% [-61.34; -23.4] after C2 and C4 respectively. Patient with PD presented ΔSSTRTV of -92.08% after C2 and -95.77% after C4 on initial disease but SPECT confirmed the appearance of a new lesion in the liver. ***Conclusion:*** The study demonstrated the feasibility of post-therapy quantitative analysis of ^{177}Lu-DOTATATE using CZT SPECT/CT imaging. This approach highlights the potential of post-therapy SPECT/CT imaging to evaluate the response to ^{177}Lu-DOTATATE treatment.

EP-0787

Performance of Large Language Models in Answering Common Patient Questions on ^{177}Lu-DOTATATE Therapy for Neuroendocrine Tumors: A Comparative Evaluation by a Panel of Medical Experts

V. Habouzit[1], *A. Durand*[2], *L. Al Mansour*[2], *B. Lachachi*[2], *M. Halilali*[3], *M. Janier*[4], *T. Walter*[4], *T. Grenier*[5], *A. Flaus*[4];
[1]*University Hospital of Saint Etienne, Saint Etienne, FRANCE,* [2]*Hospices Civils de Lyon, Lyon, FRANCE,* [3]*Université Claude Bernard Lyon 1, Lyon, FRANCE,* [4]*Hospices Civils de Lyon and Faculté de médecine Université Claude Bernard Lyon 1, Lyon, FRANCE,* [5]*Univ Lyon, INSA-Lyon, Université Claude Bernard Lyon 1, CNRS, INSERM, CREATIS UMR 5220, Lyon, FRANCE.*

Aim/Introduction: Neuroendocrine tumors (NETs) are rare diseases, and patients often have difficulties obtaining information at the beginning of medical care. Large Language Models (LLMs) are increasingly used by patients to access medical information and may support pre-treatment education for patients with NETs. Upon disease progression, they may be treated with [^{177}Lu]Lu-DOTATATE, a radiopharmaceutical that raises frequent questions due to its radioactive nature and the complexity of the treatment pathway. This study aimed to evaluate and compare the performance of several LLMs in responding to commonly asked patient questions, focusing on accuracy, conciseness, and readability. ***Materials and Methods:*** Fourteen common patient questions about [^{177}Lu]Lu-DOTATATE therapy were selected by two clinical experts. These questions were submitted to five advanced LLMs: GPT-4o (OpenAI), Gemini 2.0 Flash (Google), Mistral-Large (LeChat), Claude 3.7 Sonnet (Anthropic), and DeepSeekV3 (DeepSeek). AI-generated responses were independently assessed in both French and English by a blinded panel of seven nuclear medicine physicians and oncologists from two French tertiary care centers. Each response was rated across three domains: accuracy and conciseness (1-4 scale), and readability (1-3 scale). Higher scores indicated better performance. Descriptive statistics and Friedman's ANOVA were used for comparisons of LLM performance within each domain and language. A p-value < 0.05 was considered statistically significant. Post-hoc pairwise comparisons were conducted using the Durbin-Conover test with Bonferroni-adjusted p-values. ***Results:*** Significant differences were observed between LLMs in accuracy (English) and conciseness (both languages). For English accuracy, Claude had the highest mean score (3.56) and significantly outperformed all models except LeChat (scores: 3.24-3.36; $p < 0.05$ and $p = 0.053$, respectively). In English conciseness, Claude, ChatGPT, LeChat, and DeepSeek outperformed Gemini (scores: 3.34-3.53 vs 2.80; $p < 0.05$). In French, Claude and ChatGPT also outperformed Gemini and DeepSeek for conciseness (3.41 vs 2.67-3.10; $p < 0.05$), with LeChat showing intermediate performance (3.32). No significant differences were found for readability in either language or for accuracy in French. ***Conclusion:*** LLMs demonstrated variable performance in answering patient questions on [^{177}Lu]Lu-DOTATATE therapy. Claude and ChatGPT consistently ranked highest, especially in accuracy and conciseness. These findings suggest that selected LLMs may serve as complementary tools for patient education in nuclear medicine, which currently requires supervision by the healthcare team.

EP-0788

Correlation between organs-at-risk dosimetry and toxicity in patients with gastroenteropancreatic neuroendocrine tumours (GEP-NETs) treated with ^{177}Lu-DOTATATE: a single center experience

V. Gaudieri[1], *L. Piscopo*[1], *E. Zampella*[1], *C. Nappi*[1], *F. Volpe*[1], *E. Caiazzo*[1], *T. Faiz*[1], *M. Caroprese*[1], *A. Barillaro*[1], *A. Varallo*[2], *S. Clemente*[2], *R. Pacelli*[1], *A. Cuocolo*[1], *M. Klain*[1];
[1]*Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY,* [2]*Unit of Medical Physics and Radioprotection, University of Naples "Federico II", Naples, ITALY.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) is an established effective and, generally, well-tolerated treatment in patients with neuroendocrine tumours, however it may be limited by hematological and kidney toxicity. This study assessed the correlation between the absorbed dose burden to the bone marrow and kidneys, evaluated using image-based dosimetry, and treatment-related toxicity. ***Materials and Methods:*** Consecutive patients with well-differentiated GEP-NETs treated with four cycles of ^{177}Lu-DOTATATE every 8 weeks, from January 2023 to December 2024 and followed until disease progression or death. Adverse events (AEs) were collected and monitored until resolution. After each cycle SPECT/CT imaging scans were acquired at 4 hours (h), 24 h, 48 h and 168 h for dosimetric estimations of kidneys, bone marrow and spleen, using the software MIM SurePlan MRT (MIM, Cleveland). Spearman correlation coefficient was performed between absorbed doses and blood and kidney parameters. Kaplan-Meier method and log-rank test were used to evaluate the progression free survival (PFS). ***Results:*** In the 14 patients included, median PFS was 21 months. All patients received four PRRT cycles. Before starting therapy 7 patients had mild lymphopenia, 6 patients mild anemia, 2 patients mild thrombocytopenia, and 1 patient mild neutropenia. Most common AEs of any grade were anemia and lymphopenia (100%), thrombocytopenia (50%), fatigue (28%) and nausea (21%). Most common grade ≥3 AE was lymphopenia in 21% of patients. No renal toxicity was observed in any of the patients. Median cumulative absorbed dose (AD) by the bone marrow, spleen and kidneys was 2.05, Gy, 13.6 Gy and 10.55 Gy respectively. No association between bone marrow cumulative AD and values of hemoglobin and lymphocytes was demonstrated, as well as between the spleen cumulative AD and hematological toxicities. A significant correlation between bone marrow cumulative AD and percentage variation of platelets was found (rho=-0.621; p=<0.05). No correlation between renal function and kidneys' cumulative AD was found (rho=-0.239; p=ns). ***Conclusion:*** Our results confirm that ^{177}Lu-DOTATATE is a well-tolerated therapeutic option in patients with GEP-NETs. No hematological toxicities were associated with cumulative AD to bone marrow or spleen, apart from a correlation between the cumulative AD to bone marrow and the percentage variation of platelets. No correlation was observed between renal function parameters and cumulative renal AD.

Aim/Introduction: The established dose limits for critical organs during radioligand therapy (RLT) are 23 Gy for the kidneys and 2 Gy for the bone marrow. However, literature data suggest that some patients receiving standard RLT—four cycles of 7.4 GBq [^{177}Lu]Lu-DOTA-TATE—may not reach these thresholds, a phenomenon referred to as undertreatment. This raises the question: can the administered activity of [^{177}Lu]Lu-DOTA-TATE be increased safely without exceeding organ dose limits? ***Materials and Methods:*** We present preliminary results from the ongoing multicenter DUONEN study. Adult patients with advanced, unresectable, progressive, well-differentiated (G1/G2) gastroenteropancreatic neuroendocrine tumors (GEP-NETs) were randomized into two arms: (A) standard [^{177}Lu]Lu-DOTA-TATE RLT and (B) individualized, dosimetry-guided RLT. Outcomes included absorbed doses to kidneys and bone marrow, safety profiles, progression-free survival (PFS), and overall survival (OS). ***Results:*** To date, 24 patients (12 per group) have completed RLT. In group A, patients received mean cumulative activity of 29.2 GBq (7.3 GBq per cycle), resulting in mean absorbed doses of 19.68 Gy to the kidneys and 0.51 Gy to the bone marrow. Group B received a higher mean cumulative activity of 33.9 GBq (7.98 GBq per cycle), with corresponding mean absorbed doses of 22.71 Gy and 0.51 Gy, respectively. No statistically significant differences were observed in hematologic parameters (WBC, RBC, PLT, Hb) or renal function (creatinine, GFR) between the groups. Median PFS and OS have not yet been reached after 12 months of follow-up. ***Conclusion:*** Standard RLT activity levels may be insufficient to reach critical organ dose thresholds in many patients. Preliminary data suggest that individualized, dosimetry-based increases in administered activity can be safely implemented without compromising kidney or bone marrow function. Long-term follow-up (up to 60 months post-RLT) is ongoing. ***References:*** The study is funded by the Polish Medical Research Agency (Project number 2019/ABM/01/00077-00).

EP-0790

Radiopharmaceutical Therapy in Neuroendocrine Carcinoma using Actinium-225, FAP-targeting, and somatostatin receptor antagonists: A new therapeutic perspective in patients progressing to standard therapies

E. Perrone[1], *K. Ghai*[2], *T. Parkar*[2], *A. Eismant*[2], *L. Greifenstein*[2], *M. Pavel*[3], *R. P. Baum*[2];
[1]*Nuclear Medicine Unit, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, ITALY,* [2]*CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY,* [3]*Department of Medicine 1, Uniklinikum Erlangen, Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, GERMANY.*

Aim/Introduction: Neuroendocrine carcinoma (NEC) is a very aggressive neoplasm with high morbidity and mortality. Conventional treatments beyond first-line platinum-based chemotherapy have proven ineffective, often with significant side effects. Radiopharmaceutical Therapy (RPT) might offer a potential therapeutic option in these patients, supported by recent advancements in radiotheranostics: alpha-emitter nuclides, like Actinium-225 (high linear energy transfer); new targets, e.g. fibroblast activation protein (FAP, targeting the tumour microenvironment); new molecules, like somatostatin receptor (SSTR)-antagonists (DOTA-LM3), with high tumour uptake and prolonged tumour retention. We investigated safety, efficacy and survival of RPT as salvage therapy in patients with advanced NEC. ***Materials and Methods:*** RPT was administered following confirmation of high uptake at PET/CT with Gallium-68-labelled corresponding compound (04/2022-01/2025). RPT included Peptide Receptor Radionuclide Therapy (PRRT) and FAP-directed Radiopharmaceutical Therapy (FRT) using radiolabelled-3BP-3940 (FAP-binding peptide). CTCAE v.5.0 was used to grade acute and long-term haematological, renal and hepatic adverse events. Molecular imaging-based response was evaluated following THERCIST via PET/CT or post-therapeutic SPET/CT. Data were retrospectively analysed (03/2025). ***Results:*** We treated 6 patients (36-66 years; M:F=5:1) with metastatic pancreatic (n=4) or colorectal NEC (n=2). Tumours were NEC at initial diagnosis (n=5) or upgraded from well-differentiated neuroendocrine neoplasm G3 following repeated biopsy (n=1). Previous treatments included: chemotherapy (n=5); radiotherapy (n=4); surgery (n=3); somatostatin analogues (n=2); Everolimus (n=1); 177Lu-DOTATATE (n=1). PRRT was administered in two patients: one patient received one cycle of 225Ac-DOTA-LM3 and one of 225Ac/177Lu-DOTA-LM3 (TANDEM); the other patient received two cycles of 225Ac-DOTATOC. Four patients received FRT as follows: one cycle of 90Y-3BP-3940; one cycle of 225Ac/177Lu-3BP-3940 (TANDEM); two cycles of 177Lu-3BP-3940 and one of 90Y-3BP-3940; one cycle of 225Ac-3BP-3940 and three of 225Ac/177Lu-3BP-3940 (TANDEM). RPT was overall well tolerated, with few G1 acute adverse events (emesis, nausea, flare pain). Long-term toxicity included: anemia G2/G3 (n=2), leukopenia G2 (n=1), thrombocytopenia G1 (n=1), liver impairment G2 in patient with hepatic metastases. Nephrotoxicity was not reported. Molecular-imaging responses included: one partial remission (2 months after DOTA-LM3 PRRT); three disease progression (response duration after first RPT: range 5-7 months). Two patients experienced clinical progression (1 month and 3 weeks after first RPT). At analysis, 5 patients had died, 1 patient was alive. ***Conclusion:*** Our experience shows that RPT can offer a therapeutic chance in individual patients with advanced NEC exhausting other treatments, however response rates were low; further research is needed to enhance RPT efficacy, also exploring the synergistic effects of combination with other therapeutic strategies.

EP-0791

Visual comparison of reception expression before and after Lu177 Dotatate PRRT in patients with GEP-NET using 68Ga-DOTATATE PET-CT

J. Zivanovic[1], *M. Vadrucci*[2], *N. Mulholland*[2], *S. Reynolds*[2];
[1]*Center for Nuclear Medicine with PET, University Clinical Centre of Serbia, Belgrade, SERBIA,* [2]*Department of Nuclear Medicine, King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: The aim of this study was to compare receptor expression in patients undergoing 177Lutetium-DOTATATE peptide receptor radionuclide therapy (PRRT) by assessing their initial and post-therapy 68Ga-DOTATATE PET/CT scans. ***Materials and Methods:*** 84 patients undergoing PRRT were examined using patient data records and available PET/CT reports. The number of treatment cycles ranged from 1 to 6. Receptor expression was visually compared using both the least and most avid lesion in each patient at the baseline versus post-therapy scan. The change in receptor expression was classified as increased, decreased, stable; or not applicable if the lesion had been treated locally (e.g surgery or radiotherapy). ***Results:*** Table 1: Change in receptor expression in the least avid lesions Table 2: Change in receptor expression in the most avid lesions Follow up of the patients' post-therapy scans as compared to the initial scan was performed in order to assess the efficacy of the therapy applied. The interpretation was done using

both visual assessment as well as the reports themselves. The results were as follows: Using these tables, new data was inferred about the relationship between the changes in metabolic activity and the overall disease progression. ***Conclusion:*** Application of PRRT achieved stable disease in the majority of patients reviewed. However, the disease progressed in 25% of patients, The aspect examined was a change in receptor expression. Namely, a lesion with higher receptor expression at the post-therapy scan than initial scan corresponded to disease progression and vice versa. In 80% of patients, both types of lesions followed the pattern of the disease; meaning that if the disease had progressed, both had higher receptor expression at the post-therapy scan. However, in the remaining patients, it is interesting to note that the lowest initial receptor expression followed the course of the disease more frequently. These preliminary results may indicate that disease with higher receptor expression heterogeneity implied by the variable degree of 68Ga-DOTATATE uptake at baseline is less likely to respond to PRRT.

Aim/Introduction: In stage IV gastroenteropancreatic neuroendocrine tumors (GEP-NETs), sex-related differences in efficacy and toxicity have been documented with multi-kinase inhibitors, However, such differences remain underexplored in the context of 177Lu-DOTATATE (PRRT). Objective: To describe sex-based differences in baseline characteristics, treatment effectiveness, and toxicity among patients with stage IV GEP-NETs treated with PRRT. ***Materials and Methods:*** Patients with stage IV GEP-NETs treated with 177Lu-DOTATATE in the national SEPTRALU registry were analyzed. Baseline characteristics and toxicities were compared using chi-square and Student's t-tests. Effectiveness was assessed using Kaplan-Meier curves and log-rank tests. ***Results:*** A total of of 896 patients were included: 378 women (42%) and 518 men (58%). The median age was similar (65 years in women vs. 67 years in men) with a higher proportion of men over 65 years (56% vs. 52%). ECOG performance status 0 was comparable (women 54%, men 53%) as was Ki67 (5% vs. 6%). The most common primary tumor locations were pancreas (35% vs. 36%) and small intestine (31% vs. 29%). Metastases predominated in the liver (87% vs. 84%) and lymph nodes (61% vs. 65%). Time from diagnosis of metastasis to the start of PRRT was longer in women (62.9 vs. 49.7 months) and women received more prior lines of treatment (≥3 lines: 22% vs. 17%). Objective response rate was similar (between sexes women 22%, men 24%). Progression-free survival (PFS) was longer in women (38.2 months, 95% CI: 33.7-42.7) compared to men (29.7 months, 95% CI: 26.8-32.6). Overall survival (OS) also favored women (58.6 months, 95% CI: 51.7-65.5) compared to men (46.1 months, 95% CI: 41.6-50.6), with a HR of 0.82 (95% CI: 0.73-0.94). Grade 3-4 toxicity was low in both groups, although hematologic toxicity was slightly higher in women (4% vs. 2.5%). ***Conclusion:*** Women with stage IV GEP-NETs treated with 177Lu-DOTATATE demonstrated longer PFS and OS compared to men. Although overall toxicity rates were low and comparable, women experienced a modestly increased incidence of grade 3-4 hematologic toxicity.

PRRT with Lu-177-DOTATATE and monitoring with SSTR-PET/CT in patients with PPGL tumors

S. Kunte[1], *A. Holzgreve*[1], *M. Schöll*[1], *V. U. Wenetr*[1], *G. T. Sheikh*[1], *M. Scheifele*[1], *F. J. Gildehaus*[1], *S. Lindner*[1], *M. K. Auer*[2], *C. Lottspeich*[2], *M. Kroiß*[2], *S. Nölting*[2], *F. Völter*[2], *C. Spitzweg*[2], *C. J. Auernhammer*[2], *R. A. Werner*[3], *M. J. Zacherl*[1];
[1]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY,* [2]*Department of Internal Medicine IV, LMU University Hospital, Munich, GERMANY,* [3]*Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTATATE has demonstrated promising efficacy in somatostatin receptor (SSTR)-expressing tumors. The present study aims to evaluate its therapeutic value in a rechallenge setting in patients with metastatic tumors of the adrenal medulla and extra-adrenal paraganglia. ***Materials and Methods:*** Nine patients with metastatic paraganglioma (PGL; n = 5) or pheochromocytoma (PCC; n = 4) who received at least two cycles of PRRT were retrospectively analyzed. Patients were stratified by treatment course into continuous (sequential PRRT; 5/9, 55.6%) and discontinuous (rechallenge after ≥11-month PRRT-free interval; 4/9, 44.4%) subgroups. Eligibility was confirmed via SSTR PET using either [68Ga]Ga-DOTATOC (n = 4) or [18F]SiTATE (n = 5), applying the Krenning score. Treatment response was assessed by RECIST 1.1, total tumor volume (TTV; PET-derived), and Chromogranin A (CgA) levels. Adverse events were evaluated according to CTCAE v5.0. ***Results:*** All patients exhibited high lesional SSTR expression (mean SUVmax 32.8 ± 62.3; Krenning Score 3-4), thus confirming their eligibility for PRRT. At the conclusion of treatment, eight out of nine patients (88.9%) demonstrated stable disease according to RECIST, while one out of nine (11.1%) exhibited progressive disease. Patients receiving discontinuous PRRT demonstrated consistent reductions in both TTV and CgA, whereas those with continuous PRRT showed more heterogeneous responses. Furthermore, two patients (22.2%) experienced Grade 3 toxicity, with no occurrence of Grade 4 or 5 events. ***Conclusion:*** In cases of metastatic PGL and PCC, the use of SSTR PET, particularly with [18F]SiTATE, has facilitated the selection of appropriate patients for PRRT. The results demonstrated that PRRT led to tumor control in the majority of patients, including those who underwent rechallenge. The treatment was well tolerated, with an acceptable safety profile.

EP-0794

"Rechallenge" peptide receptor radionuclide therapy (PRRT) may be less efficient than initial PRRT while safety profile is comparable

P. Hartrampf[1,2], *A. Kosmala*[1], *S. Alwers*[1], *F. Lutz*[1], *S. Serfling*[1], *A. Meining*[3], *A. Buck*[1], *A. Weich*[3,2];
[1]*University Hospital Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY,* [2]*University Hospital Würzburg, ENETS Center of Excellence, Würzburg, GERMANY,* [3]*University Hospital Würzburg, Department of Internal Medicine II, Würzburg, GERMANY.*

Aim/Introduction: For patients with gastrointestinal, pancreatic or pulmonary neuroendocrine tumours (NET), peptide receptor radionuclide therapy (PRRT) can be performed as a re-challenge (re-PRRT) after initial PRRT (i-PRRT). We compared efficacy and adverse events between re- vs. i-PRRT, along with possible prognosticators for outcome. ***Materials and Methods:*** For 37 patients with NET, Kaplan-Meier analysis was used to assess progression-free survival (PFS) after i- and re-PRRT. The Wilcoxon test was used to compare baseline laboratory values for leukocytes, hemoglobin, platelets, C-reactive protein, lactate dehydrogenase, creatinine, glomerular filtration rate, bilirubin, gamma-GT (GGT), alanine aminotransferase and alkaline phosphatase between i-PRRT and re-PRRT. At baseline and upon follow-up, we determined SSTR-directed PET metrics (SUV_{mean}, SUV_{max} and SSTR-positive tumor volume (SSTR-TV) as well as their changes. A univariable Cox regression analysis was performed to determine the prognostic value for PFS. Adverse events were classified according to CTCAE 5.0. ***Results:*** The median interval between i-PRRT (median 4 [2-8] cycles, median activity 29.5 [13.3-60.8] GBq) and re-PRRT (median 3 [1-4] cycles, median activity 22.1 [5.0-30.4] GBq) was 36 (15-104) months. The median PFS after i-PRRT was 32 months and after re-PRRT 17 months (progression in 20/37 patients). Only median hemoglobin (12.2 vs. 13.2; p<0.01) and glomerular filtration rate (74 vs. 85; p<0.01) were significantly lower at beginning of re-PRRT, while GGT (64.0 vs. 45.7; p<0.001), AP (80.0 vs. 98.5, p<0.01) and de-Ritis (1.42 vs. 0.97, p<0.001) were higher at the beginning of re-PRRT. No significant differences were found in SSTR-TV (104.7 vs. 156.2 ml; p=0.3), SUV_{max} (36.5 vs. 50.2; p=0.1) and SUV_{mean} (9.8 vs. 11.9; p=0.2) between i-PRRT and re-PRRT. In the univariable Cox regression performed with laboratory values and the different PET parameters, only a higher CRP was significantly associated with shorter PFS in the i-PRRT (HR 8.8 95%CI 1.2-58.6, p<0.05). However, this association was not seen in re-PRRT (HR 0.79 95%CI 0.13-3.8, p=0.8) but LDH was significantly associated with shorter PFS in the re-PRRT (HR 1.007 95%CI 1.0-1.014, p<0.05). Among patients with available PET scans (i-PRRT, 33; re-PRRT, 26), 16/33 (48%) showed a reduction in SSTR-TV after i-PRRT, but only 10/26 (38%) after re-PRRT. However, two patients with no SSTR-TV reduction after i-PRRT had SSTR-TV reduction upon re-PRRT. No ≥ CTCAE 3 occurred in the re-PRRT group, but one grade 3 leukopenia after i-PRRT. ***Conclusion:*** Rechallenge PRRT in patients with GI-NET demonstrates comparable low toxicity to initial PRRT, while it may be less efficient.

EP-0795

First Real-World Evidence on the Safety and Effectiveness of ^{177}Lu-DOTATATE for Treating Gastroenteropancreatic Neuroendocrine Tumors (GEP-NETs): Insights from Post-Marketing Surveillance

Y.-i. Kim[1], *H. Suh*[2], *Y. Kang*[2], *H. Cho*[3], *S. Hyun*[4], *Y. Song*[5], *S. Ha*[6], *K. Kang*[7];
[1]*Asan Medical Center, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF,* [2]*Novartis Korea Ltd., Seoul, KOREA, REPUBLIC OF,* [3]*Severance Hospital, Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF,* [4]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, KOREA, REPUBLIC OF,* [5]*Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, KOREA, REPUBLIC OF,* [6]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF,* [7]*Seoul National University Hospital, Seoul National University, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: ^{177}Lu-DOTATATE has been used for patients with gastroenteropancreatic neuroendocrine tumors (GEP-NETs), however, the absence of clinical data in South Korean patients remains a significant gap. In this post-marketing surveillance study, we evaluated the safety and effectiveness of ^{177}Lu-DOTATATE in patients with GEP-NETs in real-world practice in South Korea. ***Materials and Methods:*** From July 2020 to July 2024, a total of 89 patients from 6 institutions diagnosed with GEP-NETs, as outlined in the approved indication for ^{177}Lu-DOTATATE, were prospectively enrolled. Safety was the primary objective, whereas effectiveness was secondary objective. Study findings were analyzed and compared with NETTER-1 and NETTER-2 trials. ***Results:*** Baseline characteristics were comparable to NETTER-1 and NETTER-2 except for the notably high proportion of G2 (77.1%) among participants. Considering the national health insurance status and patient condition, less than a half of patients (41.0%) completed four cycles of ^{177}Lu-DOTATATE treatment, a lower portion of completion rate compared to 75.7% in NETTER-1 and 87.8% in NETTER-2. Among the 83 patients, 60 patients (72.3%, 239 cases) had at least one adverse event (AE), with 6 patients (7.2%, 8 cases) experiencing serious adverse events (SAEs). The most common AE was nausea (34.9%, 46 cases), and most AEs were mild in severity (94.6%, 226 cases). Overall, the safety profile in this study presented minimal differences from NETTER-1 and NETTER-2. This study reports 37.7% of objective response rate (ORR) which is between 14.7% in NETTER-1 and 43.0% in NETTER-2. ***Conclusion:*** Our study complemented the safety and effectiveness of ^{177}Lu-DOTATATE in South Korea. The data would support the clinical use of ^{177}Lu-DOTATATE for the treatment of GEP-NETs.

EP-0796

Cycle-to-Cycle Reduction in External Dose Rate as a Predictor of Therapeutic Response in [177Lu] DOTATATE Therapy for Neuroendocrine Tumours

N. Wakabayashi[1,2], *S. Watanabe*[1,2,3], *S. Takeuchi*[4,5], *S. Takeuchi*[5,6], *K. Hirata*[1,2,3], *R. Kimura*[2,7], *J. Takenaka*[2,8], *H. Koga*[1,2], *K. Kudo*[2,3,7];
[1]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [2]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [3]*Global Center for Biomedical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, JAPAN,* [4]*Department of Medical Oncology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [5]*Neuroendocrine Tumor Center, Hokkaido University Hospital, Sapporo, JAPAN,* [6]*Department of Gastroenterological Surgery II, Faculty of Medicine, Hokkaido University, Hokkaido University, Sapporo, JAPAN,* [7]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN,* [8]*Comprehensive Heart Failure Center, University Clinic Würzburg, Würzburg, GERMANY.*

Aim/Introduction: In peptide receptor radionuclide therapy with [177Lu] DOTATATE for neuroendocrine tumours, a reduction in external dose rate (EDR) is often observed in subsequent cycles compared to the first. This may reflect a decrease in radiotracer uptake in tumours, suggesting that changes in EDR could predict therapeutic efficacy. This study aimed to identify factors associated with changes in EDR and to evaluate their relationship with treatment response. ***Materials and Methods:*** We retrospectively analysed patients who completed four cycles of [177Lu] DOTATATE therapy at our institution between October 2022 and March 2025. The difference in EDR (μSv/h) at 1 metre from the body surface on the day after administration between the first and fourth treatments was defined as ΔEDR, calculated as: EDR after the first treatment minus EDR after the fourth treatment. Post-therapy SPECT/CT images were analysed, and regions with uptake exceeding 50% of the splenic SUVmax were visually assessed and categorised as either tumour or non-tumour by a board-certified nuclear medicine physician. Tumour uptake (TU) was quantified as the product of tumour volume and SUVmean. Non-tumour uptake (non-TU) was calculated in the same manner. Simple linear regression was performed to assess associations between ΔEDR and TU or non-TU. Based on the median ΔEDR, patients were divided into a high-ΔEDR group (greater reduction in EDR) and a low-ΔEDR group (minimal reduction or slight increase in EDR). Treatment response was assessed using RECIST version 1.1 and compared between groups using Fisher's exact test. ***Results:*** A

total of 16 patients were included. The mean ± SD of ΔEDR was 4.6 ± 4.8 μSv/h. According to RECIST version 1.1, 7 patients achieved partial response (PR) and 9 had stable disease (SD) during the observation period of 16.1 ± 7.7 months. Among the low-ΔEDR group, 6 showed PR and 2 SD; among the high-ΔEDR group, 1 showed PR and 7 SD. ΔEDR was significantly correlated with TU (adjusted R^2 = 0.57, p = 0.0004), but not with non-TU (adjusted R^2 = −0.07, p = 0.93). The low-ΔEDR group had a significantly higher rate of PR compared to the high-ΔEDR group (p = 0.04). ***Conclusion:*** A greater reduction in external dose rate (i.e., a larger ΔEDR) following [177Lu] DOTATATE therapy was significantly associated with decreased tumour uptake and may predict a favourable therapeutic response.

Study of the effectiveness of PRRT in 177 Lu-DOTATATE - treated patients

B. Kalman[1], *Z. Ritter*[1], *E. Mezősi*[1], *A. Bos-Liedke*[2], *D. Dezső*[1]; [1]*University of Pécs, Pécs, HUNGARY,* [2]*Department od Biomedical Physics of Adam Mickiewicz University, Poznan, POLAND.*

Aim/Introduction: Neuroendocrine tumours (NETs) are increasingly common and often cause hormonal syndromes. First-line treatment includes somatostatin analogues (SSA), but progression may require second-line ^{177}Lu-DOTATATE therapy. This study evaluates its efficacy in progressive cases, hypothesising that target lesion activity decreases over treatment. ***Materials and Methods:*** A total of 15 patients received ^{177}Lu-DOTATATE therapy, 9 of them received 4 cycles of treatment and were included in the study. Based on SPECT/CT scans, target lesions with the highest activity were selected and measured at the first and fourth post-therapy study time points according to RECIST 1.1 criteria. The SUVmax of the lesions was recorded, and the SUVmax of intact liver and spleen tissue was used as control. After testing the normality of the obtained data, we evaluated the differences using a paired Wilcoxon test. ***Results:*** In all patients, the largest liver metastasis was found to be the dominant target lesion. Liver metastasis activity was significantly decreased relative to normal liver during treatment (liver lesion 1/normal liver activity ratio, cycle 1 vs. cycle 4: p = 0.038153). The decrease in target lesion activity relative to normal spleen approached the limit of significance (liver lesion 1/spleen activity ratio, cycle 1 vs. cycle 4: p = 0.050613).A trend towards a decrease in activity was also observed for extrahepatic lesions (extrahepatic lesion 1/spleen activity ratio, 1st vs. 4th cycle: p = 0.074736; extrahepatic lesion 1/normal liver activity ratio, 1st vs. 4th cycle: p = 0.074736), but these values did not reach the level of statistical significance. No significant decrease in activity was detected for the smaller target lesions.There was no significant change in the activity uptake of reference organs (liver, spleen) during the treatments (p = 0.952765 and p = 0.138642), supporting their use as reliable controls. There was no significant change in the size of target lesions. All but one of the patients were in stable disease (SD) status based on follow-up CT scans. ***Conclusion:*** Our results suggest that decreased lesion activity may be a better predictor of treatment efficacy than size reduction during radioligand therapy. Lesion size above a certain threshold might enhance ^{177}Lu-DOTATATE effectiveness, though larger studies are needed. Most patients showed stable disease on follow-up CT, supporting the therapy's efficacy. Future research should further explore tumour volume as a response marker.

EP-0798

Is There a Correlation between Metabolic Tumor Volume and Progression-free Survival in Neuroendocrine Tumors Treated with LU-177-Oxodotreotide?

S. Salcedo Cortes, *E. Ardila Manjarrez, A. Mari Hualde, J. Guzmán Cruz, I. Gómez Fernández, J. Ardila Mantilla, L. Reguera Berenguer, V. Castillo Morales, J. Orcajo Rincón, D. Zamudio Rodriguez, S. Álvarez Lara, G. Mera Ovalle, J. Alonso Farto; Hospital General Universitario Gregorio Marañon, Madrid, SPAIN.*

Aim/Introduction: To evaluate the correlation between metabolic tumor volume (MTV) in neuroendocrine tumors (NETs) treated with Lu-177-oxodotreotide and progression-free survival (PFS), as well as the relationship with post-treatment laboratory abnormalities. ***Materials and Methods:*** A retrospective observational study was conducted in 20 patients who received 4 cycles of Lu-177-oxodotreotide (7.4 GBq each) since 2018. MTV was measured using 68Ga-DOTATATE PET/CT, evaluating all identified lesions. PFS was determined via CT imaging and correlated with MTV. Post-treatment laboratory tests were also reviewed, and statistical analyses were performed. Patients who did not complete the 4 treatment cycles were excluded. ***Results:*** The study included 20 patients (9 men, 11 women; mean age: 59 years). NET origins were as follows: 25% ileal, 20% pancreatic, 15% unknown primary, 10% carotid paraganglioma, 10% jejunal, 10% ileal (additional cases), 5% nasopharyngeal, and 5% rectal. Of these, 75% were G2 and 25% G1. The mean MTV was 359.2 g/ml × cm^3, and the median PFS was 35 months (range: 6-61). The correlation between MTV and PFS showed a Pearson coefficient of -0.44 (p = 0.051), suggesting that higher MTV is associated with shorter PFS. Additionally, MTV was significantly correlated with creatinine levels at follow-up (r = 0.69, p = 0.0008), indicating a potential renal side effect. Hematological variables did not show significant correlations with MTV. ***Conclusion:*** There is a negative trend between MTV and PFS, suggesting that a higher MTV may be associated with worse outcomes. Creatinine levels at 2 years showed a significant correlation with MTV, possibly reflecting renal toxicity. No relevant correlations were observed between MTV and hematologic parameters.

EP-0799

Appropriate selection of pretreatment PSMA-ligand PET/CT parameters helps in candidate selection for ^{177}Lu-PSMA radionuclide therapy in men with metastatic castration-resistant prostate cancer (mCRPC)

S. Chen, *Y. Yip, S. Cheung, Y. Wong, K. Wu, K. Cheng, C. Ho; Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.*

Aim/Introduction: ^{177}Lu-PSMA radionuclide therapy has proven value in improving progression-free and overall survival (OS) in mCRPC patients. The predictors for outcome in the current practice is to perform an interim assessment after the 2nd cycle of ^{177}Lu-PSMA (Response Evaluation Criteria In Interim; RECIP-1.0), which is post initiation of treatment. We proposed to investigate if candidate selection for ^{177}Lu-PSMA therapy is possible based on pretreatment RECIP-1.0 PSMA-ligand PET/CT criteria and whether it may improve treatment response and OS. ***Materials and Methods:*** This is an Asian single-center retrospective study covering a period of 4 years (ended Dec-2024) on mCRPC patients who were treated with >=2 cycles of ^{177}Lu-PSMA-I&T (7.4 GBq at 6-week intervals). They all underwent a baseline PSMA-PET/CT (bPET) and an interim PSMA-PET/CT (iPET) at 12 weeks. Tumor lesions local and metastatic (lymph node, bone, other organ metastases) were evaluated by 2 Nuclear Medicine specialists in consensus, lesion-by-lesion, including any emergence of new metastatic lesions between bPET-iPET pairs. Total PSMA-positive tumor volume (PV) was automatically analyzed by MIMContouring software, with bPV and iPV calculated respectively for each pair, and %PV-change (δPV)=100%*(iPV-bPV)/bPV. Based on RECIP-1.0, complete-response (CR) was defined as "all PSMA-avid lesions normalized"; partial-response (PR) as "δPV-decrease ≥30% with no new lesions";

progressive-disease (PD) as "δPV-increase ≥20% and emergence of new lesions"; and stable disease (SD) as "any other conditions (non-CR/PR/PD)". CR, PR and SD was chosen as potential candidates for ^{177}Lu-PSMA treatment. PR/CR were considered good response. Multivariate analysis was applied on bPET for any independent predictors (SUV_{mean}, PV, all metastatic sites) for both candidate selection and good response. ***Results:*** This study recruited 58 patients (mean age=72.0±9.4 years, range:50-90 years). Based on RECIP-1.0, 20/58 patients achieved RECIP-PR/CR, 17/58 classified as RECIP-SD and 21/58 as RECIP-PD. Their corresponding bPV were 34±32ml, 136±46ml, and 402±249ml, respectively, with RECIP-PD patients significantly higher bPV than RECIP-SD or RECIP-PR/CR (all P<0.001). Among all the bPET parameters, only bPV was identified as an independent predictor for both potential candidates (P=0.04) and good response (P=0.001) for ^{177}Lu-PSMA treatment. ROC curve analysis calculated "bPV<=196ml" as the selection threshold for predicting candidates to achieve RECIP-CR/PR/SD post ^{177}Lu-PSMA treatment (AUC=0.989, P<0.001); "bPV<=77ml" as cut-off for good response (RECIP-CR/PR, AUC=0.968, P<0.001). ***Conclusion:*** Total tumor burden expressed in terms of tracer-avid tumor volume (bPV) on pretreatment PSMA-ligand PET/CT has evidence-based significance in selection of suitable candidates and response prediction for ^{177}Lu-PSMA therapy. Further validation in prospective setting is warranted.

[177Lu]Lu-PSMA-617 in patients with mCRPC and brain metastases : a multicentric retrospective French study

D. Tonnelet[1], *F. Sommes*[2], *K. Hebert*[3], *M. Claudin*[4], *K. Weyts*[5], *P. Robin*[6], *M. Lacombe*[7], *N. De Leiris*[8], *C. Baillet*[9];
[1]*Henri Becquerel Cancer Center, Rouen, FRANCE,* [2]*Institut de Cancérologie Strasbourg Europe, Strasbourg, FRANCE,* [3]*L'Institut du Cancer de Montpellier, Montpellier, FRANCE,* [4]*Centre Hospitalier Régional et Universitaire de Nancy, Vandoeuvre-lès-Nancy, FRANCE,* [5]*Centre de Lutte Contre le Cancer François Baclesse, Caen, FRANCE,* [6]*CHU Brest, Univ Brest, Inserm, UMR 1304, GETBO, Brest, FRANCE,* [7]*Institut de Cancérologie de l'Ouest Angers-Nantes, Angers, FRANCE,* [8]*Univ. Grenoble Alpes, INSERM, CHU Grenoble Alpes, Grenoble, FRANCE,* [9]*Centre Hospitalier Universitaire de Lille, Lille, FRANCE.*

Aim/Introduction: While [177Lu]Lu-PSMA-617 (LuPSMA) is a proven radioligand-therapy in metastatic castration-resistant prostate-cancer (mCRPC), little is known about its efficacy and tolerance on brain metastases. This retrospective analysis focuses on patients with mCRPC previously treated with at least one line of ARPI and one line of taxane-based chemotherapy, and who had and at least one brain metastases. ***Materials and Methods:*** All nuclear medicine centers in France administering LuPSMA were contacted. When treatment was initiated, the recommended protocol included 6 intravenous injections of Lu-PSMA (7.4 GBq Q6W). Patient characteristics, brain metastases imaging and safety data were collected during follow-up visits. ***Results:*** A total of 36 patients from 8 different departments were included : Age median 72.6 [63-88] years-old . ISUP≥4 in 21/36 (58%). Among them, 19/36 (53%) had de novo metastatic prostate cancer. On average, patients received 4 prior treatment lines before receiving LuPSMA. In 22/36 patients (61%), brain metastases were discovered on PSMA PET. A total of 90 brain metastases were analysed (range: 1-41/patient, median: 2) Imaging characteristics were as follows i) size: median 16.7 [4-55] mm ii) SUVmax: median 9.65 [3.57 - 24.8] iii) PSMA Total Metabolic Tumour Volume using fixed SUVmax>3 threshold: median 5.07 [0.2 - 47] cm^3. No brain metastases was FDG-positive and PSMA-negative. 7/36 (19%) patients who were eligible for LuPSMA did not received LuPSMA because of i) deterioration of general condition before the first injection (n=4) ii) Discordant imaging with extra-cerebral FDG-positive / PSMA-negative lesions (n=2) and iii) death before initiation of treatment (n=1). Of the 29 treated patients, 20 (69%) received brain-directed external radiotherapy (BDER) prior to the first LuPSMA cycle, including 12/20 (60%) who underwent stereotactic radiotherapy (median dose: 25.0 Gy). One patient received intrathecal methotrexate. Only 5/29 (17%) completed all 6 LuPSMA infusions. Reasons for early discontinuation included i) progressive disease (n=15) ii) worsening general condition (n=5) iii) grade 3/4 hematologic toxicity (n=3) and iv) external cause (e.g., severe fall (n=1)). No treatment was interrupted due to side effects related to brain metastases or due to cerebral toxicity. Among those who completed the full course, treatment outcomes were : partial response (n=3), stable disease (n=1), and progressive disease (n=1). Of note, all patients who completed full course had had BDER. ***Conclusion:*** Although LuPSMA demonstrates some intracranial activity and no additional brain toxicity, this study enhances the poor prognosis of patients with mCRPC and brain metastases referred for LuPSMA.

Aim/Introduction: Among the prognostic factors in men with metastatic castration-resistant prostate cancer (mCRPC), body mass index (BMI) is highly considered, being often related to a worst outcome when low (1,2). For mCRPC patients (pts), 177Lu-PSMA 617 (LuPSMA) is now recognized as a valid therapeutic strategy. Herein we evaluate the impact of BMI on progression-free survival (PFS) and overall survival (OS) in pts treated with LuPSMA. ***Materials and Methods:*** 142 mCRPC pts were enrolled in a prospective phase II trial (EUDRACT: 2016-002732-32) developed at IRST "Dino Amadori" Institute. The aims of the study were to evaluate efficacy, safety and dosimetry of LuPSMA. Pts received 3.7-5.5 GBq of LuPSMA every 8-12 weeks for 4 cycles plus possibly 2 additional cycles. BMI was calculated according to the standard and treated as low-normal (L-N) if <25 or elevated if ≥25 kg/m2 (EI). ***Results:*** 57/142 had L-N BMI, while 85/142 had EI BMI. The two groups were balanced in terms of age, performance status (Eastern Cooperative Oncology Group, ECOG), Gleason score, previous treatments with docetaxel, alkaline phosphatase (ALP) and PSA levels. Regarding visceral metastases, they were more frequent in pts with L-N BMI than in EI ones (26.3 and 11.8%, respectively). Pts were followed-up for a median time of 44.0 months. The overall median PFS and OS were 7.0 and 16.8 months, respectively. At the univariate analysis, PFS in EI BMI and in L-N BMI pts was respectively 7.6 vs 5.5 months (HR: 0.67, 95%CI: 0.47-0.98, p=0.037). OS in EI BMI and in L-N BMI pts was respectively 19.2 vs 13.6 months (HR: 0.63, 95%CI: 0.42-0.94, p=0.022). ***Conclusion:*** According to our results, mCRPC pts treated with LuPSMA with EI BMI had better PFS and OS. BMI may be considered as an independent prognostic factor. Further data are required to assert the role of

BMI in predicting response to LuPSMA. ***References:*** 1. 1.Peslier H et Alt. Study of predictive factors for response to 177LU-PSMA in patients with metastatic castration-resistant prostate cancer. Aim/Introduction: Following the results of the Vision study (1), 177Lu PSMA 617 (LuPSMA) was approved for patient (pts) with metastatic castration-resistant prostate cancer (mCRPC). The expanding practice in this field will probably test nuclear medicine Departments, therefore could be necessary to predict the events potentially leading to a rescheduling of the hospitalization, even not related to toxicity or underlying illness complications. Herein we report the experience of our Institute IRST "Dino Amadori", focused on the pts who delayed treatment for reasons other from toxicity or complications due to LuPSMA. ***Materials and Methods:*** Pts with mCRPC were enrolled in a prospective, open label, phase II trial (EUDRACT: 2016-002732-32), whose aim was to evaluate efficacy, safety and dosimetry of LuPSMA. The planned activity of Lu-PSMA was 5.5 GBq/cycle for 4 cycles every 8±2 weeks, plus possibly 2 additional cycles. ***Results:*** From December 2021 to October 2022, 48 mCRPC pts were enrolled in the study. Patients characteristics were: median age 68 yo (range 60.6-75.1), median baseline PSA value (µg/L) 41.5 (12.5-111), pre-treatment with surgery (50%), prostate radiotherapy (45.5%), abiraterone (75%), enzalutamide (61.4%), cabazitaxel (9.1%), docetaxel (52.1), olaparib (4.5%). The treatment was delayed in 6 pts (12.5 %). In 3 pts treatment was postponed (range 7-10 days) for logistical reasons, because of failed delivery of 177Lutethium. In 3 pts treatment was postponed for patient-related reasons (range 2.5-10 weeks), 1 of them had personal commitments, 2 were hospitalized to performe further investigation for clinical reasons other than mCRPC. ***Conclusion:*** In our experience, unexpected events could retard treatment of mCRPC only in 12.5% of the hospitalizations, equally balanced between logistical and patient-related reasons. The delayed was longer when related to the pts, up to 10 weeks. These data suggest that the incidence of unpredictable delays is not high, fortunately, but could affect everyday work activities and should be taken into consideration and monitored. ***References:*** 1.Sartor O et Alt: Lutetium-177-PSMA-617 for Metastatic Castration-Resistant Prostate Cancer. Aim/Introduction: The use of 177Lu-PSMA 617 (LuPSMA) has been recently approved by Agenzia Italiana del Farmaco (AIFA) for patient (pts) with metastatic castration-resistant prostate cancer (mCRPC) already treated with at least one androgen receptor pathways inhibitor (ARPI) and two-lines taxane-based chemotherapy (Tax). Only pts unfit to a second Tax line can receive LuPSMA. Before that, LuPSMA was delivered exclusively through trials and after multidisciplinary team (MDT) evaluation. Published results showed that Lu-PRRT could give better results when performed before Tax (1), thus bringing Food and Drug Administration (FDA) to authorize it also in Tax naïve pts. Herein we report data from our trial, regarding the pts treated out of the Tax indication. ***Materials and Methods:*** Pts with mCRPC were enrolled in a prospective phase II trial (EUDRACT: 2016-002732-32), developed at IRST "Dino Amadori" Institute. The aims of the study were to evaluate efficacy, safety and dosimetry of LuPSMA. Pts were included also if taxane naïve or after 1 line of Tax and if considered as unfit for chemotherapy by MDT or refused it. The planned activity of LuPSMA was 5.5 GBq/cycle for 4 cycles every 8±2 weeks, plus possibly 2 additional cycles. ***Results:*** From December 2021 to October 2022, 48 mCRPC pts were enrolled in the study, with median age 68 yrs (range 60.6-75.1) and median baseline PSA value 41.5 µg/L (range 12.5-111). They were all pre-treated and the previous treatments were: surgery (22 pts, 50%), prostate radiotherapy (20 pts, 45.5%), abiraterone (33 pts, 75%), enzalutamide (37 pts, 61.4%), cabazitaxel (4 pts, 9.1%), docetaxel (25 pts, 52.1%) and olaparib (2 pts, 4.5%). 23 pts (47.9%) were Tax naïve, 10 because refused it and the other ones were unfit. ***Conclusion:*** These data may suggest that currently in Italy, differently from United States, an important percentage of pts could not be treated with the drug with marketing autorization but exclusively through trials, which should be encouraged. Further data are needed to extabilish the correct timeline of LuPSMA and to integrate it into clinical practice. The evaluation of MDT should be considered as mandatory in any case. ***References:*** 1. patients with progressive metastatic castration-resistant prostate cancer (PSMAfore): a phase 3, randomised, controlled trial . The Lancet, Volume 404, Issue 10459, 1227 – 1239.

EP-0804

Addition of ^{177}Lu-PSMA-617 in the treatment of hormone sensitive metastatic prostate cancer: a prospective pilot study

***V. H**, N. Pandit, S. Kayal;*
Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, INDIA.

Aim/Introduction: Recent years have introduced several modalities and agents in the management of metastatic prostate cancer. Application and sequencing of these agents is an area of ongoing research. Lu-177 PSMA, an agent traditionally used after exhausting other lines of treatment, is now being introduced in earlier time-points of metastatic prostate cancer. We present the results of application of Lu-177 PSMA in metastatic hormone sensitive prostate cancer (mhsPC) patients alongside Androgen Deprivation Therapy (ADT) and Abiraterone. ***Materials and Methods:*** mhsPC patients on androgen deprivation therapy (ADT) who cannot tolerate docetaxel were included. After biopsy and metastatic evaluation with Ga-68 PSMA PET/CT, and initiation of ADT, patients received 2 cycles of Lu-PSMA 617 (100mCi per cycle) in addition to Abiraterone which was continued. Serial serum PSA values and FACT-P scores were obtained. ***Results:*** Of the 8 patients recruited, all patients showed sustained PSMA response 6 months post therapy. Post therapy scans obtained after 2 cycles of Lu-PSMA showed complete response of all lesions in 2 patients. 3 out of 5 patients show an increase in FACT-P scores. Considerably, the emotional well being and physical well being subscales which show significant improvement. However, 2 patients show an overall decrease in FACT-P score, evenly distributed among the subscales. ***Conclusion:*** We aim to demonstrate the use of Lu-177 PSMA therapy in mhsPC with the rationale being - improvement in the quality of life of patients in the earlier stages by delaying the need for chemotherapy and application of targeted radionuclide therapy at a time-point where PSMA expression is maximal. In line with our study, further research in the direction of optimal scheduling, sequencing and combination of Lu-177 PSMA therapy are promising prospects. ***References:*** Kim H, Tagawa ST, Sartor AO, et al. Hematological Safety of ^{177}Lu-PSMA Radioligand Therapy in Metastatic Castration-Resistant Prostate Cancer: Real-World Evidence from a Developing Country

***A. Gupta**, A. H. Nazar, M. Ora, P. K. Pradhan;*
Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: ^{177}Lu-PSMA radioligand therapy (RLT) has emerged as a promising option for patients with metastatic castration-resistant prostate cancer (mCRPC). However, data on its hematological safety, particularly from developing countries, remain scarce. This study evaluates hematologic adverse effects in mCRPC patients receiving 3 or more cycles of ^{177}Lu-PSMA RLT, comparing baseline and post-treatment hematological parameters. ***Materials and Methods:*** An ambispective observational study was conducted on mCRPC patients treated with 3 or more cycles of ^{177}Lu-PSMA RLT between 2020 and 2025. Clinical, demographic, and hematological data were collected from medical records. Hematologic toxicity was graded using CTCAE v5.0 criteria. Hemoglobin, platelet, and neutrophil levels were analyzed before and 21 days post-therapy. Statistical analysis was performed using a paired t-test. ***Results:*** Of 83 total patients, 44 were eligible for analysis (mean age: 73 years). At baseline (mean hemoglobin- 10.8), 3 patients had no anemia, 31 had Grade I, and 10 had Grade II anemia. Post-therapy (mean Hemoglobin- 10.2), 28 had Grade I, 14 had Grade II, and 2 had Grade III anemia. Anemia grade remained unchanged in 35 patients (26 with Grade I, 9 with Grade II). Among others who progressed that are two non-anemic patients progressed to Grade I, and one to Grade II. Four patients with Grade I anemia progressed to Grade II. One with Grade I progressed to Grade III, and one with Grade II worsened to Grade III. Thrombocytopenia remained unchanged in 42/44 patients. One patient developed new-onset Grade I thrombocytopenia, and one improved from Grade I to normal. No case of neutropenia was observed in any of the 44 patients post-treatment. ***Conclusion:*** This real-world data from a developing country demonstrates that ^{177}Lu-PSMA RLT is well-tolerated with minimal hematologic toxicity and confirms RLT is hematologically safe in mCRPC patients. Most adverse effects were limited to mild anemia, with rare cases of thrombocytopenia and no observed neutropenia. These findings support the safety of ^{177}Lu-PSMA RLT and reinforce its viability in resource-limited healthcare settings, enhancing its potential for broader adoption.

EP-0806

Interim Analysis of Effect of Hypoxia on F-18 MISO PET to Response to Lu-177 PSMA Treatment (LuMISO)Trial

***C. Soydal**, E. Dursun Avci, B. Demir, G. İnal, M. Araz, N. O. Kucuk;*
Ankara University Medical Faculty, Ankara, TÜRKIYE.

Aim/Introduction: We aimed to evaluate hypoxia before Lu-177 PSMA treatment in prostate cancer and to show its effect on treatment response with 18F-FMISO PET imaging. ***Materials and Methods:*** In this interim analysis pretreatment 18F-FMISO PET images of 7 men who received Lu-177 PSMA treatment for castration resistant prostate cancer (CRPC) included. 18F-FMISO PET imaging has performed within 2 weeks before treatment. Volumes of interest (VOIs) were delineated for all PSMA-avid and >2cm tumors, gluteal muscle, and the abdominal aorta for semiquantitative measurement of hypoxia. Maximum (SUVmax) and mean (SUVmean) standardized uptake values of all reference VOIs were recorded for analysis. Tumor-to-muscle ratio (T/M) and tumor-to-blood pool ratio (T/BP) were calculated. Lesion based response assessment was performed with pre and posttreatment PSMA PET images based on PSMA-volume and TL-PSMA approaches. To evaluated the effect of 18F-FMISO PET based hypoxia to response ROC analysis was performed. ***Results:*** Totally 99 (81 bone, 15 lymph nodes, 1 lung, 1 liver and 1 prostate) lesions were included to the analysis. All the lesions were Ga-68 PSMA avid (median SUVmax:26.3, volume:2.65 cm3 and TL-PSMA=39.1). All the patients were received at least 2 cycles of Lu-177 PSMA treatment. In the PSMA-volume based evaluation 29 lesions were responder and 70 lesions were non-responder. For this criterion, we have not found an optimal cutoff for T/M (AUC: 0.53, 95%CI; 0.40-0.65) and T/BP (AUC: 0.52, 95%; 0.40-0.64) ratios to predict the response (CR+PR). In the other response criterion with TL-PSMA while 64 lesions were responder, 35 of them were non-responder. Similarly, we have not found an optimal cutoff for T/M (AUC: 0.57, 95%CI; 0.45-0.68) and T/BP (AUC: 0.56, 95%; 0.45-0.68) ratios to predict

the response (CR+PR) in TL-PSMA response categories. However, when we analyzed the 7 lesions with CR separately, 1.0 cutoff for T/BP (AUC: 0.73, 95%; 0.58-0.88, p=0.002) and 1.2 cutoff for T/M (AUC: 0.67, 95%; 0.51-0.83, p=0.03) were calculated. ***Conclusion:*** Interim analysis of this trial has demonstrated that 18F-FMISO PET based assessment of tumor hypoxia may have a role in the prediction of CR to Lu-177 PSMA treatment in patients with CRPC. However due to limited number of lesions with CR this outcome should be clarified with larger data. ***References:*** Wiedenmann NE, Bucher S, Hentschel M, et al. Serial [18F]-fluoromisonidazole PET during radiochemotherapy for locally advanced head and neck cancer and its correlation with outcome. Radiother Oncol [Internet]. Do We Need to Reconsider Our Treatment Protocol for Metastatic Prostate Cancer With [^{177}Lu]Lu-PSMA-Radioligand?

T. Bogsrud[1,2], *O. Engelsen*[1], *P. Iversen*[2], *P. F. Staanum*[2], *A. T. Kendi*[3], *J. Zhang*[3], *M. P. Thorpe*[3], *F. J. Hernandez-Delima,*[3], *O. Sartor*[4], *J. M. Durski*[3];
[1]PET Imaging Center, University Hospital of North-Norway, Tromso, NORWAY, [2]Aarhus University Hospital, Aarhus, DENMARK, [3]Mayo Clinic, Rochester, MN, UNITED STATES OF AMERICA, [4]Tulane University Department of Urology and Medicine, New Orleans, LA, UNITED STATES OF AMERICA.

Aim/Introduction: Standard treatment of metastatic castration-resistant prostate cancer (mCRPC) with [^{177}Lu]Lu-PSMA-radioligand involves 6 cycles with fixed activity (typical 7.4 GBq per cycle) every 6 weeks. Tumor absorbed dose at first treatment <10 Gy predicts unsatisfactory treatment effect. However, the accumulated tumor dose from all cycles is likely more relevant for treatment effect than the dose from the first cycle. It is a prerequisite that all cycles contribute significantly to accumulated tumor absorbed dose. Some published data indicate dose per administered activity decreases over subsequent cycles. If so, we might question whether our current standard of care is optimal. We report on tumor dosimetry from each of 5 standard treatment cycles and 6 additional retreatment cycles in a single patient, and outline an ongoing pilot project to perform multi-timepoint dosimetry in 5 additional patients. ***Materials and Methods:*** A 76-year-old man with progressive mCRPC and very high lesion uptake (SUVmax=70) on [^{68}Ga]Ga-PSMA-11 PET/CT (PSMA PET/CT) was treated with 5 cycles of [^{177}Lu]Lu-PSM-I&T, achieving partial treatment response. Fifteen months later repeat treatment with 6 cycles was performed because of progression of intensely avid disease on PSMA PET/CT. Multiple time-point tumor dosimetry of target lesions was performed for each of the 11 cycles. ***Results:*** After the first cycle, PSA decreased from 154 µg/L to 53 (66% reduction). Five weeks after the 5th cycle, PSA was 1,8 µg/L. PSMA PET/CT showed substantial reduction in the size of target lesions, with high PSMA-uptake in small residual metastatic lesions. After 15 months, the disease progressed rapidly (PSA=390 µg/L, doubling time 1.5 months), with very high uptake in numerous metastases on PSMA PET/CT. Short lasting stable disease was achieved by the repeat treatment. The first cycle of each of the two treatment series achieved comparable absorbed doses to target lesions. For subsequent cycles, the dose to target lesions decreased on average 35% per cycle (median 25%). ***Conclusion:*** Only the first 2-3 cycles gave a reasonably high tumor dose. If our results are generalizable to the broader mCRPC population, adjustments to our standard procedure may enhance therapeutic efficacy, avoid ineffective treatment cycles, and mitigate unnecessary radiation dose to critical organs and futile treatment expense. Examples of possible modifications include personalized dosimetry (dosimetry of tumors and critical organs) to optimize administered activity and reducing the number of therapy cycles.

EP-0808

Prediction of Treatment Response and Progression-Free Survival Based on Pre-Treatment PSA Levels and PET/CT Parameters in Prostate Cancer with Lu-177 PSMA Therapy

S. Ceylan, *B. B. Demirel, G. Uçmak;*
Ankara Oncology Training and Research Hospital Nuclear Medicine Clinic, Ankara, TÜRKIYE.

Aim/Introduction: The aim of this study is to identify predictors of treatment response,progression-free survival (PFS) based on pre-treatment clinical, laboratory, pathological,PET/CT (Ga-68 PSMA and F-18 FDG) parameters in prostate cancer patients undergoing Lu-177 PSMA therapy. ***Materials and Methods:*** Between 2019 and 2024, 45 patients with metastatic castration-resistant prostate cancer who received at least two cycles of Lu-177 PSMA therapy in our clinic, had no discordant lesions on pre-treatment FDG PET/CT imaging were included in the study.Demographic, pathological-laboratory findings of the patients (pre-final treatment day PSA values,the difference in PSA between the first and last treatment [ΔPSA]) were recorded.Pre-treatment PET/CT scans were analyzed using a 40% threshold for WB TL-PSMA, PSMA-TV, PSMA mean, PSMA max, as well as WB MTV, TLG, SUVmean,SUVmax values. Progression was evaluated based on PSA,anatomical-molecular imaging findings.PFS was defined as the date on which a rise in PSA and new lesions on imaging were simultaneously observed. Predictive factors for Lu-177 PSMA therapy response and PFS were statistically analyzed. ***Results:*** In prostate cancer patients, pre-treatment WB PSMA max,TL-PSMA values on Ga-68 PSMA PET/CT were found to be significantly higher in the group with ΔPSA >50%, independently of the metabolic parameters from FDG PET/CT.A ΔPSA >90% was shown to be associated with longer PFS.WB PSMA max was found to be clinically associated with PFS. ***Conclusion:*** A total of 45 patients were included in the study.Of these, 11 had a pre-treatment PSA level <10, while 34 had levels >10. A treatment response was observed in 34 patients (75.6%) based on laboratory and imaging findings.Among these, 16 patients (35.5%) showed a >50% PSA response, and 6 patients (13.3%) showed a >90% PSA response.The mean PFS was 7 months (range: 3-17).WB TL-PSMA, PSMA-TV, WB TLG, and MTV values were significantly lower in the PSA<10 group (p-values: 0.024, 0.027, 0.027, and 0.02, respectively) and significantly higher in patients with both bone and lymph node metastases compared to those with only bone metastases (p=0.039).ΔPSA >90% had a significant impact on PFS (p=0.018). Although WB PSMA max did not significantly prolong PFS statistically (p=0.116), patients with a WB PSMA max cutoff value >18.57 had a clinically longer PFS [7±0.79 CL (5.4-8.5)] compared to those with <18.57 [5±0.79 CL (3.4-6.5)]. While the difference in PFS between patients with PSA <10 and >10 was not statistically significant (p=0.126), the PFS was clinically longer in the PSA<10 group [8±1.3 CL (5.4-10.5)] compared to the PSA>10 group [5±0.6 CL (3.8-6.2)].

Assessment of Sequential Radium-223 and Docetaxel Treatment in Patients with Metastatic Castration-Resistant Prostate Cancer: Insights from the Global REASSURE Study

Y. Du[1], *S. Baldari*[2], *A. Versari*[3], *S. Lastoria*[4], *J. Bourre*[5], *C. La Fougère*[6], *E. Borsatti*[7], *J. Meltzer*[8], *M. J. Korn*[8], *S. Dizdarevic*[9];
[1]Royal Marsden Hospital, London, UNITED KINGDOM, [2]University of Messina, Messina, ITALY, [3]Azienda USL-IRCCS Reggio Emilia, Reggio Emilia, ITALY, [4]IRCCS National Cancer Institute, Fondazione Senatore G. Pascale, Naples, ITALY, [5]Centre Hospitalier Métropole Savoie, Chambery, FRANCE, [6]University Hospital Tübingen, Tübingen, GERMANY, [7]Centro di Riferimento Oncologico di Aviano (CRO) IRCCS, Aviano, ITALY, [8]Bayer HealthCare Pharmaceuticals, Whippany, NJ, UNITED STATES OF AMERICA, [9]University Hospitals Sussex NHS Foundation Trust, Brighton & Sussex Medical School, University of Sussex and Brighton, Brighton, UNITED KINGDOM.

Aim/Introduction: Radium-223 and docetaxel are approved for extending overall survival (OS) in patients with metastatic castration-resistant prostate cancer (mCRPC), but optimal sequencing of these therapies is crucial to maximizing benefits while minimizing toxicity. We compared safety and OS in patients receiving radium-223 before docetaxel with those receiving docetaxel before radium-223. We utilized data from the REASSURE prospective global study, which investigated radium-223 use in mCRPC in routine clinical practice between 2014-2017. ***Materials and Methods:*** Data cut-off was Oct 24, 2024. 72 patients received radium-223 before docetaxel (R-D) and 86 radium-223 after docetaxel (D-R). Analyses focused on patients receiving the second therapy within 90 days of stopping the first, without additional life-prolonging therapies in between. Statistics were descriptive. Baseline characteristics were only available at radium-223 initiation. Safety data were collected from radium-223 initiation for both sequences. OS was calculated from start of first treatment in each sequence. ***Results:*** Almost all patients (92%) receiving R-D exhibited ECOG PS of 0-1, in contrast to 79% receiving D-R. Burden of disease at radium-223 initiation was lower in R-D vs D-R with patients exhibiting >20 bone lesions (18% vs 29%) and superscan (4% vs 9%). At radium-223 initiation, patients in R-D vs D-R had baseline median alkaline phosphatase of 118 U/L vs 173 U/L; median prostate-specific antigen of 66 ng/mL vs 130 ng/mL; median lactate dehydrogenase of 242 U/L vs 309 U/L; hemoglobin ≥10 g/dL (86% vs 70%); platelets ≥100x10^9/L (89% vs 84%); and neutrophils ≥1.5x10^9/L (56% vs 55%). Radium-223 was concomitantly administered with abiraterone (R-D: 22%; D-R:8%) or enzalutamide (R-D: 22%; D-R: 11). The median number of radium-223 cycles received in R-D vs D-R, was 6 vs 4 cycles. The incidence of treatment-emergent (TE) serious adverse events during radium-223 treatment was 11% vs 34% and TE disorders related to blood and lymphatic systems were 13% vs 9% in R-D vs D-R. Discontinuation of radium-223 due to TE drug-related adverse events was 4% vs 5%. Post-treatment grade 3/4 bone marrow suppression events were similar between R-D and D-R (21% vs 20%). Median OS from start of first treatment in the sequence was 16.3 months in R-D and 15.8 months in D-R. ***Conclusion:*** Despite differences in key baseline demographics, OS from first drug in the sequence was similar between R-D and D-R. Overall safety and treatment completion were more favorable in the R-D sequence, highlighting the importance of patient selection to optimizing patient outcomes.

[^{177}Lu]Lu-DOTA-HYNIC-panPSMA radioligand therapy for patients with metastatic castration-resistant prostate cancer

J. Roetman[1], *Y. Omar*[2], *Y. Atteya*[2], *M. Elkanawaty*[2], *A. Ahmed*[3], *G. Elhusseiny*[3], *M. El Shazly*[3], *A. Ameen*[3];
[1]Telix Pharmaceuticals, Melbourne, AUSTRALIA, [2]Misr Radiology Center, Cairo, EGYPT, [3]Alexandria University, Alexandria, EGYPT.

Aim/Introduction: [^{177}Lu]Lu-DOTA-HYNIC-panPSMA ([^{177}Lu]Lu-panPSMA) is a novel radioligand with high affinity for prostate specific membrane antigen (PSMA), expressed by most prostate cancer cells. [^{177}Lu]Lu-panPSMA may offer accessible therapy for patients in underserved regions. A retrospective translational study demonstrated promise as a theranostic pair with [^{68}Ga]Ga-PSMA-11 PET/CT, with a favorable safety and tolerability profile and efficacy.[1] We aim to contribute to existing data with preliminary results from the first prospective trial to investigate safety, efficacy, and effect on quality of life of [^{177}Lu]Lu-panPSMA for treatment of patients with progressive PSMA-positive metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Patients (N=15) with progressing mCRPC despite treatment with ≥1 novel androgen-axis drug and ≥1 taxane regimen (or unfit for chemotherapy) and have ≥1 PSMA positive metastatic lesion (with uptake higher than liver parenchyma) and no PSMA-negative disease on [^{68}Ga]Ga-PSMA-11 PET/CT are eligible to participate. Patients receive 7.4 GBq (200 mCi) [^{177}Lu]Lu-panPSMA intravenously every 6 weeks for up to 6 doses, or until disease progression or unacceptable toxicity. The primary endpoint is the percentage of patients achieving prostate-specific antigen (PSA) response, defined as a ≥50% decrease in PSA baseline. Secondary endpoints include frequency and severity of adverse events, progression-free survival, quality of life, and overall survival. To date, 11 patients have received ≥1 dose. Primary endpoint results from all 15 patients anticipated prior to EANM '25. ***Results:*** One patient received 5 doses, 3 patients received 4 doses, 2 patients received 2 doses, and 5 patients received 1 dose. Of 9 patients with available data, 8 (89%) had any decrease in PSA, ranging from 25-98% decrease; 3 patients had >80% decrease. Most common adverse events were Grade 1 fatigue (5 patients) and Grade 3 anemia (3 patients). Only 2 patients experienced Grade 1 xerostomia, which could be explained by lower than usual salivary gland uptake seen on post-injection [^{177}Lu]Lu-panPSMA SPECT images (further investigation ongoing). All patients reported an improved quality of life with majority reducing/stopping pain medication use. ***Conclusion:*** Preliminary data suggest that [^{177}Lu]Lu-panPSMA is effective for the treatment of patients with PSMA+ mCRPC, with improvements in quality of life and a favorable safety and tolerability profile. Disclosure: This is an investigator-initiated trial. ^{177}Lu, DOTA-HYNIC-panPSMA, [^{68}Ga]Ga-PSMA-11 kits, and financial support provided by Telix Pharmaceuticals. ***References:*** 1. Luna-Gutiérrez M et al. Pharmaceutics. 2023;15(7):1988. doi:10.3390/pharmaceutics15071988.

EP-0811

Dual-Tracer Deep Learning-Based Prediction of Voxel-Wise Absorbed Dose for PSMA Radioligand Therapy in mCRPC

S. Xue[1], *A. A. Nikolic*[2], *S. Wen*[1], *B. Jan*[2], *M. Hacker*[1], *C. Lapa*[2], *X. Li*[1];
[1]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA, [2]Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY.

Aim/Introduction: Theranostic imaging plays a critical role in personalizing radiopharmaceutical therapy (RPT) by enabling pre-treatment absorbed dose prediction. While previous studies have attempted to estimate absorbed doses using PSMA PET imaging alone, growing evidence indicates that elevated FDG uptake may signify resistance to PSMA-targeted therapy. This discordance challenges the predictive accuracy of PSMA-only models, particularly for PSMA/FDG concordant lesions. To address this limitation, we propose a dual-tracer deep learning framework that integrates pre-therapy PSMA and FDG PET imaging for voxel-wise absorbed dose prediction. Our approach employs a custom-designed Dual Attention Fusion U-Net (DAFNet) to enhance predictive accuracy through modality-specific modeling and differential loss weighting. ***Materials and Methods:*** This retrospective study included 35 patients with metastatic castration-resistant prostate cancer (mCRPC) who received [^{177}Lu]Lu-PSMA therapy, comprising 71 treatment cycles with pre-treatment PSMA/FDG PET imaging. Various theranostic combinations were included: [^{18}F]F-rhPSMA-7.3 or [^{68}Ga]Ga-PSMA-11 for imaging, and PSMA-I&T, PSMA-617, or rhPSMA-10 for therapy. The proposed DAFNet architecture incorporates three key components: (1) modality-specific feature extraction branches for PSMA and FDG, (2) hierarchical cross-modal attention fusion to integrate tracer-specific biological signals, and (3) a lesion- and organ-at-risk (OAR)-prioritized weighted loss function to enhance prediction accuracy in clinically relevant regions. Quantitative performance was evaluated using voxel-wise physical error metrics and dose-volume histogram (DVH) similarity. ***Results:*** DAFNet demonstrated

higher voxel-level dose prediction accuracy compared to the PSMA-only baseline model (P-Unet). For lesion regions, DAFNet achieved a significantly lower normalized root mean squared error (NRMSE) of 0.04 ± 0.01%, compared to 0.26 ± 0.10% for P-Unet ($P < 0.05$), along with improved DVH similarity (96.9 ± 0.2% vs. 87.1 ± 0.5%). In OARs, both models performed comparably, with DAFNet achieving an NRMSE of 0.05 ± 0.02% and DVH similarity of 97.1 ± 0.2%, versus 0.05 ± 0.01% and 96.2 ± 0.5%, respectively, for P-Unet. ***Conclusion:*** The DAFNet model demonstrates improved lesion-specific absorbed dose prediction by effectively integrating PSMA and FDG PET imaging, addressing key limitations of PSMA-only approaches. This work represents a step toward more accurate, personalized pre-therapy dosimetry in PSMA radioligand therapy for mCRPC.

EP-0812

Radioligand therapy for metastatic prostate cancer: the first French qualitative study exploring patient perceptions, from experience to trust

C. Lachachi[1], *P. Barthelemy*[2], *N. Houede*[3], *E. Treuveur*[4], *S. Chene*[5], *M. de Loisy*[5], *M. Wartski*[6];
[1]*Hospices civils de Lyon, Hopital Louis Pradel, Bron, FRANCE,* [2]*ICANS, Strasbourg, FRANCE,* [3]*CHU de Nimes, Nimes, FRANCE,* [4]*Aplusaresearch, Boulogne-Billancourt, FRANCE,* [5]*Novartis Pharma SAS, Rueil-Malmaison, FRANCE,* [6]*APHP, Hopital Cochin, Paris, FRANCE.*

Aim/Introduction: Patients with metastatic cancers face limited treatment options, impaired quality of life, and reduced life expectancy.^{177}Lu-PSMA-radioligand therapy (RLT) represents a promising therapeutic innovation for these patients, but it may raise some concerns or questions. The objective of this first French qualitative study involving patients with metastatic castration-resistant prostate cancer (mCRPC) was to explore patients' perception of beta-emitter based RLT - among both treated and untreated individuals - as well as their knowledge, concerns, expectations, and perceived benefits and barriers. ***Materials and Methods:*** Thirteen patients (7 treated and 6 not treated with RLT), referred via physicians or the National Association of Prostate Cancer Patients (ANAMACaP), participated in 60-minute unstructured interviews (9 sections) analyzed via full transcripts. Patients came from different regions in France, and they all had mCRPC, treated with at least two previous or ongoing lines of systemic therapy (including chemotherapy and hormone therapy). ***Results:*** Patients describe their cancer as an invisible "chronic illness", contrasting with the strong negative effects that previous treatments had on their quality of life. Nevertheless, patients express strong trust in their referring physicians on treatment decisions. RLT is perceived as an "innovative and targeted treatment" that addresses a vital therapeutic need, "inspiring hope" and offering "more benefits than disadvantages." RLT is associated with familiar procedures (e.g. PET scans in the same department) without particular concerns related to the nuclear aspect. However, further clarification is needed, mainly regarding the practical aspects of treatment administration and the appropriate terms employed to explain them. Patients who were not treated with RLT welcome this additional therapeutic option and express their interest in its targeted action while raising questions about the precautions to follow. Patients who are undergoing treatment or benefiting from a response to RLT describe an overall positive experience on PSA levels, clinical improvement, better tolerability compared to chemotherapy, and simple administration (rapid, painless injection) on an outpatient setting. The administration process and radiation safety precautions are well accepted. ***Conclusion:*** This qualitative study reveals a positive perception of RLT among mCRPC patients based on its targeted mechanism of action, a favorable benefit-risk balance, and a favorable treatment experience highlighted by patients who received it. Trust in the medical team and transparent communication regarding practical aspects are essential to accepting this innovative treatment.

EP-0813

Long-Term Outcome of Patients with Metastatic Castration-Resistant Prostate Cancer Treated with [^{177}Lu] Lu-PSMA Therapy: A Real-World Study from a Resource-Constrained Southeast Asian Tertiary Care Center

A. Nazar, *M. ora, P. Pradhan, S. Barai, A. Arya;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: To assess long-term outcomes of [^{177}Lu]Lu-PSMA therapy in metastatic castration-resistant prostate cancer (mCRPC) patients treated in a real-world clinical setting. ***Materials and Methods:*** This retrospective observational study included 63 patients with mCRPC treated with [^{177}Lu]Lu-PSMA between September 2020 and March 2025 at a tertiary care institute. Data were collected on demographics, number of treatment cycles, survival status, and follow-up duration. PSA and radiological responses were not included in this analysis. Overall survival was assessed descriptively. Patients were followed until death or last contact, and survival status was recorded accordingly. ***Results:*** The median age of the cohort was 69.5 years (range: 38-92). Patients received a median of 3 cycles (range: 1-6) of [^{177}Lu]Lu-PSMA. total 6 cycle were planned for each patients. However only 23 (36%) patients could complete the 6 cycle. 9 patients received one cycle, 11 patients two cycle, 12 patients three cycle, 4 patients four cycle and 3 patients five cycle before they expired. One patients shows complete response after 4 cycle. At data cutoff, 40 patients (63%) had died and 23 (37%) were alive. The median follow-up duration was 14.5 months (range: 0.7-57.5 months). No unexpected toxicities were reported during the observation period. The treatment was well tolerated in the majority of patients. ***Conclusion:*** [^{177}Lu]Lu-PSMA therapy demonstrated favorable long-term outcomes in mCRPC patients, with a good safety profile and sustained follow-up in a real-world setting. Further analysis incorporating PSA dynamics, imaging response, and dosimetry is planned to enhance treatment personalization.

EP-0814

Association between early scintigraphic and biochemical response after one cycle of [177Lu]LuPSMA-617 radioligand therapy in metastatic castrationresistant prostate cancer patients

A. Silva, *L. C. Silva, F. P. M. Oliveira, D. C. Costa;*
Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisbon, PORTUGAL.

Aim/Introduction: This study investigates the association between the scintigraphic response of [177Lu]Lu-PSMA-617 radioligand therapy (RLT) and early biochemical response after one cycle of RLT in metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Between Dec./2023 and Apr./2025, 21 mCRPC patients underwent at least two cycles of [177Lu]Lu-PSMA-617 (7400MBq+/-10%, 6 weeks apart). Nineteen patients were retrospectively included; two were excluded, one due to lack of PSA information after 1st cycle of RLT and another to no post-therapeutic images at the 24h-time-point available. Biochemical response was based on the relative change of serum PSA according to the Prostate Cancer Working Group 3 criteria. Scintigraphic post-therapeutic assessment was based on the relative burden and metabolic disease changes and visual evaluation, categorized according to RECIP1.0. PSA was measured at 12±8 and 32±7 days before and after 1st cycle, respectively. The geometric mean of anterior and posterior projections of 1st and 2nd cycles 24h-post-injection whole-body scintigraphic images were used to quantify disease status changes. Planar images intensity normalisation

was done through bilateral uniform-uptake regions in the soft tissue of the medial aspect of the distal thighs. All lesions were identified and then validated by an experienced nuclear medicine physician. Segmentation was performed with an already-validated semi-automatic Bayesian segmentation algorithm, from the lesion identification masks. Three quantitative measures were extracted - total disease extent (product of number of lesion pixels by pixel area), total metabolic burden (product of disease extent by mean uptake) and maximum uptake. Spearman correlation (ρ) was used to assess the relationship between PSA relative difference, and scintigraphic quantitative measures relative differences. ***Results:*** After the first cycle of RLT, median PSA dropped from 28.6(0.21-737) to 24.6(0.33-669) ng/mL. Biochemical response was seen in 3/19(15.8%) patients, stable disease in 10/19(52.6%), and progression disease in 6/19(31.6%). Scintigraphic response was observed in 5/19(26.3%), stable disease in 13/19 (68.4%), and progression disease in 1/19(5.3%) patients. A moderate correlation (ρ=0.688) was found between PSA relative difference and burden extent relative difference (p=0.001). Fair correlations were found between PSA relative difference and metabolic burden (ρ=0.600; p=0.007) and maximum uptake (ρ=0.518; p=0.023) relative differences. ***Conclusion:*** Our preliminary data in this retrospective study found fair to moderate correlations between post-therapeutic scintigraphic images and early biochemical response after one cycle of RLT in mCRPC patients. Therefore, both PSA and post-therapeutic scintigraphic assessment should be used together as indicators of early response to treatment. PSA alone does not reliably predict early response.

EP-0815

Linking Dual-Tracer Imaging and Lesion Dosimetry to Predict Outcomes in mCRPC Patients Treated with [^{177}Lu] Lu-PSMA Therapy

S. Wen[1], *S. Xue*[1], *M. Hacker*[1], *X. Li*[1], *A. A. Nikolic*[2], *L. Constantin*[2], *B. Jan*[2];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY.*

Aim/Introduction: Prostate-specific membrane antigen radioligand therapy (PSMA-RLT) has shown significant clinical benefit, particularly in patients with metastatic castration-resistant prostate cancer (mCRPC). However, treatment response remains heterogeneous. Elevated tumor uptake of FDG has been associated with poorer prognosis in mCRPC patients receiving PSMA-RLT. Meanwhile, higher lesion-level absorbed dose has been linked to improved therapeutic outcomes [1]. This study aims to explore the relationship between pre-treatment FDG uptake and therapeutic absorbed dose, and to evaluate their combined impact on therapy response and survival outcomes in mCRPC patients treated with PSMA-RLT. ***Materials and Methods:*** We retrospectively analyzed 35 mCRPC patients treated with [^{177}Lu]Lu-PSMA I&T. All underwent dual-tracer PET/CT (PSMA and FDG) prior to the first cycle and post-therapy SPECT/CT after each cycle. An automated Python-based pipeline extracted SUV-based features from PET scans and dose metrics from voxel-level absorbed dose maps at patient, organ, and lesion levels. Decision tree analysis identified features associated with treatment response (based on PSA decline) and 3-month PFS (VISION trial criteria). A survival tree model was built using time-to-event data to derive imaging-based risk stratification. Kaplan-Meier analysis with log-rank testing assessed the prognostic significance of selected features. FDG uptake and absorbed dose associations were evaluated using Mann-Whitney U and Kruskal-Wallis H tests. ***Results:*** Decision tree analysis identified several FDG-related features associated with treatment response and short-term PFS ($P < 0.05$). Survival tree modeling revealed that the SUVmean of all FDG-avid lesions was the strongest predictor of progression-free survival (PFS); patients with SUVmean ≤ 6.78 g/mL had significantly longer PFS ($P < 0.01$, HR = 0.204). At the patient level, total volume of concordant lesions ($PSMA^+FDG^+$) was inversely correlated with mean absorbed dose (Kruskal-Wallis $H = 9.6$, $P < 0.05$). At the lesion level, $PSMA^+FDG^+$ lesions exhibited significantly lower absorbed doses compared to $PSMA^+FDG^-$ lesions ($P < 0.05$). No significant dose differences were observed across organ sites ($P = 0.656$). ***Conclusion:*** This study suggests that higher FDG uptake may be associated with lower absorbed dose, poorer treatment response, and shorter survival in mCRPC patients undergoing PSMA-RLT, indicating a potential biological mechanism of resistance. Dual-tracer analysis pipeline may aid in patient selection, but further validation in larger, independent cohorts is needed to confirm its clinical utility. Additional radiobiological studies are warranted to support these findings and refine selection strategies for PSMA-RLT. ***References:*** [1]Warfvinge CF, et al. Relationship Between Absorbed Dose and Response in Neuroendocrine Tumors Treated with [177Lu]Lu-DOTATATE. JNM. 2024;65(7):1070-1075.

EP-0816

Early Prediction of Response to Treatment With ^{177}Lu-iPSMA Using ^{18}F-PSMA 1007 PET/CT in Castration-Resistant Prostate Cancer.

A. Arriaga Contreras*, R. Hernández Ramírez, M. Corza Ayala, F. Solano Caballero, O. Lucio Baez;*
Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad De México, MEXICO.

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) is a heterogeneous entity and constitutes the main cause of mortality. The therapeutic management of mCRPC incorporating diverse classes of agents that have demonstrated prolonged survival, such as ^{177}Lu-PSMA therapy, which uses beta-particle radiation to selectively target cells with high PSMA expression and the surrounding microenvironment. Identifying patients at risk of poor prognosis is clinically important. The study evaluates the correlation between the decrease in total tumour volume (TTV) and semi-quantitative parameters (SUVmax, SUVmean, TLA - Total Lesion Activity) with ^{18}F-PSMA 1007 PET/CT after the second cycle of ^{177}Lu-iPSMA. The objective is to determine whether these parameters predict a successful response at the end of treatment. ***Materials and Methods:*** Twenty-one patients who met the following criteria were analysed: mCRPC, having received at least two cycles ^{177}Lu-iPSMA, and having at least two ^{18}F-PSMA PET/CT studies (obligatorily one before therapy and a second at two cycles or at the end of therapy). Specialised software was used to calculate the TTV and semi-quantitative parameters. RECIST 1.0 criteria and prostate-specific antigen (PSA) were taken into account to classify them as a successful response (complete response (CR), partial response (PR) and stable disease (SD) + PSA decrease >50%) or as treatment failure (progressive disease (PD), PSA decrease <50%). Statistical tests such as Shapiro-Wilk and Mann-Whitney U were applied to evaluate the differences between the groups. ***Results:*** Baseline SUVmax was related to the response to the second cycle of ^{177}Lu-iPSMA treatment. Lower SUVmax values on baseline and interim PSMA PET/CT were related to CR, PR and SD (RECIST 1.0) to ^{177}Lu -iPSMA treatment, and higher SUVmax values with PD. Lower TLG values at the second cycle of treatment were related to a >30% decrease in tumour volume at the end of treatment, when compared with higher TLG values. The early decrease in total tumour volume was not conclusive as a predictor of final response. ***Conclusion:*** Elevated baseline SUVmax values predict a higher probability of successful treatment with 177Lu-PSMA. However, the early decrease in total tumour volume was not conclusive as a predictor of final response. ***References:*** Gafita et al., Radiology 2023;308(1): RECIP 1.0 in mCRPC. Immediate Renal Response to 177Lu-PSMA Radioligand Therapy: Insights from a Prospective Observational Study

A. Nazar, *R. Mehra, M. ora, P. Pradhan;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: This study aimed to evaluate the immediate effects of 177Lu-PSMA radioligand therapy (RLT) on renal function by analyzing serum creatinine changes occurring within one week after therapy administration in patients with metastatic castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** A prospective observational study was conducted on 15 mCRPC patients who underwent 177Lu-PSMA RLT. Thirteen patients completed 6 cycles of therapy, while two patients completed 5 cycles, resulting in a total of 88 treatment cycles for analysis. Serum creatinine levels were measured immediately before and one week after each therapy cycle. Changes in creatinine levels were categorized by direction (increase, decrease, or unchanged) and clinical significance (defined as changes >0.3 mg/dL). Statistical analysis included calculation of means, medians, ranges, and standard deviations, with significance set at $p<0.05$. ***Results:*** Mean pre-therapy serum creatinine was 1.09 mg/dL (range: 0.60-1.87 mg/dL), while mean post-therapy value was 1.10 mg/dL (range: 0.60-1.70 mg/dL). The mean difference between pre- and post-therapy measurements was 0.01 mg/dL, which was not statistically significant ($p>0.05$). Of the 88 treatment cycles, 47.7% (n=42) showed increases in creatinine values, 44.3% (n=39) showed decreases, and 8.0% (n=7) showed no change. Only 7.9% of all treatments resulted in clinically significant creatinine changes (>0.3 mg/dL) - with 3.4% (n=3) showing significant increases and 4.5% (n=4) showing significant decreases. Analysis across consecutive treatment cycles revealed no consistent pattern of creatinine changes, with similar distributions of increases and decreases observed throughout the treatment course. ***Conclusion:*** 177Lu-PSMA radioligand therapy does not appear to cause immediate clinically significant nephrotoxicity as measured by serum creatinine in the majority of treatment cycles. The bidirectional nature of the observed changes, with nearly equal proportions of increases and decreases, suggests that factors other than direct nephrotoxicity may influence short-term creatinine fluctuations in this patient population. These findings support the renal safety profile of 177Lu-PSMA RLT in the immediate post-treatment period, though longer-term studies are warranted to assess potential cumulative effects.

EP-0818

Effect of tumor load on physiological organs uptake of 18-F PSMA in patients with distant metastatic prostatic carcinoma

R. Mostafa[1], *T. Ahmed*[1], *M. T. Amin*[1], *G. El-Hennawy*[2];
[1]*South Egypt Cancer Institute, Assiut University, Assiut, EGYPT,*
[2]*National cancer Institute, Cairo University, Cairo, EGYPT.*

Aim/Introduction: Lutetium-177 prostatic specific membranous antigen (PSMA) represents a novel therapeutic option for metastatic castration-resistant prostate cancer [1]. Kidneys, salivary and lacrimal glands, and red bone marrow are among the organs susceptible to toxicity of radioligand therapy [2]. The tumor sink effect refers to decreased uptake in healthy organs with increased sequestration of the malignant cells, allowing for higher doses of radioligand therapy [3].In this study we aimed to investigate the association between normal organs' mean and maximum standardized uptake values (SUVmean and SUVmax, respectively) of 18-F PSMA and tumor load in metastatic cancer prostate. ***Materials and Methods:*** A total of 95 patients with distant metastatic prostate cancer who had undergone an 18-F PSMA PET/CT were included in this study. Tumor load was visually classified as high, medium, or low. A region of interest (ROI) was drawn in each patient over parotid glands, lacrimal glands, blood pool, liver, spleen, kidneys, and red marrow to extract SUVmean and SUVmax. Organs with metastasis were excluded. Data were presented in the form of median and interquartile range (IQR). Comparisons between groups were done using analysis of variance (ANOVA) and with a post hoc test for multiple comparisons. ***Results:*** Among study participants, 9 had extra pelvic lymph nodes, while the rest had bone and soft tissue metastatic sites. Age ranged from 52-85 years old. Thirty-nine patients had a high tumor load (41%), 23 (24%) had a medium tumor load, and 33 patients (35%) had a high tumor load. Higher tumor load showed significantly lower SUVmean and SUVmax of the salivary glands ($p = 0.002$, and 0.027), lacrimal glands ($p=0.011$, and 0.025), aortic arch ($p=0.018$, and 0.008), spleen ($p=0.006$, and 0.002), kidneys ($p=0.003$, and 0.002), and bone marrow ($p=0.005$, and 0.007). However, there was no significant difference between tumor load and liver SUVmean and SUVmax ($p=0.176$, 0.222). In post hoc comparison, there was a substantial considerable difference between high and medium tumor load ($p=0.014$) and low and medium tumor load ($p<0.001$)—nevertheless, there was no significant difference between medium and low tumor load groups ($p=0.594$). ***Conclusion:*** Higher tumor load showed lower uptake values of healthy organs in 18-F PSMA PET/CT, supporting the tumor sink phenomenon, which could help determine doses of Lutetium-177 therapy. ***References:*** (1) https://doi.org/10.3390/cancers13153715.(2) https://doi.org/10.2967/jnumed.123.265448. EP-0819

Radium-223 (Xofigo) for the treatment of metastatic castration-resistant prostate cancer: our experience.

C. Galindo, *M. De la Rubia Marcos, K. Guichay, D. Rodriguez Oviedo, M. Alvarez Moreno, J. Sanchez Calderón, M. Castillejos Rodriguez, A. Herrero Muñóz, C. Paniagua Correa, A. Ortega Valle, M. García Alonso, M. Tagliatori Nogueira;*
Hospital Universitario de Getafe, Madrid, SPAIN.

Aim/Introduction: To evaluate the outcomes of Radium-223 treatment in patients with metastatic castration-resistant prostate cancer, assessing risk factors, side effects, tolerance, and treatment response. ***Materials and Methods:*** A retrospective case series of patients with metastatic castration-resistant prostate cancer treated with Radium-223 for bone pain management. All patients treated between 2019 and 2024 at a single hospital were included. Clinical-pathological background, imaging results, number of doses received, treatment efficacy, and tolerance were evaluated. ***Results:*** Our series included 37 patients. The average age was 72.3 years (standard deviation, 7.99). Fifty-one percent of patients completed the treatment, and only 16.2% had to discontinue it due to poor tolerance. Clinically, 48.6% of patients improved and 18.9% stabilized, although radiologically, only 1 patient (2.7%) showed improvement, which was observed after the second dose. Sixteen percent of patients developed hematological alterations, requiring treatment discontinuation in all cases. However, for the 5 patients who experienced other side effects (13.5%), treatment discontinuation was not required. The initial weight of patients who discontinued treatment was significantly lower than that of those who did not, and this difference also influenced mortality. Thirty-two percent of patients required additional treatment (radiotherapy) for symptomatic control. ***Conclusion:*** Bone pain is common in patients with metastatic castration-resistant prostate cancer. Our results suggest that Xofigo achieves good symptomatic control with clinical improvement or stabilization in nearly 70%

of patients, despite the lack of radiological improvement. Lower initial body weight is associated with a higher rate of treatment discontinuation and mortality.

EP-0820

^{177}Lu-PSMA-617 therapy in patients with mCRPC: First descriptive analysis of efficacy and safety from a single-oncology center in Greece.

V. Chatzipavlidou, *D. Iakovoglou, T. Kalathas, I. Aisiopoulos, A. Vatalis, L. Zoglopitou, A. Paschali;*
Theagenio, Thessaloniki, GREECE.

Aim/Introduction: After getting approval from FDA&EMA for mCRPC patients previously treated with at least 1 ARPi and 1 or 2 taxanes, ^{177}Lu-PSMA-617 was available for use in Greece from 01/2024. Purpose of our study is to describe our experience so far, on the efficacy and safety of ^{177}Lu-PSMA-617. ***Materials and Methods:*** We performed a retrospective review of patients treated with up to to 6_cycles of ^{177}Lu-PSMA-617 at 6_weeks intervals from 02/2024-04/2025. PSMA-PET/CT was performed on all patients before therapy and in restaging in selected cases of biochemical progression. At each cycle, all patients underwent the same protocol of whole-body/planar and SPECT/CT, to evaluate therapeutic ligand uptake, dosimetry and alteration in the extent of the disease during the treatment. PSA response was defined as a fall-by-50% (PSA50). Hematologic toxicities and adverse events were evaluated. ***Results:*** 34 patients (mean_age:71 y; age_range:54-92y) received ^{177}Lu-PSMA-617. 8 patients completed 6_cycles of ^{177}Lu-PSMA-617. 10 patients discontinued therapy, all because of biochemical progression. 16 patients still undergo ^{177}Lu-PSMA-617 therapy. Complete Response (CR) was achieved in one patient (1/18, 6%) who received 6 cycles of ^{177}Lu-PSMA-617 and had only lymph node metastases in the baseline PSMA-PET/CT. Partial Response (PR) was achieved in two patients (2/18, 11%) who received 6 cycles of ^{177}Lu-PSMA-617 and had lymph node and bone metastases in the baseline PSMA-PET/CT. Disease Progression (PD) was seen in 15 patients (15/18, 83%), 11 of them had lymph node and bone metastases and 4 had also liver metastases and displayed PD in earlier cycles. PSA50 at 6th cycle, was achieved in 5pts (5/18_28%), with the biggest reduction of PSA in the patient with CR (99.7%), followed by the 2pts with PR and 2pts who although progressed with new lesions, had remission in preexisted lesions (bone+lymph nodes). Most patients tolerated the therapies well. Hematologic toxicity was mainly of grade 1, while patients with preexisting myelosuppression were more susceptible. Fatigue and dry mouth were the most common adverse events, nearly all of grade1/or2. Severe xerostomia grade2 developed in the patient who achieved CR. ***Conclusion:*** Our experience with PSMA therapy so far, is encouraging. Patients with mCRPC seem to get the benefits already demonstrated by phase_III trials, however the benefit-to-risk ratio should always be evaluated on a case-by-case_basis. Multidisciplinary collaboration is needed so that patients are monitored and managed safely and efficiently.

EP-0821

Treatment with [^{223}Ra]$RaCl_2$ in Metastatic Castration-Resistant Prostate Cancer Patients: Experience at Our Centre

M. Ottino, *O. Ajuria Illarramendi, A. Martínez Lorca, P. Azpeitia Hernández, M. Gutierrez Guerrero, I. Hernández Pérez, T. Navarro Martínez, U. Vera Schmülling, M. Orduña Diez, E. Pérez de los Ríos, A. Torres Consiglieri, P. Paredes Rodríguez;*
Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: To provide a descriptive analysis of treatment with [^{223}Ra]$RaCl_2$ in patients with metastatic castration-resistant prostate cancer(mCRPC) at our institution. ***Materials and Methods:*** An observational, descriptive, and retrospective study was conducted. Medical records of patients treated with [^{223}Ra]$RaCl_2$ between 01/01/2014-31/12/2024 were reviewed. Inclusion criteria were: mCRPC with symptomatic bone metastases and no visceral metastases, with progression following two lines of systemic therapy or ineligibility for further systemic treatment, in accordance with current clinical guideline recommendations. Variables collected included age, clinical data (ECOG performance status,treatment line), laboratory parameters (haemoglobin,platelets,neutrophils), radiological findings (CT and bone scan prior to treatment), and follow-up data (number of doses received and radiological progression-free survival [rPFS],defined as the appearance of ≥2new lesions on bone scan or progression according to RECISTcriteria). ***Results:*** A total of 46patients were included (50% ECOG 0, 50% ECOG 1), with a mean age of 78.8years (SD ± 7.4years). The median time between CT scan and the first [^{223}Ra]$RaCl_2$ dose was 1.9months (SD ± 1.2months), and the median time between bone scan and the first dose was 2.2months (SD ± 1month).Forty-seven per cent (22/46) of patients completed all six doses of [^{223}Ra]$RaCl_2$. Treatment discontinuation occurred in the remaining patients due to the following reasons:disease progression in 24%(11/46;8 by CT scan,1 by bone scan,3 by clinical deterioration),grade III thrombocytopenia in 2%(1/46), voluntary withdrawal in 4%(2/46), death in 4%(2/46),and unknown causes in 15%(7/46).Regarding treatment lines, 17%(8/46) received [^{223}Ra]$RaCl_2$ as second-line therapy,26%(12/46) as third-line, and 4%(2/46) as fourth-line. Treatment line data were unavailable for the remaining patients due to referrals from other institutions. Among the 22 patients who completed the full treatment course, the median rPFS was 17.7 months (SD ± 20.9 months; 95% CI: 6.8-24.3). Median rPFS by treatment line was 6.3 months (95% CI: 0.9-11.6) for second-line (n=8), 14.8 months (95% CI: 6.51-23.05) for third-line (n=12), and 57.3 months (95% CI: -177-291) for fourth-line (n=2). Comparative analysis using the Mann-Whitney U test indicated notable differences between the third- and fourth-line groups, likely influenced by population heterogeneity and unequal group sizes. ***Conclusion:*** [^{223}Ra]$RaCl_2$ showed encouraging rPFS outcomes at our centre, particularly in patients who completed all six cycles, in line with previously reported data.The observed variation in rPFS by treatment line may reflect differences in patient characteristics and underscores the need for larger, more controlled studies to support these findings.

EP-0822

A Phase 1, first-in-human, dose-escalation study of [^{225}Ac]-AZD2284 (AZD2284), a STEAP2-directed radiopharmaceutical, in patients with metastatic castration-resistant prostate cancer (mCRPC)

F. Almaguel[1,2], *L. Nordquist*[3], *B. Tran*[4], *M. S. Hofman*[4], *S. Allan*[5], *K. Buchanan*[6], *J. Charlton*[6], *J. Dise*[5], *G. Lunger*[5], *N. Mueller*[7], *M. A. Patel*[8], *D. Slade*[6], *M. Petruzzelli*[6], *M. Nawinne*[6], *M. Sathekge*[9,10];
[1]Loma Linda University School of Medicine, Loma Linda, CA, UNITED STATES OF AMERICA [2]Biogenix Molecular, Miami, FL, UNITED STATES OF AMERICA [3]Xcancer, Omaha, NE, UNITED STATES OF AMERICA [4]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [5]Fusion Pharmaceuticals, Boston, MA, UNITED STATES OF AMERICA [6]AstraZeneca, Cambridge, UNITED KINGDOM, [7]AstraZeneca, Gaithersburg, MD, UNITED STATES OF AMERICA [8]AstraZeneca, New York, NY, UNITED STATES OF AMERICA [9]Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA, [10]Nuclear Medicine Department, University of Pretoria, Pretoria, SOUTH AFRICA.

Aim/Introduction: Radiopharmaceutical therapy (RPT) is an established therapeutic modality, with the beta emitter ^{177}Lu-PSMA-617 approved for patients with prostate-specific membrane antigen (PSMA)-positive mCRPC. However, low PSMA expression or neuroendocrine differentiation are associated with limited response to PSMA-targeted RPT, and the radiobiological limitations

of beta-emitting isotopes, along with the physiological expression of PSMA in normal tissues, have curtailed widespread use of ^{177}Lu-PSMA-617, underscoring the need for novel theranostic approaches. Six transmembrane epithelial antigen of the prostate 2 (STEAP2) is overexpressed in prostate cancer cells with limited normal tissue expression, presenting a promising therapeutic target. AZD2284 is an RPT containing the alpha emitter actinium-225 conjugated to a STEAP2-directed monoclonal antibody, AZD2275. AZD2284 delivers actinium-225 to STEAP2-expressing tumor cells, where alpha particles traverse the nucleus causing DNA breaks and other cellular damage. Alpha emissions are not amenable to image acquisition; therefore, [^{111}In]-AZD2287 (AZD2287), with indium-111 chelated to AZD2275, will be used as an imaging surrogate. This first-in-human, Phase 1, non-randomized, open-label study (NCT06879041) is evaluating AZD2284, AZD2287, and AZD2275 in patients with mCRPC. ***Materials and Methods:*** Patients with histologically-confirmed adenocarcinoma of the prostate or neuroendocrine-differentiated prostate cancer and ≥1 metastatic lesion are eligible. The study will enroll ≤134 patients across Parts A (Imaging) and B (Therapeutic). Part A Cold Antibody Exploration aims to determine whether preadministration of AZD2275 (i.e., cold antibody) enables optimal biodistribution of AZD2287 and AZD2284. Patients with progressive disease who have received ≥2 prior lines of systemic treatment may receive AZD2284 at the starting dose. Part A Expansion will explore the prevalence and correlation of PSMA and STEAP2 tumor expression. Part B Dose Escalation will explore escalating doses of AZD2284 (± AZD2275 preadministration as determined in Part A) guided by a model-based time-to-event continual reassessment method. Patients will receive AZD2287 (± AZD2275) to confirm sufficient tumor uptake, followed by treatment with AZD2284 (± AZD2275). Part B Expansion will enroll ≤2 AZD2284 dose cohorts to further characterize safety and efficacy. The primary objectives are to assess the safety and tolerability of AZD2284, AZD2287, and AZD2275; to determine the recommended Phase 2 dose of AZD2284; and to assess the effect of AZD2275 preadministration on the radiation dosimetry of AZD2287 and to estimate the radiation dosimetry of AZD2284. Secondary objectives include efficacy (AZD2284 only), pharmacokinetics, and immunogenicity. Study sites are in the United States, Australia, and South Africa; enrollment began March 2025 and is ongoing.

EP-0823

The Effectiveness of Radium-223 on Metastatic Castration-Resistant Prostate Cancer: A Meta-Analysis

T. Chen, *Y. Chang;*
Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, TAIWAN.

Aim/Introduction: Radium-223 dichloride (radium-223), a bone-targeting alpha-emitting radiotherapeutic, has demonstrated efficacy in delaying the onset of symptomatic skeletal events, enhancing quality of life, and extending overall survival (OS) in patients with metastatic castration-resistant prostate cancer (mCRPC). The objective of this study is to assess the clinical effectiveness of radium-223 through a comprehensive meta-analysis. ***Materials and Methods:*** A systematic literature search was conducted using the PubMed/MEDLINE and Cochrane Library databases to identify relevant studies evaluating the outcomes of Radium-223 therapy in mCRPC patients. Eligible studies included those that enrolled patients receiving Radium-223 treatment and reported survival outcomes. The primary endpoints were overall survival (OS) and progression-free survival (PFS) following Radium-223 administration. Survival data were extracted and analyzed using the MetaSurv function in R. ***Results:*** Following the literature search conducted in March 2023, 34 (n = 6919) and 16 (n = 1779) studies were included for analysis of OS and PFS, respectively. The pooled median OS after receiving radium-223 was 16.63 months (95% confidence interval, 14.26-19.94 months); the pooled median PFS was 7.78 months. No significant difference in OS or PFS was found between radium-223 and placebo groups. Nevertheless, OS was longer in patients receiving radium-223 in combination with androgen deprivation therapy or chemotherapy than in patients receiving radium-223 monotherapy (15.64 months vs. 14.60 months, p = 0.025); similarly, PFS was longer in patients receiving combination therapy than in patients receiving radium-223 monotherapy (14.84 vs. 5.89 months, p = 0.007). Furthermore, patients who completed 5-6 cycles of radium-223 therapy had a significantly longer OS (20.22 months vs. 6.98 months, p < 0.001). ***Conclusion:*** This meta-analysis indicates that Radium-223 therapy, particularly when administered in combination with other systemic treatments, is associated with improved overall and progression-free survival in patients with mCRPC. An improvement of OS was also observed when patients completed 5-6 cycles of radium-223 treatment.

EP-0824

PSMA PET Tumor-to-Salivary Gland Ratio to Predict Response to ^{177}Lu-PSMA and ^{225}Ac -PSMA Radioligand Therapy

L. Gabela, *L. Harry, T. Nxasana, N. Ndlovu, T. Mkhize, V. Pillay, S. Masikane, M. Patel, N. Madi, P. Chiumia, C. Kalowa, B. Hadebe, M. Vorster;*
University of KwaZulu Natal, Durban, SOUTH AFRICA.

Aim/Introduction: PSMA is a type II transmembrane glycoprotein abundantly overexpressed on prostate cancer cells. In advanced metastatic castration-resistant prostate cancer, ^{68}Ga-PSMA PET/CT assesses tumour PSMA expression before ^{177}Lu-PSMA or ^{225}Ac-PSMA radioligand therapy, though patient responses vary. Hotta et al. suggested the tumour-to-salivary gland ratio may predict PSA response and overall survival post-^{177}Lu-PSMA. This retrospective study aims to assess whether the PET tumour-to-salivary gland ratio (PSG score) can predict outcomes in prostate cancer patients receiving PSMA-targeted therapy. ***Materials and Methods:*** We included a total of 44 patients with metastatic castration-resistant prostate cancer treated with ^{177}LuPSMA and/ or ^{225}Ac-PSMA in this study. A quantitative PSG (qPSG) score (SUVmax ratio of highest tumour lesion to parotid glands) was calculated on baseline ^{68}Ga-PSMA PET images. Patients were then divided into 2 groups: High (qPSG > 1.5) and Low (qPSG ≤1.5) scores. Outcome data included a more than 50% prostate-specific antigen decline and overall survival (OS). ***Results:*** Forty-four prostate cancer patients (median age: 68 years) who received PSMA-targeted therapy were retrospectively analyzed. The population in the High (qPSG > 1.5) and Low (qPSG ≤1.5) groups were 27 (61.4%) and 17 patients (38.6%) respectively. PSA response (≥50% decline) was observed in 54.5% of patients. Response rates (PSA decline of ≥ 50%) were similar between the High and Low groups; 51.9% (14/27) vs 58.3% (10/17) (p=0.658). Survival outcomes were also comparable, although notably more deaths occurred in the low group with 64.7% compared to 55.6% in the high group (p=0.555). Disease site was categorized as Bone only, Bone + Lymph, Lymph only, or Other. Patients with Lymph node-only disease showed better survival, while those with Bone involvement had higher mortality, though not statistically significant (p=0.20). ***Conclusion:*** A trend towards higher mortality was observed in patients with lower qPSG scores and those with bone involvement, which did not reach statistical significance in our relatively small sample size. Despite this lack of statistical significance, mortality of 65% in the low uptake group vs 56% in the high uptake group is certainly clinically significant and highlights the potential of a PSG score as a useful method to predict response to PSMA-targeted therapy. A larger analysis is therefore needed to validate this methods prognostic value and establish this approach for choosing suitable candidates for therapy. ***References:*** 1. Hotta, Masatoshi, et al.

"PSMA PET tumor-to-salivary gland ratio to predict response to [177Lu] PSMA radioligand therapy: Journal of Nuclear Medicine 64.7 (2023): 1024-1029.

EP-0825

Linking Dual-Tracer Imaging and Lesion Dosimetry to Predict Outcomes in mCRPC Patients Treated with [^{177}Lu] Lu-PSMA Therapy

S. Wen[1], *S. Xue*[1], *X. Li*[1], *M. Hacker*[1], *A. A. Nikolic*[2], *B. Jan*[2], *L. Constantin*[2];
[1]*Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Vienna General Hospital, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, GERMANY.*

Aim/Introduction: Previous studies have shown that elevated ^{18}F-FDG uptake is associated with poor prognosis in patients with metastatic castration-resistant prostate cancer (mCRPC) undergoing [^{177}Lu]Lu-PSMA radioligand therapy (RLT). Additionally, lesion-level absorbed dose has been linked to therapeutic outcomes. This study investigates the relationship between FDG uptake and absorbed dose, aiming to understand their combined influence on treatment response and progression-free survival (PFS). ***Materials and Methods:*** We retrospectively analyzed 35 mCRPC patients treated with [^{177}Lu]Lu-PSMA I&T RLT. All patients underwent dual-tracer PET/CT imaging (PSMA and FDG) before the first treatment cycle, and at least one post-therapeutic SPECT/CT scan following each cycle. An automated Python-based pipeline was developed to extract SUV-based imaging features from PET scans and dose-related metrics from voxel-wise absorbed dose maps at the patient, organ, and lesion levels. A decision tree model was used to identify the most predictive patient-level features for treatment response (categorized as Partial Response (PR), Progressive Disease (PD), or Stable Disease (SD) based on ΔPSA) and progression-free survival (PFS). Relationship between FDG uptake and absorbed dose were evaluated at all three levels using the Mann-Whitney U test and Kruskal-Wallis H test. ***Results:*** The decision tree model identified the following as key predictors for therapy response and PFS: SUVmean and SUVmax of all PSMA$^+$ lesions, SUVmean of all FDG$^+$ lesions, total absorbed dose of concordant lesions, and FDG TLG of concordant lesions (feature importance:0.16;0.15;0.35;0.24;0.10). At the patient level, the total volume of concordant lesions was negatively correlated with mean absorbed dose (Kruskal-Wallis $H = 9.6$, $P < 0.05$). At the lesion level, PSMA$^+$FDG$^+$ lesions exhibited significantly lower mean absorbed doses compared to PSMA$^+$FDG$^-$ lesions ($P < 0.05$). At the organ level, lesion location showed no significant effect on absorbed dose ($P = 0.656$). ***Conclusion:*** This study confirms that FDG uptake serves as a negative prognostic marker in mCRPC patients treated with [^{177}Lu]Lu-PSMA, while PSMA uptake more accurately predicts biochemical response. An inverse relationship between FDG uptake and absorbed dose was observed, suggesting a potential biological interaction that may mediate resistance to PSMA-RLT. Further radiobiological studies are warranted to validate these findings and enhance patient selection strategies for PSMA-RLT.

EP-0826

A Model for ^{177}Lu-PSMA Therapy in Nuclear Medicine Departments Without Dedicated Shielding Rooms

A. Genova, *F. Porcaro, M. Prisco, L. Turchetta, I. Annarumma, V. Piscopo, M. Catalano;*
Azienda Ospedaliera di Rilievo Nazionale Antonio Cardarelli, Naples, ITALY.

Aim/Introduction: Introduction ^{177}Lu-PSMA therapy is an effective option for metastatic castration-resistant prostate cancer (mCRPC) patients who have failed androgen receptor inhibitors and taxane chemotherapy. Due to increasing eligibility worldwide, nuclear medicine departments face higher patient volumes. Additionally, ongoing research is expanding its indications to earlier treatment stages. Italian Legislative Decree 101/2020 allows radiopharmaceutical administration without protected inpatient isolation, so the authors suggest two possible treatment settings: outpatient day-hospital administration for eligible patients, and inpatient oncology ward admission for frail individuals. Standardized radiation safety protocols differ mainly in caregiver exposure thresholds and waste disposal methods. ***Materials and Methods:*** Treatment adheres strictly to radiation safety regulations to minimize exposure for healthcare workers and caregivers. After confirming clinical eligibility and informed consent, patients receive intravenous ^{177}Lu-PSMA (e.g., Pluvicto®), typically 7.4 GBq (200 mCi), with up to six cycles at 6-week intervals, adjusted according to response and toxicity. ***Results:*** Patients are instructed to hydrate adequately and frequently urinate, given that 40-60% of the administered activity is excreted via urine within 2-7 hours post-injection.Therefore, patients stay approximately 6 hours in a dedicated area with radiation-safe toilet facilities, monitored by trained nuclear medicine staff. Discharge occurs when radiation exposure drops below set thresholds. Patients receive specific discharge instructions:• Avoid close contact (<1 meter) for 2 days• Avoid contact with children/pregnant women for 7 days• Sleep separately for 3 days (or 7-15 days if children/pregnant women are present)• Abstain from sexual activity for 7 daysRadiation levels at 1 meter from patients are measured at 6 hours post-injection to ensure compliance with Italian legislative limits (DLgs. 101/2020):• ≤3 mSv/cycle (caregivers aged 18-60)• ≤15 mSv/cycle (caregivers >60)• ≤1 mSv/cycle (caregivers of pediatric patients)• ≤0.3 mSv/cycle (general public)For hospitalized patients, oncology staff receive specific training on radiation safety, waste management, and spill control. Advanced toilet systems with filtration technologies can reduce environmental ^{177}Lu release. In both outpatient and inpatient settings, post-therapy planar imaging confirms tracer distribution. Additionally, dosimetric SPECT/CT imaging assesses treatment efficacy and toxicity risks at various intervals. ***Conclusion:*** The outpatient model enhances patient comfort, reduces costs, and improves therapy accessibility. Uniform radiation protection standards across both outpatient and inpatient settings obviate routine isolation, enabling safe early patient discharge. Individualized patient assessment maintains radiation exposure as low as reasonably achievable (ALARA), balancing safety, resource use, and healthcare sustainability.

EP-0827

Prognostic Value of a Comprehensive Analysis of Metastatic Prostate Tumor Changes from First to Last ^{177}Lu-PSMA Therapy Injections Through Serial High-Speed Whole-Body 360° CZT-SPECT

C. Boursier, *J. Kunsch, T. Zaragori, P. Olivier, M. Claudin, S. Heyer, P. Raymond, P.-Y. Marie, L. Imbert;*
CHRU Nancy, Vandoeuvre-les-Nancy, FRANCE.

Aim/Introduction: The Anger-SPECT monitoring of ^{177}Lu-PSMA therapy provides significant prognostic information in patients with metastatic castration-resistant prostate cancer (mCRPC) but with 36-to-90 min recording times and partial body coverage. This study assesses the prognostic information from a comprehensive analysis of tumor changes from the first to the last ^{177}Lu-PSMA therapy injections, as provided by whole-body ^{177}Lu-SPECT recordings from a high-speed 360° cadmium-zinc-telluride (CZT) camera in mCRPC patients. ***Materials and Methods:*** We included mCRPC patients treated by ^{177}Lu-PSMA-617 injections who underwent (i) pretreatment ^{68}Ga-PSMA-11 PET and (ii) whole-body 360° ^{177}Lu-CZT-SPECT recording of only 18 min after each ^{177}Lu-PSMA therapy injection and plasma prostate-specific-antigen (PSA) measurement obtained 24h before. We used Cox proportional hazard models to predict posttreatment overall survival ($OS_{posttreatment}$) according to (i) PSA evolution during treatment and (ii) tumor SUVmax, SUVmean, and total uptake volume (TUV) extracted from ^{68}Ga-PMSA-PET and the first and last ^{177}Lu-SPECT acquisitions. ***Results:*** We included 72 patients with a median age

of 71 [interquartile range: 64;77] years, treated with 1 to 6 ^{177}Lu-PSMA injections and among whom, 43 (59%) completed ≥ 4 ^{177}Lu-PSMA treatment cycles, and 50 (73%) died during a follow-up of 9.7 [3.9;16.4] months from the last ^{177}Lu-PSMA injection. Most PSA, PET, and SPECT variables were significant univariate $OS_{posttreatment}$ predictors, but among them, only three ^{177}Lu-SPECT variables were selected as multivariate predictors: a TUV decrease greater than the median of 25% (p<0.001) and the lack of new bone lesions (p=0.035) between the first and last ^{177}Lu-SPECT , and a residual TUV lower than the median of 270 ml (p=0.001) on the last ^{177}Lu-SPECT. Means (95% confidence intervals) of survival times were 19.5 (16.7-22.3) months in the 24 patients with both > 25% TUV decrease and < 270 ml residual TUV, 11.5 (8.4-14.5) months in the 24 patients with only one of these two criteria, and 5.3 (3.3-7.2) months in the 24 with neither one. ***Conclusion:*** A comprehensive analysis of tumor changes from the first to the last ^{177}Lu-PSMA injections, as provided by whole-body 360° ^{177}Lu-CZT-SPECT recordings provides strong prognostic information in mCRPC patients, outperforming conventional $OS_{posttreatment}$ predictors such as PSA evolution and pretreatment PSMA PET variables.

EP-0828

Which reference organ can be used on Post Therapeutic ^{177}Lu-PSMA SPECT/CT when images are performed at different timepoint?

L. Michaud[1], *S. Gnesin*[2], *J. Delage*[3], *M. Tissier*[1], *A. Fenter*[1], *J. O. Prior*[1], *N. Schaefer*[1];
[1]*Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [2]*Institute of Radiation Physics, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND,* [3]*Radiopharmacy Unit, Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.*

Aim/Introduction: For logistic reasons not all ^{177}Lu-PSMA patients might occur post-therapy imaging at the same time post-administration. We aimed comparing physiological parotid and hepatic uptake on post-therapeutic quantitative SPECT/CT imaging performed at 24, 48, or 72 hours following ^{177}Lu-PSMA-ITG-1 therapy to identify a reference tissue when post therapeutic images are performed at different timepoints. ***Materials and Methods:*** A retrospective analysis was conducted on 12 patients (mean age: 77±8 years) who provided general consent for data reutilization and underwent treatment with ^{177}Lu-PSMA-ITG-1 for metastatic recurrence of prostate adenocarcinoma. Patients received an average of four therapy cycles (range 2- 5). At each cycle, a single quantitative SPECT/CT scans (Siemens Healthineers Intevo or Pro.specta) was acquired at 24-, 48-, or 72-hour post-injection and reconstructed (xSPECT, 48 iterations, 1 subset, 5mm Gaussian post-reconstruction filtering). For each reconstruction, mean standardized uptake values (SUVmean) were measured in the left parotid gland and left hepatic lobe using a sphere of at least 10 mL totally included in the parotid/liver tissues. The rationale on the use of SUVmean, instead of SUVmax, to characterize the radiotherapeutic uptake in reference tissues, such as the parotids and the liver, is that the SUVmean is less sensitive to statistical noise than SUVmax. Comparisons of SUVmean across time points were performed using multilevel mixed-effects linear regression. ***Results:*** A total of 38 post-therapy SPECT/CT scans were analyzed (n=13@24h, 12@48h, 13@72h). The mean administered activity of ^{177}Lu-PSMA-ITG-1 was 7710 MBq (range: 7262-8103 MBq). At 24h, the mean SUVmean±SD was 5.27±1.83 for the parotid gland and 1.66±0.58 for the liver. At 48h, the corresponding values were 3.78±2.06 and 1.13±0.48, and at 72h 1.68±0.88 and 0.87±0.43, respectively. All scans were deemed interpretable regardless of acquisition time. As expected, in tested tissues, the SUVmean decreased with time and a significant SUVmean differences were observed between 24h, 48h and 72h acquisitions ($p < 0.0001$). Furthermore, effective wash out from the liver was slower without any significant difference across time (p>0.15). ***Conclusion:*** This study confirms higher physiological SUVmean values on early post-therapy ^{177}Lu-PSMA SPECT/CT acquisitions. These findings highlight the necessity of caution when comparing images across different post-therapeutic time. Hepatic SUVmean appears to be a more stable reference organ across time for this purpose.

EP-0829

Prognostic value of ^{18}FDG and ^{68}Ga-PSMA PET parameters in mCRPC patients referred for ^{177}Lu-PSMA therapy

B. Adam, *T. Zaragori, M. Claudin, A. Verger, P. Olivier, L. Imbert, C. Boursier;*
Nancy University Hospital of Lorraine, Nancy, FRANCE.

Aim/Introduction: ^{177}Lu-PSMA-617 is a well-established treatment for patients with progressive metastatic castration-resistant prostate cancer (mCRPC). According to EANM guidelines, PSMA expression should be evaluated for patient selection, with PSMA PET being the preferred modality. Several studies have suggested the added value of FDG PET in patient selection. In particular, a substudy of the TheraP trial reported worse progression-free survival in patients treated with Lu-PSMA therapy who had a tumor burden ≥200 mL on FDG PET. This study aims to assess the prognostic value of ^{18}F-FDG PET parameters in addition to ^{68}Ga-PSMA-11 PET parameters in mCRPC patients referred for ^{177}Lu-PSMA therapy. ***Materials and Methods:*** This retrospective study included mCRPC patients who received at least one cycle of ^{177}Lu-PSMA-617 between February 2022 and October 2023. Both ^{68}Ga-PSMA-11 PET and ^{18}F-FDG PET were performed before therapy as part of clinical practice. TMTV, TLA, SUVmean, and SUVmax were extracted from both PET studies. Visual analysis was performed to assess lesions mismatch between the two PET. Overall survival (OS) was estimated using the Kaplan-Meier method. Univariate Cox regression was followed by two multivariate models: i) using only PSMA PET parameters and ii) combining both PSMA PET and FDG PET parameters. Based on predicted risk scores from the full model, patients were divided into three risk groups (high, intermediate, low). A decision tree classifier was trained to reproduce these groups. ***Results:*** One hundred and five patients were included, with a median age of 72 [65-77]. Most (90%) had received at least one taxane-based chemotherapy, and 60% had received two. PSMA-SUVmax, PSMA-SUVmean, FDG-TLA, FDG-TMTV, and lesion mismatch criteria were significantly associated with OS in univariate analysis ($p < 0.001$). PSMA-SUVmax was the best independent predictor in the PSMA-only model, while PSMA-SUVmax and FDG-TMTV were selected for the combined model. The combined model significantly outperformed the PSMA-only model ($p = 0.001$). The three risk groups showed significantly different OS ($p < 0.006$) and could be predicted with 75.5% accuracy by a decision tree classifier ($p < 0.003$). Patients with PSMA-SUVmax ≥110 were low risk; those with PSMA-SUVmax <110, ECOG <2, and FDG-TMTV <228 mL were intermediate risk; the rest were high risk. ***Conclusion:*** PSMA uptake and FDG-PET tumor burden are predictive of overall survival in mCRPC patients undergoing 177Lu-PSMA-617 therapy. The use of a decision tree combining PSMA-SUVmax and FDG-TMTV may improve risk stratification and patient selection.

Prognostic Value of Baseline PSMA and FDG PET Biomarkers in Patients Treated with Lutetium-177 [^{177}Lu] Lu-PSMA-617 for Metastatic Castration-Resistant Prostate Cancer: A Real-World Analysis from the ProsTIC Registry.

N. Kovaleva[1], *L. Kostos*[2,3], *N. Papa*[1], *J. Weindler*[1], *R. Alipour*[1,2], *B. Emmerson*[1], *G. Ghosh*[1], *G. Kong*[1,2], *E. Medhurst*[1], *A. S. Ravi Kumar*[1,2], *J. Saghebi*[1,2], *A. A. Azad*[2,3], *M. S. Hofman*[1,2], *J. P. Buteau*[1,2];
[1]*Prostate Cancer Theranostic and Imaging Centre of Excellence, Molecular Imaging and Therapeutic Nuclear Medicine, Peter MacCallum Cancer Centre, Melbourne, VIC, AUSTRALIA,* [2]*Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, AUSTRALIA,* [3]*Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, AUSTRALIA.*

Aim/Introduction: Lutetium-177 [^{177}Lu]Lu-PSMA-617 radioligand therapy improves survival and quality-of-life in patients with metastatic castration-resistant prostate cancer (mCRPC). PSMA-PET SUVmean and FDG-PET metabolic tumour volume (MTV) are predictive and prognostic biomarkers in clinical trials to date. We aimed to evaluate the prognostic value of these PET biomarkers in a real-world cohort enrolled in the ProsTIC Registry. ***Materials and Methods:*** We conducted a retrospective, single-centre analysis of consecutive patients with mCRPC treated with [^{177}Lu]Lu-PSMA-617 in the ProsTIC Registry (NCT04769817). Baseline PSMA-PET SUVmean and FDG-PET MTV were measured for patients with PET/CT performed within 90 days prior to cycle 1. Outcomes evaluated were PSA response, defined as a reduction of at least 50% from baseline (PSA50), and overall survival (OS), defined as the time from cycle 1 to death or last follow-up. Data cut-off was 11 April 2025. Associations between PET biomarkers and PSA50 response were assessed using chi-square tests. Kaplan-Meier survival analyses and Cox proportional hazards regression were used to evaluate associations with OS. ***Results:*** Between 20 May 2021 and 2 May 2024, 238 patients with mCRPC commenced treatment with [^{177}Lu]Lu-PSMA-617 and met inclusion criteria; median age 75 years (IQR 68-80), time from initial diagnosis 7 years (IQR 3-12). 237 (99.6%) had prior treatment with ≥1 anti-androgen pathway inhibitor and 198 (83%) ≥1 taxane chemotherapy. PSA50 at any timepoint was observed in 142/234 (61%) of patients with evaluable PSA response. 179 deaths were recorded, the median OS was 13.3 months (95% CI: 11.4 - 15.6). PSMA-PET SUVmean ≥10 was observed in 87 (37%) of patients and was significantly associated with achieving a PSA50 response vs SUVmean <10 (80% vs 50%, p<0.001), and with longer median OS (14.6 vs 13.1 months, HR 0.74 [95% CI: 0.54-1.01]; p=0.055). Higher FDG-PET MTV (≥200 mL) was seen in 85 (36%) of patients and was associated with a lower proportion achieving PSA50 response (51% vs 66%, p=0.026) and shorter median OS (8.8 vs 17.8 months, HR 2.70 [95% CI: 1.98-3.68]; p<0.001). ***Conclusion:*** In patients with mCRPC treated with [^{177}Lu]Lu-PSMA-617 in a real-world setting, baseline PSMA-PET SUVmean and FDG-PET MTV were prognostic for PSA response and overall survival.

EP-0831

Influence of Chemohormonal History on Lu-177 PSMA Efficacy

S. Karabulut*;*
Dokuz Eylül Üniversite Hastanesi, Izmir, TÜRKIYE.

Aim/Introduction: To evaluate the impact of prior systemic therapies—namely chemotherapy and second-generation antiandrogens—on treatment response to Lu-177 PSMA therapy in patients with castration-resistant prostate cancer (CRPC), using PET-based volumetric parameters and survival analysis. ***Materials and Methods:*** In this retrospective single-center study, 33 patients with metastatic CRPC who received four cycles of Lu-177 PSMA therapy between 2015 and 2023 were included. Only patients without newly emerging metastatic lesions on baseline Ga-68 PSMA PET/CT were selected. All lesions were segmented and categorized as lymph node, bone, or organ metastases. Volumetric PET parameters including PSMA-expressing tumor volume (PSMATV) and total lesion PSMA expression (TLPSMA) were measured using LIFEx software with SUVmax ≥ 2.5 as the threshold. Normal liver and parotid gland SUVmean values were used for semi-quantitative standardization. Pre-treatment data such as PSA, ALP, Gleason scores, and systemic therapies (enzalutamide, abiraterone, chemotherapy) were retrieved from hospital records. Volumetric response (%) was calculated for each region. Comparisons between treatment subgroups were performed using the Mann-Whitney U test, with statistical significance defined as $p < 0.05$. ***Results:*** The median overall survival was 17 (11.75-22.75) months; 16 patients (48%) were deceased at follow-up. Baseline PSA, ALP, PSMATV, TLPSMA, and their bone-derived components were significantly higher in deceased patients ($p < 0.05$). Volumetric response percentages (ΔPSMATV, ΔTLPSMA) were lower in the enzalutamide group compared to the abiraterone group, though not statistically significant. Similarly, no significant difference was observed between patients with or without prior chemotherapy. ***Conclusion:*** High baseline tumor burden and PSA levels predict poor prognosis in Lu-177 PSMA-treated patients. Although a lower response trend was observed in patients pretreated with enzalutamide, statistical significance was not achieved. Volumetric analysis via Ga-68 PSMA PET/CT offers valuable insights for patient stratification and treatment planning.

Research on the Radiotherapy-Immunotherapy Effect of Sequential Combination of I^{131} with Transcription of the NIS Gene into Mouse Models of Pancreatic Cancer Based on Oncolytic Virus as the Delivery Vector

S. Yu*, S. Xinhui;*
the First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, CHINA.

Aim/Introduction: Pancreatic cancer and thyroid cancer, as two extremes among cancers, are respectively renowned for their extremely poor and excellent prognoses. To a large extent, the reason lies in the sensitivity of thyroid cancer to multiple treatment modalities, particularly the NIS gene it expresses, which can specifically uptake I^{131}, thereby achieving very favorable therapeutic effects for thyroid cancer. ***Materials and Methods:*** Therefore, we designed an oncolytic virus transfected with the NIS gene and injected it into pancreatic cancer solid tumors through intratumoral injection. As the virus replicates within the tumor and transcribes and integrates the NIS gene into tumor cells, it enables stable expression of the NIS gene. Subsequently, sequential combination with I^{131} treatment was implemented through intravenous injection. ***Results:*** It was observed that I^{131} was stably and uniformly absorbed within the tumor for up to two weeks. In the bilateral tumor model, the tumor on the treatment side not only achieved significant shrinkage through the combination of oncolytic virus and I^{131} but also led to obvious inhibition of the contralateral tumor, showing significant differences compared with the groups treated with I^{131} alone, oncolytic virus alone, and PBS. Through flow cytometry, WB, and confocal microscopy, it was distinctly observed that the combination of oncolytic virus and I^{131} significantly activated both systemic and local anti-tumor immune responses, indicating the promising prospects of the combined therapy. ***Conclusion:*** Our study reveals a therapeutic approach that combines radiotherapy and oncolytic virus to activate immunity, where the NIS gene serves as a crucial mediator for the two therapies.

EP-0833

Transarterial Radioembolization (TARE) with Yttrium-90 Microspheres in Primary Liver Lesions: Impact on Survival and Disease Progression

B. Jaramillo Lopez*, A. Suazo Montero, M. García Aragón, R. Zambrano Infantino., F. Sebastián Palacid, C. Gamazo Laherrán., J. Gómez Hidalgo, N. Álvarez Mena., M. González Soto., R. Ruano Pérez.;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To evaluate the impact of TARE on overall survival (OS), progression-free survival (PFS), and treatment response rate (TRR) in patients with primary liver lesions. ***Materials and Methods:*** A retrospective observational study was conducted including 66 patients with primary liver lesions, treated with TARE

between February 2017 and September 2024. Tumor response was assessed using RECIST 1.1 criteria with CT or MRI at 6, 12, and 24 months post-treatment. Patients were categorized into Group A (GA): complete response (CR) or partial response (PR), and Group B (GB): local progression (LP) or extrahepatic progression. Outcomes assessed included OS, PFS, and TRR. ***Results:*** A total of 94 TARE procedures were performed in 66 patients (38 received 1 treatment, 21 received 2, and 7 received 3). The mean age was 69 years, and 75% being male. Hepatocellular carcinoma (HCC) was diagnosed in 85% (56/66) and cholangiocarcinoma in 15% (10/66). Bilobar involvement was present in 25.7% (17/66) and unilobar in 74.2% (49/66). The mean dose activity delivered to the lesion was 1.5 GBq, and the mean perfused volume was 423 cc^3. Median follow-up was 21 months. The GA was 62,9%, with a CR and PR observed of 33% and 19.6%, respectively. In GB, 39.3% experienced local progression and 7.5% had extrahepatic progression. The overall TRR was 53%. OS analysis revealed that the median was 44,7 months in patients without treatment response and 29,7 months in those who exhibited a response to therapy (p=0,3). Median PFS was 42,7 months in GA and 15 months in GB (p=0,051). ***Conclusion:*** TARE with Yttrium-90 microspheres represents an effective and well-tolerated therapeutic option for patients with primary liver tumors. It demonstrates a high impacto in treatment response rate, contributes with a long-term stabilization of dissease and OS. These findings reinforce its role as a key modality in the multidisciplinary management of hepatic malignancies, with a great impact on clinical outcomes and patient prognosis. ***References:*** Kallini, J.R., Gabr, A., Salem, R. et al. Transarterial Radioembolization with Yttrium-90 for the Treatment of Hepatocellular Carcinoma. Adv Ther 33, 699-714 (2016). https://doi.org/10.1007/s12325-016-0324-7.

EP-0834

Dose-Response Relationship in Patients Who Received TARE with Y-90 Resin Microspheres for Hepatocellular Carcinoma

C. Soydal, *E. Dursun Avci, I. Mesci, E. C. Celebioglu, N. O. Kucuk; Ankara University Medical Faculty, Ankara, TÜRKIYE.*

Aim/Introduction: The aim of this study is to analyze the dose-response relationship in HCC patients who received TARE with Y-90 resin microspheres. ***Materials and Methods:*** Patients who received TARE with Y-90 resin microspheres with a multicompartment dosimetry between Feb 2020 and Dec 2024 were included to the analysis. After exclusion of patients without follow-up and posttreatment Y-90 PET totally 43 lesions of 20 (6F, 14M; mean age: 70±8.6 years) patients were included to the dose-response analysis. Multicompartment dosimetry was performed to all lesions in the perfused area. Additionally, mean tumor absorbed dose (TAD), whole liver absorbed dose (WLAD) and perfused liver absorbed dose (PLAD) were calculated. Response evaluation was performed with RECIST 1.1 criteria from liver MRI at the 3th month of treatment. ROC analysis was used for selection of optimal TAD cutoff to predict the response. ***Results:*** All the patients received Y-90 resin microspheres with lober or segmental approach. Median tumor volume was calculated as 9.4 cm3 (min-max: 1-1674). Fourteen patients has underlying cirrhosis. Pretreatment ALBI grades were 1 and 2 in 8 and 12 patients, respectively. During 3th month evaluation 21 lesions were responder (11PR and 10 CR). In the ROC analysis 103.8 Gy (AUC:0.693, 95%CI 0.532-0.853, p= 0.018) cutoff for mean TAD was calculated for response (PR+CR) with 76% sensitivity and 64% specificity. For the prediction of CR we found 158.7 Gy (AUC:0.776, 95%CI 0.598-0.953, p= 0.002) cutoff for mean TAD with 70% sensitivity and 79% specificity. ***Conclusion:*** Results of this retrospective analysis revealed that delivery of 158.7 Gy mean dose to the tumor with Y-90 resin microspheres would result to complete response in patients with HCC with high specificity.

EP-0835

Body Surface Area Method vs Partition Dosimetry Model in Y-90 Radioembolisation: A retrospective Dosimetric Analysis

A. Cuderman, *A. Štrok, J. Jamšek, L. Jensterle, P. Popovič; University Medical Centre Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: The body surface area (BSA) method was initially adopted as the standard for calculating administered activity in transarterial radioembolisation (TARE) with Y-90 resin microspheres. Due to its simplicity, it remains widely used, despite growing evidence supporting the superiority of partition dosimetry. ***Materials and Methods:*** We retrospectively analysed 17 Y-90 resin microspheres TARE procedures performed between 2015 and 2023 using the BSA method for the administered activity calculation. Dosimetric parameters - including tumor absorbed dose (TAD), normal perfused liver dose (NPLD), whole normal liver dose (WNLD) and lung dose (LD) - were calculated for the administered activities using a dedicated partition based dosimetry software. To explore the potential for TAD escalation while maintaining safe non-tumoral liver and lung dose limits, we retrospectively estimated the activities that could have been administered in the same cohort using partition model. For bilobar treatments, WNLD limit were 40 Gy for patients with good liver function and 30 Gy for impaired function. In unilobar treatments, safe NPLD limits were set at 70 Gy and 50 Gy, respectively. For patients with limited hepatic reserve (<35%), bilobar dose limits were followed. We compared calculated activities and dosimetric outcomes between BSA and partition models. TAD of ≥100 Gy was considered the minimum effective mean dose. ***Results:*** 17 patients with a total of 32 tumors were included, with 13 undergoing unilobar and 4 bilobar treatment. In multifocal cases only the largest tumor per patient was analysed. Median tumor size was 10 cm (range 4-15 cm). Activity reduction of 20-30% was applied in 10 patients per manufacturer's Instructions for Use, including 3 due to lung shunting (median 2%, range 0-19%). BSA-based activities had a median of 1,1 GBq (range 0,8-2 GBq), resulting in a median TAD of 68 Gy (range 44-181 Gy). Partition model activities had a median of 2 GBq (range 0,8-3 GBq), achieving a median TAD of 121 Gy (range 43-456 Gy). Statistical analysis showed significantly higher activity ($p < 0.0001$, $d = 1.31$) and TAD ($p < 0.001$, $r = 0.92$) using the partition model. A TAD of ≥100 Gy was achieved in 4 patients using BSA, versus 13 patients with the partition model. ***Conclusion:*** The partition dosimetry model would have enabled safe tumor dose escalation while respecting non-tumoral liver and lung dose thresholds, highlighting its advantage over BSA given the well established dose-effect relationship in TARE.

EP-0836

Initial experience with ^{32}P microparticles in the treatment of advanced pancreatic cancer

D. Sánchez-Artuñedo[1], *I. Navales-Mateu*[2], *M. Sebastián-Segura*[1], *R. Bellviure-Meiro*[2], *J. Suils-Ramón*[2], *M. Beltran-Vilagrasa*[1], *C. Gamez-Cenzano*[2];
[1]*Servei de Física i Protecció Radiològica. Hospital Universitari Vall d'Hebron, Barcelona, SPAIN,* [2]*Servei de Medicina Nuclear. Hospital Universitari Vall d'Hebron, Barcelona, SPAIN.*

Aim/Introduction: Phosphorus-32 (^{32}P) microparticles are a medical device used to treat advanced pancreatic cancer in combination with gemcitabine-based chemotherapy. The prescribed activity is based on tumor volume, aiming to deliver a mean absorbed dose of 100 Gy to the lesion. Administration is performed under endoscopic ultrasound guidance. Post-treatment, a Bremsstrahlung SPECT/CT is acquired to verify accurate delivery. At our institution, SPECT imaging is performed using a CZT gamma camera (StarGuide, GE Healthcare), which provides higher sensitivity compared to conventional Anger cameras, potentially improving the detectability of the administered activity. ***Materials and Methods:*** After patient sedation, the

endoscope is introduced into the stomach, and an ultrasound-guided puncture is performed on the lesion. The nuclear medicine physician administers the microparticles, followed by a 1.5 ml flush of physiological saline solution to clear the needle lumen and ensure full activity delivered to the lesion. A second flush is then performed into the stomach. Once the procedure is completed, contamination tests are performed on staff and surfaces, and the ambient dose equivalent in contact with the patient is measured. Following recovery, a 30-minute/bed SPECT/CT scan is acquired with a 75 keV (±30%) emission window and reconstructed with Q.clear (20 iterations, 10 subsets) with attenuation correction and resolution recovery correction. ***Results:*** Seven patients have been treated since 2023, including one who underwent re-treatment to complement the initial ^{32}P administration. The mean administered activity was 9.8 MBq (range: 1.85-14.06 MBq). In two of eight treatments, no activity was detected on SPECT/CT. In one case, 0.5 MBq (25% of the prescribed dose) remained in the syringe. Given the low activity prescribed due to the small tumor volume, the effective delivered dose was likely below the SPECT detection threshold. Gastrointestinal migration of microparticles occurred in two treatments, both in patients with metallic pancreatic stents. One was partial, with some activity visible in the lesion; in the other, no pancreatic activity was detected, and the patient is currently scheduled for re-treatment. Surface contamination was detected in two procedures, while personal contamination occurred only during the first procedure. The patient's ambient equivalent dose rate remained indistinguishable from background radiation. The treatment was generally well tolerated; in one case, the patient experienced post-recovery emesis, with the gastric contents being radioactively contaminated. ***Conclusion:*** The treatment was well tolerated, with only one patient experiencing nausea related to sedation. Dose calculation software could improve the verification of treatment delivery, especially in re-treatments.

EP-0838

MAA-Based Dosimetry for Predicting Tumor Response and Survival Post-TARE in Liver Metastasis Patients

F. Meisner[1], *E. Can*[2], *S. Wirtz*[3], *P. T. Meyer*[1], *C. Goetz*[1];
[1]*1Department of Nuclear Medicine, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [2]*Department of diagnostic and interventional radiology Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY,* [3]*Clinical Trials Unit, Medical Center of the University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, GERMANY.*

Aim/Introduction: Transarterial radioembolization (TARE) with Y90-loaded microspheres is an effective treatment for unresectable liver metastases. MAA-based dosimetry may optimize therapy planning by estimating absorbed doses, helping to maximize tumor doses while sparing healthy liver tissue. This study aims to correlate higher tumor doses with improved response and overall survival (OS) in patients with liver metastases. ***Materials and Methods:*** A retrospective analysis was conducted on 145 TARE therapies in patients (median age 64) with liver metastases (Neuroendocrine tumor, n=40; Colorectal cancer, n=38; Melanoma, n=10; Cholangiocarcinoma, n=10; Prostate cancer, n=9; Other primaries, n=38) using SIR-Spheres (Sirtex Medical Europe GmbH, Bonn, Germany). The partition model was used to estimate Y90 doses pre-therapy using Tc99m-MAA SPECT/CT data and MIM Software (MIM 7.3.4, MIM Software Inc., Cleveland, OH). Post-therapeutic dosimetric imaging determined real mean absorbed doses (Dmean) for tumors and healthy liver tissue. Tumor response was evaluated 2-4 months post-TARE using RECIST1.1 criteria, categorizing patients as responders (CR, PR) or non-responders (SD, PD). To evaluate the predictive capabilities of MAA dosimetry, we performed a ROC analysis to define an optimal Dmean cutoff value pre-therapy, and OS was compared using the Kaplan-Meier estimator. ***Results:*** Responders (15%) had a higher Dmean tumor dose (177.2 Gy) compared to non-responders (139.6 Gy). Responders showed significantly longer OS (34.6 months) than non-responders (13.5 months, p=0.0175). Regarding the predictive value of MAA-dosimetry, a Dmean cutoff value of 122.8 Gy was identified and proposed as a predictor for therapy response (sensitivity 0.96, specificity 0.39). However, sorting patients by this threshold did not show a significant OS difference (p=0.173). ***Conclusion:*** Higher tumor absorbed doses are associated with improved treatment response and prolonged overall survival (OS) in liver metastasis patients post-TARE. However, the proposed threshold based on MAA-dosimetric estimations did not significantly differentiate OS in our study groups. Nonetheless, pretreatment dosimetry should be routinely employed for personalized treatment planning to optimize tumor irradiation and minimize liver toxicity. Further research is essential to validate these findings and determine tumor-specific cutoff values for various extrahepatic cancers with liver metastases.

EP-0839

Therapeutic Outcomes of Radiosynoviorthesis: A Retrospective Analysis from a Tertiary Care Center in India

P. Baberwal*, G. B. Priyanka, Y. Khandelwal, B. Jain, S. Shamim;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: To retrospectively analyse the outcomes and treatment responses of patients who have undergone radiosynoviorthesis for various clinical conditions with [^{188}Re]Re-tin colloid or [^{177}Lu]Lu-tin colloid at a tertiary care center in India. ***Materials and Methods:*** A retrospective analysis was conducted on patients who underwent radiosynovectomy from 2017 to 2025 at Department of Nuclear Medicine, All India Institute of Medical Sciences. All patients were assessed for pain (visual analogue scale), swelling, tenderness, range of mobility, analgesic usage and imaging findings ([^{99m}Tc]Tc-MDP blood pool imaging, X-ray) and different scores were assigned to them. RSO was done using either 577 MBq (481 to 925 MBq) of [^{188}Re]Re-tin colloid or [^{177}Lu]Lu-tin colloid. Underlying etiology, joints treated, number of treatment cycles, radiopharmaceutical dose, baseline and follow-up clinical parameters, imaging findings, and response to therapy were collected and analysed. Follow-up data at multiple intervals at 3, 6 and 12 months were used to assess symptom progression and therapeutic efficacy and were defined as responders or non-responders based on the change in clinical scores. ***Results:*** A total of 52 patients were included, with radiosynoviorthesis of 59 knee joints in total. 14 patients (17 joints) were treated with [^{177}Lu]Lu-tin colloid (mean activity of 572 MBq (518 to 1369 MBq)) and 38 patients with [^{188}Re]Re-tin colloid (mean activity of 577 MBq (481 to 925 MBq)). The most common indications were rheumatoid arthritis, pigmented villonodular synovitis and hemophilic arthropathy. There were 93.23% of responders at 3 month follow up and 6.77% non-responders (2 with [^{177}Lu]Lu-tin colloid and 2 with [^{188}Re]Re-tin colloid). There is a statistically significant reduction in clinical parameters at 3-, 6- and 12-month follow-up in responder group (p value<0.0001). Patients benefited out of wide range of activity of [^{188}Re]Re-tin colloid and [^{177}Lu]Lu-tin colloid. ***Conclusion:*** Radiosynoviorthesis is a safe, well-tolerated, and effective procedure in the Indian context, particularly for large joint synovitis in rheumatoid and non-specific inflammatory joint disorders.

EP-0840

Elevated Baseline C-Reactive Protein Is Associated with Treatment Failure and Shorter Survival After Radioembolization with Yttrium-90 Glass Microspheres in Hepatocellular Carcinoma: Validation of LI-RADS R-TRA v2024

E. Kaya[1], *B. Akkas*[1], *T. Güzelbey*[2], *C. Erdim*[2], *M. Arslan*[2], *C. Şin*[1], *H. B. Kapucu*[1], *M. Kaya*[1];
[1]*Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Basaksehir Cam and Sakura City Hospital, Department of Radiology, Istanbul, TÜRKIYE.*

Aim/Introduction: To investigate the prognostic significance of baseline C-Reactive Protein (CRP) levels and evaluate treatment response using LI-RADS Radiation Treatment Response Algorithm

(R-TRA v2024) in hepatocellular carcinoma (HCC) patients undergoing Yttrium-90 glass radioembolization (TARE). ***Materials and Methods:*** Forty-two patients with HCC who underwent TARE were included retrospectively. Clinical records, laboratory tests, and dosimetry parameters were evaluated for association with treatment response and overall survival (OS). Tumor response was assessed on 6th month by MRI, patients were classified as controlled disease (LR-TR non-viable and non-progressing) and progressive disease (LR-TR viable) groups. Logistic regression was used to identify predictors of progression, survival outcomes were analyzed using Cox regression models. ***Results:*** In this retrospective analysis, 28 patients (67%) received ≥400 Gy tumor absorbed dose (TAD; range, 150-1000 Gy; median:475 Gy). Baseline CRP>11 mg/L was the only independent predictor of treatment failure (OR=54.7, p=0.005). Subgroup analysis of patients receiving TAD ≥400 Gy confirmed that high CRP remained strongly linked to treatment failure (p=0.001). Independent predictors of shorter OS were; CRP (HR=3.92, p=0.035), TAD <400 Gy (HR=3.95, p=0.014), MELD >6 (HR=5.13, p=0.006), and BCLC-C (HR=3.96, p=0.029). Patients with controlled disease (69%, n=29), the median OS was significantly longer than patients with progressive disease (n=13, 31%) (30 months vs. 6 months, p<0.001). ***Conclusion:*** In HCC patients undergoing TARE, elevated baseline CRP level predicts shorter OS and increased risk of treatment failure despite high TAD. LI-RADS R-TRA v2024 criteria demonstrated strong prognostic value for predicting OS in patients with HCC.

EP-0841

Rethinking Planning: MAA Outperforms CBCT in Predicting Final Dose in TARE

S. Salcedo Cortes[1], *L. Ramos*[2], *J. Orcajo Rincon*[1], *L. Reguera Berenguer*[1], *J. Ardila Mantilla*[1], *E. Ardila Manjarez*[1], *A. Mari Hualde*[1], *I. Gómez Fernández*[1], *V. Castillo Morales*[1], *J. Guzmán Cruz*[1], *S. Álvarez Lara*[1], *G. Mera Ovalle*[1], *J. Alonso Farto*[1];
[1]*Hospital General Universitario Gregorio Marañón, Madrid, SPAIN,* [2]*Hospital Universitario de Canarias, Canarias, SPAIN.*

Aim/Introduction: Hepatic radioembolization with Yttrium-90 microspheres is an effective locoregional technique for treating primary and metastatic liver tumors. Dosimetric precision is crucial to maximize therapeutic efficacy, particularly in terms of absorbed tumor dose. This retrospective study evaluates the factors influencing the final absorbed dose in both the angiosome and the tumor, comparing different volumetric estimation methods alongside clinical and procedural variables. ***Materials and Methods:*** Twenty radioembolization procedures were analyzed. Variables collected included tumor and liver volumes estimated by macroaggregated albumin (MAA), cone-beam CT (CBCT), and the final treated volume measured by 90Y PET/CT (Vol_Tto). Additional variables were time between planning and treatment, post-treatment residual activity, T/N ratio, and whether the same radiologist performed both planning and treatment. Correlations and linear regression models were used to identify predictors of the final absorbed dose in the angiosome and tumor. ***Results:*** The actual treated volume (Vol_Tto) was the main determinant of absorbed dose, showing negative correlations with both angiosome (r = -0.41) and tumor doses (r = -0.45). In a reduced linear regression model, Vol_Tto showed a near-significant trend in predicting tumor dose (p = 0.057). The difference between the volume planned by CBCT and the treated volume (relative volume delta) negatively correlated with the angiosome dose (r = -0.49), suggesting that underestimation of the final volume leads to higher absorbed doses, and vice versa. The T/N ratio (Ratio_Lesion) showed a positive correlation with tumor dose (r = +0.25), though it did not reach statistical significance in multivariable models. Time between the MAA study and treatment, as well as residual unadministered activity, had weak correlations with the final absorbed dose. When planning and treatment were performed by different radiologists, greater discrepancies were observed between the estimated and treated volumes, which in turn impacted tumor dose variability—suggesting an indirect effect on dosimetric consistency. ***Conclusion:*** The final angiosome volume and the tumor-to-liver ratio are key factors influencing tumor absorbed dose. The volume estimated by MAA may better reflect the actually treated volume and therefore be more useful than CBCT in determining optimal activity. Operator variability should also be considered for its indirect effect on dosimetric consistency.

EP-0842

Single-Center Experience Comparing Glass and Resin Microspheres in Lobar Y-90 SIRT for Early- to Intermediate-Stage Hepatocellular Carcinoma

X. Zheng*, H. Xi, J. v. Sluis, M. W. Nijkamp, G. C. Bloemsma, M. Kater, S. J. Ruiter, W. Noordzij;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Selective internal radiation therapy (SIRT) with yttrium-90 (Y-90) microspheres is an established locoregional treatment for early-to intermediate-stage hepatocellular carcinoma (HCC). While both resin and glass microspheres are widely used, their comparative safety and efficacy in lobar infusion remain undecided. This single-center retrospective study aimed to evaluate the safety and outcome of resin versus glass microspheres in HCC patients undergoing lobar Y-90 SIRT. ***Materials and Methods:*** Thirty-seven patients (glass: n = 15; resin: n = 22) treated with lobar Y-90 SIRT between 2016 and 2023 were retrospectively reviewed and analyzed. Safety outcomes included short to long-term adverse events (AEs) graded by CTCAE v5.0 and laboratory changes at 4-month follow-up. Efficacy endpoints included progression-free survival (PFS) and overall survival (OS). Univariate Cox proportional hazards regression identified survival predictors, while Fine-Gray regression assessed the impact of treatment modality (resin vs. glass) on OS, considering post-SIRT treatments as competing risks. ***Results:*** Baseline characteristics were comparable except for age (glass: 64 ± 6.9 vs. resin: 69 ± 7.1 years; P = 0.036); while age was not a predictor of PFS or OS in univariate analysis (all P > 0.05). Doses to tumour and non-tumour liver were comparable between groups: 260 Gy (72-366) vs. 173 Gy (119-260) and 41 Gy (29-50) vs. 28 Gy (20-51), respectively (all P > 0.05). Resin microspheres were associated with significantly longer PFS (median: 9.3 vs. 6.4 months, P = 0.039) and OS (median: 16.4 vs. 12 months, P = 0.035). Univariate analysis identified resin microspheres as independent predictors of improved PFS and OS, whereas higher BCLC stage, multifocal tumours, and tumour burden ≥25% were associated with worse survival (all P < 0.05). Fine-Gray regression further confirmed the association between resin microspheres and improved OS (SHR = 0.35, P = 0.011). Subgroup analysis showed that resin microspheres provided significantly better survival than glass microspheres in patients with tumours ≥5 cm. Safety profiles were comparable between the two groups, with no significant differences in AEs or laboratory toxicity at 4-month follow-up. ***Conclusion:*** Lobar resin-based Y-90 SIRT was associated with improved survival compared to glass-based spheres in early-intermediate HCC, without increasing toxicity. These findings warrant further validation in prospective studies.

EP-0843

Does Aberrant Tumor Vascularization Pose an Obstacle to Radioembolization?

S. Omay[1,2], *B. Esen Akkaş*[1,2], *M. Arslan*[1,2];
[1]*Basaksehir Çam ve Sakura Sehir Hastanesi, Istanbul, TÜRKIYE,* [2]*University of Health Sciences Basaksehir Cam and Sakura City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE.*

Aim/Introduction: Yttrium-90 (Y-90) microsphere radioembolization (RE) therapy is performed via hepatic

arterial infusion of Y-90-loaded microspheres through the artery supplying the tumor. The hepatic artery (HA) typically originates from the celiac artery (CA) or its most common variant, the superior mesenteric artery (SMA). However, aberrant vascularization may occur in liver tumors, potentially leading to extrahepatic perfusion that could pose challenges for RE. This study aims to present cases of intrahepatic tumors with aberrant vascularization in which patient-specific vascular access strategies enabled successful treatment, along with follow-up outcomes. ***Materials and Methods:*** Angiographic images of 221 patients who underwent hepatic RE at our clinic between January 2022 and December 2024 were retrospectively reviewed. The clinical courses of four patients who had vascular perfusion sources other than the CA or SMA and who underwent successful treatment were evaluated. Side effect profiles and operational challenges encountered were analyzed. ***Results:*** Four lesions were identified with vascular feeders other than the HA. The treated tumor sizes ranged from 4.5 to 11 cm. Pre-treatment angiography revealed tumor perfusion from the right phrenic artery in one patient, both right and left phrenic arteries in another, the left renal artery in a third, and the left gastric artery in the fourth. All treatments were performed using divided doses of Y-90 resin microspheres. Tumor absorbed doses ranged between 200 and 550 Gy. Post-RE Y-90 PET/CT imaging showed no extrahepatic microsphere accumulation.During follow-up, three patients showed response to treatment, while one experienced progression. No complications were observed during follow-up. ***Conclusion:*** In tumors with aberrant vascularization, some clinicians convert the procedure to transarterial chemoembolization (TACE) or abandon RE due to potential complications. However, limited case studies report successful application in selected patients with adrenal gland masses and lung carcinomas. Liver lesions may be supplied by arteries beyond foregut-derived vessels depending on their location. Failure to detect and utilize these feeding arteries may lead to inadequate treatment and poor tumor response. Planning RE based on patient-specific vascular variations may clearly enhance treatment success.In selected cases where extrahepatic leakage can be prevented, aberrant vascularization can be safely used for RE.Even though a tumor may be intrahepatic in location, it may develop aberrant vascularization and be supplied by multiple arteries outside the HA. We believe that in selected cases, with prevention of extrahepatic leakage, RE can be successfully performed using aberrant vascular feeders such as phrenic and renal arteries.

EP-0844

A Novel Prognostic Model for Colorectal Cancer Patients Treated with Y-90: The CRP Kinetics Approach

A. Dere, *E. M. Kaya, C. Sin, B. E. Akkas, M. Kaya;*
University of Health Sciences, Basaksehir Cam and Sakura City Hospital,Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: The Creactive protein (CRP) kinetics, which refers to the trajectory of CRP levels in the early phase, is being investigated for its potential to predict treatment response and survival in various malignancies.Our aim is to determine whether early CRP dynamics predict progressionfree survival (PFS) and overall survival (OS) after yttrium90 (Y90) microsphere radioembolisation (RE) in patients with colorectal cancer liver metastases (CLM). ***Materials and Methods:*** In this single-centre retrospective cohort, 30 consecutive CLM patients (mean ± SD age, 58 ± 10 years) treated with resin (n = 10) or glass (n = 20) microspheres between 2022 and 2024 were evaluated.Serum CRP levels were obtained immediately pre-treatment and at 1-3 months post-RE. Clinical and laboratory parameters, tumour-absorbed dose(TAD) and the presence of liver metastasis at diagnosis were also recorded at these time points.Patients were categorised as CRP responders or CRP non-responders based on the change in CRP levels.Survival distributions were estimated using the Kaplan-Meier method and compared with the log-rank test.Prognostic factors were identified using Cox proportional-hazards regression analysis. ***Results:*** Baseline serum CRP levels ranged from 0.8 to 89 mg/L, with a median (IQR) of 7.5 (3.7-17.2) mg/L. According to CRP kinetics, 23 patients were classified as responders and 7 as non-responders. The median follow-up was 15 months. Six of the seven non-responders (85%) died, compared to five of 23 responders (21%).Ten patients received resin microspheres (mean TAD: 350 Gy), and twenty received glass microspheres (mean TAD: 525 Gy). Univariate analysis showed that tumor-absorbed dose, hemoglobin, platelet count, neutrophil/platelet ratio, lymphocyte/platelet ratio, CEA, ALBI score, INR, and baseline CRP were not predictive of OS or PFS. Only early CRP kinetics emerged as a strong independent prognostic factor for OS. Responders had significantly longer OS than non-responders (25 vs. 9 months; HR: 5.4; 95% CI: 1.6-18.2; p = 0.005). Additionally, liver metastasis at diagnosis was associated with poorer PFS (8 vs. 2 months; HR: 3.63; 95% CI: 1.02-12.9; p = 0.046). ***Conclusion:*** Early CRP kinetics provides a simple, noninvasive biomarker that independently stratifies overall survival following Y90 RE in CLM, outperforming conventional clinical and dosimetric parameters. Identification of CRP nonresponders may facilitate timely intensification of systemic therapy and closer postprocedural surveillance.

EP-0845

Dose increase in perfused volumes in selective internal radiation therapy with microspheres labeled with holmium-166

J. Deportos, *S. Lafuente-Carrasco, M. Salcedo-Pujantell, N. Canchumanya-Huatuco, M. Boronat De Ferrater, M. Solà, V. Vallejos, S. Ruiz-Llama, A. Caresia Aroztegui, G. Moragas;*
Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN.

Aim/Introduction: To assess the increase in absorbed doses of holmium-166 in the targeted perfused volume in patients with primary or secondary liver tumors over a period of six years. ***Materials and Methods:*** Between December 2018 and December 2024, 59 selective internal radiation therapy procedures were performed using holmium-166 microspheres in patients with primary (hepatocellular carcinoma, cholangiocarcinoma, adenoma) or secondary liver tumors. All patients underwent a prior planning/simulation study using albumin macroaggregates labeled with technetium-99 or microspheres labeled with holmium-166. Following the administration of the treatment with holmium-166 microspheres, all patients underwent planar scintigraphy and thoracoabdominal SPECT/CT imaging, followed by dosimetry evaluation using specialized software. Patients were grouped as follows: Patients with hepatocellular carcinoma treated between 2018 and 2022. Patients with hepatocellular carcinoma treated between 2023 and 2024. Patients with cholangiocarcinoma treated between 2018 and 2022. Patients with cholangiocarcinoma treated between 2023 and 2024. ***Results:*** 12 patients with hepatocellular carcinoma treated between 2018 and 2022: mean absorbed dose in the perfused volume of 157 Gy (range: 54-311 Gy). 17 patients with hepatocellular carcinoma treated between 2023 and 2024: mean absorbed dose in the perfused volume of 264 Gy (range: 43-740 Gy). This represents a 68% increase in the mean absorbed dose compared to the 2018-2022 period. 11 patients with cholangiocarcinoma treated between 2018 and 2022: mean absorbed dose in the perfused volume of 108 Gy (range: 52-158 Gy). 11 patients with cholangiocarcinoma treated between 2023 and 2024: mean absorbed dose in the perfused volume of 159 Gy (range: 82-246 Gy). This represents a 47% increase in the mean absorbed dose compared to the 2018-2022 period. Of the 59 treatments performed, only one patient experienced significant adverse side effects, presenting with radiation pneumonitis.

Conclusion: In recent years, we have increased the absorbed doses in the hepatic perfused volume to enhance tumor response, with minimal observed side effects.

EP-0846

Voxel-by-voxel multicompartment dosimetric model in predicting the response of hepatocellular carcinoma to radioembolization with 90-yttrium spheres

J. Villa-Palacios, *E. Triviño-Ibáñez, A. Piñeiro-Donis, L. Cagua Ruiz, E. Domínguez-Polanco, J. Ciampi-Dopazzo, A. Rodríguez-Fernández;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To evaluate absorbed dose parameters for predicting tumor response and survival in HCC treated with TARE. ***Materials and Methods:*** This was an observational, longitudinal, and prospective study that included patients with HCC treated with TARE via radical segmentectomy between January 2022 and September 2023. Dosimetry was calculated using the multicompartment model, obtaining the minimum absorbed dose at 50% (D50), 70% (D70), and 90% (D90) of the tumor volume, extracted from the standard dose-volume histogram (DVH) (SimplicityTM software, Mirada Medical Ltd, Oxford, UK). Therapeutic response was assessed according to RECIST 1.1 criteria by calculating complete response (CR), partial response (PR), stabilization (SP), progression (PR), objective response (ORR), and disease control (DCR) rates. Overall survival (OS) and progression-free survival (PFS) outcomes were recorded. ***Results:*** Twenty-five patients with 33 TAREs were included (age: 69.76±8.83 years; 64 men), BCLC A (36%), B (56%), and C (8%). The mean administered activity was 1.85±1.25 GBq, the mean perfused volume was 396.16±329.20 cm3, and the mean tumor absorbed dose was 520.51±655.72 Gy. The CR and ORR were 36.4% and 75.8%, respectively. D50 and D70 dosimetry parameters were significantly associated with ORR (p=0.011 and p=0.031, respectively) and CR (p=0.012 and p=0.036, respectively). The ROC curve showed an AUC of 0.845 (95% CI 0.651-1.039) for D50, with 350 being the cutoff point with the best sensitivity/specificity ratio for ORR. The median OS was 15.5 months and PFS was 32.7 months. PFS was significantly associated with the absorbed dose at D50 (HR: 0.99, p = 0.037). ***Conclusion:*** Radiation segmentectomy is an effective treatment in patients with HCC. Tumor dosimetry is associated with response and survival.

EP-0847

Comparison of Yttrium-90 Resin and Glass microsphere Radioembolization Dosimetry and Correlation with Treatment efficacy in Hepatocellular Carcinoma

N. Too[1], *S. Koo*[2], *P. K. H. Chow*[1,2,3], *F. N. N. Moe*[3], *A. K. T. Tong*[1,2], *K. S. H. Loke*[1,2];
[1]*Duke-National University of Singapore Medical School, Singapore, SINGAPORE,* [2]*Singapore General Hospital, Singapore, SINGAPORE,* [3]*National Cancer Centre Singapore, Program in Translational and Clinical Liver Cancer Research, Singapore, SINGAPORE.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is a significant disease with high morbidity and mortality, being one of the top causes of death by cancer in Singapore. The management of HCC is stage-dependent: Early-stage: Surgical resection or liver transplantation (for eligible patients within Milan criteria) offers curative potential. Intermediate-stage: Locoregional therapies dominate, with transarterial chemoembolization (TACE) as first-line. Yttrium-90 radioembolization (Y90 TARE) are alternatives for select cases. Advanced-stage: Systemic and immunotherapy therapies (e.g., atezolizumab/bevacizumab) are standard. While Y90 TARE is established for intermediate/advanced HCC, differences between glass and resin microspheres remain understudied in Asian populations. This study aims to compares their efficacy in a Singaporean cohort. ***Materials and Methods:*** This study is a single-centre retrospective cohort analysis that enrolled a total of 269 patients who underwent Y-90 TARE between 2020 and 2023 at National Cancer Centre Singapore (NCCS) and Singapore General Hospital (SGH).Outcome measures of this study as assessed by RECIST1.1 criteria: Progression-free survival (PFS), Overall survival (OS), Time to progression (TTP), Time to response (TTR), Duration of response, Best overall response rate (BORR). Statistical test included Kaplan-Meier, Mann-Whitney U, and Fisher's exact tests. ***Results:*** Baseline characteristics: No significant difference between groups. The cohort is heterogeneous consisting of unilobar and bilobar tumors, and some (Glass: 11.8%, Resin: 16.8%) having received additional therapies. Dosimetry: Higher mean tumor dose (TD) with glass compared to resin (406±150 Gy vs. 283±174 Gy; P=0.0005). Outcomes: No significant difference across outcome measures: Median OS (Glass: 19mo; Resin: 17mo, P=0.83), PFS (Glass: 15mo; Resin: 8mo, P=0.3), TTR (Glass: 7mo Resin: 5mo, P=0.4), BORR (Glass: 35.3%; Resin: 31.1%, P=0.9), Kaplan Meier: No significant difference (P=0.31) in the overall survival although there is greater hazard ratio for the resin relative to glass. The lack of difference observed between the two groups in terms of outcomes corroborates with findings of other similar studies [1, 2]. ***Conclusion:*** Glass and resin Y90 demonstrate similar outcomes for HCC. The impact of the significantly different delivered TDs on tumor response outcomes merits further investigation, with larger studies. Including other factors that other studies shown may influence outcomes: Particle size/number differences (Glass: fewer/larger; Resin: more/smaller) may influence vascular penetration. Glass showed potential advantages in portal vein thrombosis cases. Delivery techniques including microsphere injection velocity. ***References:*** [1] Van Der Gucht et al., J Nucl Med 58:1334-1340, 2017. [2] Kim et al., CardioVasc Interv Radiol 47:1210-1221, 2024.

EP-0848

Comparison of ^{99m}Tc-MAA SPECT/CT and ^{90}Y LAFOV PET/CT-based dosimetry for patients with colorectal liver metastases

C. Schneider, *L. W. van Golen, S. M. Jansen, A. J. A. T. Braat, R. G. H. Beets-Tan, E. G. Klompenhouwer, B. J. de Wit-van der Veen;*
Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: Long-axial field of view (LAFOV) PET-scanners enable high sensitivity and wide coverage, resulting in more precise post-treatment imaging after Yttrium-90 (^{90}Y) radioembolization. The aim of this study was to compare dosimetry on pre-treatment ^{99m}Tc-macro-aggregated albumin (^{99m}Tc-MAA) SPECT/CT simulation versus ^{90}Y LAFOV PET/CT, in colorectal liver metastases (CRLM) treated with ^{90}Y resin microspheres. ***Materials and Methods:*** Retrospective cohort of CRLM patients treated in 2024 in the Netherlands Cancer Institute, with ^{90}Y resin microspheres, who underwent post-treatment ^{90}Y LAFOV PET/CT, were included. Tumors, total liver and non-tumoral liver were segmented on pre-treatment contrast-enhanced CT (MIM version 7.3.6). ^{99m}Tc-MAA SPECT/CT and ^{90}Y PET/CT were co-registered using rigid alignment; accuracy of all segmentations were visually evaluated and when needed corrected manually. The SPECT/CT-based dosimetry was scaled to administered ^{90}Y activity. Average absorbed dose (Dmean), D50 and D70 from dose-volume histograms were extracted for tumor, liver and non-tumoral liver compartments. Agreement of the dose metrics were evaluated by Pearson's correlation and Bland-Altman analysis. ***Results:*** Seven patients with in total 46 tumors were included with a median of 7 tumors per patient. The median age was 66 years. A median of 2 injection position was used. Most patients (6/7, 86%) underwent bilobar treatment, while one patient (14%) received lobar treatment. The median total administered activity was 1.81 GBq. For tumors a fair correlation was found for Dmean,

D50 and D70 (ρ = 0.54, ρ=0.57 and ρ=0.55), with small biases, but large limits of agreement in Bland-Altman analyses for all dose metrics. For liver and non-tumoral liver compartments, a strong correlation was found for D70 (ρ = 0.85 and ρ=0.89), with small bias and narrow limits of agreement in Bland-Altman analyses for all dose metrics. ***Conclusion:*** LAFOV PET/CT dose volume metrics demonstrated superior pre- and post-treatment dosimetry correlation than average absorbed dose. Tumor dose metrics showed only a fair correlation and wide limits of agreement, in line with literature. D70 showed the best correlation for liver and non-tumoral liver, conforming prior literature. These findings support the agreement of pre-treatment dosimetry and post-treatment LAFOV ^{90}Y resin microsphere dosimetry for liver and non-tumoral liver compartment in CRLM.

EP-0849

Assesment of overall survival in patients with liver tumors undergoing yttrium-90 and holmium-166 radioembolization

L. Casas Fernández*, M. Romero Otero, A. Palazón Palazón, P. Soto Muñoz, T. Peris Conejero;*
Unidad de Radiofarmacia Hospital Clí Universitario de Valencia, Valencia, SPAIN.

Aim/Introduction: Transarterial hepatic radioembolization (TARE) with beta-emitting isotopes such as yttrium-90 (^{90}Y) and holmium-166 (^{166}Ho) is used in the treatment of primary and metastatic liver tumors. Differences in their physical properties and intrahepatic distribution may influence clinical outcomes. This study aims to compare overall survival (OS) at 6 and 12 months in patients treated with ^{90}Y-labeled resin and glass microspheres (^{90}Y-RMs and ^{90}Y-GMs), and with ^{166}Ho-labeled polylactic acid microspheres (^{166}Ho-PLLAMs). ***Materials and Methods:*** A total of 155 patients who underwent TARE between February 2016 and April 2024 were included: 108 treated with ^{90}Y-RMs, 33 with ^{90}Y-GMs, and 14 with ^{166}Ho-PLLAMs. Demographic characteristics, type of liver tumor, history of alcohol use, HCV and HBV infection, mean administered activity (GBq), and number of TARE procedures were analyzed. ***Results:*** In the ^{90}Y-RMs group (mean age: 66±10 years), 76% were male and 28% had liver metastases. Risk factors: alcohol use (31%), HCV (24%), alcohol + HCV (8%), HBV (6%). Mean administered activity: 1.83 Gbq. In the ^{90}Y-GMs group (mean age: 69±9 years), 79% were male and 88% had hepatocellular carcinoma. Risk factors: alcohol use (24%), HCV (24%), alcohol + HCV (15%), HBV (12%). Mean administered activity: 1.53 Gbq. In the ^{166}Ho-PLLAMs group (mean age: 73±10 years), 79% were male and 86% had hepatocellular carcinoma. Risk factors: alcohol use (7%), HCV (29%), alcohol + HCV (7%), HBV (14%). Mean administered activity: 4.67 GBq. The 6- and 12-month OS rates were 80% and 62% for ^{90}Y-RMs, 81% and 60% for ^{90}Y-GMs, and 86% and 43% for ^{166}Ho-PLLAMs. In patients treated with ^{90}Y-RMs, 12-month OS was 57%, 82%, and 100% after one, two, and three treatments, respectively. For ^{90}Y-GMs: 60%, 50%, and 100%. For ^{166}Ho-PLLAMs: 42% after one treatment and 50% after two. ***Conclusion:*** Six-month OS was comparable among all three groups. However, at 12 months, OS was lower in patients treated with ^{166}Ho-PLLAMs (42%) compared to ^{90}Y-RMs (62%) and ^{90}Y-GMs (60%). In the ^{90}Y-RMs and ^{166}Ho-PLLAMs groups, a higher number of TARE procedures was associated with increased OS, a trend not observed in the ^{90}Y-GMs group. A larger cohort and extended follow-up are required to confirm these findings.

EP-0850

Survival Outcomes in Transarterial Radioembolization with ^{90}Y-Resin for Hepatic Malignant Tumours

A. Bagán-Trejo*[1], J. J. Martín-Marcuartu[1], J. L. Díaz-Moreno[1], G. Reynés-Llompart[2], D. Rodríguez-Puig[3], S. Maymó-Garrido[3], M. Á. Crespí-Busquets[3], E. Serrano-Alcalá[4], B. Gener-Laquidáin[4], L. Lladó-Garriga[5], E. Ramos-Rubio[5], A. Amador-Navarrete[6], M. R. Rota-Roca[6], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Medical Physics and Radiation Protection Department, Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN, [3]Radiopharmacy Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Spain, [4]Diagnostic Imaging Centre, Vascular Interventional Radiology Section, Radiology Department, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN, [5]Liver Transplant Unit, General and Digestive Surgery Department, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, SPAIN, [6]Gastroenterology Department, Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Transarterial radioembolization (TARE) is a locoregional treatment modality for patients with inoperable liver lesions, offering both embolic and biological effects. The primary goal of this study was to explore the influence of factors such as the time interval between planning and treatment (TPT), the absorbed dose in the perfused area (PA), and the administered activity (AA) on survival outcomes in patients with malignant liver tumours. ***Materials and Methods:*** Retrospective study involving 31 patients diagnosed with either hepatocellular carcinoma (n=28) or colorectal liver metastases (n=3), all of whom received treatment with TARE. Treatment planning and delivery utilised ^{m99}Tc-macroaggregates (^{m99Tc}-MAA) and ^{90}Y-resin microspheres, respectively. SPECT/CT imaging was performed after treatment planning, followed by PET/CT imaging 24 hours post-treatment. The PA and AA were calculated using two models: the partition model during planning and the voxel-based model post-TARE. The treatment response was evaluated using contrast-enhanced CT scans at least 3 months after spheres administration, classifying patients into complete response (CR), partial response (PR), or progressive disease (PD). Cox regression analysis was used to calculate the Odds Ratios (OR) based on administered activity. ***Results:*** Results were as follows: CR n=13, PR n=19, and PD n=2. The administered activity in the perfused area ranged from 1.25 GBq to 5.52 GBq, with a mean of 3.4 GBq. The OR for AA was 2.2 (p=0.048). The absorbed tumour dose ranged from 210.8 Gy to 659.4 Gy (mean: 435.1 Gy) (p=0.265). Tumour size averaged 66.9 mm (range: 29.09 mm-104.71 mm) (p=0.28). The time interval between planning and treatment was 11.9 days on average (range: 2.55 days-21.25 days), with an OR of 1.1 (p=0.027). ***Conclusion:*** Our findings suggest that the time interval between treatment-planning and treatment-administration, as well as the administered activity in the perfused area, are significant predictors of survival outcomes in patients undergoing TARE for malignant liver tumours. Although the absorbed tumour dose and tumour size did not show a strong correlation with survival, these results emphasize the importance of optimising treatment planning timelines and the delivered activity for improving patient outcomes.

EP-0851

The Role of RAI Treatment Selection and RAI Therapy in Papillary Thyroid Microcarcinoma in the Right Patient

E. Cansu Çay*, B. B. Demirel, G. Uçmak;*
Ankara Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Papillary thyroid microcarcinoma(PTMC) is a subgroup papillary thyroid cancers(PTCs) before the 2022

WHO classification and was defined as a PTC ≤10 mm.PTMCs usually have an excellent prognosis but in some cases may have an aggressive behavior.In our study, we aimed to evaluate patient selection for radioactive iodine(RAI) and factors leading to residual/recurrence during follow-up in patients diagnosed with PTMC. ***Materials and Methods:*** The study retrospectively included 263 patients with PTMC who were treated in our clinic between 1990 and 2025.Patients were divided into two groups as those who received RAI and those who did not.Pathological features, thyroglobulin (Tg)-antithyroglobulin (ATg) values,thyroid scintigraphy and RAI treatments were recorded.The clinical-pathologic and treatment effects on residual/recurrence were evaluated using Chi-square, Mann-Whitney U and T test. ***Results:*** The mean age at diagnosis was 43.2 (±11,5) years (20M, 243F). Considering the clinico-pathologic features, 187 patients received RAI, while 76 patients did not receive RAI. The median follow-up period was 204 (Range:9-420) months. A significant correlation was found between multifocality, lymph metastasis, invasion status and tumor diameter in patients receiving RAI ($p<0.05$) (Table 1).In 3 patients, F-18 FDG PET/CT examination was performed during follow-up due to negative I-131 scan and Tg elevation. It was consistent with lung metastasis.Tumor size >0.5 cm and multifocal character were common features of these patients.Dynamic risk analysis of patients receiving RAI; 93.5% had an excellent response, 4.3% indeterminate response and 2.2% structural-biochemical incomplete response. 4 patients who received RAI had residual/recurrent disease.In 9 patients who did not receive RAI, residual/recurrent disease was considered during follow-up and 8 patients received RAI. While 0.7% of all patients without multifocality had residual/recurrent disease, 6.5% of all patients with multifocality had residual/recurrent disease ($p<0.05$). 1.2% of patients without lymph metastasis and 16.7% of patients with lymph metastasis had residual/recurrent disease ($p<0.05$). The mean tumor diameter was 0.73(±0.16)cm in all patients with residual/recurrent disease. While 242 patients were alive, 21 patients died and no disease-related deaths were recorded. ***Conclusion:*** In line with the data obtained in our study, it was concluded that the current WHO classification supports the importance of RAI treatment in terms of patient management and correct patient selection, the importance of analyzing factors that may lead to residual/recurrence in follow-up, and that prognosis and RAI decision should be determined by factors such as molecular properties and biological indices rather than tumor size.

EP-0852

Thyroglobulin doubling time and prognosis in lung metastases of differentiated thyroid carcinoma

H. Wang, *Y. Wang, R. Tian;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: To assess the association of thyroglobulin doubling time (Tg-DT) with prognosis in patients with lung metastases from differentiated thyroid carcinoma (DTC). ***Materials and Methods:*** This study included 122 patients with initial lung metastases who underwent thyroidectomy and radioiodine (RAI) treatment. Outcomes included progression-free survival (PFS), overall survival (OS) and radioiodine refractory (RAIR)-free survival (RRFS). Tg-DT was calculated from at least three thyroglobulin measurements. Survival receiver operating characteristic curves were used to define optimal cutoff values for Tg-DT predicting different outcomes. Uni- and multivariate Cox regression models evaluated the associations of Tg-DT and multiple predictors with outcomes. ***Results:*** The median age was 37.4 years, with 63.1% female. Median follow-up was 96.0 months. In multivariate models, patients with a Tg-DT of ≥-8 months had a greater risk of progression (HR=17.68 [95%CI: 1.68-186.32]) and death (log-rank test: P=0.02), compared to those with a Tg-DT of <-8 months. Patients with a Tg-DT of ≥0 month had a higher risk of RAIR (16.87 [4.96-57.39]) than controls. Among 38 patients with RAIR-related scenarios, those with a Tg-DT of ≥0 month were more likely to lose RAI uptake and show structural progression, whereas patients with a Tg-DT of <0 month were more likely to have no remission despite a cumulative dose of >22.2 GBq. ***Conclusion:*** The Tg-DT is independently associated with risks of progression, death and RAIR-related clinical scenarios in DTC patients with lung metastases, which could be integrated into the dynamic prognostic risk stratification and therapeutic decision-making process for such patients.

EP-0853

Integrating Lenvatinib with High-Dose Radioiodine: A Promising Approach for Advanced well-differentiated thyroid cancer

S. Sharma, *P. Chauhan, M. Ora, P. Pradhan, S. Barai, A. H. Nazar, S. Gambhir;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: Management of well-differentiated thyroid cancer (WDTC) with systemic metastasis remains challenging, which requires a multidisciplinary approach with multiple high-dose radioiodine (HDRI) therapy being the mainstay. Morbidity and mortality benefits are noted, with sporadic complete response. The main concerns include radioiodine side effects, radioiodine refractoriness, and cumulative dose (>22.2 GBq). Lenvatinib, a tyrosine kinase inhibitor, is the standard of care for radioiodine-refractory disease. However, its role remains unexplored in radioiodine-avid metastatic WDTC. The study aims to evaluate the feasibility and response rate of a combination treatment approach using Lenvatinib and HDRI in metastatic WDTC. ***Materials and Methods:*** The study included eight patients with WDTC with systemic metastasis with or without prior HDRI. The baseline disease burden was measured with imaging (WBRI, PET-CT, or CT) and serum thyroglobulin (Tg). After ruling out any contraindications, Lenvatinib was administered for 3-4 months (10 mg/day), along with thyroxine suppression between two HDRIs. Two doses of HDRI were given after Thyroxin hormone withdrawal. Side effects and treatment response were evaluated. ***Results:*** The mean age of the patients was 52.5 ± 16.02 years. Lung, bone, and brain metastases were noted in 5 (62.5%), 6 (75%) and 1 patient(12.5%) respectively. Five (62.5%) patients had prior HDRI (98.75 ±87.08 mCi). Lenvatinib was well tolerated, with 5 out of 8 patients having grade I toxicities. The baseline, interim (first cycle), and follow-up (after two cycles) Tg values were 61133.66±81347.14 (median 6888, IQR 1274.65, 123092) ng/ml, 7560.5±9010.2 (median 1223.5, IQR 274, 16661.5) ng/mL and 2344.5±4170.7ng/ml(median 293, IQR 4204). One patient showed an initial response (227347à17090 ng/mL) but a rising Tg (72599 ng/mL) level in the second cycle. Tg fall was not associated ($p>0.05$) with age, sex, histopathology, and previous HDRI. Overall, partial response and stable disease were noted in the 6(75%) and 2(25%) patients on imaging. During follow-up (17.1 ± 3.56 months), one patient died of pneumonia unrelated to WDTC. ***Conclusion:*** The synergistic effects of Lenvatinib and HDRI are novel treatment options in bulky radioiodine-avid metastatic WDTC. The treatment regimen was well-tolerated, with manageable mild toxicities of Lenvatinib and no discontinuation. Patients demonstrated excellent partial treatment response on imaging and Tg levels. Due to accentuated treatment benefits, multiple cycles of HDRI and possible side effects could be avoided.

EP-0854

Comparison of patients with differentiated thyroid cancer in a German and an American collective in tertiary treatment centers.

F. Eilsberger[1], *A. C. Prietsch*[1], *A. Pfestroff*[1], *W. Bowl*[1], *A. Ebrahimifard*[1], *S. Bagheri*[1], *B. H. Yousefi*[1], *P. Di Fazio*[1], *M. Luster*[1], *R. M. Tuttle*[2];
[1]*University Hospital Marburg, Marburg, GERMANY,* [2]*Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: A comparison of national guidelines highlights differences in the treatment of differentiated thyroid cancer (DTC), especially concerning radioiodine therapy (RAIT). Differences in baseline conditions may have a notable impact on the further course of the tumor disease, though they have not yet been thoroughly examined. We compared the baseline conditions of an US and a German collective for the first time. ***Materials and Methods:*** We included 168 DTC patients randomly from a single endocrinologist in the Department of Endocrinology of Memorial Sloan Kettering Cancer Center (MSKCC) and 168 DTC patients from the Department of Nuclear Medicine of University Hospital Marburg (UHM) and compared them regarding baseline conditions of cancer treatment like presurgical diagnostics and surgical procedures. ***Results:*** At MSKCC 93% had a biopsy result of Bethesda 5/6 prior surgery. 99,4% of patients received a total thyroidectomy (TT) as initial surgery, in 12% no lymph node was removed. The median thyroglobulin (Tg) value post surgery was 0,2 (0-5,9) ng/ml (excluding patients with: elevated TSH (>5.4 mU/l), M1, positive antibodies and Tg <1 ng/ml). 113/168 MSKCC patients received RAIT with activities between 1.1-11.2 GBq (median 4.23 GBq). In the UHM group 5% had a biopsy. 76% received an initial TT. In 42% patients no lymph node was removed. The median Tg value post surgery was 1,1 (0-81) ng/ml (exclusion as above). All UHM patients received RAIT with activities between 1.9-11.0 GBq (median 3.7 GBq), 13/168 patients underwent more than one cycle. 54% (90/168) UHM patients showed an excellent response to therapy, 34% (57/168) an indeterminate response, 6% (11/168) a biochemical and 6% (10/168) a structural incomplete response. ***Conclusion:*** Our results clearly demonstrate differences between the cohorts. In the German cohort, preoperative diagnostics leaves room for improvement, and more patients with Nx can't be adequately classified in the risk groups postoperatively. Additionally, a higher postoperative Tg likely makes it more challenging to avoid radioiodine therapy. These differences highlight the need to reassess the adaptation of treatment decisions in different countries based on the underlying characteristics.

EP-0855

A Study on the Dynamic Changes of Anti-Thyroid Peroxidase Antibodies Before and After the First ^{131}I Treatment in Patients with Differentiated Thyroid Cancer After Surgery

W. Cao[1], *H. Chen*[2];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: To investigate the dynamic changes of anti-thyroid peroxidase antibodies (TPOAb) in patients with differentiated thyroid cancer (DTC) before and after their first ^{131}I treatment, assess the clinical significance of these changes, and evaluate their predictive value for treatment response after ^{131}I therapy in DTC patients. ***Materials and Methods:*** A retrospective data collection was conducted for 1,378 DTC patients who underwent their first ^{131}I treatment after thyroid cancer radical surgery in our hospital. A total of 202 patients with abnormal TPOAb levels (≥34 IU/ml) before treatment and within 2 years of follow-up were selected. Analyze the influencing factors of dynamic changes of TPOAb before and after treatment, and assess the impact of TPOAb trends and levels on the treatment response of DTC patients after ^{131}I therapy. ***Results:*** In patients with abnormal TPOAb levels before ^{131}I treatment, those who experienced a transient increase in TPOAb post-treatment differed significantly from those with a sustained decrease in two aspects: the time interval between thyroid surgery and ^{131}I treatment, and the amount of postoperative residual thyroid tissue (both P<0.001). There was no significant difference in efficacy response between patients whose TPOAb normalized post-treatment and those whose levels remained abnormal (P=0.149). Additionally, there was no significant difference in efficacy response among patients with differing trends in TPOAb levels before and after ^{131}I treatment (P=0.740). ***Conclusion:*** Longer waiting times for ^{131}I treatment after thyroid cancer radical surgery and greater amounts of residual thyroid tissue increase the likelihood of transient TPOAb elevation in patients with abnormal levels before treatment. TPOAb elevation is often a manifestation of radioactive thyroiditis. This suggests that, while protecting the parathyroid glands and recurrent laryngeal nerve, minimizing thyroid residue during the radical surgery for DTC patients and administering early ^{131}I treatment postoperatively are effective strategies to reduce the occurrence of residual radioactive thyroiditis after ^{131}I therapy. Higher initial TPOAb levels before ^{131}I treatment correlate with longer durations for TPOAb to normalize post-treatment, but whether TPOAb normalizes does not affect the efficacy of ^{131}I treatment in DTC patients. The dynamic changes of TPOAb before and after treatment do not influence the treatment efficacy for DTC. There is no need to develop specific follow-up treatment plans or adjust levothyroxine dosages for patients with abnormal TPOAb levels before and after ^{131}I treatment.

EP-0857

Evaluation of theTreatmentResponse to RAI Therapy in Papillary Thyroid Cancer Patients with Pulmonary Metastases

A. Akil[1], *A. Kibar*[1], *R. Alsabbagh*[2], *O. E. Şahin*[1], *S. Asa*[1], *R. L. Uslu-Beşli*[1], *M. S. Sağer*[1], *K. Sönmezoğlu*[1], *H. B. Sayman*[1];
[1]*Istanbul University – Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [2]*Biruni University, Faculty of Medicine, Istanbul, TÜRKIYE.*

Aim/Introduction: Pulmonary metastases in patients with papillary thyroid carcinoma (PTC) carry a poorer prognosis than localized disease. Prompt identification of predictors of therapeutic response in such instances is essential to optimize treatment strategies as early as possible. Radioactive iodine (RAI) therapy remains the first-line treatment for metastatic differentiated thyroid cancers. In this study, we aimed to evaluate the biochemical and metabolic response to RAI therapy in patients with PTC metastases to the lungs, and to establish if there are any correlations between clinical parameters and the response to treatment. ***Materials and Methods:*** This is a retrospective analysis of 41 patients with histologically confirmed PTC and radiologically or scintigraphically evident pulmonary metastases, who received at least one cycle of RAI therapy in our center between 2018 and 2025. Age, sex, maximum primary tumor size, RAI dose given, and patterns of uptake in post-treatment whole-body scintigraphy were recorded. Stimulated thyroglobulin (Tg) levels pre-RAI therapy and six months post-treatment were compared. In patients for whom PET/CT imaging was available before and after treatment, metabolic response were classified as regressive, stable, or progressive. Both qualitative (visual) and quantitative trends were considered. ***Results:*** Among the 41 patients, 25 were female (61%) and 16 were male (39%). The median age was 63 years (range: 11-92), and the median tumor diameter was 3.0 cm (range: 0.3-8.0 cm). Thirty-three patients had available pre- and post-treatment Tg data.: Tg levels decreased in 21 (64%) and increased in 9 (27%) patients after RAI (6 months). PET/CT evaluations revealed regression in 11 patients, stable disease in 5, and progression in 3 patients. One patient demonstrated persistently high metabolic uptake. Uptake of RAI was observed in metastatic pulmonary lesions in 21 out of 41 patients (51.2%). With heterogeneous response based on initial tumor burden and Tg kinetics. ***Conclusion:*** RAI therapy demonstrated favorable biochemical and metabolic responses in the overwhelming majority of PTC patients who had pulmonary metastases. Reduction in stimulated Tg levels and regression in PET findings

suggests treatment efficacy. However, the presence of progressive disease or persistent Tg elevation in a few patients suggests the heterogeneity of response and the need for alternative or adjunctive forms of treatment. ***References:*** Schlumberger M, et al. Strategies of radioiodine ablation in patients with low-risk thyroid cancer. N Engl J Med. 2012;366(18):1663-1673.

EP-0858

Pretreatment Predictors of Short-Term Outcomes in RAI-Treated Intermediate-Risk Thyroid Cancer

G. B. Babacan[1,2], *S. Saracoglu*[3], *O. Guven*[2], *S. Sabuncu*[2], *M. N. Acar Tayyar*[2], *T. Ozulker*[2], *M. C. Sahin*[2], *S. Karyagar*[2];
[1]*Sirnak State Hospital, Clinic of Nuclear Medicine, Sirnak, TÜRKIYE,* [2]*University of Health Sciences, Hamidiye Faculty of Medicine, Prof. Dr. Cemil Tascioglu City Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,* [3]*Van Training and Research Hospital, Department of Nuclear Medicine, Van, TÜRKIYE.*

Aim/Introduction: We aimed to investigate the effect of pretreatment parameters on early follow-up outcomes in patients with intermediate-risk group differentiated thyroid cancer (DTC). ***Materials and Methods:*** A dataset of patients who underwent total thyroidectomy and received ^{131}I radioactive iodine (RAI) treatment was analyzed between January 2016 and January 2022. Patients with intermediate-risk group DTC according to the ATA 2015 criteria were included in the study. Patients younger than 18 years of age, patients with anti-Tg positivity, patients with evidence of metastasis on post-treatment imaging, and patients with missing follow-up data were excluded. Histopathologic and biochemical results, RAI doses, and clinical follow-up results at 3 and 5 years were compared. The Chi-square and Fisher's exact tests were used to compare nonparametric variables and follow-up results. Threshold values for continuous variables were determined by drawing the ROC curve over the 3-year follow-up results. Results with p values less than 0.05 were considered statistically significant. ***Results:*** Seventy-six patients (56 women; mean age 43.14±13.6 years) enrolled in this study. Median follow-up was 72.5 (58-106) months. During follow-up, five patients received additional RAI treatment, and two patients underwent secondary surgical treatment within the first three years. Four patients underwent ^{18}F FDG PET/CT imaging. In the Chi-Square test, no statistically significant difference was found between the three and five-year follow-up groups for histopathological features, age, and gender (p>0.05) (Table 1). When the treatment doses and five follow-up results were analyzed, it was found that the group initially treated with 5.55 GigaBecquerel (GBq) had a significantly lower rate of excellent response than the group treated with 3.7 GBq or less (p=0.0112). In the ROC curve analysis generated with three-year follow-up results, the threshold value for pretreatment stimulated Tg (sTg) was determined as 4.69 (AUC:0.739, Sensitivity:76.5, Specificity:70, p=0.0001). After grouping the patients based on this value, a statistically significant difference was found between the groups in the Chi-square test (p=0.0007, p=0.0306 for three and five years, respectively). ***Conclusion:*** In this study, no statistically significant correlation was found between pathology data and treatment response at the end of the third and fifth years in DTC patients who received radioactive iodine treatment, while patients with sTg values above 4.69 were found to have a higher rate of early incomplete treatment response. This cut-off value may be guiding in terms of follow-up and treatment selection in patients who are planned for total thyroidectomy and RAI treatment.

EP-0859

To compare the response of low- and high-dose Lenvatinib in patients with radioiodine-refractory thyroid cancer: A non-inferiority trial

P. Chauhan*, S. Sharma, R. Mehra, P. K. Pradhan, S. Gambhir; Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.*

Aim/Introduction: The rising incidence of thyroid cancer highlights the need for improved therapies, especially for radioiodine-refractory differentiated thyroid cancer (RAI-R DTC). Lenvatinib, a tyrosine kinase inhibitor, is effective but often limited by adverse effects requiring dose modifications. While studies suggest lower doses may balance efficacy and tolerability, most focus on high-dose regimens in Western populations (1,2). Data on optimal dosing in South Asian patients remain scarce. ***Materials and Methods:*** This retrospective non-inferiority study at our institute, compared low-dose (10-12mg) vs. high-dose (18-20mg) Lenvatinib in RR-DTC patients, evaluating overall response and adverse events. Data from 44 patients were analyzed. Baseline clinical, biochemical, and imaging parameters were recorded. Patients were grouped by Lenvatinib dose (10-12 mg vs. 18-20 mg). Follow-up included clinical exams, Tg/ATgAb levels, and imaging. Therapeutic response was assessed after 3-5 months as clinical, biochemical, or imaging response. Continuous variables were analyzed using Mann-Whitney U test; categorical variables with Fisher's exact or chi-square test. $p < 0.05$ considered statistically significant. ***Results:*** Of the 44 patients treated with Lenvatinib, 28 received low-dose and 16 high-dose, with comparable baseline characteristics. Biochemical response was assessed in 32 patients over 5 months; Serum thyroglobulin (Tg) levels were significantly reduced by a median of 71% over 5 months, 75% showed partial response, 15.5% had stable disease, and 9.3% progressed. Imaging response in 27 patients showed 70.3% partial response, 18.5% stable disease, and 7.4% progression. Clinical response included mass reduction in three patients. Overall, 81.8% achieved partial response, 9.1% had stable disease, and 9.1% progressed. No significant differences were observed between low- and high-dose groups across biochemical, imaging, or clinical responses, indicating similar therapeutic efficacy at reduced doses. Adverse events were monitored over 2 months. Drug holidays (31.8%) and dose reductions (18.2%) were more common in the high-dose group. Proteinuria was significantly higher with high-dose Lenvatinib (p=0.018). Hand-foot syndrome was most common (61.3%), with higher incidence in the high-dose group, though not statistically significant. ***Conclusion:*** This real-world data suggests that lower initial doses (10-12mg) of Lenvatinib can be as effective as higher doses (18-20mg) while potentially reducing adverse effects. Overall, this study adds valuable evidence about optimizing Lenvatinib therapy for RR-DTC, with implications for improving patient care and quality of life. ***References:*** 1. Brose MS, et al. J Clin Endocrinol Metab. 2022;107:776-787 DOI: 10.1210/clinem/dgab731. 2. Rendl G, et al. International Journal of Endocrinology. 2020;2020:1-8 DOI: 10.1155/2020/8834148.

EP-0860

Association between early Tg elevation and subsequent reduction after I-131 therapy in differentiated thyroid carcinoma: A dynamic biomarker study.

Y. Li[1], *K. Hirata*[1,2,3], *J. Takenaka*[1,2], *S. Watanabe*[1,2], *R. Kimura*[1,4], *K. Kudo*[1,2,4];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [3]*Global Center for Biomedical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, JAPAN,* [4]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.*

Aim/Introduction: Serum thyroglobulin (Tg) is a well-established tumor marker in the follow-up of differentiated thyroid carcinoma (DTC) patients. A transient elevation Tg levels is often observed within a few days following I-131 treatment. However, the elevation of Tg observed two days after I-131 treatment, compared to the day of treatment (before treatment), which may reflect tumor destruction, remains of uncertain significance. This study aims to explore the relationship between initial Tg elevation shortly after therapy and the long-term reduction of Tg,

thereby enhancing risk stratification in DTC patients. ***Materials and Methods:*** A retrospective analysis was conducted on 94 patients with DTC who underwent thyroidectomy followed by their first I-131 adjuvant therapy stimulated by rhTSH. Tg levels were measured at three distinct time points: before RAI treatment (Tg_0), 2 days after RAI (Tg_{2d}), and 6 months after RAI (Tg_{6m}). Time-based Tg biomarkers were calculated as follows: ΔTg_02 (Tg_{2d}-Tg_0), ΔTg_26 (Tg_{6m}-Tg_{2d}), ratioTg_02 (Tg_{2d}/Tg_0), and ratioTg_26 (Tg_{6m}/Tg_{2d}) and evaluated by Spearman's correlation analysis and Mann-Whitney U tests. Subgroup analyses were further performed based on age, sex, TSH level (before RAI), lymph-node metastasis status, administered RAI dose, and histological subtype using Mann-Whitney U tests. ***Results:*** Spearman correlation analysis revealed a moderate negative correlation between ΔTg_02 and ΔTg_26 ($\rho = -0.473$, $p < 0.0001$), indicating that greater early Tg elevation was associated with more obvious decline of late Tg. Similarly, a significant negative correlation was observed between the ratioTg_02 and the ratioTg_26 ($\rho = -0.481$, $p < 0.0001$), further supporting the association between early and long-term Tg dynamics. DTC patients were stratified into high and low groups separately based on the median value of ΔTg_02 and ratioTg_02. It was statistically significant between high and low groups ($p < 0.0001$) based on ΔTg_02, with the high ΔTg_02 group showing a greater Tg reduction at 6 months later. A similar trend was observed for ratioTg: ratioTg_26 was significantly different between the high and low ratioTg_02 groups ($p = 0.0006$). We conducted subgroup analyses stratified by clinical variables. Subgroup analyses showed that both ΔTg_02 and ratioTg_02 were significantly ($P<0.05$) associated with subsequent Tg decline (ΔTg_26 or ratioTg_26) regardless of age, sex, TSH level, lymph-node metastasis status, RAI dose, and histological type of papillary. ***Conclusion:*** Early changes in Tg levels are significantly associated with long-term Tg reduction following I-131 therapy in patients with DTC. Subgroup analyses further demonstrate the robustness of this association across various clinical characteristics.

EP-0861

Preablative Stimulated Thyroglobulin, Its Post-^{131}I Treatment Decline, and Nomogram-Based Prediction of Clinical Outcomes in Differentiated Thyroid Cancer Patients Without Distant Metastasis

Y. Hou[1,2,3], *J. Wang*[1,4], *R. Wu*[1,2,3], *J. Tan*[5], *X. Xia*[1,2,3], *Z. Gao*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA,* [4]*Department of Medical Imaging, Henan Provincial People's Hospital, Zhengzhou, CHINA,* [5]*Department of Breast and Thyroid Surgery, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.*

Aim/Introduction: The detection rate and incidence of thyroid cancer have been increasing year by year, and differentiated thyroid cancer (DTC) is the most important type of thyroid cancer. This study aims to evaluate the predictive value of stimulated thyroglobulin (sTg) levels before and after the first ^{131}I treatment in predicting clinical outcomes for differentiated thyroid cancer (DTC) patients without distant metastasis. ***Materials and Methods:*** Sixty patients were categorized according to the 2015 American Thyroid Association guidelines into two groups: excellent response (ER) and non-excellent response (NER). Clinical and pathological data were analyzed using univariate and multivariate analyses. Receiver operating characteristic (ROC) curves were generated to determine optimal thresholds for pre-^{131}I sTg levels and the rate of sTg decline after the first ^{131}I treatment. ***Results:*** Univariate and multivariate analyses identified pre-^{131}I sTg levels (OR: 3.010, 95% CI: 1.004-9.029, P=0.049) and the rate of sTg decline (OR: 0.756, 95% CI: 0.590-0.968, P=0.026) as independent predictors of clinical outcomes. In the ER group, the optimal threshold for pre-131I sTg was 14.55 μg/L (sensitivity: 95.0%, specificity: 67.5%, AUC: 0.804). The optimal cutoff for the rate of sTg decline was 44.75% (sensitivity: 70.0%, specificity: 97.5%, AUC: 0.889). Additionally, a nomogram was developed incorporating sex, age, pre-^{131}I sTg, post-^{131}I sTg, T and N stages, tumour size, and thyroiditis to predict individualized outcomes. This nomogram provides a visual and quantitative method for assessing prognosis and facilitating tailored treatment. ***Conclusion:*** Both pre-^{131}I sTg levels and the rate of sTg decline are valuable early indicators of long-term outcomes in DTC patients, and nomogram analysis enhances clinical decision-making. ***References:*** This research was supported by National Natural Science Foundation of China (Grant Numbers: 81771866) and Hubei Provincial Natural Science Foundation Project (2024AFB633). Zairong Gao, Xiaotian Xia and Jie Tan contributed equally as co-corresponding authors.

EP-0862

Impact of Body Mass Index on Clinical Presentation and Outcomes in Differentiated Thyroid Cancer: A Retrospective Study

Y. Hou[1,2,3], *Y. Zhou*[1,2,3], *X. Xia*[1,2,3];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA,* [2]*Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA,* [3]*Key Laboratory of Biological Targeted Therapy, the Ministry of Education, Wuhan, CHINA.*

Aim/Introduction: Differentiated thyroid cancer (DTC) accounts for 90% of all thyroid malignancies, making it the most prevalent endocrine-related cancer. With the global rise in obesity, which has been identified as a risk factor for various cancers, this study aims to examine the effect of body mass index (BMI) on the clinical effectiveness and outcomes of initial radioactive iodine (^{131}I) treatment in patients with DTC. ***Materials and Methods:*** This retrospective study included 1,272 patients who underwent thyroidectomy followed by radioactive ^{131}I treatment at our hospital. Patients were categorized into four BMI groups: underweight (<18.5 kg/m^2), normal weight (18.5-24.9 kg/m^2), overweight (25-29.9 kg/m^2), and obese (≥30 kg/m^2). Clinical outcomes were evaluated based on the 2015 American Thyroid Association (ATA) guidelines, with a twelve-month follow-up period. ***Results:*** Higher BMI was significantly associated with increased maximum tumor diameter (MD = 0.28 cm [0.08, 0.29]), greater likelihood of extra-thyroidal gland invasion (OR = 1.65 [1.03, 1.98]), and a higher incidence of lymph node extra-nodal invasion (OR = 1.23 [1.22, 1.56]). No significant associations were found between BMI and histologic subtype, bilaterality, multifocality, vascular invasion, or TNM stage. Additionally, obese patients required the most frequent follow-up visits at the end of the twelve-month period. ***Conclusion:*** Elevated BMI is linked to more severe clinical manifestations and more complex treatment requirements in patients with DTC. Maintaining a normal body weight may help reduce the severity of clinical presentations and improve treatment outcomes. These findings underscore the importance of weight management in patients with DTC and suggest avenues for further research into the mechanisms connecting obesity and DTC.

EP-0863

Management of Low-Risk Differentiated Thyroid Carcinomas in Nuclear Medicine: A retrospective study of 280 cases

M. Nacer Khodja, *S. Rahal, S. Meza, M. Medjaher;*
Central Hospital of the Army, Algiers, ALGERIA.

Aim/Introduction: The risk stratification for recurrence of differentiated thyroid carcinomas, as outlined by the 2015 American Thyroid Association (ATA) guidelines, has enabled a therapeutic deescalation, particularly for patients classified as

low-risk for recurrence. ***Materials and Methods:*** This monocentric retrospective study held within the Nuclear Medicine Unit of the Central Military Hospital of Algiers, follows a total of 280 patients, initially classified as low-risk according to the 2015 ATA criteria (pT1bN0/NxMx, pT2N0/NxMx), who after total thyroidectomy, received 1.1 GBq (30 mCi) of iodine-131 after thyrotropin stimulation (with either of the follwoing processes : rhTSH or thyroid hormone withdrawal) for ablation purposes. Thyroglobulin (Tg) and anti-thyroglobulin antibodies (ATg) levels were measured after thyrotropin stimulation, along with a cervical ultrasound, conducted 9 to 12 months post treatment for all patients. ***Results:*** Out of the 280 patients, 265 showed a complete biological response and a normal cervical ultrasound, resulting in a success rate of 94.6%.- A cranial metastasis was identified in one patient.- Four patients presented loco-regional metastasis (metastatic cervical adeonpathies)- Ten patients presented an incomplete biochemical response with a negative cervical ultrasound and responded well to a second course of iodine-131 treatment. The results of our study are consistent with those of the ESTIMABL 1 study (98% remission), which allowed us to avoid overtreatment in more than 97% of patients. Additionally, dose reduction minimizes treatment-related side effects and has a considerable economic and organizational impact. ***Conclusion:*** The use of low-dose iodine 131 (1.1Gbq), demonstrate excellent outcomes, yielding comparable results to higher dose treatment in low-risk differentiated thyroid carcinoma, ensuring optimal patient care, all the while reducing the economic and the organizational burden associated with former protocols. ***References:*** Schlumberger M, Leboulleux S, Catargi B, Deandreis D, Zerdoud S, Bardet S, Rusu D, Godbert Y, Buffet C, Schvartz C, Vera P, Morel O, Benisvy D, Bournaud C, Toubert ME, Kelly A, Benhamou E, Borget I. EP-0864

The anti-thyroglobulin antibody trajectory and risk of structural recurrence in patients with papillary thyroid cancer

H. Wang*, R. Tian;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: To identify longitudinal anti-thyroglobulin antibody (TgAb) trajectories in patients with papillary thyroid cancer (PTC) and to investigate the associations of trajectories with the risk of structural recurrence at two-year follow-up. ***Materials and Methods:*** This retrospective cohort included 4161 patients who had no evidence of structural disease and a stimulated thyroglobulin (s-Tg) of ≤10ng/mL at the initial radioiodine (RAI) treatment. We collected repeated TgAb measurements (before RAI treatment, one-, six- and 12-months after RAI treatment). We described changes of TgAb by plotting median TgAb and percentage of positive TgAb at different time points. Latent class models were used to identify TgAb trajectories, and the optimal number of trajectories was selected by comparing the performance and interpretability of models with different numbers of trajectories. To validate the robustness and generalizability of these trajectories, we randomly divided patients into two validation datasets and identified trajectories in each validation dataset. We estimated associations of TgAb trajectories, TgAb status and history of Hashimoto's thyroiditis (HT), with the risk of recurrence using logistic regression models. All estimates were not adjusted in Model 1 and were additionally adjusted for sociodemographic predictors (Model 2), sociodemographic and clinical predictors (Model 3). ***Results:*** The median age of the 4161 patients was 41 years with a female dominance (72.7%). A total of 63 (1.7 %) patients were identified as having structural recurrence. When plotting the changes in TgAb, we observed a significant downward trend in median TgAb (e.g., from 17 IU/mL before RAI treatment to 13 IU/mL at 12m after RAI treatment) and percentage of positive TgAb status (e.g., from 26.3% before RAI treatment to 9.1% at 12m after RAI treatment). We identified four distinct TgAb trajectories, models' performances were largely comparable, and similar trajectories were identified in two validation datasets. Compared to patients belonging to consistently negative trajectory, patients with other three trajectories had higher risks of recurrence (medium-level descent: odds ratio=3.46 [95%CI=1.56-6.90], high-level descent: 8.04 [1.26-28.78], persistently increasing: 12.11 [5.73-23.75], P for trend<0.001), estimates were largely similar after adjusting for sociodemographic and clinical predictors. TgAb status before and after RAI treatment, history of HT, were also associated with risk of recurrence (odds ratio: 3.05, 2.78 and 2.41). ***Conclusion:*** TgAb trajectories within one year after RAI treatment are associated with risk of recurrence in PTC patients with an s-Tg≤10ng/mL. Our findings call for the integration of TgAb trajectories into risk stratification and surveillance.

EP-0865

Predictive Value of Pre-ablation sTg/TSH Ratio and Lateral Cervical Lymph Node Metastasis Ratio in Initial ^{131}I Treatment Response for Papillary Thyroid Cancer

R. Zhang*, W. Li, Q. Jia, H. Wang, W. Zheng, J. Tan;*
Department of Nuclear Medicine, Tianjin Medical University General Hospital, Tianjin, CHINA.

Aim/Introduction: To identify predictive factors influencing the initial therapeutic response after the first ^{131}I treatment in total thyroidectomy patients with papillary thyroid cancer (PTC), determine critical prognostic biomarkers, and establish a foundation for personalized treatment strategies. ***Materials and Methods:*** This retrospective study analyzed 312 thyroglobulin antibody (TgAb)-negative PTC patients with preoperative thyroid-stimulating hormone (TSH) >30 mIU/L undergoing postoperative ^{131}I therapy. Initial ^{131}I treatment responses were categorized: excellent/indeterminate responses as generally satisfactory (GR), and biochemical/structural incomplete responses as non-satisfactory (n-GR). Multivariate logistic regression was used to evaluate associations between clinicopathological factors (such as age, sex, tumor size, unifocal/multifocal, T and N stages, excised/positive lymph nodes count, ^{131}I doses, etc) and GR. ROC curves were used to determine optimal cutoffs for predictive indicators. ***Results:*** Multivariate analysis showed that the pre-ablation stimulated thyroglobulin /TSH ratio (Pre-sTg/TSH) [odds ratio (OR) = 17.915, p = 0.022] and the lateral cervical lymph node metastasis ratio (lateral cervical/total metastatic nodes) [OR = 1.018, p = 0.024] were independent predictors of GR after the first ^{131}I treatment. The receiver operating characteristic (ROC) curves showed that the optimal cut-off value of Pre-sTg/TSH was 0.135, with an area under the curve (AUC) of 0.949, sensitivity of 89.8%, and specificity of 90.9%. Additionally, the optimal cutoff of the lateral cervical lymph node metastasis ratio was 34.5%, with a sensitivity of 61.2%, specificity of 74.1%, and AUC of 0.669. Moreover, within the overall cohort, the n-GR rate was 10.5% for low/intermediate-risk patients and 40.0% for high-risk cases. Among patients with a Pre-sTg/TSH > 0.135, the n-GR rates for low/intermediate-risk and high-risk patients significantly increased to 57.5% and 75.0% respectively. And for patients with the lateral cervical lymph node metastasis ratio > 34.5%, the n-GR rates escalated to 20.3% (low/intermediate-

risk cases) and 62.5% (high-risk patients). ***Conclusion:*** The Pre-sTg/TSH ratio (cutoff: 0.135) and lateral cervical lymph node metastasis ratio (cutoff: 34.5%) can serve as robust predictors of initial ^{131}I treatment efficacy in PTC. These biomarkers could enhance risk stratification and guide personalized therapeutic decisions.

Multicenter Study of Spanish Therapy Units: Early Side Effects of 131I Therapy

L. Cagua Ruiz[1], *T. Aroui Luquin*[1], *J. Villa-Palacios*[1], *L. Menedez - Muros*[1], *P. Stefan*[2], *A. Piñero Donis*[1], *E. Dominguez-Polanco*[1], *R. Sánchez Sánchez*[1], *M. Muros de Fuentes*[1];
[1]*Servicio Medicina Nuclear Hospital Universitario Virgen de las Nieves, Hospital Universitario Virgen de las Nieves, SPAIN,* [2]*Servicio Medicina Nuclear Hospital Universitario Virgen de las Nieves, Hospital Universitario la Fe, SPAIN.*

Aim/Introduction: To assess the presence of physical and psychological side effects during hospitalization for 131I therapy in metabolic therapy units. ***Materials and Methods:*** A multicenter study was conducted involving 181 patients with differentiated thyroid cancer treated with 131-I . 127 (70.2%) were women, 159 (87.8%) papillary carcinoma, 54 (29.8%) presented lymphatic spread, 34 (18%) had extrathyroidal extension, and 7 (3.8%) had distant metastases. 146 patients (80.66%) received a dose ≥ 100 mCi, and 119 (65.74%) received rhTSH. Upon discharge, patients completed a survey regarding their emotional well-being (Information received about therapy, adequate relationship with staff, fear of therapy, anxiety due to isolation, stress or low mood). Responses were classified as: none, mild, or severe. Physical side effects during hospitalization (neck pain, gastric discomfort, intestinal symptoms, urinary symptoms, and insomnia) were also analyzed and categorized as: none, mild, moderate, or severe. ***Results:*** Most patients reported emotional well-being during hospitalization, indicating they received sufficient information about the therapy (88.95%) and appropriate care from the staff (93.92%). Regarding fear of radioactive therapy, anxiety due to isolation, or sadness/anxiety while in the room, incidence was low, and none to mild in intensity (87.29%, 87.29%, and 84.53%, respectively). The incidence of physical side effects was also low, with most symptoms categorized as none to mild (92.82%, 90.61%, 91.71%, 93.37%, and 85.08%, respectively). The most frequent symptom was insomnia, reported as moderate to severe in 12.15% of patients. ***Conclusion:*** Patients undergoing 131I therapy did not report significant physical or emotional side effects during hospitalization with minimal impact on short-term quality of life.. Physical side effects were generally mild and well tolerated, with insomnia being the most commonly reported moderate to severe symptom.

EP-0867

Multicenter Study of Spanish Therapy Units. II. Late Side Effects of 131I Therapy.

E. Domínguez Polanco[1], *J. Villa-Palacios*[1], *A. Piñeiro Donis*[1], *L. Cagua Ruiz*[1], *C. Mallon Araujo*[2], *R. Sánchez Sánchez*[1], *M. Muros de Fuentes*[1];
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [2]*Hospital Clínico Universitario de Santiago, Santiago, SPAIN.*

Aim/Introduction: Assessment of the presence of late side effects following 131I treatment for differentiated thyroid cancer. ***Materials and Methods:*** Multicenter study of 181 patients with differentiated thyroid cancer treated with 131I between 2020 and 2023. 127 (70.2%) were female, 159 (87.8%) were papillary thyroid tumors, 54 (29.8%) with lymphatic extension, 34 (18%) with extrathyroidal extension, and 7 (3.8%) with distant metastases. 146 patients (80.66%) received doses ≥ 100 mCi, and 119 (65.74%) received rhTSH. Patients completed a telephone survey one month and six months after discharge. The presence of physical side effects (asthenia, cervical redness, dyspepsia, oral aphthae, conjunctivitis, cervical pain, xerostomy, dysgeusia, and menstrual alterations) were assessed and categorized as none, mild, moderate, and severe. ***Results:*** One month after therapy, patients reported predominantly mild side effects. When specifically asked about cervical redness, dyspepsia, oral aphthae, conjunctivitis, cervical pain, and xerostomy, the majority were of mild intensity (92.82%, 91.16%, 92.82%, 90.61%, 86.74%, and 83.53%, respectively). The most frequent symptoms were menstrual alterations (30.55% moderate-severe), asthenia (28.73% moderate-severe), and dysgeusia (21.1% moderate-severe). Six months after therapy, patients reported predominantly mild side effects. When specifically asked about dyspepsia, oral aphthae, conjunctivitis, cervical pain, and xerostomy, the majority reported mild intensity (94.26%, 98.28%, 98.85%, 96.55%, and 92.53%, respectively). Among the most frequent symptoms, menstrual alterations persisted (33.33% moderate-severe), with a decrease in asthenia (11% moderate-severe) and dysgeusia (3.44% moderate-severe). ***Conclusion:*** Asthenia, dysgeusia and menstrual alterations were the most frequently reported side effects following 131I therapy.

EP-0868

Long-term clinical outcome of patients with differentiated thyroid cancer and raised antithyroglobulin antibody levels: a retrospective study

H. Shim*, M. Kim;*
Inje University, Haeundae Paik Hospital, Busan, KOREA, REPUBLIC OF

Aim/Introduction: Thyroglobulin (Tg) is used as a tumor marker for differentiated thyroid cancer (DTC). However, in the presence of antithyroglobulin antibody (TgAb), Tg can be a false negative. This study aims to track the changes of stimulated TgAb before radioiodine therapy (RIT) and at 1st follow up (F/U) in patients undergoing RIT after total thyroidectomy and to determine whether there is anatomic recurrence. ***Materials and Methods:*** We retrospectively analyzed 251 DTC patients (228 females, 55.37 ± 11.60 years vs 23 males, 55.22 ± 15.26 years) with Tg < 1 ng/ml and TgAb >10 U/ml before 1st RIT after total thyroidectomy. We categorized the 251 patients with serum stimulated TgAb concentrations 230.36 ± 31.44 days after RIT into five groups: (1) TgAb change <50% (n=77), (2) increase from <60 to >60 (de novo appearance) (n=5), (3) decrease from >60 to <60 (negative conversion) (n=12), (4) increase >50% (n=15), and (5) decrease >50% (n=142). ***Results:*** The dose of the 1st RIT was 113 ± 39.69 mCi. We compared stable or >50% increase in TgAb ((1)+(2)+(4), n=97) with decrease in TgAb ((3)+(5), n=154), 128-4694 days after RIT (mean 304.55 days). TgAb decreases to <10 U/ml were 17/97 (17.5%) vs. 49/154 (31.8%); decreases to <60 U/ml were 28/97 (35.9%) vs. 78/154 (50.6%); increases to >60 U/ml but <300 U/ml were 41/97 (42.3%) vs. 24/154 (15.6%); and increases to >300 U/ml were 11/97 (11.4%) vs. 3/142 (2.1%), respectively. Long-term follow-up was performed after RIT. When TgAb was stable or increased, 53.6% (52/97) of patients had an increase in TgAb above 60 U/ml, and when TgAb decreased, 82.5% (127/154) of patients had normalization of TgAb below 60 U/ml. Of the total 251 patients, 2 patients underwent reoperation after RIT due to persistently high TgAb levels and recurrence of neck lymph nodes (LNs). One patient had neck LNs remaining in the I-131 post-therapy whole body scan after RIT, so reoperation was performed 8 months later, and TgAb normalized. Among patients who represented a de novo appearance in TgAb, 2 cases showed negative conversion and 3 cases showed a sustained elevation above 60 U/ml, therefore it seems necessary to conduct research on more patients. ***Conclusion:*** Persistent TgAb increases require careful F/U for post-RIT TgAb changes and subsequent structural recurrence. Further studies involving larger cohorts are warranted to validate these findings.

EP-0869

Immunological Alterations Following Thyroidectomy in Differentiated Thyroid Carcinoma Patients: A Comparative Study

W. Zhang, *H. Liu, S. Li, P. Wang;*
Department of Nuclear Medicine, The First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is the most common malignant tumor in the endocrine system, and the most common treatment option forindividuals with DTC is surgical resection. The effects of subtotal/total thyroidectomy on immune activation and suppression of the tumor microenvironment remain unknown. This study aims to evaluate the effects of these treatments on the immune function in patients with DTC. ***Materials and Methods:*** Total 103 patients as well as 103 age- and gender- matched healthy controls (HC) were recruited in this study. Peripheral blood samples were collected from all patients and both thyroid and immune function tests were completed for each patient on pre-surgery and 30 days post-surgery via modified flow cytometry. The levels of lymphocyte subsets in different groups were compared, including total lymphocytes, T cells, B cells, NK cells, $CD4^+$ T cells and $CD8^+$ T cells. Healthy controls were selected using propensity score matching (PSM). Comparisons of continuous variables between groups were conducted using t-tests or Mann-Whitney U tests, while categorical data was performed by chi-square tests. Statistical significance threshold set at $P<0.05$. ***Results:*** DTC patients exhibited a significantly higher percentage and absolute count of $CD4^+$ T cells compared to HC group, whereas the percentages of NK cells and $CD8^+$ T cells were significantly lower. Notably, multiple lymphocyte subsets in patients post-surgery, except for B cells, showed a significant increase in absolute numbers compared to preoperative levels, while the $CD4^+/CD8^+$ ratio significantly decreased. Interestingly, we observed that the proportions of several lymphocyte subsets in post-operative patients were significantly lower than those in healthy individuals. ***Conclusion:*** This study reveals that preoperative DTC patients display a specific immune imbalance. The absolute counts of lymphocyte subsets significantly increased after surgery, yet this exacerbated the imbalance in their proportions. These findings suggest that the postoperative immune reconstitution may be biased, potentially linked to an overexpansion of T cells inhibiting the functionality of other subsets. The incomplete recovery of immune function post-surgery indicates the necessity for long-term monitoring of immune homeostasis in DTC patients.

EP-0870

Predictors of Hypothyroidism Requiring Levothyroxine Substitution after Radioiodine Therapy in Unifocal Thyroid Autonomy

K. Klimek[1,2], *C. Happel*[2], *F. Grünwald*[2], *R. Werner*[1], *D. Groener*[2];
[1]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Goethe University Frankfurt, University Hospital, Department of Nuclear Medicine, Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.*

Aim/Introduction: The purpose of this study was to identify pre-therapeutic and therapy-related factors that predict the risk of hypothyroidism requiring levothyroxine substitution following radioiodine therapy (RIT) in patients with unifocal thyroid autonomy. ***Materials and Methods:*** In a retrospective analysis of 228 patients (mean age 60.0 ± 14.6 years; median follow-up 461 days) who underwent RIT for unifocal thyroid autonomy, we investigated the ratio of target volume to total thyroid volume, the pre-therapeutic suppressed thyroid-stimulating hormone (TSH) level and the absorbed dose delivered to the autonomous adenoma. The mean ratio of target volume to total thyroid volume was 0.3258 ± 0.1875, the mean pre-therapeutic suppressed TSH concentration was 0.08 ± 0.07 mIU/L and the mean absorbed dose to the adenoma was 314.5 ± 158.7 Gy. Multiple logistic regression was employed to assess the influence of these variables on the subsequent need for levothyroxine therapy. ***Results:*** During the late follow-up interval, 26.8 % of patients developed hypothyroidism requiring levothyroxine. The ratio of target volume to total thyroid volume emerged as a strong predictor of post-therapeutic substitution ($p < 0.001$). A higher absorbed dose was also associated with an increased substitution risk ($p = 0.009$). In contrast, the pre-therapeutic suppressed TSH level did not significantly influence the risk of levothyroxine requirement ($p = 0.811$). ***Conclusion:*** Both the ratio of target volume to total thyroid volume and the absorbed dose to the autonomous adenoma are independent predictors of hypothyroidism necessitating levothyroxine substitution after radioiodine therapy in unifocal thyroid autonomy. These findings underscore the importance of meticulous pre-therapeutic dose planning to enable a more precise assessment of individual risk for post-therapeutic hypothyroidism.

EP-0871

Analysis And Optimization Of Radioiodine Therapy Based On The Study Of Radioiodine-131 Biokinetics Data

G. Grushka[1,2], *A. Savchenko*[3], *V. Bobrova*[4];
[1]*Kharkiv National Medical University, Kharkiv, UKRAINE,* [2]*SO «Grigoriev Institute for Medical Radiology and Oncology of the National Academy of Medical Sciences of Ukraine», Kharkiv, UKRAINE,* [3]*V. N. Karazin Kharkiv National University, Kharkiv, UKRAINE,* [4]*SO «Grigoriev Institute for Medical Radiology and Oncology of the National Academy of Medical Sciences of Ukraine», Kharkiv, UKRAINE.*

Aim/Introduction: Search of the optimum scheme of radioiodine therapy (RAI) with the highest clinical effect and minimum exposure of healthy tissues and organs is one of leading problems of planning and carrying out RAI. Aim: to define indicators which should be considered at RAI planning and to estimate the exposure load on the organism of the patient at carrying out RAI. ***Materials and Methods:*** The efficiency analysis of RAI was performed in 143 patients with differentiated thyroid cancer (DTC). All patients were divided into 2 groups: group 1 (G1) - 51 patients with the size of tumor pT1; group 2 (G2) - 92 patients with pT2. Activity of radioiodine for the first course RAI was 1110 - 4810 MBq. In 95 (66.4 %) patients, the thyroid cancer ablation was not reached; and the courses of RAI was proceeded. The absorbed doses in the thyroid gland, body, blood and red bone marrow were estimated using MIRD-method, the effective period of semi excretion of iodine-131 in the patient (T_{ef}) for the remnants of the thyroid gland and body of the patient, the maximum value of accumulation of radioactive iodine in the thyroid rests (U_{max}) were estimated. ***Results:*** Therapeutic effect of RAI for radically operated patients G1 was produced by absorbed dose on the whole body 0,148 Gy and in group G2 - 0,154 Gy. Average ablative activity thus varied from 5402 to 11470 MBq in both groups. The average total absorbed doses on the body for all courses of radiotherapy in patients of the both groups fluctuated within 0,13-0,21 Gy, and on the red bone marrow - 1,68-2,70 Gy. ***Conclusion:*** The study of radioiodine biokinetics serves to optimize the treatment of DTC and protect healthy tissues from irradiation. To solve the problem of individual dosimetric planning, it is advisable to determine T_{ef} and U_{max}.

EP-0872

Oncocytic Thyroid Carcinoma on the Rise: Divergent Evolution and Response to Radioiodine Treatment

M. Zambrana-Delgadillo, *M. Piñero Fernandez- Reyes, M. Cardoso-Rodríguez, M. Jerez-Jaimes, A. Lara-Hernández, J. Rodríguez-Rubio Corona, C. Quintana-Bolaño, Y. Santaella-Guardiola, F. Partida-Palma, M. Gutiérrez-Amares, M. Pajares-Vinardell;*
Hospital Universitario Puerta del Mar, Cadiz, SPAIN.

Aim/Introduction: Oncocytic Thyroid Carcinoma (OTC), recognized as a distinct entity from Follicular Thyroid Carcinoma (FTC) since 2017, continues to spark debate regarding its clinical progression, response to radioiodine (RAI) therapy, and prognosis in comparison to FTC. This study compares both subtypes, analyzing their histopathological profiles, post-RAI evolution, and factors associated with better therapeutic response. ***Materials and Methods:*** A total of 51 patients with FTC (n=33) and OTC (n=18) treated with RAI between 2013 and 2023 were included, with a minimum follow-up of 2 years until April 2025. Clinical data (age, sex), histopathological features (TNM staging, capsular/vascular invasion), date of diagnosis, follow-up duration, and treatment response based on 2015 ATA criteria were collected.Statistical analysis included Student's t-test or Mann-Whitney U, chi-square test, odds ratio, and binary logistic regression. Recurrence-free survival (RFS) was evaluated at 5 and 10 years. Oncocytic variant cases were reclassified as OTC based on WHO 2017 guidelines. ***Results:*** Mean age was similar (55 years in FTC vs. 57 in OTC), with a female predominance (82% vs. 61%). FTC had a longer follow-up duration (median 8.4 years vs. 6.1 years; p=0.055). Most patients were diagnosed at stage I (75.8% FTC, 61.1% OTC), with no significant association with histological type (p=0.47).Excellent response rates were similar between groups (51.5% FTC vs. 55.6% OTC; OR=0.85). Capsular invasion was significantly associated with better response (OR=0.0; p=0.023). However, in the multivariate model, no variable showed a significant association (global p=0.581); capsular invasion maintained the strongest effect size (OR=2.32; p=0.21).RAI doses ≥150 mCi were associated with capsular and vascular invasion, though not significantly, suggesting a possible therapeutic trend in these cases.Five- and ten-year RFS were higher in FTC (82% and 75%) than in OTC (61.5% and 50%), with no statistically significant differences. One non-cancer-related death occurred in a patient with excellent response. ***Conclusion:*** OTC showed a significantly shorter follow-up period and a trend toward earlier-stage diagnosis, suggesting evolving detection patterns over the last decade. Its 10-year RFS was lower. Capsular invasion was associated with better response, even after multivariate adjustment. These findings highlight the importance of prolonged follow-up and detailed histopathological assessment in managing differentiated thyroid cancer.

Recurrent differentiated thyroid cancer: predictive factors and outcome

J. Mihailovic[1], *I. Starcevic*[1], *J. Roganovic*[2];
[1]*Faculty of Medicine University of Novi Sad, Novi Sad,* [2]*Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA.*

Aim/Introduction: During the follow-up, some patients with differentiated thyroid carcinoma (DTC) may develop recurrent disease. Objective: To evaluate the recurrence rate, predictive factors, and outcomes in DTC patients over an extended follow-up period. ***Materials and Methods:*** A total of 765 patients with DTC treated from 2007 to 2022 were retrospectively analyzed. Tumor staging included 488 (pT1), 125 (pT2), 133 (pT3), and 19 (pT4) patients. During follow-up, 61 patients (7.97%) experienced recurrence. All were treated surgically, with some receiving additional I-131 therapy and/or external beam radiation. Recurrence probabilities and predictive factors were assessed using the Kaplan-Meier method and log-rank test (SPSS v20), with significance set at p<0.05. ***Results:*** Of the 61 patients with recurrence, 28 (45.9%) were female and 33 (54.1%) male; 22 (36.1%) were ≥55 years old, and 39 (63.9%) were <55. Histology showed 57 (93.4%) papillary, 2 (3.3%) follicular, and 2 (3.3%) Hürthle cell carcinoma cases. Median follow-up was 7.4 years (range 1.1-27.4), with a median time to recurrence of 5.25 years. Recurrence probabilities were 8%, 11%, and 14% at 5, 10, and 15 years, respectively. Gender was the only significant predictor of recurrence (p=0.017), while age and histological type were not (p=0.980 and p=0.441). At the last follow-up, 54 patients (88.5%) were alive, and 7 (11.5%) had died due to disease-related causes. ***Conclusion:*** Recurrence in DTC can occur even many years after initial treatment, highlighting the importance of long-term follow-up. Early detection and timely treatment of recurrence offer a high chance of successful management. ***References:*** 1. Palme CE, Waseem Z, S. Raza N, Eski S, Walfish P, et al. Quantitative Assessment of Salivary Gland Volumetric and Metabolic Changes Following Radioiodine Therapy in Differentiated Thyroid Carcinoma

S. Watanabe[1,2], *K. Hirata*[1,2], *H. Endo*[1], *J. Takenaka*[1,2,3], *N. Wakabayashi*[1,2], *R. Kimura*[1,4], *H. Koga*[1,4], *K. Kudo*[1,4];
[1]*Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN,* [2]*Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN,* [3]*Comprehensive Heart Failure Center, University Hospital Würzburg, Würzburg, GERMANY,* [4]*Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.*

Aim/Introduction: Salivary gland disorders are well-known side effects of radioactive iodine therapy (RAIT) for differentiated thyroid carcinoma, but there is limited research on imaging changes in salivary glands due to RAIT. ***Materials and Methods:*** From April 2020 to April 2025, we retrospectively reviewed cases of patients undergoing initial RAIT at our hospital. We included cases where FDG-PET/CT scans were performed using the same scanner before treatment and at least 3 months after treatment. RAIT was performed after 3 weeks of a low-iodine diet, more than 3 weeks of levothyroxine withdrawal, or administration of rhTSH. I-131 doses were fixed at 100 mCi or 150 mCi. Salivary glands were extracted on CT using TotalSegmentator for volume measurement, and changes in SUVmean on FDG-PET were evaluated. Acute and chronic salivary gland symptoms and visual assessments of uptake in post-therapy scintigraphy were compared for imaging changes. ***Results:*** A total of 30 cases (24 females) and 41 treatments were analysed. Mean age was 52.8±16.4 years, with histological types including papillary carcinoma (n=25), follicular carcinoma (n=3), and poorly differentiated carcinoma (n=2). Treatment purposes were adjuvant therapy (n=3) and treatment for metastasis (n=38). Levothyroxine withdrawal was performed in 37 treatments, rhTSH in 4 treatments, with 21 cases receiving 1 treatment, 7 cases 2 treatments, and 2 cases 3 treatments within the study period. Salivary gland symptoms appeared acutely in 13 treatments and chronically in 18 treatments. Following treatment, the volume of the salivary glands decreased significantly, with the parotid gland and submandibular gland measuring 90.1 ± 26.7% (p<0.001) and 94.2 ± 19.6% (p=0.032) of their pre-treatment volumes, respectively. The post-treatment SUVmean values were 103.1 ± 20.5% (p=0.579) and 101.6 ± 23.0% (p=0.387) of the pre-treatment values for the parotid and submandibular glands, respectively,

with no significant changes observed. There were no significant differences in volume changes based on acute symptoms, age, sex, histological type, or gland type, but significant volume reduction was observed I-131 uptake in post-Tx-scintigraphy (p=0.036), chronic symptoms (p<0.001), neck dissection (p=0.008), and levothyroxine withdrawal therapy (p=0.015). Clinical and imaging factors did not show significant differences in SUVmean, but subsequent treatments were associated with significant glandular volume reduction (p=0.032) and increased SUVmean (p=0.005). ***Conclusion:*** RAIT may result in salivary gland volume reduction without significant changes in SUVmean, especially in glands with scintigraphic radioiodine accumulation, post-neck dissection regions, and cases undergoing levothyroxine withdrawal therapy, suggesting a risk for significant salivary gland disfunction following RAIT.

EP-0875

Gender impact in Radioactive Iodine (^{131}I) clearance in Thyroid Cancer treatment

J. Koutsikos, *G. Thiveos, T. Petropoulos, I. Papantoniou, S. Giourgouli, A. Kokkini - Paschou, E. Skoura, I. Datseris; Henry Dunant Hospital Center, Athens, GREECE.*

Aim/Introduction: ^{131}I administration for thyroid disease treatment has been proven successful over several decades. The physical characteristics of ^{131}I, mostly half-life and photon energy, demand special care regarding radiation protection. Numerous efforts have been made to determine effective half-life (Teff) of ^{131}I and to estimate in advance ^{131}I clearance based on specific patient characteristics. Our work aims to estimate Teff based on exposure rate measurements and determine whether Teff is gender dependent. ***Materials and Methods:*** Patients treated with radioiodine in our Nuclear Medicine Department, for well-differentiated Thyroid Cancer, following total thyroidectomy, were included. Exposure rate measurements at 1 meter were made 24 and 48 hrs post administration using a calibrated survey meter. These measurements were converted to residual activity values (RA) and were plotted as percentage of the administered activities against time. The Teff was computed from exponential line fittings on the above plots. A gender based analysis was performed. Exclusion criteria were: age <18 y.o., a repeated treatment and treatment for metastatic disease. ***Results:*** 280 patients (191 females and 89 males, mean age 44.7+/-13.3 y.o.) were included in our study. The results are summarized in attached table. While Teff and average 24 and 48hrs RA values differ (lower for females), statistically significant differences were revealed in 48hr RA between males-females (p=0.027). ***Conclusion:*** Our Teff estimation for the first 48hrs is consistent with previous studies. The lower Teff and faster activity clearance observed in females might be attributed to better compliance with instructions or differences in hormonal profiles. These result in a better understanding of ^{131}I clearance and RIT patient management. However, they should be validated with more patients and additional parameters, such as glomerular filtration rates and residual thyroid tissue, among others. ***References:*** 1. Phase 1 dose-escalation study on astatine-211 labelled meta-astatobenzylguanidine ([^{211}At]mABG) for treatment of recurrent or refractory high-risk neuroblastoma: study design and rationale

L. Teles[1], *B. van der Wildt*[1,2], *M. van Noesel*[1,3], *R. van Rooij*[1,2], *A. Poot*[1,2], *A. Braat*[1,2,4]; [1]*Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS,* [2]*University Medical Center Utrecht / Wilhelmina Children's Hospital, Utrecht, NETHERLANDS,* [3]*Division Imaging and Cancer, University Medical Center Utrecht, Utrecht, NETHERLANDS,* [4]*Netherlands Cancer Institute, Amsterdam, NETHERLANDS.*

Aim/Introduction: The cure rate of high-risk neuroblastoma (NBL) is poor (<50%). Norepinephrine transporter (NET) positive patients with recurrent and refractory disease can be treated with iodine-131 labelled metaiodobenzylguanidine ([^{131}I]mIBG). Although around 30% of patients respond to [^{131}I]mIBG, its implementation has not improved survival outcomes.[1] [^{131}I]mIBG therapy is limited by the poor properties of the radionuclide iodine-131 (^{131}I). Predominantly, its high-energy gamma emission poses challenges in clinical practice. This study investigates an alternative therapy: meta-astatobenzylguanidine ([^{211}At]mABG). This compound includes astatine-211 (^{211}At), an alpha-particle emitter with more favourable properties. It combines a low tissue penetration with a high linear energy transfer, increasing the tumoricidal potential and decreasing damage to healthy tissue. Moreover, the absence of high-energy gamma radiation means patient isolation is unnecessary. A phase 1 study in adults with [^{211}At]mABG is ongoing in Japan.[2] ***Materials and Methods:*** This single-centre, phase 1 dose-escalation and dose-finding study has a classical 3 plus 3 design. Patients with high-risk NBL, refractory to first-line chemotherapy, or with recurrent disease after complete response on previous molecular imaging are eligible for this study. Based on preclinical data, the starting dose is 1.3 MBq/kg. Subsequent doses are 2.6 and 5.0 MBq/kg. Imaging with fluorine-18 labelled meta-iodobenzylguanidine ([^{18}F]mFBG) positron emission tomography (PET/CT) will be acquired at baseline and repeated throughout follow-up to evaluate preliminary response. Urine catecholamine biomarkers will also be assessed. ***Results:*** Introduction of alpha-emitting nuclear treatment in children requires a technical pre-phase. We initiated the local production of [^{211}At]mABG for the duration of this study. The phase 1 clinical trial will be aimed at determining the required phase 2 dose (RP2D) for future phase 2 studies. The study will also determine the maximum tolerable (cumulative) dose. ***Conclusion:*** Recruitment is expected to begin in 2026, and international patients can be considered. This study will provide the first clinical data on the safety and feasibility of [^{211}At]mABG therapy for patients with recurrent or refractory high-risk NBL and may lead to a more effective and less burdensome therapeutic intervention. ***References:*** 1. Efficacy and safety of Lu177-EDTMP therapy for bone pain palliation in cancer patients with multiple skeletal metastasis

K. Vidhya, *M. Negi, V. K. Saini, D. Sundriyal, M. Gupta, F. Huda, S. Sinha, V. K. Dhingra;*
AIIMS, Rishikesh, Rishikesh, INDIA.

Aim/Introduction: Metastatic bone pain (MBP) is a common and debilitating complication in patients with advanced cancers, significantly impairing their quality of life. Conventional treatments such as analgesics and external beam radiotherapy often provide limited and short-term relief, especially in patients with widespread skeletal metastases. Lutetium-177 ethylenediamine tetramethylene phosphonate (Lu-177 EDTMP) is a bone-seeking radiopharmaceutical that delivers targeted beta radiation to metastatic lesions, offering a promising alternative for effective and sustained palliation of bone pain with minimal systemic toxicity.This study aimed to evaluate the efficacy and safety of Lu-177 EDTMP therapy for bone pain palliation in cancer patients with multiple skeletal metastases. ***Materials and Methods:*** Single-arm experimental study in patients with multiple bone metastases and MBP. Baseline/follow-up assessments included pain, mobility (Parker), KPS, and toxicity over 3 months post Lu-177 EDTMP therapy. ***Results:*** 12 patients were included in this study (6 males and 6 females) with majority being carcinoma breast (n=7) and prostate (n=3) diagnosed patients, along with a patient with lung and another one with dual carcinoma- carcinoma larynx + carcinoma prostate were also included. The initial mean pain score of 8.3 reduced to 5.0 at 2 weeks and 4.2 at 1 month and 4.0 at 2 months, indicating a strong initial response to treatment before slightly increasing at 3 months. Hence, all patients experienced a significant reduction in pain scores, demonstrating the effectiveness of the treatment. Karnofsky Performance Scores (KPS) show initial improvements in patient functionality, particularly in the first month, correlating to reduced pain scores. However, variability in scores indicates differing individual responses to treatment. Regular monitoring of KPS and pain levels is crucial for optimizing patient care and adjusting treatment strategies. Mobility scores increased from 3.08, 4.58, 5.33 and 5.58 at baseline, 2wks, 1 month and 3 months (improvement). One patient experienced grade 4 adverse effects (anemia, neutropenia, thrombocytopenia), managed with transfusions and GM-CSF, resolving to grade 1 in 2 weeks. Few of the patients experienced grade 2/3 toxicity but majority showed no significant toxicities to the therapy and patients were found to tolerate the therapy well. ***Conclusion:*** Lu-177 EDTMP is a safe, effective, and cost-effective therapy for metastatic bone pain, offering sustained pain relief, improved mobility, and better quality of life with minimal side effects. It is particularly valuable in resource-limited settings, serving as a promising alternative to conventional treatments for managing metastatic bone pain.

EP-0878

Preliminary Evaluation of ^{225}Ac/^{177}Lu-DOTATATE PRRT in Advanced Meningiomas: Efficacy, Dosimetry, and Imaging Insights

M. Assadi[1], *R. Nemati*[2], *E. Jafari*[1], *N. Jokar*[1], *M. Peer-Firozjaei*[3], *S. Rekabpour*[4], *M. Khazaei*[5];
[1]*The Persian Gulf Nuclear Medicine Research Center, Department of Nuclear Medicine, Molecular Imaging, and Theranostics, Bushehr Medical University Hospital, School of Medicine, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Neurology, Bushehr Medical University Hospital, School of Medicine, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [3]*Student Research Committee, Babol University of Medical Sciences, Babol, IRAN, ISLAMIC REPUBLIC OF,* [4]*Department of Oncology, Salman Farsi Hospital, Bushehr, IRAN, ISLAMIC REPUBLIC OF,* [5]*Department of Radiology, Bushehr Medical University Hospital, School of Medicine, Bushehr University of Medical Sciences, Bushehr, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Somatostatin receptor (SSTR)-targeted peptide receptor radionuclide therapy (PRRT) represents a promising therapeutic option for meningiomas. To date, the therapeutic potential of α-emitters in this setting remains less explored. This study presents clinical outcomes of meningioma patients treated with ^{225}Ac-DOTATATE and ^{177}Lu-DOTATATE, highlighting their role in expanding PRRT options. ***Materials and Methods:*** Six patients with inoperable or refractory meningiomas, all with intense 68Ga-DOTATATE PET/CT uptake, received 225Ac-DOTATATE (100kBq/kg) and/or 177Lu-DOTATATE (3.7 GBq). The primary endpoint was clinical response after each PRRT cycle and PET response based on follow-up 68Ga-DOTATATE PET/CT after the last cycle. The secondary endpoint was improvement in quality of life (QoL), assessed using ECOG performance status scores. Additionally, dosimetric analyses were performed. ***Results:*** The study included six patients which 5 them had at least 2 lesions, with a maximum of 6 lesions. A total of 26 PRRT cycles were administered: 13 with 177Lu-DOTATATE and 13 with 225Ac-DOTATATE. Clinical responses were complete remission (n=1), partial remission (n=2), disease stability (n=2), and disease progression (n=1), with one patient dying after eight months. Follow-up 68Ga-DOTATATE PET/CT showed partial remission (n=3), disease stability (n=2), and disease progression (n=1). ECOG scores showed no significant change pre- and post-treatment, except for one patient who improved from 3 to 1. Median follow-up time was 13 months (range: 8-16). Quantitative volumetric parameters showed : median ΔSUVmax: 31.73 (range: -44.89 to 60.28), median ΔSRE-TV: 8.16 (range: -18.86 to 49.47), median ΔTL-SRE: 42.28 (range: -31.93 to 68). Dosimetric evaluation revealed considerable heterogeneity in absorbed dose across individual lesions, particularly in multifocal cases. A high-uptake lesion (SUV = 158) received an estimated absorbed dose of 2.37 Gy/GBq with ^{177}Lu-DOTATATE and 3.36 Gy/MBq with ^{225}Ac-DOTATATE—values comparable to those reported for neuroendocrine tumors. Microdistribution analysis demonstrated strong spatial overlap between alpha and beta emitters in the hottest lesion, supporting the feasibility of combined or sequential use in precision-targeted PRRT. Additionally, in four lesions,68Ga-FAPI showed consistently lower tracer uptake compared to 68Ga-DOTATATE**.** ***Conclusion:*** These preliminary results suggest that PRRT with 225Ac-DOTATATE and 177Lu-DOTATATE may have positive effects in patients with advanced meningioma. This novel approach holds promise for optimizing personalized, lesion-specific treatment strategies for patients with both unifocal and multifocal meningiomas, particularly in cases resistant to conventional therapies—advancing the principles of precision medicine. Further studies are recommended to validate these findings, refine theranostic strategies, and broaden available treatment options.

EP-0879

Peptide Receptor Radionuclide Therapy with [^{177}Lu]Lu-DOTATATE in Progressive Refractory Meningiomas: A Single-Centre Retrospective Analysis

L. Degryse[1], *L. Teles*[2], *S. De Vleeschouwer*[1], *L. Boeckxstaens*[1], *S. Jentjens*[3], *M. Lambrecht*[1], *J. Daisne*[4], *K. Van Laere*[1], *P. Clement*[1], *K. Goffin*[1], *C. M. Deroose*[1];
[1]*University Hospitals Leuven, Leuven, BELGIUM,* [2]*Princess Máxima Center for Pediatric Oncology, Utrecht, NETHERLANDS,* [3]*Maastricht University Medical Center, Maastricht, NETHERLANDS,* [4]*ZAS, Antwerp, BELGIUM.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT), targeting the somatostatin receptor subtype 2 (SSTR2), has emerged as a promising salvage therapy for progressive meningiomas that have exhausted both surgical and external beam radiotherapeutic (EBRT) interventions [1,2]. Encouraging disease-control rates (DCR) of ~ 63% upon termination of PRRT were reported in a meta-analysis of six small retrospective studies (5-34 patients/study) [3], corroborated by a recent retrospective

study by Severi et al. (DCR 57% at the end of PRRT, median progression-free survival (PFS) 16 months) [4]. We retrospectively analysed outcomes of meningioma patients treated with PRRT at our institution. ***Materials and Methods:*** All meningioma patients treated with [^{177}Lu]LuDOTATATE from June 2016 to March 2024 were identified from the institutional PRRT database. Demographics, tumour characteristics, prior treatments, and clinical outcomes were retrospectively extracted from medical records. ***Results:*** Twelve meningioma patients (mean age 61.2 years, seven male) received PRRT, of whom 3 had WHO grade 1 meningiomas (25%), 8 had WHO grade 2 (67%) and one patient had histopathological uncertainty between grades 2 and 3. Multifocal disease was present in 6 patients (50%). Baseline tumour volume on SSTR PET/CT averaged 101.7 cm^3 (range 14-411) with mean SUV_{max} of 17.9 (range 7.5-31.5) and SUV_{mean} of 5.9 (range 3.6-8.4). Eleven patients (92 %) had undergone ≥2 resections and EBRT. Eight patients (67 %) completed 4 planned PRRT cycles (7.4 GBq per cycle), while four patients discontinued early due to clinical decline (n = 2; after cycle 1 and 3) or meningioma progression (n = 2; both after cycle 2). The first MRI after completion of PRRT (on average after 30 days, range 10-60) demonstrated a DCR of 50% (6/12) in the entire cohort. Median PFS was 8 months, with 4 of 12 patients (33%) achieving a PFS of ≥12 months. Median overall survival was 20 months (range 3-89 months), with 3 patients still being alive at data censoring. Five patients received additional treatments, including bevacizumab, surgical re-resection, and/or re-irradiation. ***Conclusion:*** PRRT with [^{177}Lu]LuDOTATATE demonstrated clinically meaningful disease stabilization in heavily pretreated meningioma patients. Its therapeutic efficacy is currently being prospectively validated in the ongoing EORTC LUMEN1 phase II trial. While our findings support the role of [^{177}Lu]LuDOTATATE in disease stabilization, future directions such as α-emitting radioligands ([^{225}Ac]AcDOTATATE), high-affinity receptor antagonists, and intra-arterial delivery of PRRT are under investigation and may further improve therapeutic outcomes. ***References:*** 1.Ahmadi Bidakhvidi N, Cancers.2021;14(1):129 2.Albert NL, EJNMMI.2024;51(12):3662-3679 3.Mirian C, JNM.2021;62(4):507-5134.Severi S, JNM.202 4;65(9):1409-1415.

Assessment of 177Lu-PSMA-617 Retention in Inoperable/ heavily pretreated Pancreatic adenocarcinoma: Implication for Theranostic Feasibility

G. B. Priyanka*, N. A. Damle, A. N. Singh, K. Kuradia, S. Mishra, S. J. Bharati, R. Yadav, M. Tripathi, S. A. Shamim, C. Ganapathy, A. Choudhary, M. Aishwarya;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: PSMA PET/CT has demonstrated tracer uptake in pancreatic adenocarcinoma previously, primarily through tumor-associated neovasculature. This raises the question of whether PSMA-targeted radioligand therapy (RLT) using 177Lu-PSMA-617 has therapeutic potential in this malignancy. ***Materials and Methods:*** 5 Patients with inoperable or heavily pretreated pancreatic adenocarcinoma who demonstrated PSMA uptake on 68Ga-PSMA-11 PET/CT underwent serial imaging post 5-7mCi of 177Lu-PSMA-617. Whole-body planar and SPECT/CT imaging were performed at 30minutes (pre void, post void), 24 hours and upto 7 days post-injection(at least 3 time points) to evaluate in vivo tracer retention. ***Results:*** Despite moderate to high PSMA expression on diagnostic PET/CT (more than or equal to liver), serial planar retention scans showed negligible 177Lu-PSMA-617 retention in primary, nodal as well as metastatic tumour sites. There was significant radiotracer accumulation in early images in one patient, that washed out at 24 hrs while rest of the patients showed insignificant uptake at all time points. ***Conclusion:*** These findings reveal a critical limitation in applying 177Lu-PSMA-617 therapy to inoperable or heavily pretreated pancreatic adenocarcinoma, despite promising PET imaging results. The absence of retention implies a lack of theranostic efficacy, likely due to PSMA localization in the neovasculature without sufficient internalization or residence time to enable targeted radiotherapy. This highlights the need to differentiate between imaging results and therapeutic translatability when evaluating novel applications of PSMA-based RLT outside of prostate cancer.

EP-0881

FAP-directed Radiopharmaceutical Therapy in metastatic gastrointestinal carcinoma as rescue therapy after failure of conventional treatments: A retrospective analysis on safety, efficacy and survival

E. Perrone[1]*, K. Ghai*[2]*, T. Parkar*[2]*, A. Eismant*[2]*, R. Moretti*[3]*, L. Greifenstein*[2]*, R. P. Baum*[2]*;*
[1]Nuclear Medicine Unit, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, ITALY, [2]CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY, [3]Unità della Fisica per le Scienze della Vita, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, ITALY.

Aim/Introduction: Gastrointestinal carcinoma encompasses a group of common tumours characterized by high morbidity and mortality. In metastatic cases resistant to conventional treatments, fibroblast activation protein (FAP)-directed Radiopharmaceutical Therapy (FRT) using α- or β-emitting nuclides targets the FAP-expressing cancer-associated fibroblasts present in tumour microenvironment. We studied safety, efficacy and survival of advanced gastrointestinal cancer patients treated with FRT with β-emitters Lutetium-177 or Yttrium-90, and/or α-emitter Actinium-225, as rescue therapy after established treatments. ***Materials and Methods:*** We retrospectively analysed 23 patients who received α-FRT or β-FRT (or combined -TANDEM) with 3BP-3940, a FAP-binding peptide, following high uptake confirmation on 68Ga-3BP-3940 PET/CT (03/2021-03/2025). CTCAE v.5.0 was used to grade acute adverse events and long-term haematological, renal and hepatic toxicity in patients with ≥1 follow-up (n=21). Molecular imaging-based response was assessed in 18 patients according to THERCIST (PET/CT, or post-therapeutic SPET/CT). For remaining 5 patients, progression was determined based on clinical outcome (death). By late March 2025, survival was calculated from first FRT to death. ***Results:*** We treated 17 males and 6 females (31-81 years at first FRT) with oropharyngeal (n=1), oesophageal (n=3), gastro-duodenal (n=4), colo-rectal (n=13), anal (=1) carcinoma, and cholangiocarcinoma (n=1). Previous treatments included: chemotherapy (96%); surgery of primary (61%); radiotherapy of primary or metastases (61%); Bevacizumab (56%); surgery of metastases (35%); immune-checkpoint inhibitors (39%); tyrosine-kinase inhibitors (39%). 65 FRT cycles were totally administered over 48 months (monotherapies: thirty-six 177Lu-3BP-3940, eight 90Y-3BP-3940, three 225Ac-3BP-3940; TANDEM: fifteen 225Ac/177Lu-3BP-3940, three 225Ac/90Y-3BP-3940). Five patients received 1 cycle, six patients 2 cycles, seven patients 3 cycles, two patients 4 cycles, three patients ≥5 cycles. FRT was overall well-tolerated, with few G1 acute adverse events, mainly emesis (n=3). Long-term toxicity after FRT included anemia G1/G2 (38%), anemia G3 (9%), leukocytopenia G1/G2 (24%), leukocytopenia G3 (5%), thrombocytopenia G1/G2 (14%), hepatotoxicity G1/G2 (24%) and G3 (5%) in patients with hepatic metastases, creatinine increase G1 (5%); one patient experienced acute on chronic renal insufficiency two weeks after FRT, then recovering. No patients discontinued FRT due to toxicity. Molecular imaging-based response showed seven partial remission, and eleven disease progression; in five patients death occurred before the assessment. At analysis, 8 patients were alive (follow-up: 2-27 months) and 15 patients had died (survival: 3 days-15 months). ***Conclusion:*** FRT with radiolabelled-3BP-3940 is overall safe for patients with advanced gastrointestinal carcinoma. Considering

its palliative purpose, both therapy response and survival were encouraging, but larger, prospective trials are needed to improve clinical outcome.

EP-0882

Sustained Tumor Retention of Lu-177 PSMA-617 in Recurrent High-Grade Gliomas: a step further in theranostics

V. Arunachalam Ragupathi, *N. Damle, M. Tripathi, S. Shamim, V. Tandon, K. Haresh, S. Bharati, A. Kumar, S. Gupta, A. Singhal, S. Rastogi, A. Mohan;*
All India Institute of Medical Sciences, Delhi, INDIA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA), has emerged as a promising molecular target in non-prostatic malignancies, including high grade gliomas (HGG). This study explores if PSMA expression in recurrent HGG is sustained enough to have any potential as a therapeutic target, focusing on tumor retention kinetics of low-dose Lu-177 PSMA-617. ***Materials and Methods:*** Patients with PSMA expression more than or equal to liver on a diagnostic PET/CT and a favorable ECOG performance status underwent tumor retention scans with low-dose Lu177 PSMA-617 (5-7 mCi) tumor retention studies. Serial imaging was performed at multiple time points (minimum of three) close to 4, 24, 48, 96, and 120 hours. Tumor to liver and tumor to parotid ratios were obtained by the total counts within the regions of interest to evaluate radiotracer retention dynamics. ***Results:*** Of 24 patients who underwent PSMA PET/CT (median age: 43 years), 21 showed uptake in suspected recurrent lesions, with 18 (85.7%) more than or equal to liver background activity. Nine patients meeting inclusion criteria underwent serial low-dose Lu-177 PSMA-617 imaging. All nine demonstrated sustained tumor retention of the radiotracer up to the final imaging point with mean tumor-to-liver and tumor-to-parotid ratios progressively increased from 0.63 and 0.23 at baseline to 4.1 and 2.3, respectively, by the last time point, indicating favorable retention kinetics of Lu-177 PSMA-617 within recurrent lesion. ***Conclusion:*** These preliminary results support the potential utility of Lu-177 PSMA-617 as a theranostic agent for recurrent high-grade gliomas. The observed sustained in vivo tumor retention following low-dose Lu-177 PSMA-617 administration highlights its promise for delivering targeted radiation and provides a strong foundation for future therapeutic trials in this difficult-to-treat population.

EP-0883

^{68}Ga/^{177}Lu-PSMA Theranostics in Recurrent High-Grade Glioma

A. Karlberg[1,2], *B. E. Vindstad*[2], *H. Tøndel*[1], *H. Johansen*[1], *T. M. Keil*[1], *E. M. Berntsen*[1,2], *O. Solheim*[1,2], *S. Kjærnes Øen*[1], *T. Skeidsvoll Solheim*[1,2], *L. Eikenes*[2];
[1]*St. Olavs Hospital, Trondheim, NORWAY,* [2]*Norwegian University of Science and Technology, Trondheim, NORWAY.*

Aim/Introduction: In this ongoing study, ^{68}Ga/^{177}Lu-PSMA theranostics is evaluated as a treatment alternative for patients with recurrent high-grade glioma. The overall aim is to improve existing diagnostic and therapeutic methods and possibly increase the overall survival and quality of life for this patient group. ***Materials and Methods:*** All patients received standard treatment with surgery, radiotherapy and chemotherapy prior to inclusion, and were left with no other treatment options at recurrence/progression. Eligible patients were selected for treatment based on a positive ^{68}Ga-PSMA-PET/MRI examination. ^{177}Lu-PSMA (7.4 GBq) was administered with 6-8 weeks intervals and continued as long as the patient tolerated the treatment well and dose limits to critical organs were not met. The safety, tolerability and efficacy of ^{177}Lu-PSMA treatment were assessed during study visits in each treatment cycle using PET/MRI, SPECT/CT, neurological tests, quality of life questionnaires and blood tests. ***Results:*** To date, nine patients (CNS WHO grade 4 glioblastoma (n=6), CNS WHO grade 4 astrocytoma (n=1) and CNS WHO grade 3 astrocytoma (n=2)) have been included. ^{68}Ga-PSMA-PET prior to treatment demonstrated tumor uptake in eight patients (median SUV_{max}: 5.4, range: 2.0-10.3). The uptake in normal brain was low, yielding high TBR values (median TBR_{peak}: 40.3, range: 22.3-104.1). Five patients qualified for treatment and have either completed (n=3) or started treatment (n=2). A total of 15 treatments have been administered (1-7 treatments/patient). Absorbed doses per treatment ranged from 0.8-7.3 Gy for tumors, 1.7-4.4 Gy for kidneys and 1.1-3.3 Gy for parotid glands. A rapid wash-out of activity was observed in all glioblastomas, while the retention in the grade 4 astrocytoma was notably longer, resulting in the highest tumor dose (7.3 Gy). No grade 3 or grade 4 toxicities were observed. The most common patient reported symptoms were fatigue and transient xerostomia. Among the three patients that have completed treatment (all glioblastomas), two were stable during the treatment cycles and one progressed, based on radiological evaluation (MRI, RANO). ***Conclusion:*** Despite low tumor doses, the radiological stability of disease in two of the patients with glioblastoma is promising. The higher tumor dose and longer retention in the grade 4 astrocytoma is also encouraging, possibly indicating that the treatment could be more efficient for this glioma type. However, the study needs to be completed to draw any conclusions.

EP-0885

Potential impact of PRRT with Lutetium 177 DOTATATE in patients with recurrent high risk meningiomas

I. Dev[1], *A. Puranik*[2,3], *A. Agrawal*[2,3], *N. Purandare*[2,3], *S. Shah*[2,3], *S. Choudhury*[4,3], *S. Ghosh*[4,3], *M. M V*[4,3], *V. Rangarajan*[2,3];
[1]*Advanced Center for Training, Research & Education in Cancer (ACTREC), Tata Memorial Center Homi Bhabha National Institute, Navi Mumbai, Mumbai, INDIA,* [2]*Tata Memorial Hospital, Mumbai, INDIA,* [3]*Bhabha National institute, Mumbai, INDIA,* [4]*Advanced Centre for Treatment, Research and Education IN Cancer (ACTREC), Tata Memorial Hospital, Mumbai, INDIA.*

Aim/Introduction: There are no definite treatments available in recurrent meningioma. These tumors express somatostatin receptors (SSTR) on the cell-surface; targeted by radiolabeled-peptides such as Gallium68-DOTATOC/NOC/TATE. Gallium-68 when replaced with Lutetium-177 (Beta emitter) exhibits tumour killing properties. Lu177-DOTATATE therapy i.e. Peptide Receptor Radionuclide Therapy (PRRT), is a potential treatment option in recurrent meningioma. We therefore studied the efficacy & safety of PRRT in 20 recurrent meningioma patients who had progressed on standard-of-care treatment. ***Materials and Methods:*** 20 recurrent meningioma patients referred for PRRT were included. Maximum 4 sessions of PRRT (dose ~7.4GBq per session) were given with a gap of 8-12 weeks. Response assessment was done on MRI using RANO criteria at the end of 2nd & 4th session of PRRT. 6 month PFS rate was used as an outcome measure. CBC, LFT, RFT were performed one week before PRRT and at 2-4 weeks & 6-8 weeks after PRRT. CTCAE V.5 criteria were used for safety and toxicity assess. ***Results:*** Of 20 patients, 6M/14F with age range 26-65 & KPS range 80-90. Most common site of recurrence was frontal lobe(9) then sphenoid wing(6), occipital(2), parietal(1), clival(1) & cerebellum(1). Histopathology Grade II in 12 patients, grade I in 7, grade III in 1. Five of 20 patients had metastases; bones, lungs & adrenals. PRRT sessions ranged from 1 to 4. 2 metastatic patients showed clinicoradiological progression, 3 patients failed to follow-up after 1 PRRT. Nine patients received 4 & seven received 2 PRRT doses. Follow up data for 15 patients was available for analysis. Response assessment: Partial response (PR) was the best response. 3 of 15 (20%) patients had PR after 2 PRRT doses. 10 (66%) had stable disease (SD) & 2 (13%) progressed (PD); of these, one patient had grade 3 histology. Out of 9 patients who received 4 PRRT, 6 patients had SD, 2 PD & 1 PR. 6-months Progression Free Survival:

Overall 6 months PFS rate was 76.4%. For recurrent grade I pts was 83% & 80% for recurrent grade II (extended 1 year PFS rate dropped to 50%) & for grade III was 0%.Safety: No patient developed grade 3 or 4 toxicities during treatment. ***Conclusion:*** PRRT is an effective, safe treatment for disease control in patients with recurrent meningioma after standard treatment. Further randomised trials are required to validate these results.

EP-0886

Tumor dosimetry and correlations with pre-therapeutic SSTR PET in patients receiving [^{177}Lu]Lu-DOTATATE treatment for recurrent meningioma

M. Mair[1,2], *A. Delker*[1], *K. J. Müller*[3], *V. Stoecklein*[4], *L. Wiegand*[1], *A. C. Wehn*[4], *V. Wenter*[1], *M. Zacherl*[1], *M. Preusser*[2], *M. Brendel*[1], *P. N. Harter*[5,6,7], *C. Schichor*[4], *N. L. Albert*[1,6,7];
[1]*Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY,* [2]*Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, AUSTRIA,* [3]*Department of Neurology, LMU University Hospital, LMU Munich, Munich, GERMANY,* [4]*Department of Neurosurgery, LMU University Hospital, LMU Munich, Munich, GERMANY,* [5]*Center of Neuropathology and Prion Research, LMU University Hospital, LMU Munich, Munich, GERMANY,* [6]*Bavarian Cancer Research Center (BZKF), Partner Site Munich, Munich, GERMANY,* [7]*German Cancer Consortium (DKTK), Partner Site Munich, Munich, GERMANY.*

Aim/Introduction: Radioligand therapy with [^{177}Lu]Lu-DOTATATE has shown disease stabilization in small studies of recurrent meningioma, and trials in this indication are ongoing. However, data on dosimetry and correlations with pre-therapeutic somatostatin receptor (SSTR) PET are limited. ***Materials and Methods:*** In this retrospective study, patients with recurrent meningioma treated with [^{177}Lu]Lu-DOTATATE were included. Post-treatment ^{177}Lu-SPECT/CT was performed 24, 48 and 72 hours after administration of [^{177}Lu]Lu-DOTATATE. Lesion dosimetry was performed with a mono-exponential fit model using MIM SurePlan MRT and PETEdge+ segmentation on SPECT 24h after administration. Lesions in pre-therapeutic SSTR PET were segmented using SUV>4 as segmentation threshold. ***Results:*** Overall, 14 patients (7 [50.0%] females) were included, of whom 4 (28.6%) had CNS WHO grade 1, 5 (35.7%) CNS WHO grade 2, and 4 (28.6%) CNS WHO grade 3 meningioma. Median age at first [^{177}Lu]Lu-DOTATATE administration was 55 years (range: 33-82). In median, patients were pre-treated with 2 resections (range: 1-5) and 1 course of radiotherapy (range: 0-4), while no systemic treatments had been applied. In total, 48 [^{177}Lu]Lu-DOTATATE cycles were administered (median: 4 cycles per patient [range: 2-8]) with a median activity of 7.8 GBq (range: 7.0-8.1). Data for dosimetry calculations were available in 27 cycles, and the median number of segmentable lesions in SPECT/CT was 2.5 (range: 1-9). In median, the tumor-absorbed dose (TAD) per cycle was 0.3 Gy/GBq (range: 0-2.8), while the effective tumor half-life was 26.4 hours (range: 8.0-63.1). TAD in the first course was higher in CNS WHO grade 3 (median: 2.4 Gy/GBq [range: 0.6-2.8]) compared to CNS WHO grade 2 (median: 0.3 Gy/GBq [range: 0.2-0.8], $p = 0.016$) and CNS WHO grade 1 (median: 0.4 Gy/GBq [range: 0.2-1.3], $p = 0.005$). SUV_{mean} in pre-therapeutic SSTR PET correlated with TAD ($r = 0.639$, $p = 0.004$) of respective lesions. Analyses on associations of dosimetry with treatment response are ongoing. ***Conclusion:*** In this retrospective single-center analysis, TAD was associated with CNS WHO grade and pre-therapeutic SUV_{mean} in SSTR PET. Prospective trials are warranted to define overall efficacy and dose-response relationships.

EP-0887

Treatment with 188-Rhenium resin for non-melanoma skin cancer. First treatments performed in Spain.

D. Vega Perez*, E. Martínez Albero, A. Saviatto Nardi, C. García Donoso, B. García Bracamonte, S. Angiolillo Grau, E. López Llobet, Á. Galiana Morón, B. Manzarbeitia Arroba, P. Zaragoza Ballester, X. Guarnizo, P. Ortiz Romero, M. Tabuenca Mateo;*
Hospital 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Treatment of non-melanoma skin cancer (NMSC) with 188-Rhenium resin (188-Re) is a therapeutic alternative to conventional techniques, such as surgery (gold standard), especially in patients who are not candidates for surgical treatment, either due to comorbidities or lesion characteristics (location and extent). In these scenarios, 188-Re is a useful tool, with good tolerance, low toxicity, and excellent response rates. The main objective of this study was to assess treatment response, reported symptoms and toxicity in a prospective sample of patients with NMSC treated at our center with 188-Re. ***Materials and Methods:*** We treated 11 patients(p) (3 women, 8 men) between June/2024 and January/2025, with a total of 13 lesions(L) in 3 treatment sessions.Our population has a mean age of 75.6 years (range 57-89 years). The lesions were all basal cell carcinomas (superficial type 3 (23.1%), extensive 4 (30.7%), infiltrative 5 (38.5%) and mixed type 1 (7.7%), with an invasion depth <3 mm (mean 1.5 mm, range 0.4-2 mm) and a mean surface area of 4.8 cm2 (range 2.1-13 cm2). The location of the lesions was: nasal tip 9L (69.2%), nasal wing 2L (15.4%), scalp 1L (7.7%) and nasal tip+wing 1L (7.7%). The target dose of 188-Re resin on all lesions was 50 Gy, with a mean administered activity of 397.65 MBq (range 89-670 MBq), and a mean treatment time of 120.5 min (range 50-186 min). Symptoms were assessed 15-30 days post-treatment, acute toxicity at 30 days according to the "Common Terminology Criteria for Adverse Events" (CTCAE version 5.0) scale, and response after 3-6 months using dermoscopy and confocal microscopy. ***Results:*** An average follow-up period of 6.38 months (2-11) was performed for the lesions. At the 15-day follow-up, the symptoms were: itching (9p:81.8%), burning (4p:36.4%), pain (1p:9%) and other (1p:9%). At 30 days, itching remained the predominant symptom (8p), although of lower intensity. Toxicity at 30 days was: G1 7L(53.8%), G2 5L(38.5%) and G3 1L(7.7%), with complete resolution of toxicity during follow-up. Treatment response was assessed in two patients with a minimum follow-up of 6 months, demonstrating a complete response with no evidence of recurrence. The remaining 9p are pending review as they have not completed the 6-month follow-up required to assess response and cosmetic outcomes according to the Radiation Therapy Oncology Group (RTOG) score. ***Conclusion:*** Treatment with 188-Rhenium resin is an effective therapy for NMSC in selected cases, with very good response, acceptable symptoms and tolerable toxicity.

EP-0888

[177Lu]Lu-FAP-2286 Treatment Response in Metastatic Lesions vs Local Recurrence Lesions in Breast Cancer Patients

M. Nasiri[1], *R. Nami*[2], *S. Banihashemian*[3], *G. Divband*[4], *A. Abolhosseini Shahrnoy*[2], *S. Mazidi*[5], *M. Akbari*[6];
[1]*Department of Cellular & Molecular Biology, School of Biology, Damghan University, Damghan, IRAN, ISLAMIC REPUBLIC OF,* [2]*Parsisotop Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Cancer Research Center, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Khatam PET-CT Center, Khatam-al-Anbia Hospital, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [5]*Parsisotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [6]*Cancer Research Center, Shahid Beheshti University of Medical Sciences, Damghan, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: This study aims to evaluate the relationship between tumor-absorbed radiation dose—both total and per milliliter (dose/mL), and tumor SUVmax and SUVmean, in breast

cancer patients with local recurrence (LR) and metastatic lesions following therapy with [177Lu]Lu-FAP-2286. ***Materials and Methods:*** This retrospective analysis included six breast cancer patients with local recurrence and 16 metastatic lesions identified by [68Ga]Ga-FAP-2286 PET/CT. All patients underwent six cycles of [177Lu]Lu-FAP-2286 therapy. Pre- and post-treatment tumor metrics—including SUVmax, SUVmean, and lesion volume—were measured. Dosimetry was performed using the MIRDCALC method to determine both total absorbed dose and dose/mL for each lesion. Patients were grouped based on treatment response: Group 1 (n = 6): Non-locally metastatic lesions with significant decrease in SUVmax/SUVmean and tumor size; Group 2 (n = 16): Locally recurrence lesions with progressive disease. Statistical analysis included Spearman's correlation to assess the relationship between dosimetry parameters and response metrics, along with linear regression modeling. ***Results:*** Interestingly, all metastatic lesions showed a significant reduction in SUVmax (ΔSUVmax percentage= 80.9 ± 5.15) (P=0.022), SUVmean (ΔSUVmean percentage= 68.9 ± 8.1) (P=0.012), and Tumor volume (ΔTumor volume percentage= 77.4 ± 7.45) (P=0.012) after treatment. In contrast, local recurrence lesions demonstrated an increase in volume post-therapy (-99.9±50.5) despite equal total absorbed doses relative to metastatic lesions (204333.3±38742.4 vs 252125±1658.13 respectively). Notably, the absorbed dose/ml (mGy/ml) was significantly greater in metastatic lesions (58222.7±17.6) than in local recurrences (272.2±71.5), correlated with better response to treatment in lesion volume (ρ=0.55, p=0.008), SUVmax (ρ=0.63, p=0.002), and SUVmean (ρ=0.58, p=0.004). ***Conclusion:*** These findings suggest that despite of association between higher tumor-absorbed dose/ml with improved response in metastatic breast cancer lesions; the heterogeneity of local recurrences and potentially inflammatory rather than truly neoplastic nature of some local recurrence lesions, may lead to lower dose/ml uptake of [177Lu]Lu-FAP-2286 and consequently lack of response in these lesion.

EP-0889

Disease control rate in patients with advanced meningioma performing PRRT: an updated meta-analysis

B. Muoio[1], *C. Iacovitti*[2], *D. Bosetti*[1], *M. Cuzzocrea*[2], *G. Paone*[2], *G. Treglia*[2];
[1]*EOC IOSI Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND,* [2]*EOC Imaging Institute of Southern Switzerland, Bellinzona, SWITZERLAND.*

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) is a treatment option for patients with advanced meningioma overexpressing somatostatin receptors. The aim of this study is to perform an updated meta-analysis to establish the disease control rate in patients with advanced, progressive or refractory meningioma performing PRRT. ***Materials and Methods:*** A comprehensive literature search of studies on PRRT in patients with advanced meningioma was carried out. Four different databases (PubMed/MEDLINE, EMBASE, Cochrane library, Google Scholar) were screened until April 2025. Only original articles about PRRT in advanced, progressive or refractory meningiomas were selected. Case reports were excluded. Three review authors independently performed the literature search, the article selection and the data extraction. Main findings of eligible studies were summarized and a proportion meta-analysis on the disease control rate was carried out using a random-effects model. ***Results:*** 17 studies (251 patients) published from 2006 to 2024 were included in the meta-analysis. In most of the included studies PRRT was performed using [^{177}Lu]Lu-DOTATATE. The pooled disease control rate was 66.3% (95% confidence interval values: 58.1-74.5%). PRRT was well-tolerated in most of the patients with advanced meningioma. Moderate statistical heterogeneity was found in the meta-analysis (I-square: 51%). ***Conclusion:*** PRRT in patients with advanced meningiomas is active and well-tolerated, showing a significant disease control rate (in about two-thirds of patients). Results from well-designed clinical trials are needed to corroborate these findings, but evidence-based data seem to support the clinical use of PRRT for this indication.

EP-0890

Tumour-absorbed dose and efficacy of peptide receptor radionuclide therapy with ^{90}Y-DOTATOC in patients with refractory meningioma

L. Schweiger*;*
Medical University of Innsbruck, Department of Nuclear Medicine, Innsbruck, AUSTRIA.

Aim/Introduction: The management of treatment-refractory meningioma in patients with previous surgical resection and radiation therapy remains challenging due to a lack of further treatment options. Therefore, novel therapeutic applications, such as peptide receptor radionuclide therapy (PRRT) targeting somatostatine receptors, may offer a promising therapeutic strategy. We aimed to assess the tumour-absorbed dose and efficacy of PRRT with ^{90}Y-DOTATOC in patients with treatment-refractory meningioma. ***Materials and Methods:*** In this study, 10 patients with therapy-refractory meningioma were retrospectively included. All patients received systemic ^{90}Y-DOTATOC therapy following prior surgical resection and radiation therapy. In total, 21 lesions were assessed morphologically by contrast-enhanced MRI and ^{68}Ga-DOTATOC PET/CT both before and after therapy. All patients underwent dosimetry with ^{111}In-DOTATOC prior to ^{90}Y-DOTATOC therapy. Treatment response was evaluated according to RANO bidimensional and volumetric criteria, as well as overall survival (OS). ***Results:*** The median cumulative activity administered per patient was 3804 MBq (range: 3140 - 4050 MBq), with a median of 3 cycles (range: 1 - 7). On lesion-based analysis following PRRT, response assessment was available only in 19/21 (91.5%) lesions. Among these, tumour stabilisation according to RANO criteria was observed in 7/19 (36.8%) lesions, with a median cumulative tumour-absorbed dose of 52.7 Gy. Morphological tumour progression was noted in 12/19 (63.2%) lesions, with a median cumulative tumour-absorbed dose of 43.8 Gy. Although lesions classified as stable disease (RANO) received a higher median cumulative absorbed dose, the difference in tumour-absorbed doses between morphologically stable and progressive lesions according to RANO criteria was not statistically significant (P=0.82). Values for SUV_{max} and SUV_{mean} from pretherapeutic ^{68}Ga-DOTATOC PET/CT significantly correlated with the tumour-absorbed doses (P=0.018 for SUV_{max}, P=0.021 for SUV_{mean}, respectively). Posttherapeutic ^{68}Ga-DOTATOC PET/CT demonstrated an increase in SUV_{max} in 19/21 (90.5%) lesions (median: 40.8%, range: 13.0% - 101.2%). The median OS was 23.0 months (95% CI 12.5 - 33.5 months). ***Conclusion:*** Our preliminary results indicate no significant difference in tumour-absorbed doses between morphologically stable lesions and those with progressive disease, as defined by the RANO criteria. However, lesion-based analysis revealed a significant correlation between pretherapeutic ^{68}Ga-DOTATOC PET/CT uptake and tumour-absorbed doses following ^{90}Y-DOTATOC therapy. Lesion-based assessment of ^{68}Ga-DOTATOC PET/CT imaging showed increased tracer uptake in nearly all lesions after ^{90}Y-DOTATOC therapy. These findings suggest that baseline PET/CT may serve as a valuable tool for estimating cumulative tumour-absorbed dose and guiding the optimal cumulative activity of PRRT.

EP-0891

Gastrointestinal Adverse Effects in ^{177}Lu-FAPI-2286 Radioligand Therapy: Contributing Factors and Strategies for Reducing Uptake-Related Symptoms

N. Raeisi*, A. Saber Tanha, K. Aryana;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This study aims to evaluate the factors influencing the intensity of gastrointestinal uptake in patients

undergoing ^{177}Lu-FAPI-2286 therapy, as well as to assess strategies for reducing uptake and its associated symptoms. ***Materials and Methods:*** In this study, we included 13 patients who underwent ^{177}Lu-FAPI-2286 therapy, primarily for palliative care or as a potential end-stage treatment. The cancers represented in this cohort included papillary and medullary thyroid cancers, colorectal, breast and nasopharyngeal malignancies. Post-treatment non-tumoral gastrointestinal uptake were assessed in two time points: early whole-body scan at 24 hours and again between 48 to 72 hours post-treatment. The scans were evaluated for the presence, intensity and variations in pattern of bowel uptake. Concurrently, patient's clinical histories were reviewed, focusing on opium consumption, bowel habits (categorized as constipation, diarrhea, or normal), and post-treatment gastrointestinal symptoms. Additionally, patients were queried about the use of prokinetic agents or laxatives during this period. ***Results:*** Out of the 13 patients, 11 exhibited bowel uptake in the early post-treatment scans. One patient with diarrhea showed no bowel uptake. Other 12 patients included five patients with constipation and seven with normal bowel habits, one of whom also showed no bowel uptake. All five patients with constipation were opium users for pain relief. Of the 11 patients with bowel uptake, four patients demonstrated more intense uptake, and all four had a history of opium-related constipation. Among the opium user patients, only one demonstrated lower bowel uptake compared to the others, which is thought to be related to laxative consumption three months prior to radioligand therapy. Among four patients with opium consumption who exhibited intense bowel uptake in the early scan, three demonstrated decreased uptake in the delayed imaging following the use of laxative medications, while one patient declined to use these medications. Four patients experienced gastrointestinal adverse event grade 1-3 (according to CTCEA v3.0) following the first cycle of radioligand therapy, all of whom were opium users, and their delayed imaging indicated significant bowel uptake. Notably, after administering pre-treatment with laxatives for three of these patients in the subsequent treatment cycle, none reported gastrointestinal upset. ***Conclusion:*** Our experience suggests that intestinal accumulation of ^{177}Lu-FAPI-2286 may result in gastrointestinal complications after treatment, which is especially concerning for patients with constipation associated with opiate use. Our findings suggest that prescribing laxatives for this group of patients may help prevent gastrointestinal adverse events and improve overall comfort during treatment.

Aim/Introduction: To evaluate the therapeutic effect of radiosynoviorthesis (RSO) on clinical symptoms of non-infectious synovialitis in patients following total knee arthroplasty (TKA). ***Materials and Methods:*** This retrospective study included 13 patients (4 females, 9 males; mean age: 66 ± 8 years) who developed recurrent joint effusion and pain in the operated knee, with symptom onset occurring on average within six months post-TKA. Diagnosis of non-infectious synovialitis was confirmed via three-phase bone scintigraphy with SPECT/CT during the blood pool phase. Each patient received an intra-articular injection of 222 MBq of yttrium-90 (Y-90). Clinical follow-up was conducted for a minimum of six months. Outcome measures included objective assessments - joint range of motion, load-bearing capacity, and recurrence of effusion -and subjective evaluation of pain using a visual analogue scale (VAS) questionnaire. ***Results:*** All patients exhibited a clinically meaningful response to RSO, with significant reduction in pain, improved joint mobility, and enhanced tolerance to load. The mean pain score on VAS decreased from 6.8 prior to treatment to 0.5 after therapy. In 12 of the 13 patients, therapeutic benefits were sustained throughout the follow-up period. In one patient, symptoms recurred after six weeks, however this was due to the aseptic loosening of the prosthesis. ***Conclusion:*** Radiosynoviorthesis appears to be an effective and minimally invasive treatment option for managing non-infectious synovialitis following TKA, particularly when other conservative or surgical interventions are limited. In this smaller cohort, Y-90 administration provided durable symptom relief in the majority of cases.

EP-0893

Identification of risk factors for relapse of Graves-Basedow disease after radioiodine treatment

S. Adamantiadis[1], *L. Urso*[1], *L. Manco*[2], *F. Sartori*[3], *M. Borghesi*[4], *V. Marino Picciola*[5], *A. Gobbo*[5], *L. Uccelli*[1], *M. C. Zatelli*[5], *M. R. Ambrosio*[5], *M. Bartolomei*[6], *C. Cittanti*[1];

Aim/Introduction: Graves' disease (GD) is an autoimmune disorder that primarily affects the thyroid gland leading to hyperthyroidism, due to an overproduction of thyroid hormones. It's commonly and effectively treated with radioiodine treatment (RAI), using 131I. RAI damages and destroys thyroid cells, inducing a complete remission of hyperthyroidism in ~80% of patients. Aim of this work is to identify if any clinical/instrumental parameters collected before RAI are predictive of relapse in GD patients treated with dose-personalized 131I. ***Materials and Methods:*** GD patients treated with dosimetrically determined activities of 131I between 2010 and 2022 with a minimum follow-up of 2 years were retrieved. Clinical parameters (gender, age at RAI, FT4 and Thyrotropin Receptor Antibodies (TSHrAb) values at diagnosis, thyroid volume at ultrasound (US) performed within a month from RAI, 24h uptake of 131I, GREAT score and orbitopathy) were collected. RAI was performed by a dosimetric approach with gamma probe (Capintec Inc.) and the administered activity was calculated to achieve 300Gy to the gland, considering the 24h uptake and thyroid volume according to US. The evidence of GD relapse, defined as clinical and biochemical evidence of hyperthyroidism after RAI, was considered as outcome at multiple logistic regression. ROC curves were used to determinate cut-off values of significant clinical parameters. ***Results:*** 148 GD patients (41 males and 107 females; median age 55.72 years) treated with RAI were collected. The administered doses of 131I ranged between 5 and 16 mCi (median 9 mCi). GD Relapse was observed in 31 patients (20.9%). Of those, in 14 cases (45.2%) relapse occurred within 9 months. Only 7 patients (22.6%) relapsed after receiving >10mC of 131I. At multiple logistic regression, administered activity, 24h uptake, thyroid volume, FT4 values and GREAT score were all significantly different in patients with or without GD relapse (all

p<0.01). At ROC curves, administered activity <9.5mCi and 24h uptake >74.1% were the best cut-offs to predict GD relapse after RAI. ***Conclusion:*** The efficacy of RAI is confirmed in our cohort of GD patients, in which a definitive resolution of hyperthyroidism was achieved in 79.1% of cases. Patients who showed GD relapse were those with the higher value of 24h uptake of 131I and the lower administered dose of 131I, leading us to conclude that in glands that are very avid for iodine, predictive dosimetry using gamma probe may sometimes underestimate the 131I activity needed for an effective treatment.

EP-0894

Feasibility of Tc-99m-based pre-treatment dosimetry in patient receiving radioidine therapy for hyperthyroidism: comparison with pre- and post-treatment assessments

M. Meraldi, *C. Romanò, G. Muti, C. Carbonini, V. Piva, G. Cabrini, S. Capitanio, A. Franchini, E. Gay, A. F. Scarale, A. Spataro, C. Rossetti, P. E. Colombo;*
ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Patient-specific activity determination is recommended in radioiodine therapy for hyperthyroidism to optimize therapeutic efficacy while minimizing radiation exposition. Due to a temporary unavailability of I-131 capsules, thyroidal maximum uptake was estimated using Tc-99m at our center. This study aimed to assess the feasibility of Tc-99m-based pre-treatment dosimetry by correlating Tc-99m uptake at 20 minutes (Tc99m_U(20min)) with I-131 uptake at 24 hours (I131_U(24h)) to determine the activity required to deliver the prescribed dose. Post-treatment I-131 dosimetry was performed and used as a reference to evaluate the accuracy of pre-treatment dosimetry with Tc-99m. Iodine uptake and recommended activity (calculated according to the EANM guidelines) were derived from (i) Tc-99m pre-dosimetry and (ii) I-131 post-dosimetry, and then compared. Additionally, patient-specific activity was compared with the fixed activity of 600 MBq, recommended in absence of previous dosimetric evaluation. ***Materials and Methods:*** A logarithmic conversion equation from Tc99m_U(20min) to I131_U(24h) was derived based on a group of 82 patients who underwent both Tc-99m and I-131 pre-treatment dosimetry at our center. Iodine uptake was determined via scintigraphy: Tc99m_U(20min) was measured 20 minutes after administration, while I-131 post-dosimetry uptake was measured at 1 and 6-8 days after treatment. In a cohort of 16 patients, iodine uptake and activity based on Tc-99m pre-dosimetry were compared with those derived from I-131 post-dosimetry. In the same group, patient-specific activity was compared with the fixed one. ***Results:*** The relationship between Tc99m_U(20min) and I131_U(24h) followed the equation I131_U(24h)=11.68xln(Tc99m_U(20min))+31.50. Tc-99m pre-dosimetry overestimated iodine uptake compared to I-131 post-dosimetry, with median pre-to-post discrepancy of 36% (range: 0% to 96%). This led to a lower recommended activity from Tc-99m pre-dosimetry, with a median pre-to-post difference of -15% (range: -48% to 53%). The administration of a fixed dose resulted in 63% of patients receiving higher-than-required activities, with a median fixed-to-post discrepancy of 26% (range: -40% to 502%). ***Conclusion:*** Tc-99m proved to be a feasible alternative for pre-treatment dosimetry in case of I-131 capsule unavailability, thereby enabling the continuation of a patient-specific approach. Personalized dosimetry enabled tailored activity prescriptions and, in many cases, helped avoid unintended over- or under-dosing, which may occur with fixed-dose strategies. Further studies with larger cohorts are needed to enhance consistency.

EP-0895

Functional assessment of post-radiation xerostomia therapy with allogeneic mesenchymal stromal stem cells in patients with head and neck cancer by salivary gland scintigraphy - a phase I clinical trial

L. Lezaic[1], *A. Socan*[1], *G. Plavc*[2], *M. Kokalj*[2], *G. Mitrovic*[2], *O. Blatnik*[2], *A. Bavec*[3], *N. Tesic*[4], *K. Hartman*[4], *U. Svajger*[4], *P. Strojan*[2];
[1]*University Medical Centre Ljubljana, Division of Nuclear Medicine, Ljubljana, SLOVENIA,* [2]*Institute of Oncology Ljubljana, Ljubljana, SLOVENIA,* [3]*Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA,* [4]*Blood Transfusion Centre of Slovenia, Ljubljana, SLOVENIA.*

Aim/Introduction: Xerostomia is a common side effect of radiotherapy in patients with head and neck cancer that affects quality of life and for which there is no effective standard treatment. Mesenchymal stem cells (MSCs) represent a potential therapeutic option for these patients as they have both regenerative and immunomodulatory effects. The aim of this phase I study was to investigate the safety and preliminary efficacy of MSC treatment in patients with xerostomia following radiotherapy. ***Materials and Methods:*** Ten patients with grade 2-3 xerostomia after curative (chemo)radiotherapy for squamous cell carcinoma of the oropharynx and no evidence of disease recurrence >=2 years after treatment were to be included in the study. Allogeneic umbilical cord-derived MSCs were injected into both parotid glands and both submandibular glands. Salivary gland scintigraphy was performed before and 4 months after MSC injection. Qualitative (visual assessment per Schall criteria) and quantitative (ejection fraction, excretion velocity) parameters were evaluated at both time points, correlated to clinical outcome (clinical xerostomia grade, CTCAE v5.0) and evaluated statistically by non-parametric methods (p<0,05 considered for statistical relevance). ***Results:*** At the time of analysis, 5 patients had completed the functional assessment. Before and after MSC injection, there was no statistically significant change in Schall grade (2,9±0,8 vs. 2,9±0,9), ejection fraction (17,2±20,6% vs. 17,5±19,7%), excretion velocity (12,3±16,6%/1min vs. 13,1±15,0%/1min) and clinical grade of xerostomia (2,2±0,4 vs 2,2±0,4). ***Conclusion:*** In the interim analysis, no significant change was demonstrated by the MSC injection in the functional evaluation by salivary gland scintigraphy, which correlated with the results of the clinical findings. A full analysis after completion of enrollment and functional assessment is planned, as well as comparison with radiological, physiological and quality of life assessments (US, MRI, salivary flow and composition, biopsy).

EP-0896

The evaluation of radioiodine therapy out come after five years in patient with subclinical hyperthyroidism

S. Abdelrazek, *P. Szumowski, J. Mysliwiec, I. Sulima;*
Medical University of Bialystok, Bialystok, POLAND.

Aim/Introduction: Subclinical hyperthyroidism (SCH) is a state of increased thyroid function with few or no clinical definitive signs or symptoms of hyperthyroidism, characterized by a subnormal serum TSH level, with normal serum levels of free thyroxine (FT4), and free triiodothyronine (FT3). The prevalence of endogenous SCH varies considerably, between 0.6 and 16% . SCH is associated with increased risk of coronary heart disease mortality, incident atrial fibrillation, heart failure, fractures and all-cause mortality in patients with serum TSH levels < 0.1 mIU/l (grade 2 SCH). The risk of progression to overt hyperthyroidism (OHT) varies between studies 1-15% / year. The aim of our study was to evaluate the short term (5years) effect of radioiodine therapy (RAIT) on the achievement of euthyroidism, and prevention evolvement to overt hyperthyroidism. ***Materials and Methods:*** We treated 980 patients, aged 30-70 years; 370 patients with toxic multinodular goitre (TMNG), and 610 patients with toxic adenoma (TA). Malignant changes were excluded in all nodules by fine needle

aspiration biopsy. All the patients had serum TSH levels less than 0.1 mU/l and effective T-half measured by the use of T6 and T24 was more than 3 days at the time of treatment. The activity dose was calculated by the use of Marinelli's formula and ranged between 200-600 MBq. The absorbed dose (Gy) for TMNG ranged between 150 and 260, and for TA: 200-300. Follow up control was done every 6 weeks in the first year. Then every 6 months for four years. ***Results:*** In general the success of treatment after one year was: 99% of patient with TA and 92% of patient with TMNG achieved euthyroidism. 1% of patient with TA and 7% of patient with TMNG develop hypothyroidism. 1% of the patients had persistent hyperthyroidism and received second dose of radioiodine therapy. After 3 years of RAIT 2% of patient with TA and 8% of patient with TMNG develop hypothyroidism. After 5 years of RAIT 2% of patient with TA and 9% of patient with TMNG develop hypothyroidism. In all the patients the symptoms and signs of subclinical hyperthyroidism disappeared (palpitation, tachycardia, atrial fibrillation, exercise tolerance improved, the blood pressure normalised and the quality of life improved). ***Conclusion:*** The achievement of euthyroidism and the remission of the symptoms and signs of subclinical hyperthyroidism, were due to good diagnosis, well preparation of the patients; accurate measurement of administered activity, effective half-life, and well-organised follow up.

EP-0897

Radioactive iodine therapy in hyperfunctioning thyroid nodules: who are doomed to hypothyroidism?

D. Carvalho, *S. Barata, S. Paiva, I. Casimiro, J. Silva, L. Lemos, M. Monteiro, P. Lapa, G. Costa;*
ULS Coimbra - HUC, Coimbra, PORTUGAL.

Aim/Introduction: Radioactive iodine (RAI) therapy is a safe and effective treatment of hyperthyroidism caused by hyperfunctioning thyroid nodules (HTN). Although euthyroidism is the therapeutic target of RAI treatment in HTN, some patients develop hypothyroidism. This study aims to identify which factors may increase the risk of developing hypothyroidism after RAI in patients from our institution. ***Materials and Methods:*** A retrospective analysis was conducted using clinical data from the 64 patients with HTN who underwent RAI therapy in our department between February 2021 and April 2023. Parameters evaluated included age, gender, number of HTN, size of the dominant nodule, presence of hypofunctioning nodules, pre-RAI dose of thiamazole (pills per day), serum TSH levels prior to RAI therapy both with and without antithyroid medication, estimated mass of functioning thyroid parenchyma based on thyroid scan, RAI uptake at 24 hour (RAIU), degree of functional suppression of the extranodular parenchym and RAI activity (both total and per gram of thyroid tissue). The outcome, euthyroidism or hypothyroidism one-year after RAI treatment, was recorded. Univariate statistical analyses and multivariate logistic regression were employed to identify factors associated with treatment response. Statistical analysis was performed using SPSS-Statistics v.30.0., with a significance threshold set at $p<0.05$. ***Results:*** Of the 64 patients (50 female, 78.1%; mean age 65.50±12.21y, range:25-90), 43 (67.2%) had toxic adenoma, whereas 21 (32.8%) had toxic multinodular goiter. 21 patients (32.8%) develop biochemical hypothyroidism (defined as TSH>4.0µUI/mL). Older age was significantly associated with a higher risk of hypothyroidism (mean 70.5 vs. 63.0y, p=0.008), and logistic regression confirmed that each additional year increased the odds of hypothyroidism by 6.1% (OR=1.061; 95% CI:1.006-1.118; p=0.028). No significant differences were found regarding the other evaluated parameters. Regarding thyroid function markers, TSH levels under antithyroid therapy prior to treatment showed a borderline significant association (OR=2.63; 95% CI:0.97-7.15; p=0.058), suggesting higher TSH while on therapy may increase the risk of hypothyroidism. TSH levels without antithyroid drug, and thiamazole dose prior to treatment, were not significantly associated. ***Conclusion:*** Older age was the only significant predictor of post-RAI hypothyroidism. A borderline association with pre-treatment TSH under antithyroid therapy was observed. Although age emerged as a significant predictor, the limited sample size may have reduced the statistical power of the multivariable analysis, potentially obscuring other meaningful associations. These findings highlight the need for further investigation in larger cohorts to clarify additional predictive factors.

EP-0898

Ensemble learning model for the prediction of a response to ^{131}I-NaI therapy in hyperthyroidism - ablative dose concept

N. Pantic[1], *B. Radovic*[1,2], *B. Pantic*[3], *M. Kotur*[1], *L. Grujicic*[1], *J. Zivanovic*[1], *A. Novkovic*[1], *J. Petrovic*[1,4], *I. Grozdic Milojevic*[1,4], *D. Sobic Saranovic*[1,4], *V. Artiko*[1,4], *S. Odalovic*[1,4];
[1]*Center for Nuclear Medicine with PET, University Clinical Center of Serbia, Belgrade, SERBIA,* [2]*Faculty of Medicine, University of Pristina with temporary headquarters in Kosovska Mitrovica, Kosovska Mitrovica, SERBIA,* [3]*Freelance IT researcher, Belgrade, SERBIA,* [4]*Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.*

Aim/Introduction: According to the European Association of Nuclear Medicine (EANM) guideline, there are two concepts for radioactive iodine (RAI) therapy delivery in patients with Graves disease (GD). In the functional dose concept, the aim of RAI therapy is to correct subclinical or overt hyperthyroidism with the goal of reaching euthyroidism as soon as possible, while in the ablative dose concept, the aim is to achieve hypothyroidism as soon as possible. The second approach is based on evidence that the definitive success rate in controlling hyperthyroidism with the utilization of the ablative dose concept is much higher than that obtained with the functional dose concept (> 90% vs. < 70%, respectively) (1). We are developing a model that will be able to predict a response to RAI therapy in patients with GD, a solitary hyperfunctioning nodule, and multiple hyperfunctioning nodules in multinodular goiter. ***Materials and Methods:*** A total of 901 patients who received RAI for the treatment of hyperthyroidism were included in the study. Achievement of hypothyroidism in the first six months after RAI therapy was the aim of the treatment. The adaptive boosting algorithm was utilized for the development of the model, with the main laboratory, nuclear medicine imaging, and clinical features serving as predictors. Further development of the model through the usage of an ensemble learning algorithm is in process. ***Results:*** Current test accuracy is 0.7. Free T4 (free thyroxine) level before the application of RAI, 24-h radioactive iodine uptake (RAIU), and 3-h RAIU contributed the most to the development of the model, with 26.18%, 23.56%, and 22.50%, respectively, followed by thyroid-stimulating hormone (TSH) level before the treatment with the contribution of 8.43%, duration of the previous pharmacotherapy in months with 8.01%, and age with 6.02%. Applied dosage in MBq contributed only 4.69%, while the diagnosis, type of previous pharmacotherapy, and gender didn't have a significant impact on the development of the model. ***Conclusion:*** A machine learning model can predict a response to RAI therapy with high accuracy. Its' further development will make decision-making in patients with hyperthyroidism more automated. ***References:*** 1. Campennì A, Avram AM, Verburg FA, Iakovou I, Hänscheid H, de Keizer B, et al. The EANM guideline on radioiodine therapy of benign thyroid disease. Eur J Nucl Med Mol Imaging. 2023 Sep;50(11):3324-3348. doi: 10.1007/s00259-023-06274-5.

EP-0899

Early and sustained thyroid volume reduction following radioiodine therapy in Graves' hyperthyroidism: A 6-month prospective study

R. Zhang, *H. Wang, Q. Jia, P. Chang, J. Tan, W. Zheng;*
Department of Nuclear Medicine, Tianjin Medical University General Hospital, Tianjin, CHINA.

Aim/Introduction: This prospective study aimed to investigate the temporal dynamics of thyroid gland weight (TGW) reduction in patients with Graves' hyperthyroidism during the first six months following initial radioiodine (^{131}I) therapy. ***Materials and Methods:*** A total of 239 consecutive patients undergoing ^{131}I therapy were analyzed through serial ultrasound assessments. Three overlapping cohorts were established based on paired measurement intervals: Cohort A (n=217, baseline vs 2 weeks post-treatment), Cohort B (n=106, 2 weeks and 3 months post-treatment), and Cohort C (n=66, 3 months and 6 months post-treatment). Nonparametric statistical analysis using Wilcoxon signed-rank tests was performed for paired comparisons for the three Cohorts, respectively. ***Results:*** The mean baseline TGW was 33.1 ± 22.1 g (n=239 cases). Rapid initial reduction (to 23.1±15.5g) occurred within two weeks (n=217), followed by progressive declines to 18.1±12.1g at 3 months (n=120) and 14.4±10.8g at 6 months post-treatment (n=96). Cohort A showed a significant decrease in TGW from 27.3 g (IQR: 18.4-40.5) to 18.0 g (IQR: 12.5-30.1) at 2 weeks ($P < 0.001$, $Z=-12.329$). Continued reductions were observed in Cohort B (19.7 g to 14.7 g, $P < 0.001$, $Z=-7.519$) and Cohort C (15.6 g to 10.3 g, $P < 0.001$, $Z=-6.966$). ***Conclusion:*** ^{131}I therapy significantly reduces TGW in patients with Graves' hyperthyroidism, with maximal therapeutic effect occurring within the first 2 weeks post-treatment, followed by sustained but attenuated volume reduction over time within 6 months, highlighting the importance of early monitoring in clinical management.

EP-0901

Radiation Synovectomy with 177Lu-MAA in Patients with Inflammatory Knee Joint Disorders

K. Saglam[1], *M. S. Sağer*[1], *S. Bilgiç*[2], *E. Karayel*[1], *H. Pehlivanoğlu*[1], *A. Aygün*[1], *N. Yeyin*[1], *M. K. Özşahin*[1], *M. Özer*[1], *C. D. Davulcu*[1], *H. Botanlıoğlu*[1], *S. Asa*[1], *O. E. Şahin*[1], *R. L. Uslu*[1], *H. B. Sayman*[1];
[1]*Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE,* [2]*Uludag University, Bursa, TÜRKIYE.*

Aim/Introduction: Pigmented villonodular synovitis (PVNS) is a benign, proliferative, and inflammatory synovial disease of unknown etiology. In the treatment of PVNS or PVNS-like chronic inflammatory conditions characterized by synovial hypertrophy, both surgical synovectomy and radiation synovectomy are considered as therapeutic options. The radionuclides commonly used for radiosynovectomy include 90Y, 177Lu, and 188Re. However, the routine use of 90Y often poses challenges in terms of cost and availability. 177Lu, when labeled with macroaggregated albumin (MAA), forms a complex with particle sizes between 10-90 µm and binds with >99.5% efficiency. This study aimed to evaluate the use of 177Lu-MAA for radiosynovectomy in patients with PVNS-like inflammatory knee conditions, with the goal of reducing inflammation and pain. ***Materials and Methods:*** Patients with clinical, laboratory, and imaging findings indicating the need for radiosynovectomy were prospectively selected. 10 patients were included. Pre-treatment knee MRI and bone scintigraphy were performed. On the day of treatment, 8-10 mCi of 177Lu-MAA was injected intra-articularly into the knee. Follow-up imaging at 3 and 6 months post-treatment was requested. Clinical outcomes were assessed using the KOOS (Knee Injury and Osteoarthritis Outcome Score) and VAS (Visual Analog Scale) for pain at baseline and at 1, 3, 6, and 12 months post-treatment. ***Results:*** Post-injection scintigraphy on the day of treatment and day 7 showed intra-articular distribution of the radiopharmaceutical. Whole-body planar imaging confirmed that there was no significant extra-articular leakage. Only two patients developed transient effusion, and no persistent side effects or radiation-induced damage were observed. Among nine patients with follow-up imaging, five showed partial regression in at least one modality, four were stable. The KOOS scores showed the most improvement at 3 months post-treatment, rising from 48.58% pre-treatment to 60.29%—a 24% relative increase. Although the scores declined to 58.22% at 6 months and 53.50% at 12 months, they remained significantly improved compared to baseline. The mean VAS score decreased from 50.5% at baseline to 29.5% at 1 month, reached a low of 22% at 6 months, and returned to 29.5% at 12 months. ***Conclusion:*** This study demonstrated a rapid improvement in KOOS and VAS scores in the early post-treatment period. Although a slight decline was observed by the 12th month, the improvements remained notable compared to pre-treatment values. The results suggest that 177Lu-MAA is a promising radiopharmaceutical with a favorable safety profile for use in routine radiosynovectomy. However, repeated dosing may be required for sustained benefit in long-term follow-up.

EP-0902

Graves' Disease: Is Hyperthyroidism Still Present 6 Months After Radioactive Iodine Treatment Really a Failure?

M. Acar Tayyar, *E. Uyanık, M. Mülazımoğlu, M. Ö. Tamam, S. Karyağar, M. Biçen Altın, F. Yıldız Kabaca, M. Cinoğlu Karaca, A. Vergili, T. Özülker;*
University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Graves' disease is one of the most common causes of hyperthyroidism and effective treatment options include radioactive iodine (RAI) therapy. According to the American Thyroid Association guidelines, if the patient is still hyperthyroid 6 months after RAI, it is considered a treatment failure and repeat treatment is recommended.The aim of this study was to examine the accuracy of the 6-month assessment and factors associated with late hypothyroidism to accept treatment failure or to decide on dose repetition after a single dose of RAI for Graves' disease. ***Materials and Methods:*** In our study, who developed hypothyroidism or euthyroidism within 24 months after single dose RAI treatment with a diagnosis of Graves' disease between 2003 and 2022, who were followed up regularly for at least 2 years, who had no extrathyroidal symptoms, who had no nodules on pre-treatment ultrasound, and who had iodine uptake tests were analysed retrospectively.The study group was divided into 2 groups as patients who developed hypothyroidism within the first 6 months and patients who developed hypothyroidism after the 6th month. ***Results:*** The mean age of 104 patients (74 females,30 males) included in our study was 46.7±13.0years.The mean RAI dose was 10.6±4.4mCi and the mean duration of hypothyroidism was 5.5±5.4months.15 patients were euthyroid and 89 patients were hypothyroid.65 patients developed hypothyroidism in the first 6 months and 24 patients developed hypothyroidism after 6 months. In patients with late hypothyroidism(>6 months); 2-hour iodine uptake value was higher and TSH values after RAI were statistically significantly lower.While 58.5% of patients with early hypothyroidism(<6 months)required antithyroid drug(ATD) treatment after RAI, all patients who developed hypothyroidism after 6 months received supportive treatment with ATD.The 24-hour iodine uptake percentage values were statistically significantly higher in the hypothyroid group than in the euthyroid group.In follow-up data, 26.9% of patients were hypothyroid at 0-3 months and 62.5% at 3-6 months,while this rate increased to 77.9% at 12 months. 20.1% of patients were still hyperthyroid at 6 months,while this rate decreased to 3.8% at 12 months.

Conclusion: This study has shown that the 6th month after RAI treatment in Graves' disease patients may be an early time to assess treatment failure.Hypothyroidism develops at a cumulative rate and this rate increases gradually in the first 12 months.Iodine uptake tests at 2-24 hours for dose calculation are indicative of the course of hypothyroidism/euthyroidism and the development of early and late hypothyroidism in the patient.

EP-0903

Impact of attenuation correction on SPECT/CT myocardial perfusion imaging in relation to Body mass Index (BMI)

S. Mammeri[1], *A. Bouzidi*[2];
[1]*University Military Hospital of Ouargla Algeria, Ouargla, ALGERIA,* [2]*University Military Hospital of Constantine, Constantine, ALGERIA.*

Aim/Introduction: Obesity is an increasing health concern in the worldwide, and attenuation artifacts are more commonly observed in individuals with higher mass index (BMI). This study aimed to assess the role of CT-AC in improving interpretation agreement for myocardial perfusion imaging and explored whether its efficacy differs among BMI groups. ***Materials and Methods:*** In this prospective study, 85 patients with known or suspected coronary artery disease underwent stress/rest Tc-99m MIBI SPECT/CT myocardial perfusion imaging (MPI) over two days.Two blinded readers independently analyzed MPI results,comparing attenuation-corrected(AC) and non-attenuation-corrected (NAC) images. the cohort was stratified by BMI (<30 [n=55] and ≥30 [n=30]).Invasive coronary angiography performed within± 3 months of MPI , served as the reference standard.Readers were blinded to clinical data and AC/NAC status. ***Results:*** For detection of significant CAD (≥ 70% stenosis)Overall performance: AC -SPECT showed lower sensitivity (86% vs 96%) but higher specificity (88% vs 51%) and accuracy (87% vs 78%) compared to NAC-SPECT . By BMI category: BMI <30: sensitivity : 84%(AC) vs 87%(NAC). Specificity: 87%(AC) vs 54% (NAC).BMI ≥30: sensitivity: 89%(AC) vs 94% (NAC).Specificity: 91%(AC) vs 45% (NAC).AC-SPECT demonstrated significantly improved specificity versus NAC -SPECT overall (p <0.001) and in both BMI groups (both p<0.001). ***Conclusion:*** Our study indicated that CT-based attenuation correction (AC) significantly improved specificity across all BMI categories, including both BMI< 30 and BMI ≥30 ,as well as in the overall study population.Althought a slight reduction in sensitivity was observed, the use of AC resulted in a net improvement in the diagnostic accuracy of Tc-99m sestamibi myocardial perfusion imaging (MPI). Key Words: Attenuation correction. single photon emission tomography.Body mass index.CT. ***References:*** 1. Hendel RC, Berman DS, Cullom SJ, Follansbee W, Heller GV, Kiat H, et all. Towards 3D: an advanced flow phantom to validate dynamic renal SPECT imaging

H. Suoraniemi[1], *M. Seppänen*[2], *T. Noponen*[1];
[1]*Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services county of Southwest Finland, Turku, FINLAND,* [2]*Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland, Turku, FINLAND.*

Aim/Introduction: Next-generation ring-design SPECT/CT systems enable the transition from dynamic two-dimensional (2D) region of interest (ROI) planar imaging to three-dimensional (3D) volume of interest (VOI) SPECT imaging. While dynamic 3D SPECT offers improved quantification and accuracy, its validation requires a phantom capable of 3D dynamic acquisition. Most available renal flow phantoms are designed for 2D planar imaging. We introduce an advanced dynamic flow phantom with a realistic anatomical structure simulating normal renal perfusion, uptake, and clearance kinetics to evaluate the feasibility of dynamic renal 3D SPECT acquisitions. ***Materials and Methods:*** Custom-designed models representing left and right kidneys were 3D-printed and integrated into a flow system. The kidney model was designed as an anatomically realistic 3D structure mimicking the renal cortex, medulla, and pelvis. In the measurements 30 MBq of ^{99m}Tc pertechnetate was injected into the flow system to simulate renal perfusion, while additional 40 MBq was administered to a torso phantom containing the 3D-printed kidneys to simulate background activity. Acquisitions were performed with a ring-design SPECT/CT system. Data were acquired in list-mode format and reconstructed using a regularized iterative algorithm with (AC) and without (NC) CT-based attenuation correction. Left and right kidney VOI time-activity curves (TAC) were analyzed to compare kinetic parameters, including time to peak (T_{peak}), time to half-out ($T_{1/2out}$), and area under the curve (AUC), between AC and NC images. The uptake and clearance of left and right kidneys were compared by calculating relative functions (1-2, 1-3, 2-3 min) and residual activities (at 4, 6, 10 and 13 min). ***Results:*** Kinetic parameters (left/right) for AC reconstructions were 130±11/140±12 s (T_{peak}), 230±8.0/248±7.2 s ($T_{1/2out}$), 4000±190/4300±250 kcounts (AUC) and for NC reconstructions 123±7.8/106±6.1 s (T_{peak}), 225±5.8/235±8.3 s ($T_{1/2out}$), 567±23/587±35 kcounts (AUC), respectively. Relative renal functions (left/right) for AC reconstructions were 50.6±2.4%/49.4±2.4% (1-2 min), 49.5±1.9%/50.5±1.9% (1-3 min), and 48.4±1.8%/51.6±1.8% (2-3 min). Residual activities (left/right) were 43.1±3.1%/47.5±2.6%, 22.7±2.7%/25.3±1.5%, 11.6±1.6%/12.4±1.5%, and 8.6±1.4%/9.6±0.5% at 4, 6, 10, and 13 min, respectively. ***Conclusion:*** Our results demonstrate reproducible flow patterns in the phantom resembling normal renal functions. AC and NC reconstructed TACs showed comparable uptake and clearance patterns. Relative renal functions and residual activities indicate symmetrical functions between the left and right kidney phantoms. The developed flow phantom models the normal kidney functions reproducibly, serving as an excellent accessory for dynamic renal 3D SPECT validation. Our results show that 3D renal SPECT is feasible with a ring-design SPECT/CT system.

Evaluation of the SIMIND Monte Carlo Program on a planar and SPECT system using ^{177}Lu demonstrated potential for personalized dosimetry

M. Dias[1,2], *P. Ferreira*[1], *R. Parafita*[1], *M. Costa*[1], *F. Oliveira*[1], *L. C. Silva*[1], *Â. Silva*[1], *J. Cruz*[2], *D. C. Costa*[1];
[1]*Champalimaud Foundation, Lisboa, PORTUGAL,* [2]*Faculdade de Ciências e Tecnologia, Universidade Nova de Lisbon, Lisbon, PORTUGAL.*

Aim/Introduction: Single-photon emission computed tomography (SPECT) images of ^{177}Lu-radioligand therapy (RLT) are of paramount importance for ^{177}Lu-RLT dosimetry. Digital SPECT scanner simulations can help determine the best parameters to be used in the real SPECT acquisitions for each patient, and consequently improve dosimetry estimation. This work aims to evaluate SIMIND's ability to accurately reproduce phantom images using ^{177}Lu in our real SPECT scanner. Additionally, we aim to compare the results obtained with the benchmark results obtained with ^{99m}Tc. ***Materials and Methods:*** SIMIND Monte Carlo software (v8.0) was used to simulate projections to be reconstructed with the PyTomography library, based on the ordered subset expectation maximization (OSEM) algorithm. CT attenuation correction and scatter estimation based on the triple energy window (TEW) method were utilized. Our SIMIND SPECT scanner was validated by comparing the simulation results of the National Electrical Manufacturers Association (NEMA NU 1-2007) tests with those obtained from experimental measurements performed on our Phillips BrightView SPECT scanner. Intrinsic spatial resolution (ISR) and intrinsic spatial linearity (ISL) were measured using the NEMA slit transmission test pattern. A point source and planar acquisitions were used to complete these tests and obtain the intrinsic energy resolution (IER). A petri dish and a cylinder water phantom were used to calculate system planar and SPECT sensitivity. The first three tests employed ^{99m}Tc, while the sensitivity experiments also included ^{177}Lu. Low-energy high-resolution (LEHR) and medium-energy general purpose (MEGP) collimators were used for ^{99m}Tc and ^{177}Lu experiments, respectively. ***Results:*** Based on ^{99m}Tc, ISR was 3.395 mm and 3.227 mm, ISL was 0.71 mm and 0.76 mm, and IER was 9.85% and 9.68%, for simulated and real systems, respectively. System planar sensitivity was 76.2 cps/MBq and 75.4 cps/MBq for ^{99m}Tc, and 7.6 cps/MBq and 7.7 cps/MBq, with ^{177}Lu for simulated and real systems, respectively. The measured and simulated SPECT sensitivity for ^{99m}Tc were 2.90x10^5 cps/(MBq/cm^3) and 3.17x10^5 cps/(MBq/cm^3), respectively. SPECT sensitivity for ^{177}Lu were 3.26x10^4 cps/(MBq/cm^3) and 3.38x10^4 cps/(MBq/cm^3), respectively. The computed SIMIND simulations agree (within 5%) with real measurements made in our SPECT scanner, except for the ISL and SPECT sensitivity for ^{99m}Tc, which presented deviations of about 6-9%. ***Conclusion:*** We can conclude that SIMIND is suitable for modelling our real SPECT scanner. These results motivate further investigation of SIMIND's potential to reproduce real clinical images. They have the potential to allow personalized dosimetry in ^{177}Lu-RLT of real patients.

EP-0906

Breathing artifact remotion in SPECT/CT images of liver lesions: a phantom-based study

G. Abbatini[1,2], *B. Cassano*[1], *M. D'Andrea*[1], *R. Sciuto*[3], *A. Soriani*[1], *S. Ungania*[1], *L. Miseo*[4], *G. Iaccarino*[1];
[1]*Medical Physics Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [2]*Post Graduation School of Medical Physics, University of Rome "Tor Vergata", Rome, ITALY,* [3]*Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY,* [4]*Medical Physics Service, USL Umbria 2, Foligno, ITALY.*

Aim/Introduction: Dosimetry of liver lesions in Selective Internal Radiotherapy (SIRT) is affected by respiratory motion, which causes blurring and artifacts in SPECT images leading to activity mis-estimation. This effect is amplified by the co-registration with a CT scan acquired during an unknown respiratory phase. The aim of this study is to propose a method to compensate for respiratory motion during SPECT acquisition, in order to obtain a breath-hold like image suitable for co-registration with an inhalation-phase CT. Consequently, having both the SPECT and CT in the same respiratory phase allows for improved accuracy in prescribing the activity of ^{90}Y-labelled resin microspheres to be administered for therapy. ***Materials and Methods:*** The method consists of a free-breathing SPECT acquisition (FB-SPECT), a planar scintigraphy and a CT, both acquired during the breath-hold (BH) inhalation phase. A camera tracks respiratory motion during FB-SPECT by capturing positions of a marker-box placed on the patient's abdomen. The developed algorithm computes the optimal breathing kernel to achieve the best agreement between the first FB-SPECT projection with the BH-image. The method was validated by performing four studies (S1-S4) on a moving respiratory phantom. Spheres filled with ^{99m}Tc were inserted to simulate lesions. In S1 and S2, a sphere with a radius of 0.8 cm was used. S3 and S4 were performed with a 2 cm radius sphere including a cold spherical insert (radius = 1 cm) simulating a necrotic lesion. The phantom moved sinusoidally (2 cm amplitude) in S1 and S3, and in a real patient's breathing pattern in S2 and S4. Performance was evaluated using a relative recovery coefficient (rRC). By contouring a ROI on the BH-CT along the physical dimensions of the sphere, rRC was defined as the ratio of the counts within the ROI for the SPECT reconstructions to the counts in the BH-SPECT (gold standard). Both uncorrected and corrected images were evaluated (rRC_u and rRC_c, respectively). ***Results:*** In S1 and S2, rRC_u was 41% and 17%, whereas rRC_c was 95% and 96%, respectively. Similarly, in S3 and S4, rRC_u was 63% and 53%, while rRC_c reached 93% and 95%. ***Conclusion:*** The results demonstrate the ability of the algorithm to compensate for respiratory motion in SPECT images. Studies on patients undergoing liver radioembolization treatments with ^{90}Y-labelled resin microspheres are needed to verify the clinical potential of the proposed method and to assess dosimetric implications of respiratory motion artifact.

EP-0907

Optimization of ^{99m}Tc SPECT in the presence of ^{90}Y: towards a single-session radioembolization workflow

C. Kerckhaert*, M. M. A. Dietze, R. van Rooij, M. B. M. Meddens, N. Wijnen, M. L. J. Smits, M. G. E. H. Lam, H. W. A. M. de Jong; University Medical Center Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: Technetium-99m macro aggregated albumin (^{99m}Tc-MAA) imaging is typically used for treatment planning of yttrium-90 (^{90}Y) radioembolization, with planning and therapy performed in separate sessions [1]. Our hospital is exploring a single-session workflow that combines these procedures using a hybrid C-arm SPECT/CBCT scanner for intra-procedural ^{99m}Tc-imaging [2]. To validate this interventional scanner, an additional ^{99m}Tc SPECT will be acquired post-procedurally on a conventional clinical system. However, residual ^{90}Y activity may compromise image quality of the post-procedural ^{99m}Tc SPECT through crosstalk. This study investigates the feasibility of ^{99m}Tc SPECT imaging from combined ^{99m}Tc+^{90}Y acquisitions and identifies the most effective method for mitigating ^{90}Y-induced image degradation. ***Materials and Methods:*** An anthropomorphic torso phantom with two liver tumor inserts was imaged using single-isotope (^{99m}Tc) and dual-isotope (^{99m}Tc +^{90}Y) configurations. Three collimators (low energy high resolution: LEHR, medium energy: ME, and high energy: HE) and three methods to compensate for ^{90}Y crosstalk (Monte Carlo-based, dual-energy-window and triple-energy-window correction) were evaluated. Quantitative analyses included tumor contrast recovery, extrahepatic activity recovery and lung shunt fraction accuracy. In addition, potential dead-time effects due to high ^{90}Y flux were investigated using point-source measurements. ***Results:*** Point-source measurements indicated no substantial dead-time effects up to approximately 12 GBq with LEHR, 29 GBq with ME and >30 GBq with HE (^{99m}Tc:^{90}Y ratio 1:20). Compared to the clinical standard (single-isotope ^{99m}Tc imaging with LEHR collimator), contrast recovery typically decreased from 80.0 ±1.5 % to 56.8 ±1.2 % (LEHR), 70.3 ±1.9 % (ME) or 72.5 ±1.5 % (HE) due to ^{90}Y crosstalk. Use of compensation methods increased the contrast recovery level, with the combination of Monte Carlo-based compensation with a ME or HE collimator

producing the best contrast recovery at 78.6 ±2.0 and 79.4 ±1.7 %, respectively. Lung shunt estimations were substantially degraded by ^{90}Y crosstalk, but this could be effectively mitigated by using a ME or HE collimator. In terms of visual quality, the ME collimator resulted in the best resolution and the least scatter contamination. ***Conclusion:*** Dual-isotope imaging with ^{99m}Tc and ^{90}Y is feasible at clinically relevant activities without introducing significant dead-time effects. Monte Carlo-based compensation method in combination with a ME collimator offers the most accurate, robust and visually optimal reconstruction method for post-radioembolization ^{99m}Tc SPECT. ***References:*** 1. EP-0908

Use of myocardial SNR in optimisation of myocardial perfusion scintigraphy

T. Biggans*, J. Asogan Vaishnavi, A. K. Raofi, P. Guntur Ramkumar; NHS Tayside, Dundee, UNITED KINGDOM.*

Aim/Introduction: Signal-to-noise ratio (SNR) is an objective measure that can be used to determine appropriate reductions in both administered activity and acquisition time while maintaining sufficient image quality. SNR is typically calculated using an area of uniform uptake which is not found in myocardial perfusion scintigraphy (MPS). The aim of this work was to develop and assess a novel technique to determine myocardial SNR based on the methods described by Armstrong et al. and Schmidtlein et al. and use this metric to determine an optimised protocol for MPS. ***Materials and Methods:*** An anthropomorphic torso phantom was filled with ^{99m}Tc in three configurations: no defects, mid anterior defect and basal inferior defect. SPECT-CT acquisitions were performed with the phantom in each configuration with and without simulated breast attenuation. Patients with a BMI ≥ 35 kg/m^2 who underwent Stress MPS at Ninewells Hospital, Dundee, Scotland between 1st March 2023 and 30th November 2024 were selected for retrospective analysis. Acquisitions were reconstructed using conventional ordered subsets expectation maximisation (OSEM) and cardiac dedicated maximum a posteriori (MAP) algorithms. SNR within the myocardium was derived from parametric images (mean and standard deviation) generated from multiple replicate images created through repeated Poisson resampling of the acquisition data. An optimised protocol was determined and simulated using Poisson resampling. Current protocol and proposed protocol image sets were shown as a side-by-side comparison and two consultant radiologists were asked to score image quality for each set using a scale of 0-3 and to comment on any discrepancy between the two image sets. ***Results:*** The phantom study using OSEM resulted in a mean SNR of 9.3 and 10.3 with and without breast attenuation respectively. Mean SNR with and without breast attenuation improved by 41% and 32% respectively using the cardiac dedicated MAP algorithm. Simulation of the derived optimised protocol gave a mean SNR of 9.8. The mean image quality score for both image sets was 2.4 out of 3 and only minor differences were noted on four occasions. ***Conclusion:*** Myocardial SNR can be measured and used to determine an optimised MPS SPECT-CT protocol that maintains image quality. ***References:*** Armstrong et al. EP-0909

Incidental detection of ATTR cardiac amyloidosis by ^{99m}Tc-DPD bone scintigraphy and SPECT/CT

M. Corza Ayala*, R. Hernandez Ramírez, K. Cárdenas Soto, A. Arriaga Contreras, F. Solano Caballero, O. Lucio Baez; Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, MEXICO.*

Aim/Introduction: Cardiac transthyretin amyloidosis (CA-ATTR) is an underdiagnosed genetic disease caused by the deposition of misfolded TTR protein, resulting in multiorgan dysfunction and death. Recent data suggest that it may be responsible for up to 30% of cases of heart failure with preserved ejection fraction in patients over 75 years of age. Early detection is crucial to improve patient prognosis and quality of life. 1, 2. Underdiagnosed CA-ATTR predominantly affects adults and is associated with high morbidity and mortality. 2 Early detection is crucial to initiate timely treatment and improve prognosis. Incidental myocardial uptake of bone tracers in BS, although relatively common (1.46% to 3.6%), often goes unrecognized, delaying diagnosis and treatment of the disease. The high prevalence of this uptake underscores its epidemiological importance 3,4,5. Early detection using BS could improve patient outcomes, providing a scalable and cost-effective screening tool. Aim: To determine the prevalence of incidental cardiac amyloidosis detected by bone scintigraphy in patients studied for different indications. ***Materials and Methods:*** This was an observational, descriptive, cross-sectional, analytical, and retrospective study. Imaging records from BS at the Salvador Zubirán National Institute of Medical Sciences and Nutrition were reviewed from January 1, 2022 to January 1, 2025. The Perugini index was assessed, and echocardiographic and clinical data were analyzed for those with an index ≥2. ***Results:*** A total of 834 bone scans were evaluated within the study period, a total of 25 patients with Perugini ≥ 2 and 2 patients with index 4 were identified (prevalence of 2.9%), echocardiographic data of these patients were evaluated, of which 45% presented alterations. ***Conclusion:*** Targeted evaluation of cardiac topography on any bone scan is advisable, as it may aid in the incidental diagnosis of cardiac amyloidosis. ***References:*** 1 Briseño Godínez et al. Imaging the Impractical: Optimising Imaging for Therapies With Under 10 MBq of Beta-Emitting P32

C. Oldfield*, S. Sargant; Manchester Foundation Trust, Manchester, UNITED KINGDOM.*

Aim/Introduction: Pancreatic cancer has a poor prognosis. With a one-year survival around 10 %[1]. Clinical trials using P32 as a molecular radiotherapy agent are currently underway for patients with locally advanced non-resectable pancreatic cancer. Due to the small size of the tumours these treatments require activities from 2 to 60 MBq with the pure beta emitting isotope. Imaging following administration is important to confirm the P32 is correctly localised, and with this treatment the production of

high quality images proves a unique challenge. Whilst lessons can be learnt from the imaging of Y90 SIRT, the fact that this therapy can use up to three orders of magnitude less activity means that image formation is inherently high noise. A combination of phantom work and reprocessing of the acquired data for first two patients treated at Manchester Foundation Trust was used to develop robust acquisition and reconstruction for these patients. ***Materials and Methods:*** A series of SPECT-CT acquisitions were performed of a water phantom containing an insert representing focal administration of 16 MBq of P32. Scan lengths were varied to acquire data consistent with patient administrations from 2 to 60 MBq. Choices of energy window were explored at acquisition. At reconstruction the matrix size, number of iterations, number of subsets, and size of the post-reconstruction Gaussian smoothing filter were all varied and the impact on image quality explored. After establishing an appropriate acquisition protocol for the first patient only the impact of choices in reconstruction were explored using clinical data. ***Results:*** The primary barrier for lower administered activities is image noise. As such, steps to suppress this in the reconstruction were valuable. Using a 64x64 matrix, only using 20-30 updates with 1 subset, and applying a smoothing filter of 15-25 mm was necessary to provide images useful for clinical interpretation. The use of a wide energy window such at 75-125 keV captures an adequate fraction of the output bremsstrahlung photons, and the use of low septal-penetration collimators helps preserve the limited spatial information. ***Conclusion:*** It is a key part of the role of a physicist to be involved in optimisation. Imaging in a high noise environment requires serious compromise in the way that data are acquired and reconstructed. The tools used to produce images of diagnostic utility here will be applicable to other radiopharmaceuticals and clinical scenarios and may provide a useful reminder. ***References:*** [1] Survival for pancreatic cancer, CRUK https://www.cancerresearchuk.org/about-cancer/pancreatic-cancer/survival 04/05/2025.

EP-0911

Clinical implementation of an Advanced SPECT/CT service on the GE Healthcare Aurora Gamma Camera

L. Rowley, *E. Comber, C. Low, V. Leung, O. Adesanya;*
University Hospitals Coventry and Warwickshire, Coventry, UNITED KINGDOM.

Aim/Introduction: Following the installation of the GE Healthcare Aurora gamma camera with a 128-slice Revolution Ascend CT scanner, our institution transitioned from planar radionuclide imaging and low dose SPECT/CT imaging to high resolution, diagnostic quality SPECT/CT, incorporating intravenous contrast when clinically indicated. This shift necessitated the development of a new vetting and imaging workflow. Protocol optimisation was undertaken using Clarify Deep-Learning (DL) reconstruction to reduce acquisition time, and a "one-stop" imaging approach incorporating contrast-enhanced CT for Whole-Body Bone SPECT/CT and Sestamibi parathyroid imaging. ***Materials and Methods:*** Patients with prior history of widespread metastatic disease, confirmed on previous planar bone imaging, continued with planar imaging to enable accurate follow-up and comparison of like-for-like images. New referrals and patients with previously negative or limited disease underwent both planar and whole-body SPECT/CT imaging. Similarly, new referrals for Sestamibi parathyroid imaging without a positive Ultrasound scan SPECT/CT and patients with previously negative or limited disease underwent both planar and Dynamic contrast-enhanced 4D CT imaging of the parathyroid.A retrospective analysis of 20 bone scans was performed to evaluate reduced imaging times using the new low energy high-resolution sensitivity (LEHRS) collimators. Phantom studies and patient image reconstructions were used to determine the optimal beta value for Clarify-DL, with image quality assessed by experienced radiologists.A dedicated workflow was developed for intravenous contrast-enhanced CT in patients referred for prostate and breast cancer staging and a separate dedicated workflow was developed for 4D dynamic intravenous contrast-enhanced parathyroid SPECT-CT in patients referred for hyperparathyroidsm. These included the implementation of one-stop imaging services. Patient and referrer satisfaction was assessed via surveys, and a cost analysis was conducted. ***Results:*** The new workflow was successfully implemented for bone scans and parathyroid imaging, supported by comprehensive staff training. An initial adjustment period was required due to legacy referrals not aligning with the updated protocol. While the inclusion of SPECT imaging and contrast-enhanced CT increased the reporting workload, this presented challenges in aligning with existing radiology reporting allocations.Use of Clarify DL reconstruction enabled a reduction in imaging time, maintaining comparable throughput to planar imaging while preserving diagnostic quality. Patient feedback was overwhelmingly positive. ***Conclusion:*** The transition to whole-body SPECT/CT bone imaging and 4D dynamic contrast enhanced parathyroid imaging for all new referrals has been successfully achieved. This has resulted in enhanced image quality and diagnostic detail, improved service efficiency, and a better patient experience, with favourable implications for both clinical practice and cost-effectiveness.

EP-0912

Impact of Reduced Acquisition Time on Quantitative Gated SPECT Parameters Using a Dedicated CZT Cardiac Camera

T. Cakir[1], *A. Guner*[1], *V. Beylergil*[2];
[1]*Medipol University, Istanbul, TÜRKIYE,* [2]*Memorial Sloan Kettering Cancer Center, Istanbul, TÜRKIYE.*

Aim/Introduction: CZT gamma cardiac cameras allow for shorter imaging times due to their high count rate capability. The aim of this study was to evaluate whether the efficiency of gated myocardial perfusion imaging (MPI) can be maintained with a further reduction in acquisition time using a dedicated CZT cardiac camera. Specifically, we investigated the repeatability of quantitative parameters when the manufacturer-recommended imaging time of 3.5 minutes was reduced to 2 minutes. ***Materials and Methods:*** A total of 114 consecutive patients underwent gated stress MPI using a dedicated CZT gamma camera. For each patient, two sequential stress acquisitions of 3.5 minutes and 2 minutes were obtained without repositioning. The following quantitative parameters were analyzed in both acquisitions: summed stress score (SSS), ejection fraction (EF), peak filling rate (PFR), mean filling rate (MFR), and time to peak filling (TTPF). Statistical comparisons were performed using the paired t-test. ***Results:*** The mean age of participants was 62.8 ± 11.4 years (59 female, 52%). The average height was 160 ± 10 cm, and mean weight was 84 ± 15 kg. Table 1 summarizes the comparison between the 3.5-minute and 2-minute protocols: Although EF was statistically higher in the 3.5-minute scan (mean difference: 0.688, SD of difference: 3.037), the effect size was small (Cohen's d = 0.23), suggesting limited clinical relevance. No significant differences were found in SSS and TTPF. ***Conclusion:*** The findings suggest that a 2-minute gated stress imaging protocol is a viable alternative to the standard 3.5-minute acquisition when using dedicated CZT cardiac cameras, particularly for perfusion assessment. While statistically significant differences were observed in EF, PFR, and MFR, the magnitude of change in EF was small and may not be clinically meaningful. Caution is advised in interpreting systolic and diastolic functional parameters—especially in clinical scenarios where these metrics are critical. In such cases, the standard 3.5-minute acquisition remains preferable. Nevertheless, the 2-minute protocol may be acceptable for clinical or research settings where reduced scan time is necessary, provided that minor variations in functional measurements are considered during interpretation.

EP-0913

Optimization of Imaging Parameters for Posttherapeutic SPECT/CT in Patients with PSMA-Positive mCRPC Following ^{177}Lu-PSMA Radioligand Therapy

D. Sfiligoj Planjsek, *K. Senica, A. Strok, B. Simonic, I. Slodnjak, S. Rep;*
UMC Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Radioligand therapy with ^{177}Lu (^{177}Lu-PSMA-RLT), when combined with standard-of-care treatment, has proven safe and effective for patients with PSMA-positive metastatic castration-resistant prostate cancer (mCRPC). Although PSMA PET/CT remains the gold standard for imaging-based restaging, it is expensive and not always readily available [2]. SPECT/CT imaging of gamma emissions from ^{177}Lu, performed 1-2 days post-treatment, represents a more accessible and cost-effective alternative for posttherapeutic response monitoring. This study aimed to optimize SPECT/CT imaging parameters by reducing acquisition time, while preserving image quality. Specifically, we investigated the feasibility of switching from a double-bed SPECT/CT (neck to upper thighs) to a triple-bed SPECT/CT protocol (vertex to mid-thigh), better aligning with the coverage of PSMA PET/CT. ***Materials and Methods:*** We shortened the per-frame duration from 20 seconds (used in double-bed SPECT/CT) to 8 seconds for each of the 60 frames per bed position in the triple-bed setup. This reduced the total scan time from 60 minutes to 24 minutes. Image quality was assessed using a NEMA IEC PET Body phantom with six ^{177}Lu filled spheres with a sphere-to-background concentration ratio of 10:1 (spheres - 323 kBq/ml; background - 30.6 kBq/ml). Both visual and quantitative evaluations were performed. Quantitative metrics included maximum and mean activity concentration (Bq/ml), standardized uptake values (SUVmax and SUVmean), and contrast-to-noise ratio (CNR). ***Results:*** Visual assessment revealed no substantial difference in image quality between 20 s/frame and 8 s/frame protocols for larger spheres with diameter ≥ 17 mm. However, smaller spheres (diameter ≤ 13 mm) appeared less clearly defined in both acquisitions. The suboptimal visualization of smaller spheres may result from the relatively low activity of the ^{177}Lu isotope used. Quantitatively, there were no statistically significant differences in measured Bq/ml (max and mean) (p=0.16; p=0.74) and SUV values (max and mean) (p=0.26; p=0.83) for different sized spheres between the two protocols. The CNR for both acquisitions showed statistically significant differences in both Bq/ml (max and mean) with p=0.04 and p=0.03, respectively, and in SUV (max and mean) with p=0.041 and p=0.031, respectively. ***Conclusion:*** Our findings suggest that a shortened acquisition time for triple-bed SPECT/CT is a viable approach for imaging response assessment following ^{177}Lu-PSMA-RLT. The reduced imaging time improves patient comfort and minimizes motion artifacts, with only minor compromise in the detection of small lesions. Given the typically high metastatic burden in this patient population, the reduced resolution for small lesions is unlikely to impact clinical decision-making.

Assessing Reduced Ga^{68} Activity and Shortened Acquisition Times on Image Quality and Lesion Contrast in LAFOV PET/CT: A Phantom Study.

G. Muti[1], *C. Romano*[1], *A. Didonna*[1], *M. Meraldi*[1], *C. Pettinato*[2], *C. Carbonini*[1], *C. Rossetti*[1], *P. Colombo*[1];
[1]*ASST GOM Niguarda, Milan, ITALY,* [2]*Fondazione IRCCS Ca' Granda, Milan, ITALY.*

Aim/Introduction: PET/CT scanners with a long axial field-of-view (LAFOV) enhance sensitivity, allowing for adjustments in imaging parameters such as reduced injected activity, shortened acquisition times, or extended uptake periods. This phantom study aimed to assess the effects of reduced Ga-68 activity doses on image quality and lesion detectability using the uMI Panorama GS PET/CT scanner. ***Materials and Methods:*** The NEMA IEC PET Body Phantom was filled with a 4:1 sphere-to-background activity ratio, with approximately a total activity of 37 MBq. Scanning was performed at 0, 3, 4, and 5-hours "post-injection". List mode reconstructions were conducted with five different acquisition durations (600, 300, 150, 120, and 60 seconds) using OSEM with 3 iteration and 10 subsets configuration, TOF and PSF corrections. SUV values (mean, max, min, peak) were calculated for five hot spheres (VOI_1: largest sphere, VOI_6: smallest sphere) and a background sphere (VOI_7). Tumor-to-background ratios (TBR: the SUV Lesion Peak divided by the SUV Background Mean) were used to assess lesion contrast and coefficient of variation of VOI_7 (CoV: the SUV standard deviation divided by the SUV Mean of the background) to asses image noise. A threshold of CoV <15% was considered for interpretation, as recommended by EFOMP [1]. ***Results:*** The SUV values for the acquisition at time 0-hours at varying reconstruction times had the same trend as the 600s acquisition as the activity decays. For these reconstructions, median values were: SUVMean 2% [Q1: 0.1%; Q3: 5%], SUVMin 5% [Q1: 1%; Q3: 10%], SUVPeak 2% [Q1: 0.1%; Q3: 5%], and SUVMax 7% [Q1: 3%; Q3: 12%]. Differences increased significantly for shorter acquisition times at 3, 4, and 5-hours "post-injection". CoV is <15% for all reconstructions at time 0, except for the 30 seconds scan, at 3-hours for 600 seconds and 300 seconds scans; at 4-hours only for 600 seconds; and at 5-hours, no scans achieved a CoV<15%. Polynomial fitting of CoV data suggests that for a 5-hours late acquisition a 15-minute scan is required to get a CoV <15%. ***Conclusion:*** These results indicate that for 4 hours (~4 half-lives) a 600s scan is sufficient, that a reduced activity level or extended uptake periods can be balanced with a not much longer acquisition, and that preliminary phantom estimates provide guidance on the scan duration needed for patient imaging. ***References:*** 1) EFOMP Protocol for Quality Control in PET/CT and PET/MRI. EP-0915

Design and Initial Evaluation of a 2-Meter Axial FOV Total-Body PET System With Integrated DOI and TOF Capability

D. Liang, *Y. Lin, Z. Zhao, H. Zou, Y. Xu, H. Liu, Y. Lin, W. Ma, W. Zhu, J. Tao, H. Zhao, W. Li, Y. Zhang, Q. Peng;*
Shenzhen Bay Laboratory, Shenzhen, CHINA.

Aim/Introduction: Total-body positron emission tomography (TB-PET), with its ultra-long axial field of view (AFOV), enables high-sensitivity, low-dose, and rapid whole-body imaging in a single scan [1]. This study presents a TB-PET system designed with time-of-flight (TOF) and depth-of-interaction (DOI) readout capabilities [2], aiming to address the limitations of conventional scanners and support improved performance for both clinical and research applications. ***Materials and Methods:*** The proposed TB-PET system features a 2-meter AFOV and a bore diameter of 82.6 cm. It comprises seven axial units, each consisting of 22 detector panels. Each panel includes 6 detector blocks circumferentially and 12 blocks axially. Every block contains an array of 8 × 10 LYSO crystals (2.05 × 2.05 × 20 mm^3), optically coupled to a 4 × 5 silicon photomultiplier (SiPM) array. Initial performance was assessed using a Hoffman brain phantom to evaluate spatial resolution and image quality. System sensitivity was further evaluated through Monte Carlo simulations. ***Results:*** Using an energy window of 411-611 keV and without TOF or DOI correction, the system was able to resolve fine structural details in the Hoffman brain phantom. Monte Carlo simulations yielded a total sensitivity of 180.34

cps/kBq at the center and 173.63 cps/kBq at 10 cm radial offset. Additional evaluations incorporating TOF and DOI capabilities are currently underway. ***Conclusion:*** We have developed a TB-PET system with a 2-meter AFOV and high detector density, enabling full-body coverage in a single bed position. Compared to existing TB-PET systems, the use of smaller crystals and DOI decoding is expected to provide improved spatial resolution. Preliminary phantom and simulation results demonstrate high sensitivity and promising image quality, even in the absence of TOF and DOI corrections. These findings indicate strong potential for clinical and research applications, with ongoing efforts focused on integrating advanced timing and spatial decoding technologies to further enhance system performance. ***References:*** [1] Hicks R J, Ware R E, Callahan J. Optimisation of scanning protocols for the Siemens Biograph long-axial field-of-view scanner: Can higher patient throughput with improved image quality be achieved at reduced patient dose?

G. Krokos*, S. Chicklore, J. MacKewn, J. John, S. Pereira, S. Gould, S. Jin, G. Testanera, A. Hammers, P. K. Marsden, G. Cook;*
King's College London, London, UNITED KINGDOM.

Aim/Introduction: The introduction of high sensitivity long-axial-field-of-view PET-CT scanners has revolutionised PET imaging. Key clinical optimisation parameters include scan duration, administered activity, and image quality. We investigated how to achieve a balance between these for the Biograph Vision Quadra system (Siemens Healthineers). ***Materials and Methods:*** A NEMA Image Quality phantom (46MBq ^{18}F; 5:1 sphere-to-background ratio) was scanned at three axial positions (centre, quarter, eighth) along the 106cm FOV, for durations of 5-10 minutes. Reconstructions used OSEM with time-of-flight/point spread function correction and maximum ring differences of 85 (MRD85) and 322 (MRD322) corresponding to opening angles of 18° and 52°, respectively. Accuracy was assessed using the recovery coefficients (RCmax, RCpeak, RCmean) and noise using image roughness (IR) and background variability (BV). Twenty patients underwent PET-CT with 2MBq/kg [^{18}F]FDG. Clinical images were reconstructed as described. Image noise was assessed using Coefficient-of-Variation (CoV) in liver. Tumour-to-background ratio (TBRmax, TBRpeak) and contrast-to-noise ratio (CNR) were also estimated. MRD85 images at 5, 7, and 10 minutes were rated 1-5 (5 = best) by two experienced clinicians for image quality, liver noise, and bone marrow/small lesion conspicuity. ***Results:*** Phantom analysis showed increasing errors in RC, albeit minimal, and higher noise with shorter durations and greater axial offsets for both MRDs with the highest biases (10% for RCmean) measured at the eighth FOV and 5-minute scan for MRD322. A twofold increase was measured for BV for both MRDs when moving from the middle to the eighth FOV. A similar increase was noticed for IR for MRD322 and up to 40% increase for MRD85. The noise difference between MRD85 and MRD322 decreased with offset from approximately 50% to 6% for IR and from 25% to 2% for BV. For the same axial position and reducing duration from 10 to 5 mins, an increase of 40-50% was noticed for both MRDs. Nevertheless, IR and BV, exhibited relatively low values of up to 7% and 4%, respectively. Overall clinical image quality decreased from 4.8 (10min) to 4.2 (5min) and liver/bone marrow noise from 4.6 (10min) to 3.7 (5min), with the 7-min acquisition being midway between these. Lesion conspicuity remained at 4.5. TBR values changed minimally, while CNR and CoV deteriorated by ~29% with the highest CoV being 12% (5min, MRD85). ***Conclusion:*** The system provides excellent image quality even at reduced scan time. For increased throughput a 7-minute acquisition might offer a practical compromise with minimal loss in performance.

EP-0917

Comparison of Detectability Between Digital LYSO and Digital BGO-Based PET/CT Scanners: A Phantom Study using an Anthropomorphic XL-Thorax Phantom

A. Stenvall*[1], S. Kvernby[1,2], D. Minarik[1,2];*
[1]Radiation Physics, Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, SWEDEN,
[2]Department of Translational Medicine and Wallenberg Centre of Molecular Medicine, Lund University, Malmö, SWEDEN.

Aim/Introduction: Detector material plays a critical role in PET performance. LYSO-crystals provide time-of-flight (TOF), while modern BGO-based scanners lack intrinsic TOF but have higher sensitivity. This study compares a digital LYSO PET/CT to a digital BGO PET/CT with an AI-based TOF-model, evaluating lesion detectability in a challenging anthropomorphic XL-thorax phantom geometry. ***Materials and Methods:*** An XL-thorax-phantom (16L) with liver, kidney and two spherical inserts (inner diameter 9.9mm and 12.4mm were filled with ^{18}F-FDG at clinically relevant activity concentrations at 4:1 (9.9mm) and 3:1 (12.4mm) sphere-to-background ratios. Scans were acquired consecutive on both a digital LYSO PET/CT with an axial field-of view (aFOV) of 20cm and a digital BGO PET/CT (aFOV=32cm), with matched decay corrected acquisition times representing 300s, resampled to 80%(240s), 70%(210s), 60%(180s), 40%(120s), 30%(90s), 20%(60s) and 15%(45s). Data were reconstructed using block sequential regularized expectation maximization (BSREM) with β-values ranging from 200-600 (steps of 100) for the LYSO-scanner with 256x256-matrix and BGO-scanner with 384x384-matrix, using three AI-TOF models (Low(L), Medium(M) and High(H)). Metrics for comparison included SNR in background (SNR=SUVmean_b/SD_b), contrast in cold region (Contrast_cold=(SUVmean_b-SUVmean_cold)/SUVmean_b) and detactability as the peak value within the hot sphere to the peak value in the background (P2P=peak_sphere/peak_b). A peak-ratio>1 was considered detectable. ***Results:*** SNR in the homogeneous background increased with both acquisition time and β-value for both scanners. Across all combinations, the BGO-based system yielded consistently higher SNR than the LYSO-scanner (8% (240s,β600) to 44% (45s,β200)). AI-TOF increased SNR further, with largest increase for TOF-model(L). Cold contrast decreased with increasing β-value for both systems. The LYSO-scanner demonstrated consistently higher cold contrast for all beta-time-combinations (0.97-0.99), while the BGO-system ranged from 0.90-0.98. AI-TOF gave a slight increase in cold contrast for higher beta-values, thus not to the level of the LYSO-scanner. The small 4:1-sphere and the larger 3:1-sphere, were detectable on the LYSO-scanner across all β-values for acquisition times ≥90s and ≥60s respectively, whereas the spheres were detectable for the BGO-scanner at 90s,β 200 and 180s,β200. For detectability across all spheres, 90s and 300s were required for the BGO-scanner. For detectable spheres, AI-TOF increased detectability at average 6% (4:1-sphere)/3% (3:1-sphere). TOF-model(M) increased detectability the most 11% (4:1-sphere)/8% (3:1 sphere). ***Conclusion:*** In a challenging XL-thorax phantom geometry, the BGO-scanner showed higher SNR in homogenous background, lower cold-contrast and lower detectability of hot spheres compared to the LYSO-scanner. Applying AI-TOF increased detectability of detectable spheres, although not to the level of the LYSO-scanner.

Development of ultrahigh sensitivity brain-PET system

A. Krol[1], *W. Zheng*[1], *E. S. Harmon*[2], *M. O. Thompson*[3], *C. R. Schmidtlein*[4];
[1]*SUNY Upstate Medical University, Syracuse, NY, UNITED STATES OF AMERICA,* [2]*LightSpin Technologies, Inc., Norfolk, MA, UNITED STATES OF AMERICA,* [3]*Cornell University, Ithaca, NY, UNITED STATES OF AMERICA,* [4]*Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: Currently, diseases of the brain are the leading cause of disabilities. The brain Positron Emission Tomography (PET) is a powerful noninvasive tool for clinical studies and neurology research. However, existing brain PET technologies are limited with relatively low sensitivity. Thus, there is a critical need to improve imaging performance of brain-PET. Consequently, we are developing an ultrahigh sensitivity brain-PET that will provide a new device to accelerate research and advance clinical performance. In this work, we are exploring design approaches to maximize brain-PET geometric sensitivity while preserving patients' wellbeing during PET scans. ***Materials and Methods:*** We performed Monte Carlo simulations of different variants of our proposed ultrahigh sensitivity brain-PET scanner with 20-mm-thick monolithic LYSO scintillator. It is based on cylindrical geometry with 25-cm inner diameter and 50-cm axial field-of-view. We simulated systems with: (i) rectangular (10 x 13 cm^2) "windows" located at various distances from the base; (ii) rectangular "door" 20 cm high. The simulations were performed for scanners with and without rectangular shoulder-cut-offs that allowed positioning of the brain closer to the isocenter. For each geometry, we calculated slice sensitivity profile by single-slice-rebinning method from simulated data for F-18-line source. We also obtained such profiles for the state-of-the-art brain-PET NeuroEXPLORER (NX) scanner geometry [1]. ***Results:*** We found that the regional sensitivities for brain and carotid artery territories were 45 (45) cps/kBq and 12 (18) cps/kBq, respectively for the proposed system without (with) shoulder-cut-offs vs. 32 cps/kBq and 13 cps/kBq for NX PET (1.4X gain). Introduction of a "window" in front of patient's face lowered brain ROI sensitivity to 39 (40) cps/kBq and carotid ROI sensitivity to 11 (14) cps/kBq, without (with) shoulder-cut-offs. Introduction of a 20-cm door in front patients produced 36 cps/kBq sensitivity for brain ROI (20% loss). ***Conclusion:*** We found that small diameter cylindrical brain-PET with a large rectangular face "window" and with shoulder-cut-offs reduced the brain-ROI sensitivity by only 12.5% vs. no window geometry while potentially ameliorating claustrophobia and allowing direct contact of patient with outside world. However, the proposed system has 1.3X-1.4X higher sensitivity for the brain-ROI, and higher sensitivity for the carotid-ROI (1.1X-1.4X), as compared to NX PET. ***References:*** [1] Li H, Badawi RD, Cherry SR, Fontaine K, He L, Henry S, Hillmer AT, Hu L, Khattar N, Leung EK, Li T. Aim/Introduction: The J-PET scanner is the world's first positron tomograph based on plastic strip scintillators to image the lifetime of the ortho-positronium (o-Ps) atom [1]. During conventional PET examination about 40% of positron annihilations occur through the creation of positronium, an exotic atom formed from a tissue electron and a radionuclide-emitted positron. The mean o-Ps lifetime is sensitive to tissue nanostructure and metabolism [2], and our ex-vivo and in-vivo imaging has shown significant differences in positronium mean lifetime between healthy and cancerous tissues [3-5]. Due to their diverse biogenesis and morphology, neuroendocrine tumors (NETs) require a specific diagnostic approach. Diagnostic needs in the field of NET imaging are met mainly based on a biomarker defined as overexpression of somatostatin receptors and this indicator can also be used to assess the prognosis of response to radioligand therapy of metastatic NETs [6]. Galium-68 is a radionuclide of choice for NET diagnosis with physical properties useful for positronium imaging if a routine carrier [^{68}Ga]Ga-DOTA-TATE is applied. This suggests that positronium lifetime could serve as a valuable indicator for identifying NETs. ***Materials and Methods:*** This study approved under agreement (1072.6120.92.2023; NCT06242119), we analyzed a total of 6 patients (2 woman) aged 33 to 82 years. After [^{68}Ga]Ga-DOTA-TATE administration, patients were first examined with a standard PET/CT system and then with the J-PET prototype constructed at the Jagiellonian University which is the first multiphoton system capable of simultaneous PET and positronium imaging [3,5,7,8]. ***Results:*** We successfully calculated the mean lifetime of o-Ps in liver, spleen and surrounding tissue and observed o-Ps in rage of 2.0-4.2 ns which was comparable to our previous ex-vivo measurements [4]. The relationship between o-Ps in tissue and NETs is presented. ***Conclusion:*** Our results demonstrate the feasibility of positronium imaging, a novel diagnostic method gaining popularity with the development of high-sensitivity PET systems. ***References:*** [1] P. Simulation studies of performance of an advanced brain-PET system with novel multi-concentric-ring geometry

A. Krol[1], *W. Zheng*[1], *E. S. Harmon*[2], *M. O. Thompson*[3], *C. R. Schmidtlein*[4];
[1]*SUNY Upstate Medical University, Syracuse, NY, UNITED STATES OF AMERICA,* [2]*LightSpin Technologies, Inc., Norfolk, MA, UNITED STATES OF AMERICA,* [3]*Cornell University, Ithaca, NY, UNITED STATES OF AMERICA,* [4]*Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.*

Aim/Introduction: In industrialized nations, the brain maladies are presently the leading cause of infirmities. The brain Positron Emission Tomography (PET) is a powerful noninvasive tool for neurology research and clinical examinations. Nevertheless, existing brain PET approaches are inadequate with limited sensitivity and spatial resolution. Accordingly, there is an acute need to improve imaging performance of brain-PET. To address this demand, we are developing of an advanced brain-PET scanner based on thin-slab monolithic detectors with LYSO/SiPM arrays arranged in a novel multi-concentric-ring geometry [1]. ***Materials and Methods:*** Monte Carlo simulations for a 250-mm-long cylindrical four-ring concentric system was performed with slab thicknesses of 3-3-3-3 mm; 7-mm air-gaps between rings; and inner rings diameters of 250, 270, 290 and 310 mm, respectively. The brain was simulated by a sphere of radioactive (F-18, 33 MBq) water with 170 mm diameter confined by 8-mm-thick spherical bone shell. The coincidence events studied involved photoelectric absorption (PA) and first-order Compton scatter (CS) interactions occurring within predefined coincidence time

window. ***Results:*** We found that the ratio of the number of first-order Compton events to that of true coincidences is 2.5. The ratio of the probability of intra-ring to inter-ring first-order Compton scattering is the lowest (1.3-1.7) for the central rings (i.e., with neighbors on both sides), followed for the proximal ring (1.9), and the highest for the distal ring (3.7). The relative probabilities for forward-to-backward scattering events are 66%, 92%, 98% for the first, second and third neighbor, respectively. The distribution of estimated sensitivity versus mean distance between the points-of-first-interactions (PFIs) for two anti-collinear annihilation photons interactions can be approximated by a mono-exponential function for true coincidences (PA=PA) and a slower decreasing monotonic function for triplet (PA=CS-PA) and quadruplet (PA-CS=PA-CS) events. ***Conclusion:*** We conclude that multi-concentric-ring geometry for a system with optimized air-gaps and sufficiently short coincidence time resolution may allow utilization of inter-ring CS photons to increase spatial resolution of brain-PET via more accurate determination of PFI. ***References:*** [1] Harmon, E. Modular PET detector (patent No. US20210223414 A1). U.S. Patent and Trademark Office. https://www.uspto.gov/patents-application-process/search-patents. 2021.

Impact of the hydration protocol on contrast enhancement in ^{18}F-FDG whole-body PET/CT imaging of lymphoma lesions at Apeksha Hospital, Maharagama, Sri Lanka

J. M. A. D. Jayasinghe[1], *D. D. N. Wimalarathne*[1], *H. G. D. Pasindu*[1], *W. S. N. Madhumali*[1], *W. C. Perera*[2], *S. P. D. Wijethunga*[2];
[1]*General Sir John Kotelawale Defence University, Ratmalana, SRI LANKA,* [2]*Apeksha Hospital, Maharagama, SRI LANKA.*

Aim/Introduction: ^{18}F-FDG PET/CT is vital for lymphoma diagnosis and treatment, a growing global concern. Optimal image quality requires post-radiotracer hydration. This study investigates the hydration protocol's impact on lesion contrast enhancement in lymphoma PET/CT imaging at Apeksha Hospital, Sri Lanka. ***Materials and Methods:*** A descriptive-cross sectional, prospective study was conducted at the PET scan unit at Apeksha Hospital, Sri Lanka. Water consumption was measured in patients following the administration of ^{18}F-FDG (2 deoxy 2 [18F]fluoroglucose) and PET/CT scan images were acquired. SUVmean, SUVSD values of the lesions, and healthy liver were measured. CE of the lesions was calculated by the standard formulas. For the liver, SUVmean and SUVSD values were measured by using a 1.0cm3 VOI. For lesions SUVmean and SUVSD values were measured by using a 0.25cm3 VOI. Hydration Groups were labeled as follows, 750mL(A), 750-1000mL(B), 1000mL(C) and 1000-1500mL(D). 3 lesion size groups; <2.5 cm^3, 2.5 cm^3- 4.5 cm^3 and >4.5 cm^3 were identified. Statistical data analysis was done by IBM SPSS 23.0 Software. Variations of CE with hydration levels were explored. ***Results:*** In the sample of 22 patients, the mean oral hydration was 994.55±317.61 mL. For hydration levels, CE was normally distributed. Thus, Welch's ANOVA test was performed. A correlation was investigated by the Spearman test. CE showed a positive correlation for oral hydration, the highest mean CE was observed in the hydration group C. Group D also shows a moderate CE as well as group B. In hydration group A, the mean CE of the lesions tends to decrease compared to other groups. The underweight and obese patients have low CE while others have a moderate value. Further, CE is increasing with the increasing lesion size. Conclusion- Oral hydration of at least 750mL, notably 1000mL, can positively impact the CE of lesions. Similarly, there is a positive correlation between lesion size and CE. ***Conclusion:*** Oral hydration of at least 750mL, notably 1000mL, can positively impact the CE of lesions. Similarly, there is a positive correlation between lesion size and CE. ***References:***Ceriani, L. et al. Design and Evaluation of a Pediatric Total-Body PET Scanner for Enhanced Sensitivity and Reduced Dose

P. Sheikhzadeh[1], *H. Rezaei*[2];
[1]*Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Shiraz University of Medical Science, Shiraz, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Positron Emission Tomography (PET) is a powerful tool in molecular imaging, yet conventional PET scanners are limited by low sensitivity, long scan times, and high radiation doses, especially problematic for pediatric imaging. Current systems with short axial fields of view (AFOV) require multiple passes to image the whole body, increasing scan duration and radiation exposure. This study aims to design a dedicated total-body PET scanner tailored for pediatric use, enhancing sensitivity while minimizing radiation dose. ***Materials and Methods:*** Using the GATE Monte Carlo simulation platform, a total-body pediatric PET scanner was designed and benchmarked against the Biograph 40 PET/CT system. The new design features an AFOV of 952 mm and a reduced ring diameter of 640 mm, employing smaller LSO crystal elements (1.98×1.98×20 mm^3) for higher spatial resolution. Both systems were evaluated using NEMA NU-2 2018 protocols to calculate sensitivity, resolution (using a mini-Derenzo phantom), and quantitative image metrics (SUV, SNR, noise) through imaging of an XCAT 5-year-old child phantom with a liver tumor. Data was reconstructed using CASTOR with OSEM algorithms. ***Results:*** The proposed pediatric scanner achieved a sensitivity of 147.1 kcps/MBq, approximately 18.5 times greater than the 7.9 kcps/MBq of the Biograph 40. Mini-Derenzo phantom images confirmed that both systems offer comparable spatial resolution, with clear visualization of 2.4 mm rods. However, the pediatric PET scanner, due to its higher detected counts and improved signal-to-noise ratio, was additionally able to resolve 1.2 mm rods more distinctly than the conventional PET system. The pediatric scanner demonstrated superior image quality and quantitative accuracy in the XCAT phantom evaluation, with higher SNR and lower image noise. The total-body design enabled simultaneous dynamic imaging across multiple organs and facilitated low-dose scanning suitable for pediatric use. ***Conclusion:*** The proposed pediatric total-body PET scanner significantly improves sensitivity and image quality while reducing scan time and radiation exposure. These advancements are critical for safe and effective pediatric imaging, enabling applications such as longitudinal therapy monitoring and dynamic studies. This design offers a promising solution for high-performance, child-specific PET imaging.

Exploring the Clinical Feasibility of a Wearable Brain PET System: Early Imaging Results and Outlook

H. Liu, *W. Qu, X. Yu, D. Liang, Z. Zhao, Y. Lin, J. Tao, W. Li, H. Zhao, Y. Zhang, Q. Peng;*
Institute of Biomedical Engineering, Shenzhen Bay Laboratory, Shenzhen, CHINA.

Aim/Introduction: Wearable brain positron emission tomography (PET) systems offer unprecedented opportunities for dynamic and naturalistic neuroimaging. However, achieving sufficient image quality remains challenging. This study evaluates the initial imaging performance of a compact wearable brain PET

system, highlighting current limitations and exploring the anticipated benefits of incorporating time-to-digital converter (TDC) technology. ***Materials and Methods:*** The system was evaluated using phantom and human imaging studies. A Derenzo phantom was used to assess spatial resolution, and the Hoffman brain phantom was employed to evaluate anatomical fidelity. Additionally, an initial human brain scan was conducted to explore potential clinical applicability. Further comparative experiments involving Hoffman phantom imaging with and without TDC technology are currently underway to quantify expected improvements in image quality. ***Results:*** The Derenzo phantom imaging demonstrated the system's ability to clearly resolve rods with a diameter of 1.7 mm, indicating good spatial resolution. The Hoffman phantom images showed reasonable anatomical structure differentiation, and the initial human brain scan enabled visualisation of major brain regions. However, signal-to-noise ratio and image clarity were not yet optimal. Ongoing studies suggest that incorporating TDC technology will substantially enhance image quality. ***Conclusion:*** Our results affirm the promising clinical potential of the wearable brain PET system due to its compact size, low cost, and ability to enable natural, free-motion imaging. Current image quality limitations may be substantially mitigated by integrating advanced TDC technology, thus significantly enhancing its suitability for clinical and neuroscientific applications. ***References:*** [1] Xu J, Zhao Z, Xie S, et al. FDG PET/CT Based Radiomics Analysis in Endometrium Cancer: Correlation of Tumor Heterogeneity Parameters with Pathological Findings

F. Avci[1], *A. Tunc*[1], *B. K. Erkek*[2], *A. A. Ozsaran*[3], *G. Serin*[4], *O. Zekioglu*[4], *Z. Burak*[1];
[1]*Ege University, Nuclear Medicine, Izmir, TÜRKIYE,* [2]*Agri Training and Research Hospital, Nuclear Medicine, Izmir, TÜRKIYE,* [3]*Ege University, Obstetrics and Gynecology, Izmir, TÜRKIYE,* [4]*Ege University, Pathology, Izmir, TÜRKIYE.*

Aim/Introduction: The aim of our study was to evaluate the relationship between texture parameters—such as skewness, kurtosis, and entropy—derived from FDG PET/CT images using the LIFEx software, and pathological findings in patients diagnosed with endometrial cancer. In this context, we sought to investigate the potential role of PET/CT, a non-invasive imaging modality, in assessing tumor heterogeneity and biological behavior. ***Materials and Methods:*** This retrospective study included 50 patients diagnosed with endometrial cancer who underwent preoperative FDG PET/CT imaging. Texture analysis was performed using the LIFEx software, and tumor regions were evaluated to extract radiomic features including skewness, kurtosis, and entropy. These imaging-derived parameters were then compared with postoperative histopathological data. Statistical analyses were conducted using IBM SPSS version 25. ***Results:*** The mean age at diagnosis was 62.4 years. Histological subtypes included 37 endometrioid, 9 mucinous, 3 serous, and 1 carcinosarcoma. The mean tumor size was 3.99 cm (range: 1.5-9 cm). Staging distribution revealed Stage 1 in 5 cases, Stage 2 in 36 cases, and Stage 3 in 9 cases. Lymphovascular invasion (LVI) was present in 13 patients, and cervical involvement in 4 patients. A moderate, statistically significant negative correlation was observed between skewness/kurtosis and tumor size (p=0.01; r=-0.45/-0.40). Additionally, an inverse relationship was found between entropy-log10 values and p53 expression levels (p=0.01; r=-0.3). Entropy-log10 was significantly higher in cases with LVI (p=0.035). In patients with cervical invasion, skewness was significantly lower and kurtosis was higher (p=0.04 and p=0.01). No statistically significant associations were observed between the radiomic features and histologic grade, subtype, or depth of myometrial invasion. ***Conclusion:*** Although some associations have been identified between radiomics-based tumor heterogeneity features derived from FDG PET/CT and histopathological characteristics in endometrial cancer, these findings have generally been inconsistent. Nonetheless, the potential of radiomics-derived heterogeneity parameters to contribute to personalized treatment strategies is emphasized, underlining the critical need for methodological standardization and validation in this field.

EP-0925

SUV and SUL Analysis in Ga-68 DOTATATE PET/CT: Is Liver or Spleen a More Reliable Reference?

F. Davarci*, Y. Parlak, F. Gümüşer, E. Sayit Bilgin;*
Manisa Celal Bayar University, Faculty of Medicine, Department of Nuclear Medicine, Manisa, TÜRKIYE.

Aim/Introduction: Ga-68 DOTATATE PET/CT is a highly sensitive and specific imaging modality for neuroendocrine tumors and has consequently become the standard technique for staging these tumors and assessing treatment response. While the standardized uptake value (SUV) is commonly used in tumor imaging with FDG-PET, its application in DOTA-PET imaging remains relatively limited. This study aimed to evaluate the relationship between SUV normalized to body weight (SUVbw) and SUV normalized to lean body mass (SUL), to identify the most appropriate internal reference organ for Ga-68 DOTATATE PET/CT imaging based on physiological uptake. ***Materials and Methods:*** A total of 52 patients undergoing Ga-68 DOTATATE PET/CT imaging were included in this study. Patient preparation, acquisition parameters, and reconstruction protocols were standardized across all subjects. SUVbw and SUL values were measured for the liver and spleen. Regions of interest (ROIs) were placed with a diameter of 3 cm in the right hepatic lobe and 1 cm in the spleen. The mean SUVbw and SUL values were calculated for each ROI. Statistical analysis was conducted using SPSS version 15.0 to evaluate the relationships between SUV parameters. ***Results:*** The variance of SUL values in the liver and spleen was significantly lower than that of SUVbw values ($p < 0.0001$). Additionally, both SUVbw and SUL values from the liver exhibited significantly lower variability compared to those from the spleen. Among all measured values, liver SUL demonstrated the lowest variance. This indicates that SUL is considerably less variable than SUVbw and represents a more consistent and reliable metric. ***Conclusion:*** Based on the findings, SUL particularly in the liver was determined to be the SUV measurement least affected by potential confounding factors in Ga-68 DOTATATE PET/CT imaging. Consequently, liver SUL was identified as the most reliable internal reference. Moreover, a strong correlation between liver and spleen SUV values suggests that the spleen may serve as an alternative reference organ, particularly in cases involving diffuse liver metastases. ***References:*** 1.Campana D, Ambrosini V, Pezzilli R, et. al.: Standardized uptake values of (68)Ga-DOTANOC PET: a promising prognostic tool in neuroendocrine tumors. EP-0926

Improving Brain PET/CT Accuracy with 3D Data-Driven Motion Compensation in Head CT

A. Ashfaq[1], *R. Fulton*[2], *M. Luster*[1];
[1]*Department of Nuclear Medicine, Philipps-University Marburg, Marburg, GERMANY,* [2]*University of Sydney, Sydney, AUSTRALIA.*

Aim/Introduction: Head motion during brain PET/CT imaging can significantly degrade image quality, leading to inaccurate quantification and reduced diagnostic value. This study evaluates a fully automated, 3D data-driven motion compensation (MC) method for correcting head motion during CT acquisition in brain PET/CT imaging, and evaluate its impact on both the qualitative and quantitative accuracy of the final images. ***Materials and Methods:*** The Hoffman 3D brain phantom, which simulates the anatomical and radiological properties of the human brain, was filled with fluorodeoxyglucose (^{18}F-FDG) and scanned using a Siemens Biograph mCT system equipped with a 128-slice CT scanner. A reference helical CT scan without motion served as the gold standard. Additional scans were acquired with induced head motion during the CT phase, while the PET phase remained stationary. Each motion-affected CT dataset was reconstructed using a 3D iterative, data-driven motion correction algorithm. Attenuation correction maps were generated from both uncorrected and motion-corrected CT scans. The PET raw data were reconstructed offline using the JSrecon algorithm with an attenuation map from motion-corrected CT and compared with the PET scan reconstructed with an attenuation map from motion-corrupted CT. ***Results:*** Motion-corrected CT scans produced PET images with significantly improved quality compared to uncorrected datasets. In the phantom studies, the normalized mean square error (NMSE) improved from 0.069 (uncorrected) to 0.0453 (corrected). The correction method effectively removed motion artifacts for translations up to 24 mm and rotations under 10°, which in our opinion are unlikely to be exceeded in clinical scans. ***Conclusion:*** The proposed data-driven 3D motion compensation technique for CT imaging substantially enhances the quality and accuracy of brain PET/CT scans affected by head motion, offering promising clinical utility for routine neuroimaging. ***References:*** 1. Evaluation of the new-generation digital bismuth germanium oxide PET/CT system according to the Japanese brain tumor phantom test for ^{18}F-fluciclovine imaging

F. Sasaki[1], *S. Fukai*[2], *H. Daisaki*[1], *M. Sato*[1], *A. Yumoto*[1], *T. Kita*[1], *N. Imaizumi*[1], *M. Shiga*[2], *H. Yoshida*[2], *K. Motegi*[2], *N. Shimada*[2], *A. Osawa*[2], *T. Terauchi*[2];
[1]*Gunma Prefectural College of Health Sciences, Gunma, JAPAN,* [2]*The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, JAPAN.*

Aim/Introduction: Malignant gliomas are common and difficult-to-treat brain tumors. Although MRI aids surgical planning, its limitations have led to the recent approval of ^{18}F-fluciclovine (FACBC) PET/CT imaging in Japan for improved tumor visualization. FACBC enhances detection of tumor infiltration not visible on MRI and supports accurate surgery. The Japanese Society of Nuclear Medicine established the Japanese brain phantom test (JBT) to standardize brain PET imaging [1], including FACBC. Omni Legend, a new digital BGO PET/CT system, offers high-quality imaging without TOF. This study evaluated its image quality using JBT criteria and explored its applicability in FACBC brain tumor imaging. ***Materials and Methods:*** A brain tumor phantom (BT-phantom) which includes six hot spheres with different diameters, was filled with ^{18}F-labeled solution with a radioactivity concentration ratio of 3 (sphere):1 (background). The PET scan was performed with 30-min list mode acquisition using Omni Legend (GE Healthcare). The PET data were reconstructed using ordered subset expectation maximization (OSEM), OSEM with a point spread function (OSEM+PSF), and Bayesian penalized likelihood (BPL). The image index of %contrast for 7.5-mm sphere, recovery coefficient (RC) for 10.0-mm sphere, standardized uptake value of total background (SUV_{TOT}), and the detectability for 7.5-mm sphere were evaluated according to the JBT criteria. ***Results:*** The %contrast, RC, and SUV_{TOT} were 25.1%, 0.70, and 1.00, respectively in OSEM; 25.8%, 0.80, and 0.99 in OSEM+PSF; and 33.8%, 0.93, and 0.99 in BPL. The 7.5-mm sphere was detected using all three reconstruction methods. All JBT criteria were satisfied, regardless of the PET image reconstruction methods. ***Conclusion:*** This study demonstrated that the Omni Legend satisfies all JBT image quality criteria even without TOF capability and has the potential to provide high-quality images in ^{18}F-fluciclovine brain tumor imaging. ***References:*** [1] https://jsnm.org/wp_jsnm/wp-content/themes/theme_jsnm/doc/StandardPETProtocolPhantom20170201.pdf.

EP-0928

Feasibility and Comparative analysis of ultrafast F-18 imaging for enhanced bone scan efficiency in obese patients

L. Ghadhanfer[1], *M. Alqabandi*[1], *E. Alawadhi*[1], *T. Alahmad*[1], *Z. Alqallaf*[2], *A. Sadeq*[2], *F. Marafi*[2];
[1]*Kuwait University, Kuwait, KUWAIT,* [2]*Ministry of Health, Kuwait, KUWAIT.*

Aim/Introduction: Advancements in PET technology aim to reduce imaging time for patient comfort, minimize motion artifacts, and lower radiation exposure by decreasing the injected dose, with digital molecular imaging systems offering performance competitive to traditional scanner. 18F-NaF PET/CT is an effective bone-seeking agent that outperforms conventional imaging, showing a superior target-to-non-target ratio than 99mTc-MDP, with twice the bone uptake and faster soft tissue clearance. In our department, the standard 18F-NaF dose for bone scans is 2.2 MBq/kg. For patients with a BMI between 40 and 50, imaging time per bed position is extended. This study investigates the feasibility, image quality, and tracer uptake of ultrafast 18F imaging in comparison to standard acquisition durations. It emphasizes image contrast, noise metrics, SUV quantification. ***Materials and Methods:*** A Jaszczak Deluxe Flangeless Esser PET phantom was filled with 20 KBq/ml, maintaining a sphere-to-background ratio of 8:1. Two 3-minute acquisitions were performed using 256×256 and 128×128 matrix sizes. These datasets were retrospectively re-binned into shorter acquisition times of 90 seconds (standard duration for obese patients) versus 18 seconds (20% of the standard duration). Images were reconstructed using OSEM with 3 iterations and 17 subsets for standard imaging, and adjusted parameters for ultrafast imaging. Image noise (<15%) and lesion contrast (>50%) were the primary accepted quality metrics. Furthermore, images from 10 patients with a BMI greater than 40, who were administered either 18F-NaF or 18F-FDG, were visually assessed to evaluate lesion detectability and SUV measurements at varying acquisition times. The reconstruction parameters applied were consistent with those used in the phantom study. ***Results:*** The 128×128 matrix yielded superior image quality for the 18-second acquisition, especially when using 2 iterations and 8 subsets. Under these conditions, noise remained below 15% and lesion contrast exceeded 50%. In patient cases, the number of

lesions and their detectability were comparable between standard and ultrafast acquisitions for both 18F-NaF and 18F-FDG, with no perceptible differences in image quality. However, ultrafast imaging introduced variability in SUV measurements for 18F-FDG, with deviations of up to ±10%. ***Conclusion:*** Ultrafast PET imaging offers image quality comparable to standard protocols, making it a valuable tool in high-throughput clinical environments. It is particularly advantageous for 18F-NaF imaging, where quantitative accuracy is less critical. For ^{18}F-FDG studies, caution is warranted due to potential variability in SUV measurements, which could impact quantitative assessments.

Extended Data-Driven Motion Detection Method for PET Imaging

N. Beriashvili[1], *L. Tellmann*[1], *C. Régio Brambilla*[1], *J. Scheins*[1], *K. Ciantar*[1,2], *M. Chikhradze*[3], *N. Shah*[1,4,5], *C. Lerche*[1];
[1]Institute of Neuroscience and Medicine 4 (INM-4), Forschungszentrum Jülich GmbH, Jülich, GERMANY, [2]Institute of Imaging and Computer Vision, RWTH Aachen University, Aachen, GERMANY, [3]Department of Engineering Physics, Georgian Technical University, Tbilisi, GEORGIA, [4]Institute of Neuroscience and Medicine 11 (INM-11), Forschungszentrum Jülich GmbH, Jülich, GERMANY, [5]Department of Neurology, RWTH Aachen University, Aachen, GERMANY.

Aim/Introduction: Spontaneous patient motion during medical imaging can degrade image quality and compromise quantitative accuracy. In PET, high spatial resolution requires motion correction of the emission data and the realignment of the attenuation map. Effective correction relies on accurate tracking of subject movement, which can be achieved by analyzing listmode PET data to extract translational and rotational parameters. This work is focused exclusively on spontaneous, rigid head motion in dedicated brain imaging. ***Materials and Methods:*** We extended the existing center of distribution (COD) method by incorporating an approach to extract angular information of rigid head motion. While similar in concept to previously proposed PCA-based techniques for motion estimation [1], our method does not require back-projection of the lines of response (LORs), making it suitable also for scanners without time-of-flight (TOF) information and allowing for direct use with list-mode data [1]. The COD method estimates translational movement along three axes [2]. In addition, principle component analysis (PCA), has been previously applied to reconstructed data by forming spatial point clouds from LOR centers. By projecting these clouds onto 2D planes and analyzing the principal axes, rotational motion can be quantified through the angle between the principal direction and a fixed reference vector. We validated this approach using a head phantom [3], which was injected with nearly 46 MBq and subjected to controlled manual rotational motion simulations. To separate spontaneous (fast) motion components, the fast fourier transform (FFT) filtering was applied to the COD signals, isolating high-frequency variations. The filtering method was also applied to the angle estimates and validated with phantom measurements. ***Results:*** 2D ellipsoidal point clouds emulating the LOR midpoints were simulated for method validation. The PCA method was also applied to corresponding measurement data, and the results were found to be in good agreement with the expected controlled angular changes. FFT filtering of both simulated and real COD data demonstrated its capability to isolate fast motion components. ***Conclusion:*** Initial evaluation showed that the detected signal captured consistent relative variations over time, aligning with the timing and magnitude of controlled manual rotations. To further validate the method, measurements using a custom-designed spherical glass phantom are planned. These measurements will enable the assessment of defined angular changes under controlled conditions. Results from these experiments will be presented at the conference. ***References:*** [1] Schleyer et al. (2015) https://doi.org/10.1088/0031-9155/60/16/6441[2] Lu et al. Evaluating the Impact of MR Contrast on ^{18}F-FDG Quantification in Neuro PET-MR Studies through Comparison of Pre- and Post-Contrast Images

L. Westhead;
Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM.

Aim/Introduction: A key challenge in PET imaging is attenuation of tracer emissions by body tissues and scanning equipment, which can affect quantification. Attenuation correction (AC) compensates for this effect, typically using attenuation maps derived from CT image data. Alternatively for PET-MR, MR attenuation correction (MRAC) uses segmentation of MR images with assigned CT numbers to generate pseudo-CTs for attenuation mapping. This study investigates whether gadolinium-based contrast agents influence two commonly used MRAC methods in neural PET-MR studies. ***Materials and Methods:*** A retrospective semi-quantitative analysis was conducted on 8 neuro PET-MR studies on Alzheimer's disease and metabolic imaging. Each subject underwent ^{18}F-FDG imaging with MRAC sequences acquired both before and after gadolinium contrast administration. Analysed data included: 1) Dixon and Zero-Time-Echo (ZTE) MRAC series acquired Pre- and Post-contrast, 2) pseudo-CTs generated for attenuation mapping, 3) PET images reconstructed using the vendor's Atlas-based and ZTE MRAC methods. Percentage differences between Pre and Post image pairs were assessed by image subtraction using image analysis software. Brain structures were contoured using a neuro tool to extract whole-brain and regional PET statistics (maximum counts, mean counts, and count concentration). ***Results:*** Initial investigation found observable differences in the PET subtraction image of up to 20% in certain areas of the brain. After correcting for misalignment between Pre and Post MRAC images, differences in Atlas-based reconstructions were reduced to around 5%. Regional analyses similarly showed minimal variation in maximum and mean counts reaching 8.5% in the medial temporal lobe for one subject. Normalisation of the regions to the pons gave negligible differences except in one subject with a ratio of 13.3 in posterior cingulate gyrus compared to the pons. Statistical analysis is ongoing to further assess the significance of these differences. ZTE reconstructions could not be fully assessed due to limitations when generating valid pseudo-CTs from the registered Post-contrast MRAC images. ***Conclusion:*** The majority of viable cases (4/5) showed no differences above 5%, suggesting that gadolinium administration may not substantially impact PET quantification in neuro PET-MR. Some higher subtraction values and regional normalisation ratios could indicate that different factors are having an effect such as misalignment between Pre and Post which can introduce artefactual differences. Further work is needed to confirm these findings and address the challenges posed towards attenuation mapping by misalignment and other processing discrepancies.

Targeted biopsy of bone metastases: an innovative technique in diagnostic evaluation

S. Rama Alonso, *E. Campaña Díaz, F. Caltagirone Gutiérrez, B. Santos García, J. Badell Martínez, P. García-Talavera San Miguel, E. Casillas Sagrado, J. Cañadas Salazar, L. Díaz González, E. Martín Gómez, J. Villanueva Curto, A. Peñaherrera Cepeda, F. Gómez-Caminero López;*
Salamanca University Hospital, Salamanca, SPAIN.

Aim/Introduction: To identify the exact location of bone metastases detected by bone scintigraphy or [18F]FDG-PET/CT facilitating biopsy to obtain tissue samples for diagnostic purposes and to evaluate the most appropriate therapeutic option, as well as to describe and evaluate the efficacy of radioguided bone biopsy in patients with bone metastases. ***Materials and Methods:*** Four patients diagnosed with bone metastases were included in the study, who previously underwent a bone scan with [99mTc]Tc-HDP, marking the optimal puncture point thanks to the portable gamma camera. On the day of surgery, 20 mCi of [99mTc]Tc-HDP was administered 2 hours before surgery. In the operating room, both the portable gamma camera and the gamma detector probe were used to identify the point of maximum radiopharmaceutical uptake, marking the most accurate approach. ***Results:*** Despite the small number of patients included and taking into account the difficulty of access in this type of procedure, targeted bone biopsy proved to be effective in the correct localization of all lesions identified by scintigraphy, allowing optimal samples to be obtained for histopathological analysis, with a low rate of complications and without the need for additional invasive techniques. ***Conclusion:*** Targeted bone biopsy is a safe and effective technique to improve diagnostic accuracy in patients with metastatic cancer. By accurately localizing these metastases, it facilitates the etiological diagnosis and helps to select the best therapeutic option, all with minimal risk to the patient.

The impact of EARL harmonization on interscanner variability of volume-based PET metrics: a phantom study and patient validation

A. Khalimon[1], *A. Nikiforuk*[1], *A. Shakirova*[1], *I. Baltabaev*[1], *M. Khodzhibekova*[1], *G. Khamadeeva*[1], *D. Khodakova*[1], *T. Lazutina*[1], *I. Pylova*[1], *A. Leontev*[1], *A. Pronin*[2], *E. Bezumova*[2];
[1]*P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION,* [2]*N.N. Blokhin National Medical Research Center of Oncology of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: To assess the impact of ^{18}F-based PET EARL harmonization on interscanner variability of MTV and TLG. ***Materials and Methods:*** The phantom study was performed on three PET/CT-systems (with BGO-, LSO- and LYSO-based detectors) using the NEMA IEC Body Phantom NU2-2018. True volume of each sphere of the phantom was previously measured. The phantom filling and acquisition procedure were performed in accordance with the EARL 18F-standards manual. A total of 54 reconstructions (36 3D-OSEM+PSF, 1 3D-OSEM+TOF, 17 3D-OSEM+TOF+PSF) were included and categorized into three groups: 20 EARL2-compliant, 17 partially non-EARL2-compliant and 17 significantly non-EARL2-compliant (2-5 spheres' RCs and ≥6 spheres' RCs falling outside the EARL2-range across all metrics, respectively). The validation study was performed on 36 patients who underwent both [^{18}F]FDG and [^{18}F]PSMA-1007 PET/CT using only the BGO-system. Raw PET data were used to obtain 25 3D-OSEM+PSF reconstructions: 10 EARL2-compliant and 15 non-EARL2-compliant. 96 lesions approximately spherical in shape were selected, with diameters almost evenly distributed from 10mm to 37mm, grouped according to intervals of phantoms' spheres diameters. MTV and TLG of each sphere and lesion across all reconstructions were measured using 3D-isocontour with 41% threshold of the maximum voxel value. The coefficients of variation (CoV) for the MTV and TLG measurements were calculated for each phantom's sphere and patient's lesion within each group of reconstructions. CoV≤10% was considered acceptable. ***Results:*** The CoVs for all spheres, as well as for each sphere, were lower in the EARL2-compliant group than in the partially and significantly non-EARL2-compliant groups: mean values were 10.3%, 14.6% and 22.9% for MTV; 6.0%, 8.4% and 12.1% for TLG, respectively. In the EARL2-compliant group, the CoVs were below the 10% for the 17-37mm and 13-37mm spheres when measuring MTV and TLG, respectively. The CoVs for all lesions, as well as for each interval of lesions' diameters, were significantly ($p<0.001$) lower in the EARL2-compliant group: mean values were 8.6% vs 18.0% for MTV and 6.1% vs 11.3% for TLG. In the EARL2-compliant group, the CoVs were below 10% for lesions larger than 23.5mm and 15.5mm for MTV and TLG, respectively. The correlations between CoV and lesion diameter were lower in the EARL2-compliant group: r=-0.74 vs r=-0.84 for MTV and r=-0.63 vs r=-0.66 for TLG. ***Conclusion:*** EARL harmonization reduces interscanner variability for both MTV and TLG regardless of lesion size as well as its correlation with lesion size when standard 41% SUVmax threshold segmentation tool is used.

EP-0933

Leveraging Vision-Language Models for Automated Reporting of ^{99m}Tc-MAG3 Scintigraphy

W. B. Bosbach[1], *C. L. Clement*[1], *F. Strunz*[1], *N. Gözlügöl*[1], *F. Aghapour Zangeneh*[1], *C. M. Bregenzer*[1], *C. Mingels*[1], *C. Beisbart*[2], *P. Koller*[1], *K. Zeimpekis*[1], *K. Shi*[1], *A. Rominger*[1], *R. Seifert*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Institute of Philosophy, University of Bern, Bern, SWITZERLAND.*

Aim/Introduction: This study evaluated the capability of a vision language model (VLM), Qwen2.5-VL-72b, to generate reports for ^{99m}Tc mercaptoacetyltriglycine (MAG3) renal studies. The goal was to assess AI-generated reports as a potential tool to reduce administrative burdens in nuclear medicine practice. ***Materials and Methods:*** Fifty MAG3 studies with reports written during clinical routine were retrospectively included. The dataset was enriched with pathological cases (24 pathological, 26 physiological). Qwen2.5-VL-72b was prompted to analyze MAG3 images, label kidney function status (regular, accumulation, nephrectomy, delayed peak). Corresponding reports were generated under a python-routine. Four nuclear medicine residents evaluated anonymized and randomized reports from both clinical routine and Qwen, rating correctness of findings, suitability of impressions, need for manual correction, and time-saving potential. Raters also attempted to identify the text source (human or AI). Interrater reliability was calculated using Gwet's AC1 and Fleiss' kappa.

Results: Qwen demonstrated high accuracy (96.2%) in labeling studies with two regular kidneys but lower accuracy (62.5%) for pathological cases. Human-written reports received consistently higher quality ratings. However, when analyzing only correctly labeled cases by Qwen, the quality gap narrowed considerably. Two of four raters found no statistically significant differences between human and Qwen reports, while two identified significant differences favoring human reports. The ability to correctly identify report source (human vs. AI) strongly correlated with quality assessments ($R^2 = 0.998$). Interrater reliability was fair (Gwet's AC1: 0.288, Fleiss' kappa: 0.238). ***Conclusion:*** The Qwen-based routine successfully generated MAG3 reports that partially resembled those written during clinical routine, particularly for physiological cases. Although human-written reports were generally preferred, the quality difference decreased substantially for correctly identified cases. This suggests that with further advancements, VLMs may eventually provide valuable support in nuclear medicine reporting, potentially freeing healthcare staff from administrative tasks.

EP-0934

Uncertainties in ILP leakage monitoring: residual activities and effective half-lives

A. Rintala*, K. Nousiainen, T. Miettinen, M. Tenhunen, P. Vikatmaa, M. Laine, A. Granvik, A. Ristikankare, V. Reijonen;*
Helsinki University Hospital, Helsinki, FINLAND.

Aim/Introduction: In hyperthermic isolated limb perfusion (ILP), vascular leakage from the limb to rest of the body is monitored during high-dose drug perfusion to prevent systemic toxicity. A collimated gamma probe is positioned over the precordial region, and radioactive tracer is injected into the surgically isolated limb circulation with a ten-fold activity ratio compared to the systemic circulation. Many factors contribute to the uncertainty of the leakage rate quantification: in this work, we studied the impact of residual activities in tracer syringes and effective half-life of the tracer. ***Materials and Methods:*** We analyzed a subset of ILP treatments, where no leakage was indicated during the perfusion, retrospectively. Five patients with metastasized melanoma in lower extremity had been treated with a one-hour melphalan perfusion and monitored with a commercial measurement system. Technetium-99m labeled human serum albumin (Tc-99m-HSA) was used as the tracer. The ratio of the activity injected into the perfusion circulation ("big activity") to the activity injected to the systemic circulation ("small activity") was measured with a radionuclide calibrator before the operation, and this constant ratio was used during monitoring. A literature value (4.81 hours) was used for the effective half-life of the tracer. The total leakage was not to exceed 10%. The reported mean leakage after the end of isolation ("end leakage") was 3.5% (range: 0.7%-6.3%). To assess the leakage uncertainties, firstly, we corrected the activity ratio with the residual activities measured after ILP. Secondly, we determined the systemic effective half-life from the monitoring data 1) prior to the isolation phase and 2) from the isolation phase (assuming no leakage during this time). Based on these results, we then re-calculated the end leakage. We also studied the effect of different effective half-life for the perfusion circulation compared to the systemic circulation. ***Results:*** The activity ratio corrected with the measured residual activities changed by a mean 5.7% (range: -0.1-17.7%). The mean effective half-life appeared 1) 2.2 h (1.5-2.7 h) prior isolation and 2) 4.1 h (3.4-4.6 h) during isolation. Subsequently, the mean end leakage was 3.4% (2.1-5.8%). One patient had higher end leakage than originally reported (2.1% vs 0.7%), the other four lower. If the physical half-life of Tc-99m (6.01 h) is used for the perfusion circulation, the mean end leakage turned out 3.0% (1.7-5.1%). ***Conclusion:*** Neglecting tracer residues and especially patient-specific effective half-lives of the tracer contribute to the uncertainty of the indicated leakage in ILP monitoring.

Aim/Introduction: Clinical translation of radiopharmaceuticals with novel radionuclides proceeds in several phases. In each phase, the calibration and standardised use of equipment is essential for the preclinical and clinical analysis of administered activity and its distribution in vivo. Therefore, quantitative imaging, treatment planning and optimization needs traceable and accurate activity determination. As part of the PRISMAP harmonisation and standardisation work package, we explored the metrology and medical physics challenges related to this evolving field. ***Materials and Methods:*** We performed a nuclear medicine equipment standardisation (NMES) study using the novel radionuclide terbium-161 (Tb-161). Over 2 years, calibration and verification measurements were carried out using radionuclide calibrators, SPECT/CT cameras and a gamma counter. The Tb-161 activity, provided by the Belgian Nuclear Research Centre (SCK CEN), was systematically determined in a reference geometry (10 ml Schott glass vial) using a Fidelis secondary standard radionuclide calibrator, traceable to a designated metrological institute. The activity was used to calibrate and verify activity meters (CRC-55tR, Capintec/Mirion; VIK-202, Comecer). We studied the geometric influence of recipients that are relevant for the clinical and preclinical practice (vials, syringes, Eppendorf tubes). The activity was used to prepare imaging phantoms, such as a uniform cylinder and a NEMA/IEC body phantom. We performed SPECT/CT imaging (Symbia Intevo, Siemens) to calibrate and verify the quantitative imaging properties of the system. Along the calibration and verification chain, samples of activity concentrations were taken for gamma counter analysis (1480 Wizard 3", PerkinElmer). ***Results:*** We determined Tb-161 calibration factors (CFs) for a number of activity meters in reference conditions and verified the accuracy and reproducibility over the NMES measurement campaign. Due to the low-energy photon emission of Tb-161, CFs show to be device specific and highly influenced by the recipient, its positioning and source geometry. We derived SPECT/CT calibration factors for low and medium energy collimators. Gamma counter measurements were used to obtain counting efficiencies over a range of activity concentrations in the NMES calibration and verification chain. In our gamma counter data, we observed the influence of terbium-160, as a contaminant of the production of Tb-161. ***Conclusion:*** We demonstrated the importance of equipment calibration and standardisation in the clinical translation of novel radionuclides and radiopharmaceuticals and the need for metrology and medical physics support. ***References:*** Decristoforo C, et al. Homogeneity of the radioactivity distribution in 3D-printed PET phantoms

N. Jörg*[1], A. J. Zounek[1], G. Palumbo[1], R. Oos[1], F. J. Gildehaus[1], N. L. Albert[1,2,3], K. Parodi[4], S. Ziegler[5,1], L. Kaiser[1];*
[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [2]German Cancer Consortium (DKTK), Partner Site Munich, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [3]Bavarian Cancer Research Center (BZKF), Erlangen, GERMANY, [4]Department of Medical Physics, LMU Munich, Munich, GERMANY, [5]Department of Nuclear Medicine, Hannover Medical School (MHH), Hannover, GERMANY.

Aim/Introduction: For a reliable quantification of activity distributions in positron emission tomography (PET) and to be able to refer to benchmark data in the evaluation of real patient data, validation measurements with radioactive phantom models are of great importance. 3D-printed phantoms made of resin and radioactive liquid have been shown to offer several advantages over conventional fillable phantoms. However, to use 3D-printed phantoms reliably, the activity must be homogeneously distributed throughout the printed material. This work aimed to assess various resins, mixing, and printing techniques to determine which factors affect the homogeneity of the activity distribution and which configuration is optimal in this regard. ***Materials and Methods:*** Rectangular patches with the dimensions 60 mm x 20 mm x 1 mm were printed using a stereolithographic (SLA) 3D printer with water-washable and conventional resin. The resin was mixed with the radiotracer [^{18}F]fluorodeoxyglucose ([^{18}F]FDG) by stirring or shaking, and the patches were printed in different orientations (horizontal, vertical) and with different layer thicknesses of [0.025, 0.05, 0.1] mm. The activity distribution in the patches was then analyzed with autoradiography using a phosphor imaging plate as well as PET scans with a high-resolution PET/CT system for small animals. The autoradiography images were evaluated with line profiles along the patches and by extracting radiomic features. Radiomics were also analyzed for the PET scans. ***Results:*** Visual analysis of autoradiography, PET images, and line profiles, as well as calculation of radiomic features, yielded differences in the homogeneity of activity distributions for different 3D printing configurations. Four out of five evaluated radiomic features for both PET and autoradiography indicated the highest homogeneity for patches printed with hydrophilic resin (mixed with [^{18}F]FDG using a magnetic stirrer) and vertical orientation. ***Conclusion:*** Printing with hydrophilic resin mixed with [^{18}F]FDG using a magnetic stirrer and vertical orientation yielded a homogeneous activity distribution. Hence, such radioactive 3D-printed phantoms can also be reliably used to create more complex benchmark data for the validation of [^{18}F]FDG-PET quantification methods.

Assessment of the Accuracy and Linearity of Radionuclide Calibrators for I-131 and Lu-177 Theranostic Radioisotopes in nuclear medicine therapy centers in Iran During 2024

E. Farajzadeh[1], *S. Golshaiyan*[1], *M. Sadeghi*[2], *A. Shirzadi Golzar*[1], *M. Akbari*[1], *N. Habibi*[3], *M. Davarpanah*[3];
[1]Secondary Standard Dosimetry Laboratory (SSDL), Pars Isotope Co., Karaj, IRAN, ISLAMIC REPUBLIC OF, [2]Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [3]Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Radiopharmaceuticals play a critical role in both diagnostic and therapeutic procedures in nuclear medicine. Ensuring the accuracy of administered activity is essential for patient safety and effective treatment. Dose calibrators are the primary tools for this measurement, and their calibration must be traceable to a standard dosimetry laboratory, as mandated by the International Atomic Energy Agency (IAEA). In Iran, the Secondary Standard Dosimetry Laboratory (SSDL) conducts annual evaluations of these devices. This study aimed to assess the accuracy and linearity of dose calibrators used in nuclear medicine therapy centers across Iran in 2024, focusing on I-131 and Lu-177. ***Materials and Methods:*** A total of 39 dose calibrators from 35 centers were evaluated using standard reference sources (Cs-137, Co-57, Ba-133) and a reference dose calibrator, in accordance with Protocol 93 of the NPL Guide. Devices assessed included models from manufacturers such as RAMS-88 (Iran), AMERSHAM, BIODEX, CAPINTEC, COMECER, ISOMED, PICKER, PTW, and SIEMENS. Accuracy limits were defined as ±2% for reference standards and ±5% for field devices. Devices with errors between 5% and 10% were recalibrated, and those with errors exceeding 10% were marked for servicing. ***Results:*** Among the 39 calibrators tested, 84.61% showed acceptable accuracy for Cs-137 and Co-57, 79.48% for Ba-133, 71.79% for I-131, and 74.35% for Lu-177. Linearity tests using Tc-99m confirmed compliance within ±5% for most devices, except for three that required corrective maintenance. ***Conclusion:*** This evaluation underscores the importance of routine calibration and quality control of dose calibrators to maintain measurement accuracy and radiation safety. The findings support the necessity of regular oversight by the SSDL to ensure metrological traceability and optimal device performance, particularly in sensitive clinical contexts such as pediatric therapy. ***References:*** International Atomic Energy Agency (2006). Activity painting with 3D Printer for arbitrary PET phantom

J. Kiss[1], *P. Szuszik*[2], *K. Kukuts*[3], *A. Forgács*[3], *I. Garai*[2], *L. Balkay*[2];
[1]Division of Radiology and Imaging Science, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [2]Division of Nuclear Medicine and Translational Imaging, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [3]Mediso Ltd., Budapest, HUNGARY.

Aim/Introduction: This study aimed to investigate the potential simplification of the so-called activity painting phantom technique to see if the expensive industrial robotics [1,2] used so far could be replaced by cheaper and simpler 3D printers. A further aim was to demonstrate that even complex distributions, such as brain FDG accumulation [3], could be simulated with this more straightforward technique. ***Materials and Methods:*** In the activity painting, the fundamental principle is to move a point source within the PET camera's field of view during continuous data acquisition. An ordinary, frequently used 3D printer and a Na22 point source of 9.9 MBq activity were used to simulate 3D shapes. The point source was moved continuously in time but at varying speeds. All examinations were performed on a standard digital PET/CT camera with TOF capability, using the reconstruction used in routine diagnostics. Based on accurate calibration between the velocity and the activity concentration, the required point source velocity map was determined to trigger each 3D print in the field of view. ***Results:*** Initial measurements were made to compare the 3D printer method with the industrial robotics technique to ensure similar movement and image quality. After painting the homogenous rectangles, we obtained a COV=3.24% with the robotic technique and 2.80% with the help of the 3D printer. Furthermore, arbitrarily shaped checkerboard-type activity patterns were created, and from these, the ratio of expected to measured activity concentration ratios was 1.004±0.017. In addition, theoretical FDG brain accumulation was also simulated in air and water-filled environments. In comparing the activity-painted brain image with the theoretical distribution, the related voxel correlation plot yielded a correlation coefficient of 0.9758 and 0.9680 in the air and the water-filled environment, respectively. Based on the actual activity of the point source, a slice of the brain scan took about 1 hour. ***Conclusion:*** This study demonstrated that a more affordable and accessible method utilizing a conventional 3D printer could serve for activity painting phantom measurements in PET imaging. ***References:*** https://doi.org/10.1371/journal.pone.0309540,https://doi.org/10.1088/1361-6560/ad84b5, https://doi.org/10.1002/mp.14218.

Aim/Introduction: In Japan, two types of breast-specific PET systems (positron emission mammography [PEM] and dedicated breast PET [dbPET]) have been clinically adopted. They provide high-resolution functional images that enable the detection of small breast cancers. However, the comparison of images from each system and the optimal acquisition protocol have not sufficiently investigated. In this study, 1) a phantom with appropriate sphere-to-background ratios (SBRs) based on clinical images of breast-specific PET was prepared, 2) breast-specific PET phantom images acquired and reconstructed using standard protocols routinely employed at each institution were evaluated, and 3) their clinical validity was verified. ***Materials and Methods:*** Three breast-specific PET systems—PEM, photomultiplier tube (PMT)-based dbPET, and silicon photomultiplier (SiPM)-based dbPET—were evaluated using a cylindrical phantom containing four small spheres (3-10 mm). SBRs of 2:1, 4:1, and 8:1 were determined by measuring clinical PET images. The phantom was scanned for 10 minutes in list-mode with the spheres positioned at the center and periphery of the detector. Images were reconstructed at 1, 3, 5, 7, and 10 minutes. Visual and quantitative evaluations were performed, including coefficient of variation (CV_{BG}), detection index (DI), and contrast recovery coefficient (CRC). Representative clinical images were also reviewed. ***Results:*** Phantom images with SBRs of 2:1 and 4:1 failed to adequately visualize small spheres; therefore, subsequent evaluations focused on 8:1 SBR images. Visual assessment showed that dbPET systems yielded clearer visualization than PEM, particularly for small spheres. All scanners exhibited reduced image quality at the periphery compared to the center. SiPM-based dbPET was the only system able to visualize 3-mm spheres at the periphery with ≥5 minutes of acquisition, whereas PEM failed to detect 5-mm spheres even at 10 minutes. In quantitative analysis, DI decreased with shorter acquisition time, while CRC remained relatively stable. SiPM-based dbPET achieved the highest detectability but showed greater background noise. Clinical findings were consistent with phantom results. ***Conclusion:*** An SBR of 8:1 was appropriate for phantom studies using small spheres in breast-specific PET. Based on phantom and clinical validation, dbPET required ≥5 minutes and PEM ≥7 minutes of acquisition to achieve diagnostic image quality.

EP-0940

Implementing a computer model of a Capintec ionisation chamber in GEANT4

H. Benderz*, J. O'Brien, B. Thomson;*
Sandwell and West Birmingham NHS Trust, Birmingham, UNITED KINGDOM.

Aim/Introduction: Errors in administered activity should be ±10% (diagnostic) and ±5% (therapeutic). Emissions from some radionuclides can give differences between vial activity and syringe activity, as well as having volume effects, e.g. I123 which should be measured with a copper filter. A Capintec computer model allows such effects to be examined without direct measurements. ***Materials and Methods:*** The cross-sectional dimensions and materials for the Capintec chamber were modelled in GEANT4. The model was checked against the Capintec calibration curve for standard radionuclides. We used Tc99m sensitivity as a reference for lower energies (<300keV) and Co60 (~1200keV) as reference for higher energies. ***Results:*** The model errors were all below 3% and are shown (gamma range 27keV-2754keV): Tl201 2.7%, I125 1.2%, Co57 0.1%, Cs137 1.1%, F18 1.5%, Na24 1.9%. Also, I123 was modelled with the copper filter, and gave a setting of 51, which represents an error of 2.4% from the NPL calibrated number 54. ***Conclusion:*** With this model we can examine improved filter systems for radionuclides e.g. Y90. We can also examine the differences between vials and syringes. The energy curve can also be mathematically modelled, allowing calibration factors to be theoretically determined using emission data, for any radionuclide without a calibration factor. There is increased interest in the application of alpha-emitting radionuclides in MRT, such as Ra223, At211, Pb212 and Ac225. These have associated decay chains, with varying relative activities with time after production. The model will allow the calibration number to be determined for such chains at particular times after production and for the relative contributions of each radionuclide in the decay chain to be recognised. This should give increased accuracy of administered therapy activity.

EP-0941

Validation of a vented well-type ionization chamber with specifically designed vial holders for in-house Lu-177 reference activity samples

V. Reijonen[1], *P. Toroi*[2], *R. Nylund*[2], *M. Tenhunen*[1];
[1]*Helsinki University Hospital, Helsinki, FINLAND,* [2]*STUK - Radiation and Nuclear Safety Authority, Vantaa, FINLAND.*

Aim/Introduction: When compared to the requirements agreed for reference dose measurements in external beam radiotherapy (EBRT) and brachytherapy (BT), molecular radiotherapy (MRT) lags behind. If the Lu-177 setting of a clinical radionuclide calibrator is not properly verified, a systematic error may be transferred to patient vial measurements as well as to quantitative imaging, and subsequently to absorbed dose distributions and reported outcome in MRT. An international code of dosimetry practices in MRT should be developed to align with those in EBRT/BT: similar standardisation of measurements could be applied. In this study we evaluated the use of a reference-class well-type chamber, commonly employed in BT quality assurance (QA), for preparing Lu-177 reference solutions intended for regular QA in MRT. ***Materials and Methods:*** We acquired a commercial Lu-177 reference sample "CR" (500 MBq in 1 ml) in a 10R vial and measured it using 1) a secondary standard radionuclide calibrator "SSRNC", 2) a clinical radionuclide calibrator "CRC", and 3) an unsealed, unpressurized well-type chamber used for BT QA with two versions of a specifically designed 10R vial holder ("W+VH1" and "W+VH2"). We prepared two in-house Lu-177 samples, "HM1" and "HM2", in 10R vials using left-over no-carried-added Lu-177 from MRT treatments (~150 MBq/g). HM1 contained a liquid mass similar to CR, while HM2 had a similar activity to CR. After initial measurements, we gradually added aqua to each of them to

examine the volume effect in the range of 1-10 ml. A calibrated precision scale was used for mass determination, and the ambient conditions were monitored using a mercury-based thermometer/barometer. ***Results:*** The manufacturer's reference activity of the CR sample agreed with the SSRNC measurement within 0.4%. The observed volume dependence followed the SSRNC volume correction function and was within 0.3% for all three samples. Using the CRC's factory setting, there was a discrepancy of -1.3%. Calibration factors including volume correction functions were defined for the CRC, W+VH1 and W+VH2 combinations based on CR measurements. There was a 0.3% difference between VH1 and VH2. The activities of HM1 and HM2 were then determined. The measured values agreed within 0.8%. ***Conclusion:*** Vented reference-class well-type ionization chambers combined with specifically designed vial holders can be validated for the preparation of in-house Lu-177 reference samples. In this study, we defined calibration factors as a function of solution volume. Next, we will determine accuracy, constancy and linearity of the measurement system, including an uncertainty analysis.

EP-0942

A Calibration Workflow for Accurate Quantification of Rhenium-188 in RHN001-Tx for Theranostic Applications.

M. Qebetu[1], *J. Cardinale*[2], *K. Banda*[1], *P. Goorhoo*[1], *K. M. Legodi*[1], *H. Ndlovu*[1], *C. Davis*[1], *L. Smith*[1], *S. Sibiya*[1], *A. Mdlophane*[1], *S. Mdanda*[1], *M. Shungube*[1], *M. Sathekge*[1], *K. Ramonaheng*[1]; [1]*Nuclear Medicine Research Infrastructure, Pretoria, SOUTH AFRICA,* [2]*Department of Nuclear Medicine, Medical Faculty and University Hospital, Heinrich Heine University Düsseldorf, Düsseldorf, GERMANY.*

Aim/Introduction: Rhenium-188 is a promising generator-produced radionuclide with substantial potential for therapeutic applications. When used in conjunction with technetium-99m, it enables a practical theranostic approach, particularly valuable in settings without PET imaging infrastructure. RHN001 is a PSMA-targeting ligand that makes use of this matched pair facilitating both, the diagnosis and treatment of prostate cancer, and is currently being investigated in the RHINO clinical trial. Accurate activity quantification is essential for ensuring therapeutic efficacy and patient safety. In this context, the aim of this work is to establish a robust workflow for the determination of the true activity of the ^{188}Re-labeled RHN001-Tx. We present our experience in calibrating local instrumentation to support precise dosimetry and reliable therapeutic dosing in clinical practice. ***Materials and Methods:*** [^{188}Re]$NaReO_4$ was obtained from a ^{188}W/^{188}Re-generator (OncoBeta) and used to prepare a dilution series for calibration. Decay curves were measured using three independently calibrated dose calibrators for the determination of linearity and radionuclide purity. Following sufficient decay, cross-calibration was performed using a certified Iodine-123 reference standard measured on the liquid scintillator counter (LSC), and Mucha Nova gamma counter. Based on these results the individual calibration factor/responsivity for the dose calibrators was determined. ***Results:*** Decay curve fitting for [^{188}Re]$NaReO_4$ demonstrated excellent agreement with theoretical expectations, yielding a coefficient of determination (R^2) of 1.0, indicating a perfect linear correlation on the semi-logarithmic decay plot. The experimentally determined physical half-life of [^{188}Re]$NaReO_4$ deviated from the accepted value with the following range; 0.67-0.92 % for the undiluted (pure) sample and by; 0.92-1.43 % for the diluted sample set, confirming linearity of the dose calibrators and radionuclidic purity. Cross-calibration using the Iodine-123 reference standard further validated the measurement system. The I-123 activity measured using the LSC closely matched the theoretical value, with an absolute deviation of only 0.001 MBq. Comparative measurements on the Mucha Nova gamma counter showed consistent results, reinforcing the robustness of the calibration approach. ***Conclusion:*** From these measurements, a cross-calibration factor was derived, enabling traceable, instrument-specific correction for accurate quantification of RHN001-Tx (^{188}Re-PSMA) activity in clinical dosimetry applications. The calibration factor derived from the certified Iodine-123 standard can be applied in future measurements to ensure that the dose calibrator yields accurate and traceable activity readings. All measurement results were within the expected range, confirming the reliability and validity of the calibration workflow.

EP-0943

Sensitivity and count rate performance studiesof a UHF-MRI compatible BrainPET insert with standard and non-standard tracers

D. Niekämper[1,2], *J. Scheins*[1], *L. Tellmann*[1], *C. Hoffmann*[3], *S. Spellerberg*[3], *E. Pfaehler*[1], *N. Beriashvili*[1], *N. Shah*[1,4,5], *C. Lerche*[1]; [1]*Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine 4, Jülich, GERMANY,* [2]*RWTH Aachen University, Department of Physics, Aachen, GERMANY,* [3]*Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine 5, Jülich, GERMANY,* [4]*RWTH Aachen University, Department of Neurology, Aachen, GERMANY,* [5]*Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine 11, Jülich, GERMANY.*

Aim/Introduction: The BrainPET-7T is a high performance PET insert for neuroimaging combined with ultra high-field MRI [1]. Its design allows for a high sensitivity which is even more important for applications such as dual-isotope imaging [2], requiring the detection of triple coincidences of β^+-γ-emitters. In comparison with pure β^+-emitter count rate performance and sensitivity studies, we present measurements with β^+-γ-emitters to assess the feasibility of detecting triple coincidences at an acceptable noise level. ***Materials and Methods:*** The BrainPET-7T employs scintillators of LSO crystals in three layers with a total height of 2.4 cm and a digital Silicon Photomultiplier readout. Its dimensions are an inner diameter of 38.85 cm and an axial FOV of 24.8 cm. We evaluate the sensitivity for double coincidences with ^{18}F as a standard β^+-emitter and for double and triple coincidences using ^{124}I as a β^+-γ-emitter via an extrapolation from attenuated line source measurements. Additionally, we obtain the triple coincidence sensitivity with a ^{22}Na-point source with an activity of 0.76 MBq moved axially in 5 mm steps. Furthermore, we determine the true and noise-equivalent count rate (NECR) using a scaled NEMA phantom. The coincidence window is 2.6 ns for ^{18}F and ^{124}I, and 6 ns for ^{22}Na to account for positronium lifetime. ***Results:*** The measured sensitivity at the axial center and without RF coil, including multiple coincidences, was 13% at both the radial center and 7.5 cm offset for double coincidences of ^{18}F and an energy window of 420—650 keV. The triples sensitivity depends strongly on the energy window and the coincidence identification schemes. It is 2.4% for the identification of three singles in an energy window of 420—1500 keV and 0.6% for two singles in a two times full width at half maximum region around the annihilation peak and one around the prompt peak for the ^{22}Na measurement and 1.2% for ^{124}I for two energy regions. The NECR peak is at 13 kBq/ml with 241 cps/Bq and the true rate peak is at 16 kBq/ml with 619 cps/Bq when considering all combinations of singles within a coincidence window and an energy window of 450—580 keV. ***Conclusion:*** The presented performance studies with pure β^+-emitters and β^+-γ-emitters indicate the scanner's capacity for applications with β^+-γ-emitters. ***References:*** [1] C. W. Lerche et al., 2023 NSS MIC RTSD. Vancouver, BC, Canada: IEEE, (2023), pp. 1-2.[2] E. C. Pratt et al., Nat. Biomed. Eng, 7 (2023) 8 pp. 1028-1039.

EP-0944

Impact of the manufacturer new scatter correction for the market oldest CZT ring SPECT-CT on ^{99m}Tc contrast of small hot and cold objects

A. Seret[1], *C. Bernard*[2];
[1]*University of Liege, Liege, BELGIUM,* [2]*CHU of Liege, Liege, BELGIUM.*

Aim/Introduction: The recently modified scatter correction of the market oldest CZT-based ring SPECT-CT was tested on phantom data from our recent study of this system [1]. Still based for ^{99m}Tc on the dual energy window method, the correction is now (SC25) performed in the iterative loop of the reconstruction whereas it was previously (SC23) a subtraction of the two images reconstructed in the main and secondary windows. ***Materials and Methods:*** Data of NEMA NU2-94 and custom hot (diameter 4-20mm) and cold (diameter 6-25mm) bar contrast phantoms have been reconstructed with (SC) and without (NoSC) scatter correction. Scatter residual fraction (RF) in NEMA phantom, recovery coefficient (RC) in bars and coefficient of variation (COV) in uniform region of contrast phantom were compared to the values obtained with actual (25) and previous (23) versions of the software. Sixteen subsets were used in the OSEM-based reconstruction for different numbers of iterations in order to span a wide range (48-240) of EM updates. The optional resolution recovery for quantification purpose (PSFRq) was also tested. ***Results:*** Results are given for 192 updates where convergence seemed to be reached. RF-SC23 < RF-SC25 < RF-NoSC23 ≈ RF-NoSC25 in water and Teflon inserts of NEMA. For the cold rods: RC-SC23 > RC-SC25 > RC-NoSC25 ≥ RC-NoSC23. For the largest (≥16mm) hot rods, RC-SC25 ≈ RC-NoSC25 > RC-SC23 ≈ RC-NoSC23 and for the thinnest (≤8mm), RC-NoSC25 ≈ RC-NoSC23 ≈ RC-SC23 > RC-SC25=0. SC25 appeared to boost the central part of the two largest hot rods with a RC peaking at 160% for a centered ROI of half the rod physical diameter. In the contrast phantom uniform area, COV-NoSC25 ≈ COV-NoSC23 ≈ 6,5% and COV-SC25 ≈ COV-SC23 ≈ 8,0%. SC25 removed about 11% of counts in this uniform part whereas SC23 removed as much as 32%. With or without SC (23 or 25), PSFRq did almost not change RF and RC of cold or hot rods, neither COV or the percentage of counts removed by SC. ***Conclusion:*** The most striking effect of SC25 was much less count removal in large hot areas. Cold contrasts were slightly reduced whereas the impact on hot contrasts was very size dependent. The thinnest rods were absent from the images and the contrast of the central part of the largest rods was considerably boosted resulting in an increased mean rod contrast. ***References:*** 1. Seret A, Bernard C. EJNMMI Physics 2025; In Press.

EP-0945

Establishing metrologically traceable activity measurements for alpha-emitter astatine-211 to improve the accuracy of equipment routinely used in the clinic

E. Leidermark[1,2], *B. Sabot*[3], *H. Jensen*[4], *T. Bäck*[1], *L. Persson*[5], *S. Palm*[1];
[1]*Medical Radiation Sciences, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN,* [2]*Department of Radiation Physics in Nuclear Medicine, Sahlgrenska University Hospital, Gothenburg, SWEDEN,* [3]*CEA, LIST, Laboratoire National Henri Becquerel, Gif-sur-Yvette Cedex, FRANCE,* [4]*Department of Clinical Physiology and Nuclear Medicine, Cyclotron and Radiochemistry Unit, Rigshospitalet, Copenhagen, DENMARK,* [5]*Swedish Radiation Safety Authority, Stockholm, SWEDEN.*

Aim/Introduction: Targeted alpha therapies (TAT) are currently evaluated in several clinical trials, but the requirement of metrological traceability for the activity measurements of alpha-emitters are typically not met. For ^{211}At ($t_{½}$=7.2h) reference sources are not available. In anticipation of a new clinical trial involving ^{211}At, a measurement using absolute 4pi-alpha liquid scintillation counting was performed [1] to establish metrological traceability to the equipment used in the hospital. The resulting activity measurements were then compared with those derived for a previous clinical trial [2] (without metrological traceability). The aim was to evaluate the impact of metrological traceability when measuring ^{211}At for three radionuclide calibrators and three HPGe detectors. ***Materials and Methods:*** A sample from an aqueous solution of ^{211}At (0.2M NaOH and 20mM NaI) was measured using absolute 4pi-alpha liquid scintillation counting with a combined relative standard measurement uncertainty of 1.1% [1]. Samples from the same solution were then measured in three radionuclide calibrators and the first of three HPGe detectors. The combined standard measurement uncertainty of the radionuclide calibrators was 3.4%-3.8% (excluding the uncertainty that originates from the calibration). Another comparison was performed (using an identical ^{211}At solution) between the first HPGe detector and two HPGe detectors in different labs. Their combined relative standard measurement uncertainties ranged between 5.7%-6.2%. The first two HPGe detectors used decay data from DDEP and the third used data from NuDat3. ***Results:*** For the three radionuclide calibrators, the difference in activity between the setting used for the previous clinical trial and the traceable calibration was 3.9%, 3.9% and -6.9%, respectively. The HPGe detectors differed compared to the traceable calibration 6.6%, -0.1% and 1.7%, respectively. Had the third site also used decay data from DDEP the difference would have been -4.5% (instead of 1.7%). ***Conclusion:*** Before establishing metrological traceability, the radionuclide calibrators underestimated the activity of ^{211}At by up to 7%. HPGe measurements rely on accurate data on the intensity of the 687keV gamma associated with ^{211}At decay. DDEP lists an uncertainty of 5% for this intensity, which is the largest contributor to the uncertainty of the measurements. There is a 6.5% difference in listed gamma emission intensity between DDEP and NuDat3. This highlights the need for better decay data for ^{211}At if HPGe detectors are used for activity measurements. ***References:*** 1.PMID:40184906 2.PMID:19525452.

EP-0946

Novel Scatter and Tail Corrections Improve Low-Activity Lu-177-PSMA Imaging in Digital 3D Ring SPECT/CT

L. Kääriä[1], *M. Seppänen*[2], *T. Noponen*[1];
[1]*Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND,* [2]*Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND.*

Aim/Introduction: ^{177}Lu-PSMA has established a foothold in clinical practice recently for treating metastatic castration-resistant prostate cancer. Dosimetry imaging is typically conducted within a few hours to one week post-treatment. Therefore, reliable imaging at low activity levels is critical, especially at late time points. We previously demonstrated that calibration factors (CFs) for both ^{177}Lu photopeaks (113 and 208 keV) in a digital 3D ring-design SPECT/CT system remain stable over a wide range of activity levels. However, at lower activity levels - particularly for the 113 keV peak - CFs begin to drift due to the known tailing effect in CZT detectors. New reconstruction techniques have been introduced to mitigate this drift, including enhanced scatter correction (SC), tail correction (TC), and a combined peak reconstruction option. This study evaluates the impact of these correction methods on CFs at low activity levels in ^{177}Lu imaging. ***Materials and Methods:*** A uniform cylindrical phantom (6480 cm^3) was filled with 3.70 GBq of ^{177}Lu and imaged at multiple time points during decay until near depletion. Activity concentration was determined for each 20 min acquisition. Data were reconstructed for each photopeak

using the Bayesian penalized likelihood (Q.Clear) algorithm (20it15ss). Three reconstruction configurations were used: 1. CT-based attenuation correction with traditional SC, 2. CT-based attenuation correction with novel SC, and 3. CT-based attenuation correction with novel SC and TC. For the combined peak (113+208 keV), only the second and third configurations were applied. At one time point, reconstruction effects were evaluated step-by-step, adding one correction at a time. Total counts were measured using a cylindrical VOI. ***Results:*** The mean CFs for the 113 and 208 keV peaks using the first configuration were 69.58 ± 1.63 and 71.42 ± 2.38 cps/MBq (activity ranges: 3700-140 MBq and 3700-16 MBq), respectively. For the second configuration, CFs were 113.89 ± 2.97 and 64.07 ± 2.99 cps/MBq, and for the third, 148.84 ± 4.26 and 80.04 ± 3.57 cps/MBq (range: 3700-16 MBq). For the combined peak, mean CFs were 177.94 ± 5.18 and 228.94 ± 7.09 cps/MBq for the second and third configurations, respectively. ***Conclusion:*** The novel SC significantly improved CFs at low activity levels, especially for the 113 keV peak, where CFs remained stable over the same activity range as those acquired with the 208 keV peak. This improves the quantification capability of the 113 keV peak in late post-therapy dosimetry and supports potential clinical use of the combined peak.

EP-0947

Cross calibration of a dose calibrator with a gamma counter for ^{68}Ga and ^{18}F activity measurements

T. Assoignon[1], *M. Hesse*[2], *F. Dupont*[2];
[1]*UCLouvain, Woluwe-Saint-Lambert, BELGIUM,* [2]*Cliniques Universitaires Saint-Luc, Woluwe-Saint-Lambert, BELGIUM.*

Aim/Introduction: Gallium-68 (^{68}Ga) is used in theranostics, mainly for PET imaging in neuroendocrine and prostate cancers, as a surrogate to the same pharmaceutical agent marked with Lutetium-177 used for therapy. Accurate PET quantification requires precise activity measurements from dose calibrators. However, differences of activity measurements have been reported between similar devices for ^{68}Ga. Common verification methods to find the correct dose calibrator setting, such as the use of a traceable source or the PET/CT cross calibration, are not always available or reliable. In this study, we propose to use a gamma counter together with Monte Carlo (MC) simulations to overcome these limitations. ***Materials and Methods:*** Samples of about 23 and 10MBq of ^{18}F-FDG and $^{68}GaCl_3$ were measured using a dose calibrator, then diluted by a factor of 1000 to be measured on a gamma counter for 60 minutes. MC simulations were performed using GATE to model the gamma counter's response. The measured and simulated spectra for both isotopes were compared for validation. Sensitivity factors were calculated by dividing the total number of disintegrations by the number of counts in the 511 keV and 1022 keV energy windows ([450-570]keV and [900-1150]keV). These factors were then used to evaluate the samples activities and compared them to dose calibrator values. ***Results:*** The simulated energy spectra were in good agreement with experimental data. Sensitivity factors computed from the simulations allowed an accurate recovery of the samples activities from gamma counter data, with predicted activities being within less than 5% of the dose calibrator values. The sensitivity factors derived from the 511keV energy window displayed variations below 2% for changes of the samples volume up to 50%. ***Conclusion:*** This study presents a method to verify the dose calibrator settings for PET isotopes based on an activity measurement with a gamma counter. The method does not require traceable source, nor cross calibration with a PET scan, and is little dependent on the samples volume. This approach is not limited to PET isotopes: its extension to Lutetium-177 is a work in progress.

EP-0948

Exploring Activity and Scan Time Reduction of [^{18}F]PSMA-1007 within EARL2 Standards

L. Kloosterboer*, L. Heijmen, J. W. J. van Brecht, P. Dibbets-Schneider, T. Ruytenberg, L. de Geus-Oei, D. D. D. Rietbergen, F. H. P. van Velden;*
Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Ongoing advancements in PET/CT detector technology significantly improved image quality and sensitivity, enabling reduction of scan duration and/or the administered radiopharmaceutical activity. Van de Burgt et al. (Physica Medica, 2015) have shown in a phantom study that reduction in scan duration or administered activity of at least a factor four is possible for [^{18}F]FDG on an Omni Legend 32. Our aim is to evaluate on patient data whether either scan duration or the administered activity of [^{18}F]PSMA-1007 can also be reduced, while complying with the EARL Fluorine-18 standards 2 accreditation (EARL2). ***Materials and Methods:*** Fifteen subjects received a [^{18}F]PSMA-1007 PET/CT scan (3 MBq/kg, 120 sec/bed) on an Omni Legend 32 PET/CT between February, 2025 and April, 2025. Four administered activity regimes are simulated by varying the time/bed (120, 60, 45 and 30 sec) in each EARL2 (4 mm) reconstruction. To obtain the coefficient of variation (COV) within healthy tissue as an indication of the noise level, a 2-cm diameter sphere is manually drawn inside the spleen. Lesions (n=31; median volume: 6.5 mL, range: 1.1-35.1 mL) are delineated semi-automatically using an absolute threshold of SUV of 4 and a lower volume limit of 1 mL to assess SUV_{max}, SUV_{mean} and SUV_{peak}. Statistically significant differences ($p \leq 0.05$) between these quantitative measures are assessed using the Wilcoxon signed-rank test. ***Results:*** No statistical differences were found for lesion SUV_{mean} and SUV_{peak}, comparing the simulated reconstructions to the 120 sec/bed reconstruction. Lesion SUV_{max} for the simulated reconstructions were statistically different from the 120 sec/bed reconstruction. Median COV of the spleen were 4.7% (2.6-7.8%), 5.0% (3.7-11.8%), 5.5% (3.7%-12.7%) and 6.0% (4.0%-12.8%) for 120, 60, 45 and 30 sec/bed, respectively. ***Conclusion:*** These preliminary results suggest that the scan duration or administered activity of [^{18}F]PSMA-1007 can be reduced by at least a factor four. The noise level increases while decreasing scan duration (resulting in increased SUV_{max}), but remains below 15% as required by EARL for [^{18}F]FDG images. Further research should demonstrate whether this assumption can be translated to [^{18}F]PSMA-1007. Analysis of additional data is necessary to obtain definite conclusions and should at least include the assessment of: a larger patient group, EARL1 and EARL2 (2 mm) reconstructions, lower time/bedposition(s) and a qualitative image analysis. ***References:*** Van de Burgt et al. "[^{18}F]FDG administered activity reduction capabilities of a 32-cm axial field-of-view solid-state digital bismuth germanium oxide PET/CT system while maintaining EARL compliance." Physica Medica 131 (2025): 104935.

3D Printed PET/CT Phantom with Mixed Target Uptake Characteristics to Investigate Lesion Development

O. Caselles[1,2], *S. Nalla*[1,3], *Q. Maronnier*[1], *T. Palchan-Hazan*[4], *J. Kennedy*[4,5];
[1]*Oncopole Claudius REGAUD - IUCT Oncopole, Toulouse, FRANCE,* [2]*Tachyons SAS, Toulouse, FRANCE,* [3]*Universite de Toulouse, Toulouse, FRANCE,* [4]*Rambam Health Care Campus, Haifa, ISRAEL,* [5]*Technion Israel Institute of Technology, Haifa, ISRAEL.*

Aim/Introduction: Precise lesion characterisation is a common challenge in practice due to heterogeneity within tumours. Conventional quality control practices, such as fillable acrylic spheres have limitations in assessing the heterogeneity. In contrast, 3D printing enables the creation of versatile phantoms that are customisable to include complex features such as fillable printed grids which can simulate multitude of contrasts within

a phantom using single tracer injection. This work builds upon a previous 3D printed phantom inserts design [1] to introduce a more complex design including heterogeneous uptake patterns with minimal phantom preparation time. ***Materials and Methods:*** 4 cm gyroid cubic grids were 3D printed (75% Infill) in Acrylonitrile butadiene styrene (ABS). Spherical voids of 17mm and 28mm were incorporated centred on the cube. A second region with different infill (50% or 100%) was added leading to primary targets (Target Background Ratio ~ 4) of either a sphere or crescent shape. Heterogeneity was either multifocal (TBR ~ 2) or necrosis (TBR ~ 0) based on second regions density. These inserts were placed in a conventional QC phantom and filled with water, soap and [^{18}F] FDG (96 MBq). Acquisitions were performed on two different PET/CT scanners (β:650). Recovery coefficient (RC) was evaluated for quantitation of primary lesion along with TBRMax of overall insert. Additionally, standardised uptake value (SUV) profiles were extracted on Transaxial slice for heterogeneity impact analysis. ***Results:*** Heterogeneity was apparent visually on PET images for all 28mm targets whereas only primary lesion was predominant for 17mm targets due to partial volume effects on secondary regions. TBRMax for 17mm set were in the range of 1.22 - 4.21 and for 28mm targets were 1.34 - 4.52. Mean RC for primary lesions ranged from 0.71 - 0.82 (PET 1) and 0.61 - 0.73 (PET 2) for 17mm, and 0.81 - 0.88 (PET 1) and 0.74 - 0.82 (PET 2) for 28mm. Maximum RC ranged from 0.65-1.02. SUV profiles showed reduced / shifted peak values and evident transitions between multiple regions. Reference cubes without targets yielded SUV values of 0.19-0.27 against expected 0.25 (SUVWater ~1). SUVNecrosis were slightly higher than 0. ***Conclusion:*** Our results highlight that 3D printed inserts effectively model mixed uptakes while demonstrating the impact of lesion size and heterogeneity on PET/CT visual interpretation and quantitation. ***References:*** [1] Nalla, S.K.K., Maronnier, Q., Kennedy, J.A., Palchan-Hazan, T. and Caselles, O., 2025. Quantitative accuracy of clinical PET systems in the UK (2019-2023)

A. Fenwick, *A. Robinson, A. Denis Bacelar, K. Ferreira, D. Deidda, D. Roddy, W. Heetun;*
National Physical Laboratory, Teddington, UNITED KINGDOM.

Aim/Introduction: Quantitative accuracy in PET is a critical factor when considering multi-centre comparability. To assess the comparability of PET systems in the UK a specialised traceably calibrated solid phantom was designed and distributed to 16 centres. The results were analysed centrally and are reported. ***Materials and Methods:*** The phantom was adapted from the NEMA NU-2 Image quality phantom which consists of 6 spheres ranging in size from 10 mm to 37 mm diameter. A seventh sphere with a 5 mm diameter was added to the phantom in a position optimised using monte carlo techniques. The phantom was prepared with ^{68}Ge spiked epoxy resin with a total activity of 99.0(30) MBq (k=2) with a sphere:background ratio of 4:1. The Phantom was shipped to 16 sites for measurement between 2019 and 2023 with images acquired using a decay-corrected acquisition time simulating a 3 min per bed position scan. An additional scan with a single frame centred over the sphere axis was also obtained at most sites. The phantom was periodically returned to NPL and scanned to confirm stability of the phantom. Images were reconstructed using typical clinical protocols at the participating site, and image analysis was performed centrally by two individuals (independently). Results were calculated for quantitative accuracy of background and sphere activities and recovery coefficient curves were generated for each scan made. ***Results:*** The results showed good agreement between sites with all participants complying with EARL recommended recovery coefficient curves. uncertainty analysis was included to provide comparative data. ***Conclusion:*** This study has demonstrated the comparability between clinical PET/CT sites in the UK using a standardised phantom and has created a dataset which can be used in future studies when investigating performance capability and for validation.

EP-0951

Development and Evaluation of a 3D-Printed Thyroid Phantom for Simulating Hot and Cold Nodules in SPECT Imaging

J. Kiss[1], *K. Kukuts*[2], *A. Forgács*[2];
[1]*Division of Radiology and Imaging Science, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY,* [2]*Mediso Ltd., Budapest, HUNGARY.*

Aim/Introduction: Thyroid scintigraphy is among the most frequently performed procedures in nuclear medicine; therefore, robust quality assurance protocols tailored to SPECT imaging are essential. These protocols often rely on phantom-based evaluations. However, commercially available thyroid phantoms typically represent only healthy tissue, limiting their relevance for simulating pathological conditions such as hot or cold nodules. [1,2] Recent advances in 3D printing technology enable the design and fabrication of customized phantoms, including those that mimic pathological features. In this study, we present a modified anthropomorphic thyroid phantom capable of simulating both hot and cold thyroid nodules. ***Materials and Methods:*** A commercially available 3D thyroid phantom was redesigned using 3D modeling software to alter anatomical volumes and incorporate pathological structures. Spherical nodules (1 cm diameter) were added: a solid (cold) nodule was embedded in the left lobe, and a fillable hollow sphere (0.3 ml) representing a hot nodule was placed in the right lobe. The models were printed in two sizes (20 ml and 40 ml fillable thyroid volumes) using PLA material via fused deposition modeling (FDM) technology. Reproducibility of the manufacturing process was assessed through repeated printing and CT imaging. For realistic attenuation and scatter conditions, the thyroid phantoms were placed within a standard neck phantom. SPECT/CT acquisitions using Iodine-131 were performed on a triple-head SPECT/CT system equipped with a multi-pinhole collimator. The activity concentration ratio between the thyroid tissue and the hot nodule was set at 1:10. ***Results:*** The fabrication process demonstrated high reproducibility, with no leakage observed during phantom preparation. The printed phantoms were fully compatible with conventional neck phantoms. Reconstructed SPECT images clearly depicted both nodules, with the hot and cold lesions showing 88% higher and 28% lower uptake, respectively, compared to the uniform thyroid background. ***Conclusion:*** Results confirm that fillable 3D-printed thyroid phantoms can reproducibly simulate pathological conditions, providing a valuable tool for image quality assessment in SPECT imaging. ***References:*** 1. https://doi.org/10.1097/HP.0000000000000995 ; 2. https://doi.org/10.1016/j.radphyschem.2019.108462.

EP-0952

Manufacturer improvement of ^{99m}Tc scatter correction for its long bore collimator CZT ring SPECT-CT

A. Seret[1], *K. Di Bartolomeo*[2], *C. Bernard*[3];
[1]*University of Liege, Liege, BELGIUM,* [2]*GE Healthcare, Brussels, BELGIUM,* [3]*CHU of Liege, Liege, BELGIUM.*

Aim/Introduction: The manufacturer of the long bore collimator CZT-based ring SPECT-CT is currently releasing an upgraded version of its reconstruction software where dual energy window scatter correction is performed in the iterative loop of the reconstruction whereas it was previously a subtraction at the projection level. Phantom data of our past study of this system

[1] were reprocessed with the new (25) software and results were compared to those obtained with the past version (23). ***Materials and Methods:*** Previously recorded data of ^{99m}Tc filled cylindrical NEMA NU2-94 phantom (NEMA), custom hot and cold bar contrast phantom (TOM) and uniform phantoms of two different sizes (L and XL) were reconstructed using manufacturer OSEM (10 subsets and 20 iterations), attenuation correction, resolution recovery with (SC) or without (NoSC) scatter correction. Considered parameters were residual fraction (RF) in NEMA, recovery coefficient (RC) in TOM bars, coefficient of variation (COV) in TOM uniform area and quantification error (QE) in L using XL as calibration phantom. Parameter values were compared to those obtained previously [1] as well as those obtained using a single 136-145 keV narrow energy window (NW) to spectrally reject scattered photons. ***Results:*** Both software versions led to very similar NoSC values for all parameters. In NEMA, RF-SC25 < RF-NoSC in all three inserts with RF-NoSC < RF-SC23 in air and RF-SC23 < RF-SC25 in water and Teflon. RC-NW > RC-SC23 > RC-SC25 > RC-NoSC in TOM cold rods. RC-NW > RC-NoSC > RC-SC25 > RC-SC23 in TOM hot rods but RC-SC25 ≥ RC-NoSC when only considering the central part of the rods. SC25 very moderately increased COV and the increase was lower than with SC23. In large hot areas, SC25 removed a total number of counts which amounted only to roughly one half of the counts removed by SC23. QE was in the range ±3% depending on the size (smaller or larger than the phantom physical size) of the regions of interest. ***Conclusion:*** The upgraded scatter correction removed much less acquired counts in large hot areas than the past version. Cold contrasts were slightly lower whereas hot contrasts were much larger especially in the thinnest rods which were not present (RC=0) on the SC23 images. Nevertheless, the contrast obtained with a single narrow energy window were higher. Quantification with SC25 in uniform phantoms was very satisfactory with error below 3%. ***References:*** 1. Seret A, Bernard C. EJNMMI Physics 2025; In Press.

EP-0953

FDG Extravasation in PET/CT Imaging: A Visual Grading Approach Based on Clinical Observations

S. Bilgic*;*
Bursa Uludag University, Bursa, TÜRKIYE.

Aim/Introduction: FDG extravasation is a frequently overlooked issue in PET/CT imaging, potentially impacting standardized uptake value (SUV) measurements used in clinical interpretation. This study aims to introduce a visual grading system to classify FDG extravasation severity and assess its quantitative impact on reference SUV values in oncologic patients [1,2]. ***Materials and Methods:*** A total of 235 consecutive FDG PET/CT scans performed for oncologic indications were retrospectively analyzed. Patients were categorized into four groups based on extravasation severity (Grade 0-3), using a newly proposed visual grading system. Liver and mediastinal blood pool regions were selected as reference sites for SUV analysis. Mean SUVmax and SUVmean values were recorded and compared across extravasation grades. One-way ANOVA and Kruskal-Wallis tests were used for group comparisons, followed by post-hoc testing to identify statistically significant differences. ***Results:*** FDG extravasation was observed in 75 patients (31.9%), with 43 classified as Grade 1, 26 as Grade 2, and 6 as Grade 3. Compared to Grade 0, both Grade 1 and Grade 2 patients exhibited statistically significant increases in liver and mediastinal SUV values ($p < 0.001$ for all parameters). For instance, liver SUVmax increased from 3.13 ± 0.44 (Grade 0) to 3.58 ± 0.50 (Grade 1), and mediastinal SUVmean rose from 1.80 ± 0.31 (Grade 0) to 2.17 ± 0.40 (Grade 2), representing a relative difference of up to 20.6%. Grade 3 cases showed variable results without consistent trends, likely due to small sample size [1,3]. ***Conclusion:*** Low-to-moderate FDG extravasation (Grades 1-2) can significantly elevate reference SUV measurements in PET/CT imaging, which may affect response assessments. Incorporating a structured visual grading system into routine clinical practice could improve diagnostic accuracy and reduce unnecessary repeat imaging. These findings highlight the need for heightened awareness and standardized reporting of FDG extravasation in quantitative PET/CT analysis [2,3]. ***References:*** Osman MM, Muzaffar R, Altinyay ME, Teymouri C. Evaluation of Costs and Accuracy a 3D-Printed Four-Organ Phantom Using a Commercial Desktop Printer for Standardized Dosimetry in Molecular Radiotherapy

A. Yumoto[1]*, F. Sasaki*[1]*, T. Kita*[1]*, N. Imaizumi*[1]*, M. Sato*[1]*, M. Shiga*[2]*, S. Fukai*[2]*, Y. Tajika*[1]*, H. Daisaki*[1]*;*
[1]*Gunma Prefectural College of Health Sciences, Gunma, JAPAN,* [2]*The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, JAPAN.*

Aim/Introduction: Accurate dosimetry in molecular radiotherapy (MRT) is essential to optimize therapeutic outcomes while minimizing radiation to healthy tissues. However, substantial inter-institutional variability persists due to differences in imaging protocols, segmentation methods, and software. While digital phantoms are useful for software validation, physical phantoms are critical for evaluating the full clinical workflow, including imaging and dose calculation. Three-dimensional (3D) printing enables low-cost and flexible production of customized physical phantoms, especially valuable in multicenter studies where standardized, reproducible models are required. To address these needs, we aimed to evaluate the production time, cost, and geometric accuracy of a proposed 3D-printed physical phantom for MRTDosimetry using commercially available printing technology. ***Materials and Methods:*** We utilized the 4-organ phantom developed as part of the MRTDosimetry Challenge, which includes anatomically representative models of the liver, spleen, kidneys, and a tumor. In this study, we employed polygon mesh in STL file format derived from the ICRP 110 adult female phantom, provided by Robinson AP et al., specifically designed for ^{177}Lu-DOTATATE dosimetry [1]. The phantom was fabricated using a FlashForge Adventurer 5M Pro printer with PLA filament, maintaining cost-efficiency. ***Results:*** Geometric accuracy was evaluated by comparing the printed organ volumes to ground truth values, with an average deviation of -0.8%, indicating high fidelity. Phantom fabrication required approximately 41 hours of printing time. The initial setup cost was estimated to be €2,560 for a 3D printer and related equipment, and the material cost per phantom was €70 (1€ = ¥162), making the method accessible and scalable. ***Conclusion:*** Our results suggest that cost-effective organ phantoms, as proposed by the MRTDosimetry project and fabricated using commercially available 3D printing technology, represent a promising tool for validating dosimetry workflows. Future studies will evaluate the effects of different printer models and filament types on accuracy, and examine the reproducibility of repeated prints using the same 3D printing settings. ***References:*** [1] Ferreira KM, Lassmann M, Tran-Gia J; MRTDosimetry Collaboration. EP-0955

The impact of EARL harmonization on PET kinetic parameters

G. Khamadeeva, *A. Khalimon, I. Baltabaev, A. Shakirova, M. Khodzhibekova, T. Lazutina, I. Pylova, D. Khodakova, A. Leontev; P. Hertsen Moscow Oncology Research Institute - Branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Kinetic parameters such as influx rate (Ki) and distribution volume (Vd) obtained from dynamic PET may improve diagnostic performance; however, their interscanner stability has not been sufficiently studied. The aim of this study was to assess the impact of ^{18}F-based PET EARL2 harmonization on variability of Ki and Vd. ***Materials and Methods:*** Image QC dataset obtained on the 5-ring BGO PET/CT system according to ^{18}F-based PET EARL2 standard was used. 5 EARL2-compliant reconstructions (BSREM with β350 and β450, 3D-OSEM+PSF with 10i6s6mm, 11i6s5mm, and 4i12s6mm, respectively) and 5 EARL2-incompliant reconstructions (BSREM with β100 and β600, 3D-OSEM+PSF with 3i6s8mm, 9i12s5mm, and 3i12s1mm) were selected. The choice of such set of EARL2-incompliant reconstructions was aimed at achieving a wide diversity of recovery coefficients for SUVmax. On average, the mean square errors of SUVmax in EARL2-incompliant reconstructions were 1.3 times higher than in compliant ones (0.148 vs. 0.111). Next, nine patients with twelve metabolically active lung lesions were enrolled in this prospective single-center study. Single-bed dynamic 50-minute PET (dPET) started simultaneously with the IV injection of [^{18}F]FDG. Raw PET data were used to obtain above mentioned sets of 10 reconstructions. Twenty-five time frames (6×30s, 7×60s, 8×150s, and 4×300s) for each reconstruction were applied for kinetic analysis. Ki and Vd of each lesion were calculated via graphical Patlak analysis using various spherical VOIs covering the whole lesion; the image-derived input function was obtained from the region of the descending aorta. Additionally, SUVmax and SUVpeak of each lesion were measured on the last frame of the dPET scan. The coefficients of variation (CoV) for the mentioned metrics (Ki, Vd, SUVmax, SUVpeak) were calculated. ***Results:*** All lesions were well distinguishable on dPET images, and VOI diameters varied from 5mm to 35mm (median 15mm). The CoVs of each metric were statistically lower in the group of EARL2-compliant reconstructions: median of the COVs were 4.5% vs. 11.3% (p=0.0032) for Ki; 6.9% vs. 21.6% (p=0.0407) for Vd; 4.14% vs. 24.3% (p=0.0022) for SUVmax; 2.8% vs. 21.3% (p=0.0022) for SUVpeak. ***Conclusion:*** Preliminary data may indicate the presence of inter-scanner variability in PET kinetic parameters comparable to that discovered for SUVmax and SUVpeak, as well as the potential for its reduction through EARL harmonization.

Harmonization of Quantitative Values in Bone SPECT/CT for Medication-related Osteonecrosis of the Jaw

T. Kita[1], *I. Kuromori*[1], *H. Daisaki*[1], *M. Sato*[1], *F. Sasaki*[1], *A. Yumoto*[1], *N. Imaizumi*[1], *Y. Owaki*[2], *T. Tsuchitani*[3], *N. Hayashi*[4], *M. Tsujimoto*[5], *Y. Maeda*[6], *N. Ueno*[7], *Y. Iwabuchi*[2], *T. Norikane*[8], *Y. Inui*[5], *H. Kaida*[7], *K. Ito*[9], *K. Kitajima*[3];
[1]Gunma Prefectural College of Health Sciences, Gunma, JAPAN, [2]Keio University School of Medicine, Tokyo, JAPANJAPAN, [3]Hyogo College of Medicine College Hospital, Hyogo, JAPAN, [4]Kochi Medical School Hospital, Kochi, JAPAN, [5]Fujita Health University Hospital, Aichi, JAPAN, [6]Tokushima Bunri University, Tokushima, JAPAN, [7]Kindai University Hospital, Osaka, JAPAN, [8]Kagawa University Hospital, Kagawa, JAPAN, [9]National Cancer Center Hospital, Tokyo, JAPAN.

Aim/Introduction: Medication-related osteonecrosis of the jaw (MRONJ), often associated with antiresorptive and anti-angiogenic treatments used in osteoporosis and cancer patients, significantly affects patient quality of life. Early and accurate diagnosis is essential, and recent advancements in quantitative single-photon emission computed tomography/computed tomography (Q-SPECT/CT) have improved its diagnostic utility for MRONJ. However, variability in standardized uptake values (SUVs) across different SPECT/CT systems poses a challenge to multicenter studies, as there is currently no established harmonization criterion for Q-SPECT/CT. To address this limitation, a multicenter phantom study was conducted across seven institutions using eight SPECT/CT scanners. The study aimed to establish a harmonization criterion for SUV measurements and assess the efficacy of a software-based harmonization method. ***Materials and Methods:*** A custom-designed brain tumor phantom containing six hot spheres [1] was filled with ^{99m}Tc-HMDP (hot/background ratio of 4) and imaged using clinical protocols. A cylindrical phantom was used to determine the Bq calibration factor, and SUV conversion and harmonization were performed using the RAVAT software platform (Nihon Medi-Physics Co.,Ltd.) [2]. The harmonization criterion was defined as SUVmax within ±30% of the median value across scanners. If this range was exceeded, a 3D Gaussian filter was applied for harmonization. ***Results:*** The results demonstrated that the SUVmean values in the background region remained stable (0.95-1.05) before and after harmonization, indicating consistent background calibration. In contrast, for the hot spheres, inter-scanner variability in SUV measurements was significantly reduced after harmonization. The coefficients of variation (CVs) for SUVmax, peak SUV, and SUVmean improved from 122%, 68%, and 71%, respectively, before harmonization to 48%, 35%, and 37% afterward. ***Conclusion:*** This study is the first to propose a harmonization criterion for Q-SPECT/CT in MRONJ and to validate a software-based harmonization approach. The method effectively reduced inter-scanner variability without degrading clinical image quality or requiring changes to the image reconstruction process. These findings support the feasibility and utility of this harmonization strategy in multicenter clinical settings, paving the way for more reliable and standardized Q-SPECT/CT studies of MRONJ. ***References:*** [1] Hayashi N, Tokorodani R, Kenda S, Ogasawara D, Yabe F, Ito K. Brain MRI-guided PET Reconstruction in a New PET/MRI System with State-of-the-art TOF resolution

J. Cabello[1], *K. Kettless*[2], *P. Lehmann*[2,3], *A. B. Rodell*[2], *J. Schaefferkoetter*[1], *I. Law*[4], *F. L. Andersen*[4,5], *T. L. Andersen*[4,5], *P. Schleyer*[1];
[1]Siemens Medical Solutions USA, Inc, Knoxville, TN, UNITED STATES OF AMERICA, [2]Siemens Healthcare A/S, Ballerup, DENMARK, [3]Research & Clinical Translation, Magnetic Resonance, Siemens Healthineers AG, Erlangen, GERMANY, [4]Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital—Rigshospitalet, Copenhagen, DENMARK, [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK.

Aim/Introduction: PET imaging inherently exhibits limited spatial resolution and high image noise. Recent improvements in Time-of-Flight (TOF) performance have resulted in increased effective sensitivity, signal to noise ratio and accelerated image reconstruction convergence. Simultaneous PET/MRI acquisition

provides spatially overlapping metabolic/functional and soft tissue anatomical information at the same time point. By leveraging anatomical MR-images as prior information in the PET reconstruction, MRI-guided (MRIg) MAP-EM PET reconstruction reduces image noise, and improves spatial resolution and quantification accuracy. The current work presents preliminary results of MRIg-MAP-EM PET reconstruction of several brain FDG-PET datasets acquired on the BIOGRAPH One, a second-generation PET/MRI system (Siemens Healthineers) with best-in-class TOF performance. ***Materials and Methods:*** Several subjects were injected with 200.0 MBq FDG, and underwent a brain PET scan for 16-18 min in the PET/MRI system, while simultaneously acquiring multiple MRI sequences. PET data were acquired in list-mode format and rebinned to different scan lengths. The datasets were reconstructed using OP-OSEM and MRIg-MAP-EM reconstruction, based on the Bowsher prior combined with a novel algorithm to adaptively calculate the anatomical strength, using a high resolution 3D-T1w SE (MPRAGE) MRI sequence as anatomical reference. ***Results:*** Results demonstrated that MRI-guided MAP-EM PET reconstruction yielded lower image noise and enhanced delineation of both cortical and subcortical brain structures, compared to OP-OSEM. This improvement enabled a reduction in scan time—or administered dose—by up to 75% without perceptible degradation in image quality. While the high TOF resolution OP-OSEM reconstructions exhibited high image quality, MRIg-MAP-EM further improved image sharpness and reduced noise. Notably, noise levels in the cerebellum increased consistently with OSEM as scan time decreased, whereas MRIg-MAP-EM maintained relatively stable noise levels even at a 1-minute scan duration, while preserving the sharper tissue boundaries such as gray-white matter delineation. ***Conclusion:*** In conclusion, the TOF resolution achieved by this new PET/MRI system significantly improved image quality compared to non-TOF reconstruction, resulting in more precise visualization and delineation of small structures within the brain. Moreover, the integration of anatomical information further refined spatial resolution and reduced image noise. This synergistic approach not only maintains high image quality but also enables reduced scan times or lower radiation doses, thereby improving patient comfort and safety without compromising diagnostic accuracy. Furthermore, we plan to explore the combination of MRIg-MAP-EM PET reconstruction with accelerated deep learning-based MRI, to shorten clinical brain MR protocols, in addition to applying this technique to other radiotracers.

EP-0958

Robustness of Radiomics Parameters to Respiratory Motion: a Phantom Study

H. Halvorsen[1], *L. M. Bonney*[1,2], *G. M. Kalisvaart*[3], *F. H. P. van Velden*[3], *W. Grootjans*[3], *D. R. McGowan*[1,4];
[1]*Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM,* [2]*Sir William Dunn School of Pathology, University of Oxford, Oxford, UNITED KINGDOM,* [3]*Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS,* [4]*Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Radiomic features in PET/CT provide quantitative information that can aid in disease characterisation and prediction of treatment response. Great efforts have been put into the standardisation of such biomarkers [1]. However, it is not well known how these features are affected by motion. Breathing motion is inherent to PET imaging, and various reconstruction algorithms have been developed to correct for this. This study evaluates the robustness of standardised radiomic features to breathing motion, with and without motion correction, using a respiratory motion platform simulating a typical patient and sinusoidal respiratory waveforms. ***Materials and Methods:*** A modular heterogeneous phantom [2] was filled with F-18 and placed on a respiratory motion platform (Quasar). The phantom was scanned on a GE Discovery 710 PET/CT scanner whilst moving sinusoidally and with a typical patient respiratory waveform. Acquisitions were performed with varying motion amplitudes, and a static acquisition was performed for reference. The images were reconstructed using a Bayesian Sequential Regularisation Expectation Maximisation (BSREM) algorithm and a data driven Quiescent Period Gating (QPG) motion correction algorithm. A total of 93 radiomic features were extracted from each image and compared between images of varying motion amplitude using the coefficient of variation (COV) to determine feature stability and Spearman's rank correlation coefficient (ρ) to determine the relationship between features and motion amplitude. A 15% COV threshold was used for ongoing analysis of feature stability, and we defined a monotonic relationship with motion as $\rho \geq 0.8$. ***Results:*** Of the 93 radiomic features analysed, 47% were found to be impacted by sinusoidal motion when using BSREM. This was reduced to 35% when using QPG. Of these features, 80% and 70%, respectively, had a monotonic relationship with motion. For typical patient respiratory motion, 35% were impacted by motion when using BSREM, and 27% when using QPG. Of these, 79% and 48% had a monotonic relationship with motion. ***Conclusion:*** A high proportion of radiomic features were found to be affected by motion for both simulating patient breathing and sinusoidal motion. Most of the affected features had a monotonic relationship with motion amplitude, meaning they increased or decreased consistently with motion. Future research should consider how to implement this knowledge to accurately interpret radiomic features in images containing respiratory motion. ***References:*** [1] Zwanenburg et al. Radiology. 2020;295:328-38. [2] Kalisvaart et al. Med Phys. 2022;49:3093-106.

Preliminary results from a deep learning PET-derived attenuation correction of paediatric FDG brain images

I. Armstrong[1], *A. Coates*[1], *L. Partin*[2], *R. Fahmi*[2], *J. Schaefferkoetter*[2], *B. Spottiswoode*[2], *S. Muthu*[1];
[1]*Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM,* [2]*Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: In paediatric imaging, keeping the radiation burden to the patient as low as possible is an extremely important consideration. Attenuation correction (AC) in an essential component of PET-CT for accurate quantification, and normally performed using CT. For brain studies, this AC CT offers no additional use in clinical image interpretation. We have previously demonstrated the utility of a deep learning algorithm to produce synthetic CT (SynCT) from non-AC PET data for AC purposes. The method leverages the fine anatomical detail visible on non-AC PET images, made possible by high performance time of flight (TOF) PET. This study presents new data from an expanded training model that includes paediatric FDG brain cases. A comparison of the AC PET images using CT and SynCT is presented. ***Materials and Methods:*** A 3D U-net was trained to produce a SynCT using non-AC FDG brain PET images from 100 adult and 20 paediatric patients, acquired on a SiPM PET-CT with 214ps TOF resolution. A testing set of 15 paediatric cases (age 11.6±3.6yr; [range 6-17yr]) was separately acquired with attenuation corrected images produced from the CT and SynCT, derived from the 15-minute non-AC FDG PET images. PET images with AC were reconstructed with 3D iterative OSEM using 8 iterations, 5 subsets, no post-filter, and included TOF and resolution modelling. Voxel-wise differences in AC PET voxels were expressed as the root mean squared error (RMSE), mean voxel ratio (MVR) and structural similarity (SSIM). Paired, but blinded, PET images were assessed visually in synchronised 3-plane orthogonal views using a matched "Spectrum" colour scale, by an experienced nuclear medicine physician to identify any clinically relevant

discrepancies in FDG distribution between the paired images. ***Results:*** Across the 15 patients, the mean and standard deviation RMSE was 469 ± 284 Bq/ml, the MVR was 0.978 ± 0.046 and SSIM was 0.836 ± 0.045. Visual review found no perceivable differences in FDG distribution in all but two cases, which showed very minor perceivable differences. However, neither case were judged to demonstrate clinically significant differences. ***Conclusion:*** This work has demonstrated the expansion of PET-derived synthetic CT for AC of FDG brain scans to paediatric patients. Work continues to evaluate the source of visual differences and refine the model. ***References:*** I Armstrong, A Coates, L Partin, R Fahmi, C Hayden, J Schaefferkoetter, B Spottiswoode, S Muthu. Monte Carlo Based SPECT Reconstruction: Improvements to Quantitative Imaging

L. Polson[1], *J. Grudzinski*[2], *S. Kurkowska*[3], *P. Esquinas*[4], *C. Uribe*[1], *A. Rahmim*[1];
[1]*University of British Columbia, Vancouver, BC, CANADA,* [2]*University of Wisconsin – Madison, Madison, WI, UNITED STATES OF AMERICA,* [3]*Pomeranian Medical University, Szczecin, POLAND,* [4]*BC Cancer, Vancouver, BC, CANADA.*

Aim/Introduction: Patient-specific dosimetry in radiopharmaceutical therapy requires accurate SPECT-derived activity maps to enable individual treatment planning. For the isotopes Lu-177 and Tc-99m, conventional SPECT with triple energy window (TEW) scatter correction reasonably estimates activity but suffers from positive bias and contrast overestimation in hot regions (~10%) due to larger scatter angles acquired in the lower energy window . For other isotopes such as Pb-212 (alpha emitter) and Y-90 (Bremsstrahlung emitter), conventional reconstruction is inadequate. This study demonstrates that Monte Carlo (MC)-based reconstruction yields more accurate quantitative imaging for Lu-177, Ac-225, Pb-212, Y-90, and Er-165. ***Materials and Methods:*** An MC-based SPECT system matrix, which estimates the expectation of all acquired photons in a given energy window, was implemented using PyTomography with SIMIND serving as the physics simulation backend. The MC-based reconstruction approach was evaluated on synthetic and real SPECT data. Synthetic datasets were generated in SIMIND using phantoms composed of three spheres (72 mm, 40 mm, and 20 mm in diameter) embedded in a cylindrical background with a 10:1 source-to-background ratio. The simulations modeled a Siemens Symbia T2 system with 128 projections acquired at a 15 cm radius and 15 seconds per projection. Reconstructions were performed with OSEM using (i) a conventional system matrix, with triple-energy window (TEW) correction used for Lu-177, Ac-225, and Pb-212, and (ii) the proposed MC-based system matrix. Conventional and MC-based reconstruction were then compared using real SPECT phantom data (Lu-177, Ac-225, and Y-90) that were each acquired on a Siemens Symbia T2 system. ***Results:*** Computed contrast (sphere/background) in the 72 mm sphere from simulated data are listed as (conventional, MC) and were as follows: Lu-177 (11.92, 10.13) , Ac-225 (11.47, 9.58), Pb-212 (4.36, 9.27), Y-90 (3.22, 10.28), Er-165 (5.38, 10.38), showing MC reconstruction is quantitatively superior in all cases. In the real data, the Lu-177 NEMA phantom (32 mm sphere) had a -8.62% contrast difference between MC and conventional , the Ac-225 phantom (60 mm) showed a -20.1% difference, and the Y-90 NEMA phantom (32 mm) showed a +97.1% difference. MC reconstructions thus corrected for contrast overestimation in Lu-177 and Ac-225 and underestimation in Pb-212, Y-90, and Er-165; such differences can be explained via spectral analysis of each isotope. ***Conclusion:*** A MC-based reconstruction framework (implemented via PyTomography and SIMIND and made publicly available) was demonstrated to quantitatively outperform conventional reconstruction in SPECT by reducing isotope specific bias for Lu-177, Ac-225, Pb-212, Y-90, and Er-165.

AI-based denoising of multi-scanner fast-acquisition brain [^{18}F]FDG PET allows for reliable regional quantification

L. C. Silva*, C. S. Constantino, F. P. M. Oliveira, D. C. Costa; Champalimaud Foundation, Lisbon, PORTUGAL.*

Aim/Introduction: This study aimed to assess the feasibility of deep-learning-based denoising of 1-3min brain [^{18}F]FDG PET to improve patient cooperation and enhance clinical workflow. ***Materials and Methods:*** 120 patients were included for the training (N=80) and testing (N=40) of a denoising-specific 3D U-Net. Local brain [^{18}F]FDG PET and external[1] whole-body [^{18}F]FDG PET (cropped to simulate brain acquisitions) training/test datasets comprised 29/20 and 51/20 patients, respectively. Local fast acquisitions corresponded to durations of 2, 3 and 5min, and external 1, 2.5 and 5min, against reference acquisitions of either 10 or 15min. Local dataset included acquisitions at 30min, 45min and 2h30-3h post-injection, and external dataset at around 60min post-injection. This resulted in 351 training pairs. For testing, 1-3min acquisitions from a single time post-injection were used, resulting in 80 pairs (20 pairs/duration). Average injected activity was similar for both datasets, averaging around 3MBq/kg. Local acquisitions were performed either on a Philips Gemini or Philips Vereos PET/CT scanner, and external acquisitions on a United Imaging uExplorer or Siemens Biograph Vision Quadra PET/CT scanner. Mean squared error (MSE), intraclass correlation coefficient (ICC) and peak signal-to-noise ratio (PSNR) were used for a voxel-wise comparison between not denoised (ND) and respective deep-learning-denoised (DL) sets against reference images. Anatomical segmentation was based on the automated anatomical labelling (AAL) 2 atlas, which was deformed into each patient's native space. Agreement between ND and DL sets against the reference was assessed through the ICC and absolute deviation in SUV_{min}, SUV_{max} and SUV_{mean} for each AAL2 region-of-interest (ROI). ***Results:*** Voxel-wise MSE, ICC and PSNR between reference and DL showed a statistically significant improvement relative to ND ($p<0.001$). Regional SUV_{mean} quantification of ND and DL revealed an absolute deviation from the reference no larger than 4% and an ICC no lower than 0.83. For SUV_{min} and SUV_{max}, statistically significant differences in ICC and absolute deviation from the reference were observed in favour of DL, against ND ($p<0.001$). In particular, ultra-fast acquisitions (1/2min) yielded an average ICC of 0.74[ND] against 0.83[DL] in SUV_{min}, and 0.81[ND] against 0.92[DL] in SUV_{max}. Average SUV_{min} and SUV_{max} relative absolute deviation from the reference were approximately 10%[ND] and 5%[DL]. ***Conclusion:*** The proposed DL-based denoising was proven suitable for the restoration of fast-acquisition brain [^{18}F]FDG PET, having resulted in images similar to the standard-of-care acquisitions. Acquisition duration reductions to 1 or 2min, depending on scanner sensitivity, demonstrated to be enough for reliable quantification. ***References:*** [1]Xue et al.(2022)(DOI:10.1007/s00259-021-05644-1).

EP-0962

AI generated attenuation correction maps for DaT SPECT image reconstruction outperforms Chang method.

Z. Wilson[1], *A. Sohlberg*[1,2], *J. Lilja*[2,1], *K. M. Bradley*[3], *D. McGowan*[1,4];
[1]*Oxford University Hospital NHS FT, Oxford, UNITED KINGDOM,* [2]*HERMES Medical Solutions, Stockholm, SWEDEN,* [3]*Cardiff University, Cardiff, UNITED KINGDOM,* [4]*University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: This study evaluates the performance of two AI-generated attenuation correction maps for dopamine active transporter (DaT) scans against two conventional attenuation

correction methods: CT-based attenuation correction (CTAC) and the Chang (uniform) method. Use of neural networks for AC would enable reducing patient radiation exposure by eliminating CT scans and improving workflow efficiency by minimizing scan time and costs. ***Materials and Methods:*** Two AI models, both based on a standard U-Net architecture, were trained to convert pre-reconstructed SPECT images (ordered-subsets expectation maximization without corrections) into CT-like attenuation maps. Model 1 uses a Mean Squared Error loss function; Model 2 uses a Mean Absolute Error loss function. The training data was obtained from two sites: Oxford, UK (1000 training cases, 50 validation) and Lahti, Finland (100 training cases, 10 validation). A total of 54 sequential DaT SPECT scans (November 2024-March 2025) were then reconstructed with Hybrid Recon Neurology using four attenuation maps: (1) a CT-based attenuation map (ground truth), (2) the mean squared error model, (3) the mean absolute error model, and (4) Chang. Ten scans were excluded because of registration artifacts or abnormal uptake. The specific 123I-FP-CIT binding ratios (SBR) across 6 brain regions of interest (ROI) were assessed using Hermes BRASS (version 7.0). ***Results:*** Pair-wise Wilcoxon signed rank tests with Bonferroni corrections for multiple comparisons demonstrated the images reconstructed with the two AI-generated mu maps yielded SBRs comparable to the standard CT based attenuation corrected images. Model 2 had no statistically significant difference ($p>0.05$) between the SBRs across all 6 brain regions with the standard. While Model 1 only had statistically significant differences in the frontal lobe ($p=0.008$) and right caudate ($p= 0.049$), while the Chang images had statistically significant SBRs across all regions ($p<0.05$) except the cerebellum (which has no diagnostic value for DaT scans). Linear regression testing on SBR between models and regions similarly showed the UNET models more comparable to the standard than the Chang method. Chang AC had the highest slope across all region regression models with a mean of 8.1±1.3% compared to Model 1 (3.1±0.6%) and Model 2 (2.2±0.9%). ***Conclusion:*** Pair-wise tests in agreement with the regressions test results indicate the AI models successfully produce AC maps statistically similar to the standard CT based AC and outperformed the uniform AC images. This demonstrates the potential of AI-based AC for these patients and future work will expand this analysis to a larger dataset.

EP-0963

Reconstruction of dual-tracer PET images for the simultaneous acquisition of 68Ga and 18F

E. Pfaehler, *D. Niekämper, J. J. Scheins, J. N. Shah, C. W. Lerche; Forschungszentrum Jülich, Jülich, GERMANY.*

Aim/Introduction: A simultaneous acquisition of two radiotracers, one labelled with 68Ga and one with 18F, is of high clinical interest. To decrease patient burden, injecting both tracers simultaneously and separating the tracer signals during reconstruction is desirable. ***Materials and Methods:*** To separate the signal of both tracers, a dual-tracer reconstruction approach[1] is adapted based on the detection of the additional prompt gamma-ray emitted by 68Ga in 1.2% of the cases. The list-mode data is separated into double and triple-coincidences, whereas a triple-coincidence consists of two annihilation photons and corresponding gamma-ray. A double-coincidence can have its origin in either 18F or 68Ga. The amount of double-coincidences with origin in 68Ga is estimated using the detected triple-coincidences and a triple-to-double ratio, estimated via simulations, indicating how many 68Ga double-coincidences are expected if one triple-coincidence is detected. We reconstruct the 68Ga image combining the detected triple-coincidences and the triple-to-double ratio. Due to the low number of gamma-rays of 68Ga, the triple-coincidence signal is very sparse. We combine the difference prior [2] and information from the image reconstructed using all double-coincidences to increase the image quality of the 68Ga image. A simple PET scanner with an axial length of 20 cm and a diameter of 30 cm, containing an approximately sized head filled with water and a skull was simulated. Two partly overlapping cylinders, one containing 1 MBq 18F and one containing 1.5 MBq 68Ga, were simulated in the middle of the skull scanned during 3 minutes. We compare the mean activity present in the reconstructed cylinders with the expected activity for both tracers, and analyse how much of the 68Ga signal remains in the reconstructed 18F image in regions where only 68Ga is present. ***Results:*** The activity in the cylinder containing 68Ga was underestimated by 11.4% while the activity in the cylinder containing 18F was overestimated by 7%. In the image part where only 68Ga was present, 9.3% of the 68Ga signal remained in the 18F image. ***Conclusion:*** Our results indicate that the reconstruction approach can separate the signal of 68Ga and 18F. However, it still needs to be tested in different scenarios. ***References:*** [1] Pfaehler,Elisabeth, et al. EP-0964

Deep Learning-Driven Total-Body PET Imaging with Concurrent Tracer and CT Dose Reduction

H. Wang[1,2], *G. Chen*[2], *C. Kong*[2], *X. Qiao*[1], *W. Ding*[2], *M. Zhang*[1], *Q. Huang*[2], *B. Li*[1];
[1]*Department of Nuclear Medicine, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA,*
[2]*School of Biomedical Engineering, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) plays a pivotal role in clinical imaging, offering both metabolic and anatomical insights. However, concerns persist regarding radiation exposure, which stems from both the injected radiotracer and the ionising radiation of the CT scan. Advances in PET hardware and reconstruction algorithms, especially the development of total-body PET with extended axial coverage, have significantly reduced radiation burden. Nonetheless, further reduction—particularly in the form of ultra-low tracer dose and CT-free acquisition—is urgently needed. Although recent deep learning (DL) approaches have addressed either PET denoising or CT-free attenuation correction individually, few have explored both challenges simultaneously. In this study, we propose a DL-based framework that enables precise imaging from ultra-low-dose, non-attenuation-corrected (NAC) total-body PET without requiring a CT scan. ***Materials and Methods:*** We developed a two-stage 3D U-Net architecture termed NLE (Noise Level Estimation). The first stage predicts the noise level in NAC images, while the second performs denoising and image enhancement. Pixel shuffle and unshuffle layers are integrated to improve memory efficiency. The model was trained on 500 total-body PET datasets acquired at Ruijin Hospital using a United Imaging uExplorer scanner. Each case comprised a standard-dose, attenuation-corrected image (D1) and four corresponding NAC images at descending dose levels (D1, D4, D10, D20). During training, all dose levels were used to promote generalisation, with 3D anatomical patches of 128×128×128 extracted per case. The model was trained for 40 epochs using the Adam optimiser with a decaying learning rate. Performance was assessed on a separate test set of 62 patients using Peak Signal-to-Noise Ratio(PSNR), Structural Similarity Index Measure(SSIM), and mean absolute errors(MAE). ***Results:*** The NLE model demonstrated robust performance across all dose levels, even in the absence of CT-based attenuation correction. For NAC-D1, D4, D10, and D20 images—none of which were attenuation corrected—the

enhanced outputs closely approximated standard-dose images with CT-based attenuation correction. PSNR values reached 31.78, 28.37, 26.85, and 25.75, respectively. Corresponding SSIM scores were 0.99, 0.98, 0.98, and 0.97, while mean absolute errors were 0.06, 0.10, 0.12, and 0.14. These results confirm the feasibility of high-fidelity total-body PET imaging from ultra-low-dose, CT-free acquisitions when guided by deep learning. ***Conclusion:*** The proposed deep learning framework enables accurate PET imaging from ultra-low-dose, CT-free total-body acquisitions, reducing patient radiation risk and enhancing the clinical accessibility of PET. This represents a promising step toward safer and more scalable molecular imaging.

Null space evaluation for multi-focal collimator SPECT on a digital brain phantom

M. Nau[1,2], *A. Vija*[3], *M. P. Reymann*[1,2], *A. Maier*[1];
[1]*Pattern Recognition Lab, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, GERMANY,* [2]*Siemens Healthineers AG, Molecular Imaging, Forchheim, GERMANY,* [3]*Siemens Medical Solutions Inc., Molecular Imaging, Hoffman Estates, IL, UNITED STATES OF AMERICA.*

Aim/Introduction: In tomographic imaging, the null space refers to components of the object that the imaging system cannot detect. These structures cannot be recovered by any reconstruction method and contribute to uncertainty in the final image [1]. We investigate how multi-focal collimator geometry affects the null space in SPECT imaging using a digital Hoffman brain phantom. We use a system model that accounts for attenuation and spatially varying point spread functions (PSFs) to evaluate whether multi-focal collimators reduce the magnitude of null space components in neurologically relevant regions of interest (ROIs). Specifically, we investigate the SMARTZOOM™ collimator (SZC), originally developed for cardiac imaging, and the SMARTZOOM™ high resolution with extended magnification field (SZHRX) collimator, which was adapted for brain imaging. ***Materials and Methods:*** We compute null space components using the iterative Wilson-Barrett method [2] with a custom projection operator and a voxelized 128^3 Hoffman brain phantom configured with a gray/white matter contrast ratio of 4:1. The projection operator models a Siemens Symbia scanner with attenuation correction, a depth-dependent 3D collimator response, and three collimator types: a standard low-energy high-resolution (LEHR) parallel-hole collimator, as well as multi-focal designs modeling SZC and SZHRX. We simulate a full 360° acquisition with 3° angular steps and a rotation radius of 15 cm for LEHR and 28 cm for SZC and SZHRX. ***Results:*** Our null space analysis identifies structures that the system can or cannot reliably reconstruct. Across the full image domain, we observe that the null space magnitude increases by 11.07 % from LEHR to SZC and by 2.10 % from LEHR to SZHRX. In contrast, within a central brain ROI of 32^3 voxels, we find a substantial reduction of 11.34 % for SZC and 8.28 % for SZHRX. SZC shows a stronger local reduction due to higher central magnification, while SZHRX achieves broader improvement through its extended magnification field. ***Conclusion:*** We show that null space characterization provides a principled framework for evaluating reconstruction uncertainty across different acquisition geometries. Our results demonstrate that multi-focal collimators reduce the null space in central brain regions and improve estimation. ***References:*** [1] Nau, M., et al., Computing Null Space Hallucinations on Simulated SPECT Image Reconstructions. 3D diffusion models for synthesizing CT image volumes from uncorrected PET data

J. Schaefferkoetter*, P. Schleyer, M. Conti;*
Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: In hybrid PET systems, the umap used for attenuation correction (AC) is derived from a modality like CT or MRI. In general, this is effective but has limitations, e.g. extra radiation dose, segmentation errors and subject motion. Convolutional neural networks (CNNs) have been applied for umap synthesis, typically generating synthetic CT-AC umaps from the PET in a single forward pass. Diffusion Probabilistic Modeling (DPM) is an advanced generative technique but hasn't been adopted for the generation of 3D data due to network complexities, computational overhead and longer times needed to generate images. Here, various 3D methods for umap synthesis based on single-shot CNN and conditional DPM with different sampling strategies are compared. ***Materials and Methods:*** The DPM model was a Residual-UNet with conditioning and time step encoding blocks, and 3 sampling strategies were investigated: Denoising Diffusion Probabilistic Model (DDPMs) [1], Denoising Diffusion Implicit Models (DDIM) [2] and DPM-solver [3]. The original DDPM approach used 1,000 steps, and for each accelerated sampling technique, 10, 20 and 50 steps were tested. PET images were reconstructed using each umap, and values in the brain, heart, hip, liver and regions were compared. Twelve subjects with multiple PET tracers were reserved solely for testing. ***Results:*** The generation time of all methods scaled with the number of steps. In general, the DPM model produced superior image quality to that of the single-shot CNN, but differences in the PET quantification were less pronounced. For each anatomical region, the range of VOI means was relatively small, within the standard deviation of the VOI itself. ***Conclusion:*** This work compared various umap synthesis techniques including 3D diffusion models. Fast diffusion sampling techniques were implemented, and all converged to similar images. The DPM model produced higher quality images relative to the single-shot CNN - especially in regions with low PET signal. However, there was less impact on the PET quantification. A larger evaluation including abnormal anatomy or pathology may highlight other potential benefits or pitfalls of diffusion models. ***References:*** [1] Ho, Jonathan, Ajay Jain, and Pieter Abbeel. Aim/Introduction: Quantitative SPECT/CT imaging is the preferred modality for dosimetry in radiopharmaceutical therapy, but partial volume effects (PVEs) remain a major challenge. Deep learning-based partial volume correction (DL-PVC) [1] has shown promise in mitigating PVEs, yet models are typically scanner-specific, limiting clinical applicability. In this study, we investigated
